4. *Cerbera Parviflora*. Leaves stellate, obovate.—Native of the Friendly Islands, and Savage Island, in the South Seas.

5. *Cerbera Salutaris*. Leaves and fruits oval. This is a middle-sized tree, with a milky juice and spreading branches; flowers white, inodorous, in small subterminating racemes; drupe oval, large with a smooth skin, yellow on one side, red on the other, containing a fibrous woody nut, with a single kernel in it, not poisonous.—Native of Cochinchina, near the coast.

Cercis; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, very short, bell-shaped, gibbous below, melliferous; mouth five-toothed, erect, obtuse. *Corolla*: pentapetalous, inserted into the calix, resembling a papilionaceous corolla; wings, petals two, bent upwards, affixed by long claws; standard, petal one, roundish, clawed beneath the wings, and shorter than the wings; keel, petals two, converging into a cordate figure, including the organs of generation, affixed by claws; nectary a style-shaped gland, below the germen. *Stamina*: filamenta ten, distinct, subulate, bent downwards, of which four are longer than the rest, covered; antheræ oblong, incumbent, rising upwards. *Pistil*: germen linear lanceolate, pedicelled; style of the length and situation of the stamina; stigma obtuse, ascending. *Pericarp*: legume oblong, obliquely acuminate, unilocular. *Seeds*: somewhat roundish, connected to the superior suture. **ESSENTIAL CHARACTER.** *Calix*: five-toothed, gibbous below. *Corolla*: papilionaceous. *Standard*: short, beneath the wings.—These plants may be propagated by sowing their seeds upon a bed of light earth, towards the latter end of March, or the beginning of April; and if a little hot dung be put under the bed, it will greatly facilitate the growth of the seeds. When they are sown, sift the earth over them about half an inch thick, and cover the bed with mats whenever the season turns out wet; otherwise the great rains will burst the seeds, and cause them to rot. When the plants appear, they should be carefully cleared from weeds, and in very dry weather must be now and then refreshed with water, which will greatly promote their growth. In the following winter, if the weather be very cold, it will be proper to shelter the plants, by covering them with mats or dry straw during hard frosts; but they should constantly be opened in mild weather, otherwise they will grow mouldy and decay. About the beginning of April you should prepare a spot of good fresh ground, to transplant them out, for the best time to remove them is immediately before they are beginning to shoot, which is done by taking up the plants cautiously, being careful not to break their roots, and replanting them as soon as possible. They are generally planted two feet row from row, and a foot asunder in the rows, which is full room enough for them to grow two or three years, by which time they should be transplanted whither they are intended to remain. The ground between the plants should be carefully kept clean from weeds in summer, and in the spring should be well dug to loosen the earth, in order to allow the roots to extend themselves every way: at that season prune off all strong side branches, especially if you intend to train them up for standard trees, that their top branches may not be checked by their side-shoots, which often attract the greatest part of the nourishment from the

roots : and should their stems be crooked, you must place a strong stake down by the side of each plant, and fasten the stem to it in several places, so as to bring it straight, which direction it will soon take as it grows larger, and thereby the plants will be rendered beautiful. When they have remained in this nursery two or three years, they should be transplanted in the spring to the places where they are to remain.—The species are,

1. *Cercis Siliquastrum*; *Common Judas Tree*. Leaves cordate, orbicular, smooth. The Portuguese and Spaniards call this, the tree of love : it rises with an upright trunk, to the height of twenty feet, covered with a dark brown bark, divided upwards into many irregular branches ; leaves on long foot-stalks, pale green above, greyish underneath. The flowers come out on every side of the branches, and in many instances in large clusters from the stem of the tree, arising from the same point, upon short peduncles ; they are of a very bright purple colour, and make a fine appearance, especially when the branches are covered pretty thick with them ; they come out in the spring with the leaves, and are in full beauty before the leaves have attained half their size. The flower is papilionaceous, and, having an agreeable pungency, is frequently eaten in salads. This tree is usually planted with other flowering trees and shrubs, for ornaments to pleasure-gardens, and, for their singular beauty, deserve a place as well as most other sorts ; for when they are arrived to a good size, they are productive of flowers, so as that the branches are often closely covered with them ; and the singular shape of their leaves affords a very pretty variety in the summer. It flowers in May, when planted in the full air ; but when placed against warm walls, a fortnight or three weeks earlier. The wood of this tree is very beautifully veined with black and green, and as it takes a fine polish, might be converted to many uses. There are two varieties of this tree, but are greatly inferior in beauty.—Native of the Levant, Spain, the south of France, on the Apennines, near Rome in Italy, and in Japan.

2. *Cercis Canadensis*; *Canada Judas Tree*, or *Red-bud Tree*. Leaves cordate, pubescent, ovate, acute. It grows naturally in most parts of North America ; where it is called Red-bud, probably from the red flower-buds appearing in the spring, before the leaves come out : it grows to a middle stature in that country, but in England it rarely rises with a stem more than twelve feet high, branching out near the root : the flowers are not so beautiful as those of the first species, but the trees are equally hardy, and will thrive in the open air. The flowers of this, as well as those of the first species, are frequently put into salads by the Americans ; and the French in Canada pickle them, but they have little flavour. The young branches of this tree will dye wool of a very fine Nankin colour.

Cerinthæ; a genus of the class Pentandria, order Monogynia. GENERIC CHARACTER. *Calix*: perianth five-parted; divisions oblong, equal, permanent. *Corolla*: monopetalous, bell-form ; tube short, thick ; border tube-bellied, rather thicker than the tube ; mouth five-cleft ; throat naked, pervious. *Stamina*: filamenta five, subulate, very short ; antheræ acute, erect. *Pistil*: germen four-parted ; style filiform, length of the stamina ; stigma obtuse. *Pericarp*: none ; calix unchanged. *Seeds*: two, bony, glossy, subovate, outwardly gibbous, bilocular. ESSENTIAL CHARACTER. *Border of the Corolla* tube-bellied ; throat pervious. *Seeds*: two, bilocular.—These plants are propagated by seeds, which should be sown soon after they are ripe. They form a pretty variety for large borders in gardens, where, if only suffered to drop their seeds, they will propagate themselves without further care.—The species are ;

1. *Cerinthæ Major*; *Great Honeywort*. Leaves stem-

clasping ; corollas bluntish, spreading. Stems rather more than eighteen inches high, round, smooth, branching, and leafy. Leaves glaucous, becoming blue by age, ciliated about the edges, dotted with white ; branches leafy, nodding ; flowers among the leaves, hanging on long peduncles ; the tube of the corolla is yellow, but the border purple ; the toothlets very short and revolute.—This is one of the most common herbs all over Italy ; hence Virgil's expression of *Cerinthæ ignobile gramen*. It is no less common in Sicily, and is found also in the south of France, Switzerland, Germany, and Siberia. There is abundance of honey juice in the tube of the flower, for which reason it is much resorted to by bees ; and is therefore peculiarly adapted for planting near apiaries.

2. *Cerinthæ Minor*; *Small Honeywort*. Leaves stem-clasping, entire ; corollas acute closed, yellow, without any spot. The entire plant smooth, and flowering the whole summer.—It is annual when sown in the spring, but biennial when sown in autumn ; in the wild state it is therefore biennial.—Native of Italy, Germany, Austria, Syria, and Switzerland.

Ceropegia ; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, five-toothed, acute, permanent. *Corolla*: monopetalous, with a large globose base, which is terminated by a cylindrical oblong tube ; border very small, five-toothed, acuminate, with the tip converging, gaping at the side. *Stamina*: filamenta five, in the base of the corolla, very small, incurved, converging ; antheræ small. *Pistil*: germen very small ; style scarcely any ; stigmas two. *Pericarp*: follicles two, cylindric, acuminate, very long erect, unilocular, univalve. *Seeds*: numerous, imbricated, oblong, crowned with a pappus. ESSENTIAL CHARACTER. Contorted. *Follicles*: two, erect. *Seeds*: plumose. *Border of the Corolla*; converging.—The species are,

1. *Ceropegia Candelabrum*. Umbels pendulous ; flowers erect. A twining plant ; stems slender, round, green or reddish. The peduncle, and at first the flowers, hang down. but when open, they erect themselves, and, being placed in a circle, have the appearance of a set of lamps hanging up.—Native of the East Indies.

2. *Ceropegia Biflora*. Peduncles two-flowered. Stem twining ; perennial.—Native of the island of Ceylon.

3. *Ceropegia Sagittata*; *Arrow-leaved Ceropegia*. Umbels sessile ; leaves sagittate. Stem twining, filiform, tomentose.—Native of the Cape of Good Hope.

4. *Ceropegia Tenuifolia*. Leaves linear-lanceolate. Stems slender, milky, red, bay, or green ; flowers outside yellowish-green, inside reddish.—Native of the East Indies.

5. *Ceropegia Obtusa*. Leaves blunt ; stem twining. Stem perennial, filiform, smooth ; flowers pale.—Native of Cochinchina.

6. *Ceropegia Cordata*. Leaves cordate ; umbels pendulous. Stem long, round, branching ; perennial ; flowers greenish yellow, in large hemispherical axillary umbels, on long peduncles.—Native of Cochinchina, climbing in the hedges.

Cestrum ; a genus of the class Pentandria, order Monogynia. GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, columnar, obtuse, very short ; mouth five-cleft, erect, obscure. *Corolla*: monopetalous, funnel-form ; tube cylindric, very long, slender ; throat roundish ; border flat, plaited, five-cleft ; divisions ovate, equal. *Stamina*: filamenta five, filiform, attached longitudinally to the tube, emitting a toothlet inwards at the middle ; antheræ roundish, quadrangular, within the throat. *Pistil*: germen cylindric, ovate, length of the calix ; style filiform, length of the stamina ; stigma thickish, obtuse, scarcely emarginate. *Pericarp*: berry ovate, unilocular, oblong. *Seeds*: very many,

foundish. **ESSENTIAL CHARACTER.** *Corolla*; funnel-form. *Stamina*: emitting a toothlet from their middle. *Berry*: unilocular.—The species are,

1. *Cestrum Nocturnum*; *Night-smelling Cistrum*. Filamenta toothed; peduncles subracemed, equal to the leaf. It rises with an upright stalk, about six or seven feet high, dividing upward into many slender branches; leaves alternate, near four inches long, and one and a half broad: the flowers are produced at the wings of the leaves in small clusters, standing upon short peduncles, each sustaining four or five flowers of an herbaceous colour; they appear in August, but are not succeeded by berries in this country; those which come from America are small, and of a dark brown colour.—It is a native of the island of Cuba: whence Mr. Miller received the seeds under the name of *Dama de noche*, or *Lady-of-the night*, probably so called from the flowers sending out a strong odour after sunset. It requires to be placed in a dry-stove, with a moderate share of heat in winter, and in the summer to be set in a warm situation in the open air: with this management they will thrive, and produce flowers much better than when they have been under a greater heat. All these plants growing naturally in very hot countries, require to be placed in a warm stove, especially in winter. They may all be propagated by seeds, or by cuttings, but principally the latter, although those produced from seeds are always the straightest and most vigorous, because they do not ripen the seed in England, and it is rarely imported. The best time to plant these cuttings is about the end of May, by which time the shoots will have had time to recover their strength, after confinement during the winter season: the shoots which come out from the lowest part of the stalk should always be preferred; these should be cut about four inches long, and five or six of them should be planted in each halfpenny pot: the earth should be fresh and light, but not full of dung; it must be pressed pretty close to the cuttings, and then they must be gently watered, after which the pots must be plunged into a moderate hot-bed of tanner's bark, and every day shaded from the sun; their waterings should be often repeated in the summer, and if sprinkled all over their leaves, it will wash and cleanse them from filth, and greatly promote their growth.

2. *Cestrum Vespertinum*; *Cluster-flowered Cestrum*. Filamenta toothless; tube filiform; peduncles very short. A tree twelve feet in height; the stem not very strong. The leaves are alternate, on short petioles; corolla larger than the spike, green; tube filiform; border expanding, five-parted; divisions subulate, sharp, one third shorter than the tube, equal, greenish white; the berries are blue; the bark and fruit fœtid.—Native of the West Indies.

3. *Cestrum Diurnum*; *Day-smelling Cestrum*. Filamenta toothless; segments of the corolla roundish, reflected; leaves lanceolate. This rises with an angular stalk to the height of ten or twelve feet, covered with a smooth, light green bark. Towards the upper parts of the shoots the flowers come out from the wings of the leaves, standing in clusters close to the branches; they are very white, shaped like those of the first sort, and smell sweet in the day-time, from which it derives the name of *Lady-of-the-day*.—It flowers in September, October, and November; and is a native of the Havannah.

4. *Cestrum Tomentosum*. Flowers crowded, sessile, terminal; branches, leaves, and calices tomentose.—Found by Mutis in South America.

5. *Cestrum Laurifolium*; *Laurel-leaved Cestrum*. Filamenta toothletted or naked; leaves elliptic, coriaceous, shining very much; peduncles shorter than the petiole. Stem shrubby, erect, round, with an ash-coloured bark, eight or nine feet high; corolla four times longer than the calix; seg-

ments of the rim obtuse, spreading, pale yellow, marked with a gold-coloured streak. The flowers emit a disagreeable odour, and are succeeded by oval berries of a violet colour, full of juice; they are reckoned very poisonous, and are called *poison-berries* in Jamaica, of which it is a native: it flowers in August.

6. *Cestrum Auriculatum*; *Ear-leaved Cestrum*. Filamenta toothless; stipules lunate. This is a very fœtid shrub, about two fathoms high. The natives of Lima, in Peru, use it externally to cleanse foul ulcers, and internally in the venereal disease; they look upon it as a pectoral, but it seems to be a plant of suspicious character.—Dombey observed it in wet places about Lima.

7. *Cestrum Parqui*. Filamenta toothletted or naked, floriferous; stem panicled; stipules linear. This is a fœtid shrub, six feet high; flowers odorous in the night.—Native of Chili.

8. *Cestrum Hirtum*. Flowers subspliked, axillary; leaves subcordate, ovate-acute; underneath, with the branchlets, rough with hairs.—Native of the West Indies, Jamaica, &c.

9. *Cestrum Nervosum*. Leaves lanceolate, opposite, with transverse nerves; peduncles branching. Stem shrubby, five or six inches high, covered with a brown bark, and dividing at top into very small branches; corolla white, and inodorous.—Native of Carthage, in New Spain.

Chærophyllum; a genus of the class Pentandria, order Digenia.—**GENERIC CHARACTER.** *Calix*: umbel universal spreading; partial nearly equal as to the number of rays. *Involucre* universal, none; partial, subpentaphyllous; leaflets lanceolate, concave, reflected, nearly the length of the umbellule; perianth proper obscure. *Corolla*: universal nearly uniform; florets of the disk abortive; proper of five petals, heart inflected, with the point bent in, flattish; exterior ones rather larger. *Stamina*: filamenta five, simple, length of the umbellule; antheræ roundish. *Pistil*: germen inferior; styles two, reflected; stigmas obtuse. *Pericarp*: none; fruit oblong, acuminate, smooth, bipartite. *Seeds*: two, oblong, attenuated upwards, convex on one side, flat on the other. **ESSENTIAL CHARACTER.** *Involucre*: reflected, concave. *Petal*: heart inflected. *Fruit*: oblong, even.—The first and fourth species of this genus are common weeds; the rest are admitted into botanic gardens only, not being much esteemed either for culinary or medical purposes: if the seeds be permitted to scatter, the plants will come up without further care; or they may be sown, in spring, wherever they are to remain.—The species are,

1. *Chærophyllum Sylvestre*; *Wild Cicely*, or *Cow-weed*; *Common Cow-parsteley*, or *Chervil*. Stem even, striated, two feet high and upward, hollow, grooved, generally villose, and purplish, much branched; joints somewhat swelling; branches suberect, less hoary than the stem; petals flat, obovate, whitish, at first yellowish-white; seeds columnar, glossy, grooved, blackish, without scent, and almost tasteless. It is very common in pastures, orchards, and under hedges, flowering in May, and in warm situations in April. Linnæus remarks, that this plant indicates a luxuriant soil, and that the flowers communicate a green and yellow dye to wool: he also says, that horses, sheep, and goats are not fond of it. Mons. Villars declares, that horses will not eat it, even in the stable; and, according to Mr. Miller, there are few animals who care to eat it, except the ass. Mr. Ray, on the contrary, asserts, that it has the name of *Cow-weed*, because it is grateful food, before it runs up to stalk, to cows, in the spring; and, in confirmation of this account, Mr. Wainwright says, that the cows like it so well, that when a pasture is overrun with it, which is often the case about Dudley, they always turn them in to eat it up. Rabbits are well known to be very fond of it; and Mr.

Curtis relates, that in time of scarcity the young leaves have been used as a pot-herb. John Bauhin, however, mentions instances of two families having been poisoned by eating a small quantity of the root. Haller says, that the Dutch use it in gangrenes. Meyrick and Hill both agree in stating, that the leaves operate by urine, and are good in obstructions of that viscera; they should be given in decoction, and in small doses of a wine glass each.

2. *Chærophyllum Bulbosum*; *Tuberous Chervil*. Stem even, swelling at the joints, rough with hairs at the base; root like the navew, and biennial; petals white, obcordate, unequal; some florets of the disk abortive. The roots, taken up early in the spring, are eaten boiled, with salt, oil, and vinegar. Gmelin, however, affirms that both these and the seeds occasion vertigoes, but this is certainly incorrect, at least as far as concerns the fresh root, which many persons have eaten with impunity.—It flowers in June and July; and is a native of Germany, Austria, Switzerland, and Norway, in hedges, and by wood-sides.

3. *Chærophyllum Aristatum*. Stem even, swelling at the joints; seeds rough with hairs, two-awned. Stem round, striated, smooth, erect.—Native of Japan.

4. *Chærophyllum Temulum*; *Wild Chervil*, or *Rough Cowparsley*. Stem rugged; joints swelling. Stem two feet or more in height, branched, round, solid; petals white. The stem being generally spotted with purple, it is frequently mistaken for Hemlock.—It derives the name of *temulum*, or *temulentum*, from its supposed narcotic or inebriating quality, which it probably possesses only in a very small degree.

5. *Chærophyllum Hirsutum*; *Hairy Chervil*. Stem equal; leaflets gashed, acute; fruits two-awned. This is a pubescent plant; it is perennial, four feet high; corolla in some plants red, in others white.—Native of Switzerland, Germany, Austria, and Carniola.

6. *Chærophyllum Aromaticum*; *Aromatic Chærophyllum*. Stem equal; leaflets serrate, entire; fruits two-awned. Stem and petioles rough with hairs. It flowers in July and August.—Native of Lusatia, Misnia, Austria, and Silesia.

7. *Chærophyllum Coloratum*. Stem equal; leaves super-decompound; involucls coloured.—Native of Illyria.

8. *Chærophyllum Aureum*; *Golden Chærophyllum*. Stem equal; leaflets gashed; seeds coloured, grooved, awnless. Stem angular, striated, spotted, rough with hairs at bottom, and not hollow; corollas white, reddish on the outside.—Native of the country about Geneva, of Switzerland, Austria, and Germany.

9. *Chærophyllum Scabrum*. Stem equal; leaves gashed, acute, rough with hairs; peduncles rugged. Root fibrous. It flowers in April and May.—Found near Jedo in Abyssinia, and in Japan.

10. *Chærophyllum Arborescens*. Shrubby.—Native of Virginia.

Chaffweed. See *Filago*.

Chamærops; a genus of Palms, of the class Polygamia, order Diœcia.—GENERIC CHARACTER. *Hermaphrodite Flower*. *Calix*: spathe universal, compressed, bifid; spadix branching; perianth proper, tripartite, very small. *Corolla*: tripartite; petals ovate, coriaceous, erect, acute, inflected at the tip. *Stamina*: filamenta six, subulate-compressed, scarce cohering at the base; antheræ linear, twin, growing to the interior side of the filamenta. *Pistil*: germen three, roundish; styles as many, distinct, permanent; stigmias acute. *Pericarp*: drupes three, globose, unilocular. *Seeds*: solitary, globose. *Male Flower*, in a distinct plant, flowering in the same manner. *Calix* and *Corolla*: as in the hermaphrodite. *Stamina*: a gibbous receptacle, ending in six filamenta, not

marked by perforations; in every thing else as the hermaphrodites. **ESSENTIAL CHARACTER.** *Hermaphrodite*. *Calix*: three-parted. *Corolla*: three-petalled. *Stamina*: six. *Pistil*: three. *Drupes*: three, one-seeded. *Males*: diœcous, as in the hermaphrodite.—The species are,

1. *Chamærops Humilis*; *Dwarf Fan Palm*. Fronds palmated, plaited; stipes thorny. This tree never rises with an upright stem, but the footstalks of the leaves rise immediately from the head of the root, and are armed on each side with strong spines; they are flat on their upper surface, and convex on their under side; the centres of the leaves are fastened to the footstalk, and spread open like a fan, having many foldings, and at the top are deeply divided like the fingers of a hand; their borders are finely sawed, and have white narrow edgings; they are from nine to eighteen inches long, and near a foot broad in the widest part. Fruit a drupe, nearly globular; rind thin; flesh thickish, fibrous, when old cork-like, hard, inodorous. The pith near the root is sweetish and tender, and is sometimes eaten in deserts.—It grows naturally in Italy, Sicily, and Spain, particularly in Andalusia, where, in the sandy land, the roots spread and propagate so fast, as to cover the ground in the same manner as Fern in England. The leaves of these plants are tied together, to make besoms for sweeping.—It is commonly propagated by heads, which separate from the main root; if these be carefully taken off with fibres, and planted, they will grow; but the plants so raised are not so good as those produced from seeds: the seeds should be sown in small pots, filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark, where they must now and then be refreshed with water when they appear; if they be not too close to each other in the pots, they will not require transplanting the first year; they should remain in the tan-bed all the first summer, having plenty of air in warm weather, and be removed into the stove in autumn: if they be plunged into the bark-bed in the first winter, it will greatly promote their growth. They should be carefully turned out of their pots in the following spring, so as to preserve their roots entire, for all the Palms have tender roots, and are frequently killed when the roots are broken; and then be each replanted into a separate small pot, filled with light, sandy, undunged earth, and placed in a fresh hot-bed, to encourage their taking root. They should be gradually hardened in the ensuing summer, and in the following autumn may be placed in a dry-stove, but as they advance and acquire strength, they may be placed in the open air in summer, in a warm situation, and preserved in a warm green-house in winter, without artificial heat: they require but little water, except in very dry weather, especially during the winter season. They should have larger pots as they advance in growth.

2. *Chamærops Excelsa*. Fronds palmated, nervous, serrate; stipes unarmed. This is a lofty tree.—Native of Japan.

3. *Chamærops Cochinchinensis*. Fronds palmate, plaited; stipes thorny; spathes partial; corollas monopetalous; trunks eight feet high, an inch in diameter, bifid, straight, equal.—Native of the woods of Cochinchina.

Champignon. See *Agaricus*.

Changeable Rose. See *Hibiscus Mutabilis*.

Chara; a genus of the class Monœcia, order Monandria.—GENERIC CHARACTER *Female Flower*. *Calix*: perianth four-leaved; leaflets subulate, erect, permanent; the two opposite exterior ones longer than the others. *Corolla*: none. *Pistil*: germen turbinate; style none; stigma five-cleft, oblong, deciduous. *Pericarp*: crust, ovate, unilocular, adhering. *Seed*: single, ovate, spirally striated. *Male Flowers*, at the base of the germen, beyond the calix. *Calix*: none.

Corolla: none. *Stamina*: filamenta none; antheræ globose, before the germen; beyond the calix, beneath. **ESSENTIAL CHARACTER.** *Male.* *Calix* and *Corolla*: none. *Antheræ*: before the germen, underneath. *Female.* *Calix*: four-leaved. *Corolla*: none. *Stigma*: five-cleft. *Seed*: one.—These plants possessing no beauty, and growing only in water, are not cultivated in gardens.—The species are,

1. *Chara Tomentosa*; *Brittle Chara*, or *Stonewort*. Prickles on the stem, ovate. This plant is always flesh-coloured when alive, but when dry it becomes ash-coloured; stem twisted, brittle, and gritty in the mouth.—In summer it abounds in oblong berries, growing yellow when ripe, and having very small black seeds in them. It is annual, flowering from June to October; and is found in salt marshes, ditches, pools, lakes, &c. in many parts of Europe. In England it has been seen near Evansham Ferry, three miles beyond Oxford; near Chislehurst in Kent; near Bath, and Besorsleigh; in the rivulet that runs from Malham Tarn; and is very common in the peat-ditches of Lancashire and Westmoreland.

2. *Chara Vulgaris*; *Common* or *Stinking Chara*, or *Stonewort*. Stems glossy; leaves toothed on the inside; prickles on the stem capillary, crowded. The whole plant is yellowish or reddish green when fresh, and extremely fetid.—It is an annual, flowering in July and August: found in ditches and pools.

3. *Chara Hispida*; *Prickly Chara*, or *Stonewort*. Prickles on the stem capillary, crowded. The whole plant has a strong scent of garlic.—It is found upon the sea-coasts, &c. in several parts of Europe; and with us upon Hinton-moor, near Cambridge; Ellingham in Norfolk; near Gayton, Staffordshire; in Yorkshire, Lancashire, and Westmoreland; East Lothian, in Scotland; and in the turf-bogs of Ireland. Annual; flowering from June to October.

4. *Chara Flexilis*; *Smooth Chara*, or *Stonewort*. Joints of the stem unarmed, diaphanous, broader upwards. Stems eight or ten inches long, fistular, tender, dull green, pellucid.—Native of the sea-coasts in several parts of Europe; in England it is found in lakes, ponds, ditches, and bogs; as, about Henley, near Ipswich, near Knaresborough, near Hornsey, and in Loch Lomond, and several of the Scotch lakes.—It is annual, flowering from June to October.

Charlock. See *Sinapis Arvensis*.

Chaste-Tree. See *Vitex*.

Cheese Renning or *Rennet.* See *Galium*.

Cheiranthus; a genus of the class Tetradynamia, order Siliquosa.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, compressed; leaflets lanceolate, concave, erect, parallel-converging, deciduous, the two outer gibbous at the base. *Corolla*: four-petalled, cruciform; petals roundish, longer than the calix; claws the length of the calix. *Stamina*: filamenta six, subulate, parallel, the length of the calix, two of them within the gibbous leaflets of the calix, a little shorter than the other four; antheræ erect, bifid at the base, acute at the tip, and reflected; a nectarous gland surrounds the base of the shorter stamina on each side. *Pistil*: germen prismatic, four-cornered, the length of the stamina, marked with a tubercle on each side; style very short, compressed; stigma oblong, two-parted, reflected, thickish, permanent. *Pericarp*: silique long, compressed, the two opposite angles obliterated, marked with a toothlet, two-celled, two-valved, furnished with the very short style, and the erect bifid stigma. *Seeds*: many, pendulous, alternate, subovate, compressed, with a membranous edge. **ESSENTIAL CHARACTER.** Germen with a glandulous toothlet on each side. *Calix*: closed, with two leaflets gibbous at the base. *Seeds*: flat.—The species are,

1. *Cheiranthus Erysimoides*; *Wild Wallflower*, or *Stock*. Leaves lanceolate, toothed, naked; stem erect, quite simple; siliques four-cornered. Root perennial; flowers yellow, and in loose spikes or corymbs.—It is a native of Italy, Spain, France, Switzerland, Germany, Austria, Hungary, Sweden, and England, where it is found about Godstow, near Oxford, and East Grinstead, in Sussex. It flowers in June, and ripens its seed in autumn. If the seeds be allowed to scatter themselves, the plants will come up without care, and will thrive in any soil or situation, and upon walls among rubbish, as the common Wallflower.

2. *Cheiranthus Helveticus*: *Swiss Wallflower*, or *Stock*. Leaves lanceolate, toothed, naked; stem erect; siliques four-cornered, acuminate with the style. Root perennial; stem somewhat angular, eighteen inches high; leaves pale green. It flowers in May and June, and the seeds ripen in July.—Native of Switzerland.

3. *Cheiranthus Alpinus*; *Alpine* or *Straw-coloured Wallflower*, or *Stock*. Leaves linear, entire, subtomentose; stem branching. The whole plant is roughish: root biennial: the flowers are pale yellow, or sulphur-coloured, and have little or no smell. They appear in June and July, and the seeds are perfected in September.—It is found on banks and walls in Austria and Provence, in Switzerland, and on the mountains of Piedmont. This sort, when cultivated, grows as large as the common Wallflower, and makes a fine appearance, the racemes being longer, and the flowers growing much closer: but as it has little scent, it has on that account been much neglected.

4. *Cheiranthus Strictus*. Leaves linear, acute, smooth; stem shrubby, erect.—Native of the Cape of Good Hope.

5. *Cheiranthus Callosus*. Leaves lanceolate, entire, callos; stem angular, shrubby.—Native of the Cape.

6. *Cheiranthus Cheiri*; *Common Wallflower*. Leaves lanceolate-acute, smooth; branches angular; stem shrubby. On walls it is seldom more than six or eight inches high, with very tough roots, and firm stalks, the leaves short and sharp-pointed, and the flowers small; but in gardens it is two feet high, and branches wide; the leaves are broader, and the flowers much larger. The principal varieties are, 1. Common Dwarf Yellow; 2. Large Yellow; 3. Large Yellow Bloody; 4. True Bloody; 5. Narrow-leaved Straw-coloured; 6. Variegated-leaved Yellow; 7. Winter; 8. White, and these are either single or double.—The Common Wallflower is a native of Switzerland, France, Spain, &c. and is common on old walls and buildings in many parts of England. It is one of the few flowers which have been cultivated in our gardens from time immemorial, on account of their fragrantcy: being of a firm texture, with little sap, it is never affected by cold, so that in severe winters, when the plants are frequently killed in the gardens, those upon the walls receive no injury, though they are much more exposed to wind and frost. The variety of this with very double flowers, is propagated from slips planted in the spring, which readily take root. Another variety, which has variegated leaves, is not so hardy: the Large Bloody Wallflower will frequently rise with double flowers from seeds, if they be carefully saved from such as have five petals; and these double flowers may be increased from slips, but the plants so raised will not produce such large racemes of flowers, as those which are propagated by seeds. The old Bloody Wallflower, the petals of which are shorter and more numerous, approaching to the common double, but much larger, is propagated also by slips; as are likewise all the intermediate varieties, distinguished by florists from the size and colour of the petals. The Wallflowers that are single, produce seeds in plenty, but the largest and deep-

est-coloured flowers should always be selected for seeds; these should be sown in April, upon poor undunged soil, and when the plants are fit to remove, they should be transplanted into nursery beds, at about six inches' distance each way, observing to water and shade them until they have taken fresh root, after which they will require no further care but to keep them clean from weeds all the summer, and at Michaelmas they may be transplanted into the borders of the flower-garden, where they are intended to remain, that the plants may root before the frosts come on. The above is the common method of treating these flowers; but if the seeds be sown upon poor land, where they are designed to remain, and not transplanted, they will thrive and endure the frost much better than those which are removed; so that the seeds of these plants may be sown upon ruins or rubbish, where they will thrive, and continue much longer than in good land; and if properly disposed, they will be very ornamental in such places, while their flowers, with their strong odour, will fill the air to a considerable distance with an agreeable perfume.—According to Hill, the flowers are used; and an infusion of them when fresh is good against the head-ache, and in all nervous disorders: they are also good to steep in oil, to which they give a cordial warmth, and make it good against pains in the limbs; but they are not much used either way at present.

7. *Cheiranthus Fruticulosus*. Leaves lanceolate-acute, smooth, subserrate; stem shrubby. This strongly resembles the preceding species, but is a lower plant, only three or four inches high; flowers one eighth of the size of the common Wallflower, less fragrant, pale yellow.—Native of Spain.

8. *Cheiranthus Chius*. Leaves obovate, veinless, emarginate; siliques subulate at the tip.—Native of the isle of Chios, and Russia. The seeds of this, and the next species, are sown in patches at two or three different times; the first in autumn, the second at the end of March, and the third at the end of April or beginning of May, in the borders of the flower-garden, where they will make a variety, when intermixed with other low-growing annual flowers, for three months.

9. *Cheiranthus Maritimus*; *Dwarf Annual Stock-Gilliflower*. Leaves elliptic, obtuse, naked, roughish; stem diffused, rough. It seldom rises more than six inches high; it is an annual plant. See the foregoing species.—Grows on the coast of the Mediterranean.

10. *Cheiranthus Salinus*. Leaves lanceolate, obtuse, quite entire; stem erect; antheræ included; corolla purple, with a yellowish throat. It has the smell of the Stock-Gilliflower.—Native of the salt marshes of Siberia and Tartary.

11. *Cheiranthus Incanus*; *Stock-Gilliflower*. Leaves lanceolate, quite entire, obtuse, hoary; siliques truncate at the end, and compressed; stem undershrubby. The Stock-Gilliflower rises with a strong stalk, which is almost shrubby, a foot high or more, having oblong, spear-shaped, hoary leaves, frequently waved on their edges, and turned downward at the extremity; from the stalk come out many lateral branches, with smaller leaves; these side-branches are each terminated by a loose spike of flowers, each having a woolly calix, and four large roundish petals indented at the end; these usually appear in May and June, but the same plants frequently continue flowering most part of the summer. The seeds ripen in autumn, and the plants generally perish soon after; but when any of them grow in dry rubbish, they will last two or three years, and become shrubby; but those with single flowers are not worth preserving after they have perfected their seeds. The flowers of this species vary in their colour, some are of a pale, others of a bright red, and some are

curiously variegated, but those of the bright red are generally most esteemed: if the seeds be well chosen, three-fourths of the plants will frequently be double; and as they divide into many branches, they make a fine appearance during their continuance in flower. There are three principal varieties: 1. The *Brompton Stock-Gilliflower*, with bright red flowers; 2. The *White Stock-Gilliflower*, with flowers pale-coloured purple, and sometimes purple variegated with white; 3. The *White Wallflower*, with flowers which are of a pure white, and have a great fragrantcy, especially in the evening, or in cloudy weather.—Native of the sea-coasts of Spain: found also in Italy, Greece, Corsica, and the adjacent isles. These flowers are of very long standing in the English gardens. The old English name of Gilliflower, which is now almost lost in the prefix *Stock*, is corrupted from the French *giroflier*. Chaucer writes it *gylofre*; Turner, *gelover* and *gelyfoure*; Gerarde and Parkinson, *gilloflower*. Having been thus far removed from its original orthography, it was easily corrupted by those who knew not whence it was derived, into *July-flower*. Pinks and Carnations also having the name of Gilliflower, from their smelling like the clove, which is called *giroffe* in French, from the Latin *caryophyllum*: they were called Clove-gilliflowers, and these Stock-gilliflowers for distinction. Gerarde says, they were also called *Garnsey Violet*, and *Castle Gilliflower*.—*Culture*. All the varieties of this species flower in May and June, at which time they are the greatest ornaments to the flower-garden, and therefore deserve as much attention as any of the beautiful flowery tribe. In order to raise double flowers, great care must be taken in choosing plants for seed, without which there can be little hopes of having these flowers in perfection. A very sure way of obtaining many double flowers, is to make choice of those single flowers which grow near many double ones, for those seeds saved from plants growing in beds close to each other, if there happened to be a good many double flowers among them, have been always found to produce a much greater number of plants with double flowers, than those which have been saved from plants of the same kinds which grow single in the borders of the flower-garden. There should be a small bed of each kind planted in the flower-nursery, on purpose to save seeds; or if they be sown there, and the plants properly thinned when they are young, they need not be transplanted, for those plants which spring up from scattered seeds, which have not been transplanted, endure the frost much better than those which have been removed; because, as these plants send out horizontal roots from the bottom of their stems, which spread near the surface of the ground, so, when they are transplanted, the roots are forced downwards out of their natural direction, and if their stalks were grown tall before removal, they are generally planted low in the ground, whereby they are apt to rot, if the ground be moist and the winter should prove wet; therefore where they can be left unremoved, there will be a better chance of their living through the winter; and as these beds need not be of great extent, so when the winter proves very severe, it will not be much trouble or expense to arch the beds over with hoops, and cover them with mats in frosty weather, by which method they may be always preserved. The ground where these seeds are sown must not have any dung, for the plants will grow very vigorous in rich land during summer, but frost, or the heavy rains in autumn, will soon destroy them; for they will thrive upon rock or old wall, when all those which are planted in gardens are destroyed. The best time to sow the seeds is about the beginning of May; and if the season should prove dry, it will be proper to shade the beds with mats every day, to prevent the earth from drying too fast;

but the covering must be taken off every evening to admit the dews of night, and they should be gently watered in the evening, twice or thrice a week. When they first appear with their two seed-leaves, they are often attacked by flies, especially in dry hot seasons; therefore, to prevent them from destroying the plants, the above-mentioned covering should be continued over them during the heat of the day, and the plants ought to be frequently refreshed with water, which will keep them in a growing state, and the flies will not infest them; for they never attack any plant until they have been stunted in their growth: after this they will only require to be kept clean from weeds, and to be thinned to the distance of nine inches or a foot, that they may have sufficient room to grow, and not draw each other up tall and weak. There are some who propagate the double Stock-gilliflowers by slips and cuttings, which will take root when properly managed; but the plants so raised are never so strong as those which come from seeds, their spikes of flowers are always very short, and have not half the beauty of those raised from the seed.

12. *Cheiranthus Fenestralis*; *Cluster-leaved Stock Gilliflower*. Leaves crowded in heads, recurved, waved; stem undivided. Stem shrubby, from six to eight inches high; corolla petals obovate, reflexed, channelled, notched, purple, glittering with gold. It continues three or four years, flowering the second; the third and fourth, it puts out branches, which flower the same year.—This plant is proper to stand in windows on account of its smallness, and the very grateful odour it exhales, especially in the evening. It flowers from May to July.

13. *Cheiranthus Annuus*; *Annual Stock Gilliflower*, or *Ten-week Stock*. Leaves lanceolate, somewhat toothed, obtuse, hoary; siliques cylindric, acute at the end; stem herbaceous. It rises with a round smooth stalk, about two feet high, dividing into several branches at top. Of this sort, there are the red, purple, white, and striped, with single flowers; and the same colours with double-flowers; which are very great ornaments in the borders of the flower-garden, in autumn.—Grows naturally on the sea-coast of the southern countries of Europe. If the seeds of this plant be sown at three different times, a succession may be kept up during several months. The first sowing should be about the middle of February, upon a very slender hot-bed, just to bring up the plants, which must be guarded against frost; and when they are fit to remove, they should be transplanted into nursery beds, at about three or four inches' distance, observing to water and shade them till they have taken root, and afterwards to keep them clean from weeds; in these beds they may remain five or six weeks to acquire strength, and may then be planted in the borders of the flower-garden, where they are to remain: if they be transplanted during rain, they will the sooner take root, and afterwards require no farther care. To succeed these, another parcel of seeds should be sown in March; and a third parcel at the end of May. If the last be sown upon a warm border, where they may be covered by placing glasses before them in winter, or covering them with mats, they may be continued in flower till Christmas: and if some of the plants be potted and placed under a hot-bed frame in autumn, where they may enjoy the open air in mild weather, and be screened from hard rains and frost, they will keep flowering all the winter, when the weather is not very severe.

14. *Cheiranthus Littoreus*; *Sea Stock Gilliflower*. Leaves lanceolate, somewhat toothed, tomentose, and fleshy; petals emarginate; siliques tomentose. Stem a foot high, alternately branching, hoary. The flowers are smaller than those of the common Stock, of a bright red at first, but fading to a

purple. The whole plant is very white, and, having woody stalks, has the appearance of a perennial plant, but it generally perishes in autumn.—It grows naturally near the sea-coast, in the south of France, Spain, and Italy. The seeds should be sown in autumn on a warm border, where the plants are designed to remain. These will flower early in June, and produce good seeds.

15. *Cheiranthus Tristis*; *Dark-flowered Stock-Gilliflower*. Leaves linear, subsinate; flowers sessile; petals waved; stem shrubby. This seldom rises above eight or nine inches in height. The whole plant is roughish, and of a hoary ash colour. It has a grateful odour at night, somewhat resembling that of the *Geranium Triste*.—Native of the south of Europe.

16. *Cheiranthus Trilobus*. Leaves toothed, obtuse; calices even; siliques knotted, mucronate, filiform, even. Root annual; stems seven or eight inches high, branched, spreading, hoary; flowers rather large, purple.—Native of Spain, and of Italy, on the sea-shore near Terracina.

17. *Cheiranthus Triuspidatus*; *Trifid Stock-Gilliflower*. Leaves lyrate; siliques three-toothed at the tip. An annual plant, branching out from the root into many declining stalks; lower leaves two inches long, hoary; flowers in loose spikes or racemes; corollas purple.—Native of Barbary. If the seeds be sown in autumn on a warm border, the plants will live through the winter, and flower early in June, so that good seeds may be obtained from them.

18. *Cheiranthus Sinuatus*; *Prickly-podded Stock-Gilliflower*. Leaves tomentose, obtuse, subsinate; branch-leaves entire; siliques mucronate. Stalk erect, and the whole plant covered with a white down; lower leaves broad, lanceolate, obtuse, alternately indented; flowers flesh-coloured, succeeded by long woolly pods.—Brought from the Isle of Rhé, near Rochelle. Found also upon the rocks at Aberdovry in Merionethshire; on the sandy coast of Anglesea, about Abermenyfferry, at Aberdare in Caernarvonshire; and on the coast of Cornwall. It is biennial; and may be increased by seeds in the same manner as the other sorts.

19. *Cheiranthus Farsetia*. Siliques oval, compressed; leaves linear, lanceolate; stem shrubby, erect. Stem a foot high, hoary, stiff, straight, and branching: the flowers are of a dull colour, smelling sweet only in the night.—Native of Egypt and Arabia; and observed by Forskael in the kingdom of Tunis.

20. *Cheiranthus Tenuifolius*; *Narrow-leaved Shrubby Stock-Gilliflower*. Leaves filiform, quite entire, somewhat silky; stem frutescent, branched. This is a shrub, a foot and a half in height, the branches becoming bald at bottom.—It flowers in May and June; and is a native of Madeira. Both this and the next species are quick of growth, and may be propagated by cuttings put into the ground, as soon as the plants have done flowering. These cuttings will produce handsome plants to place in the green-house upon the approach of winter, to decorate it in the ensuing spring: they will survive a mild winter under a wall in sheltered gardens, and appear to be almost as hardy as the common Stock.

21. *Cheiranthus Mutabilis*; *Broad-leaved Shrubby Stock-Gilliflower*. Leaves lanceolate, acuminate, sharply serrate; stem frutescent; siliques peduncled. This is a shrub, growing to the height of two or three feet: it flowers from March till May. Its chief merit consists in its early flowering. The showy blossoms on first opening are white, sometimes inclined to yellow; in a few days they become purple; and hence its trivial name *mutabilis*, or changeable. For the propagation and culture, see the preceding species.

22. *Cheiranthus Quadrangulus*. Leaves linear, entire, siliques sessile, oblong, quadrangular. This grows a cubit

height, with an herbaceous stem, becoming a little shrubby at bottom, upright, branched, round; leaves bright green, three or four inches long; flowers in terminating, very long, proliferous, subdecumbent spikes, alternate, sessile, sulphur-coloured, odorous; siliques short; seeds not margined.—Native of the deserts of Siberia.

Chelidonium; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved, roundish; leaflets subovate, concave, obtuse, caducous. *Corolla*: petals four, roundish, flat, spreading, large, narrower at the base. *Stamina*: filamenta very many (thirty) flat, broader at top, shorter than the corolla; antheræ oblong, compressed, obtuse, erect, twin. *Pistil*: germen cylindrical, the length of the stamina; style none; stigma headed, bifid. *Pericarp*: silique cylindrical, subbivalve. *Seeds*: very many, ovate, increased, shining; receptacle linear, between the valves, of a kind of circumambient suture, not gaping. ESSENTIAL CHARACTER. *Corolla*: four-petalled. *Calix*: two-leaved. *Silique*: one-celled, linear.—If the seeds of the four first species be permitted to scatter, the ground will be plentifully stored with plants; and if a few of them be thrown among rock-work, they will come up without trouble, and produce a good effect. Seeds sown in the autumn will grow with more certainty than in the spring, and come earlier to flower: they should be sown where they are intended to remain, and will then require no care but to thin them where they are too close, and to keep them clean from weeds.—The species are,

1. *Chelidonium Majus*; *Common or Great Celandine*. Peduncles umbelled. Stem erect, from a foot to eighteen inches in height, cylindrical, a little hairy. It is common in hedges and other shady places, in uncultivated grounds, upon walls, and among rubbish; flowering from May to July, during which time it is in the greatest perfection for use. The juice of every part of this plant is saffron-coloured, and very acrimonious: it cures tetters and ring-worms: diluted with milk it consumes white opaque spots on the eyes: it destroys warts, and cures the itch. There is no doubt but a medicine of such activity will one day be converted to more important purposes. Hill observes, that it is an admirable medicine in obstructions of the viscera. The root, beat into a conserve with sugar, operates both by stool and urine, and is good in the jaundice. An infusion of the sliced roots is a cordial, and greatly promotes perspiration; and the juice, both taken inwardly and applied externally, is said to be singularly useful in disorders of the eyes. The root dried and reduced to powder, is sometimes given to the quantity of half a drachm for a dose, in the bloody flux and other hæmorrhages. Meyrick says, that both the roots and leaves of Celandine have a very acrid and somewhat bitterish taste, which is however much the strongest in the roots. The plant is often used in obstinate jaundices, dropsies, suppressions of the menses, and other disorders; but the utmost caution should be employed in administering a medicine so highly acrimonious and irritating.—There is a variety of this species with double flowers, which generally rises the same from seeds; and may also be preserved by parting the roots.

2. *Chelidonium Glaucium*; *Sea Celandine, or Yellow Horned Poppy*. Peduncles one-flowered; leaves stem-clasping, sinuated; stem smooth. The whole plant is glaucous; stem strong, nearly two feet high, much branched; petals large, ovate, yellow. The large and numerous flowers, which, although of short duration, succeed one another in great abundance during most part of summer, make a fine contrast with the sea-green dew-bespangled leaves, and are a great ornament to our sandy shores. The whole plant abounds in a yellow

juice, is fetid, and of a poisonous quality, being reputed to occasion madness.—Native of sandy soils, in Switzerland, France, Italy, Austria, Carniola, Denmark, Virginia; and on the coasts of Britain, frequently within reach of the spray of the sea, as in Norfolk, Suffolk, about Dunwich, &c. Lancashire, the isle of Wight, Kent, Essex, Wales, and Scotland. It flowers from June to August.

3. *Chelidonium Corniculatum*; *Red Celandine, or Horned Poppy*. Peduncles one-flowered; leaves sessile, pinnatifid; stem hispid. Plant glaucous; root spindle-shaped; petals oval, deep orange, veined, with an elliptic purplish spot at the base of each, soon falling off.—Native of Hungary, Bohemia, Moravia, Austria, about Montpellier, in Piedmont, and in Spain: annual; flowering in July and August. Found in the sandy corn-fields of Norfolk.

4. *Chelidonium Hybridum*; *Violet Celandine, or Horned Poppy*. Peduncles one-flowered; leaves pinnatifid, linear; stem glossy, slightly hairy; siliques three-valved. Stem erect, a foot high, petals violet, fugacious, seldom lasting above three or four hours; antheræ twin, pale blue.—Native of the southern countries of Europe, and of sandy corn-fields, between Swaffham and Burwell in Cambridgeshire, and in Norfolk. Annual: flowering in July and August.

5. *Chelidonium Japonicum*. Peduncles one-flowered; leaves petioled, pinnate, ovate. Stem herbaceous, striated, smooth, weak, erect; corolla a little longer than the calix, and yellow.—Native of Japan.

Chelone; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, very short, permanent; divisions erect, ovate. *Corolla*: monopetalous, ringent; tube cylindrical, very short; throat inflated, oblong, convex above, flat beneath; border closed, small; upper lip obtuse, emarginate; lower almost equal to the upper, very slightly trifid. *Stamina*: filamenta four, hid beneath the back of the corolla, the two side ones a little longer; antheræ incumbent; the rudiment of a fifth filamentum, like the point of a dagger between the upper pair of stamina. *Pistil*: germen ovate; style filiform, situation and length of the stamina; stigma obtuse. *Pericarp*: capsule ovate, two-celled, longer than the calix. *Seeds*: very many, roundish, surrounded with a membranous rim. ESSENTIAL CHARACTER. *Calix*: five-parted. *Rudiment* of a fifth filamentum between the upper stamina. *Capsule*: two-celled.—The seeds of all the species succeed best, if they be sown in autumn; for when they are sown in the spring, they frequently lie a whole year before the plants come up; for which reason, where the seeds scatter, the plants will come up much better than those which are sown by hand.—The species are,

1. *Chelone Glabra*; *White Chelone*. Leaves petioled, lanceolate, obsolete serrated; upper ones opposite.—This grows naturally in most parts of North America, and is called the *humming-bird tree* by Joscelyn, in his *New England Rarities*. It has a pretty thick jointed root, which is perennial, fibrous, and creeping; stems three feet high, erect, cylindrical: the flowers grow in a close spike at the end of the stalks; they are white, and have but one petal, which is tubular and narrow at the bottom, but swells toward the top almost like the Fox-glove flower. It flowers in August, and when the autumn proves favourable, will sometimes ripen in England; but as the plants propagate so fast by their creeping roots, the seeds are seldom regarded.—The best time to transplant the roots is in autumn, that they may be well established in the ground before the spring, otherwise they will not flower so strong, especially if the season prove dry; but when they are removed in the spring, it

should not be later than the middle of March, by which time their roots will begin to push out new fibres. They will thrive in almost any soil or situation; but their roots are apt to creep too far, if they be not confined, and sometimes intermix with those of other plants; and then their stalks stand so far distant from each other, as to make but little appearance; therefore they should be planted in pots, which will confine their roots, so that eight or ten stalks will be growing together in each pot; which makes a good appearance. This plant being very hardy, is not injured by cold, but it must have plenty of water in hot weather. These plants flower in the autumn, when there is a scarcity of other flowers, which makes them the more valuable, especially the second species, the flowers of which make a very pretty appearance when they are strong: and if some of them be placed in a shady situation in the summer, they will flower later.

2. *Chelone Obliqua*; *Red Chelone*. Leaves petioled, lanceolate, serrate, all opposite; corolla bright purple.—Native of Virginia, from whence the roots were sent to England.

3. *Chelone Hirsuta*; *Hairy Chelone*. Stem and leaves hirsute; flower purely white.—Native of New England.

4. *Chelone Pentstemon*. Leaves stem-clasping; panicle dichotomous. Stem cylindric, pubescent, a foot and half high; corolla purple; tube the length of the calix; throat oblong, bellying.—Native of North America. The seeds of this species should be sown in autumn: when the plants are grown strong enough to remove, they should be transplanted into a shady border, which will prevent their flowering the same year; and in the autumn they may be planted in the borders of the flower-garden. The roots seldom last above two or three years.

5. *Chelone Campanulata*. Leaves opposite, sessile, ovate-lanceolate, extremely acuminate, deeply serrate. The whole plant is smooth; stem round, a foot and half high, purple, wad-like.—Native of Mexico.

Chenolea; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, globular, somewhat fleshy, five-parted; segments bent in. *Corolla*: none. *Stamina*: filamenta five, filiform, from upright bent in, inserted at the base of the calix, and of the same length; antheræ minute. *Pistil*: germen superior; style filiform, very short; stigmas two, simple, subulate acute, from spreading bent back, a little longer than the style. *Pericarp*: capsule round, slightly depressed, umbilicate, one-celled. *Seed*: single, roundish, bifid at the tip, smooth. ESSENTIAL CHARACTER. *Calix*: globular, one-leaved, five-parted. *Capsule*: one-celled, containing one smooth seed, bifid at the tip.—The only known species is,

1. *Chenolea Diffusa*. Stems several, radical, filiform, herbaceous, diffused, simple, and branched, covered with leaves, purple, smooth at bottom, submentose at top, unequal, the ends upright; branches alternate, scattered, few, very short; flowers axillary, solitary, or in pairs. It flowers in August and September.—Native of the low coast of the Cape.

Chenopodium; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, concave, permanent; divisions ovate, concave, membranaceous on the margin. *Corolla*: none. *Stamina*: filamenta five, subulate, opposite the leaves of the calix, and of the same length; antheræ roundish, twin. *Pistil*: germen orbiculate; style two-parted, short; stigmas obtuse. *Pericarp*: none; calix closed, five-cornered, five-angled; (angles compressed) deciduous. *Seed*: single, lenticular, superior. ESSENTIAL CHARACTER. *Calix*: five-leaved, five-cornered. *Corolla*: none. *Seed*: one, lenticular, superior.—Most of these plants are to be eradicated as weeds, rather than culti-

vated; being very succulent and exhausting, and abounding very much in seeds, they should be carefully destroyed, especially on dunghills.—The species are,

* *With angular Leaves.*

1. *Chenopodium Bonus Henricus*: *Angular-leaved Goosefoot*, *English Mercury*, or *Allgood*, *Good Henry*, *Good King Harry*, or *Wild Spinach*. Leaves triangular-sagittate, quite entire; spikes compound, leafless. Root perennial, branched; stem twelve to eighteen inches high, branched below, striated, leafy; leaves alternate, petioled, green above, covered with an unctuous mealiness below, flowers green, mealy; spikes numerous, axillary and terminal. It is gathered while young and tender, to eat as Spinach; and is preferred before Spinach at Boston in Lincolnshire, where it is generally cultivated. The young shoots, peeled and boiled, may be eaten as Asparagus, and are gently laxative; the leaves are often boiled in broth: the roots are given to sheep afflicted with coughs.—As a medicine, this herb is ranked among the emollients, but rarely made use of in practice. The common people apply the leaves to old ulcers and slight wounds, to cleanse and heal them. The dried herb is used in decoctions for clysters.—It grows in waste places, by road-sides, about farm-yards, &c. flowering and seeding from May to August. To propagate this plant, sow the seed in March, on a deep loamy soil, prepared as for Asparagus; let the seedlings continue to grow till autumn: about the middle of September, taking advantage of a wet season, set the plants on a bed similar to that on which they were sown, about a foot apart; keep them clear of weeds, and in the ensuing spring and summer they will afford an abundant crop. The young shoots, with their leaves and tops, are to be cut as they spring up; and being a perennial plant, it will continue thus plentifully to produce for a great number of years. In the winter the bed is to be covered with dung, which should be raked off as the spring advances, when the earth round the roots is carefully to be dug or forked up.

2. *Chenopodium Urbicum*: *Upright Goosefoot*. Leaves triangular, somewhat toothed; racemes crowded, very straight, approximating to the stem, and very long.—grows abundantly on dunghills, and in waste places, flowering from July to September. Annual.

3. *Chenopodium Atriplicis*; *Orach* or *Purple Goosefoot*. Leaves deltoid, coloured beneath; stem erect. This has the appearance, erect stature, height, colour, and leaves, of red Garden Orach: annual.—Found in Siberia, by Pallas; and is a native of China.

4. *Chenopodium Rubrum*; *Red Goosefoot*. Leaves cordate-triangular, bluntish-toothed; racemes erect, compound, somewhat leafy, shorter than the stem. Stems decumbent, and close to the ground, somewhat branched, smooth, grooved, becoming reddish as the seeds ripen; flowers reddish, in axillary and terminal, rather dense racemes.—Grows in waste places, flowering in August. Annual.

5. *Chenopodium Murale*; *Wall* or *Nettle-leaved Goosefoot*. Leaves ovate, shining, toothed, sharp; racemes branched, naked. The whole plant is sometimes tinged with red. Mr. Curtis observes that this, and most other species of this genus, afford plenty of seeds for the support of small hard-billed birds.—Native of waste places, under walls and by road-sides, flowering in August and September. Annual.

6. *Chenopodium Serotinum*; *Fig-leaved Goosefoot*. Leaves deltoid, sinuate-toothed, wrinkled, smooth, uniform; racemes terminal.—Annual.—Native of Spain.

7. *Chenopodium Album*; *Common* or *White Goosefoot*. Leaves rhomboid triangular, erose, entire behind, uppermost oblong; racemes erect. Stem upright, from one to three feet

high, slightly crooked, somewhat angular and striated, solid, branched, smooth, sometimes purplish; branches alternate; racemes axillary, upright, forming a spike of flowers growing in little clusters. It is whiter than most of the *Chenopodia*, and varies exceedingly both when young and in its seeding state. It is the commonest plant of the genus, occurring in every garden, on every dunghill, and in almost every corn-field. It is mentioned by Lightfoot and several other authors, as being boiled and eaten for greens, and is known by the name of *fat-hen*, or *muckweed*. Linneus affirms that swine are extremely fond of it; and yet the fifth and the ninth species, (*Murale* and *Hybridum*) are said to be fatal to this animal; which is contrary to all probability, since the common *Goosefoots* seem to be mild and gently laxative like *Spinach*.

8. *Chenopodium Viride*; *Green Goosefoot*. Leaves rhomboid, tooth-sinuate; racemes branched, somewhat leafy; stem upright, green, with purplish angles. This much resembles the foregoing; but the appearance of the whole plant is greener; the bright red colour at the angles of the joints is constant; the leaf is much longer; and the parts of fructification are smaller.—Native of dunghills, &c. and flowers in August.

9. *Chenopodium Hybridum*; *Bastard Goosefoot*. Leaves cordate, angular acuminate; racemes branching, naked. Stem from one to two feet high, upright, branched, angular, and perfectly smooth. This species varies the least of any; the panicle of flowers is peculiarly branched and naked, and has a strong disagreeable smell.—Mr. Lightfoot enumerates it among the Scottish plants. It is not common near London, being observed only in Battersea-fields, and about Northfleet: it has been found also near Ely and Colchester. If any of the genus be poisonous, this must be the species.

10. *Chenopodium Botrys*; *Cluster or Cut-leaved Goosefoot*, or *Oak of Jerusalem*. Leaves oblong sinuate; racemes naked, multifid. This sends up several stems from the root, which rise about two feet high; flowers axillary from the upper part of the branches, in loose racemes: they appear in July, and the seeds ripen in September. When bruised, the leaves emit a very strong odour; somewhat like that of *Ambrosia*; and for this principally the plant is preserved in gardens, for the flowers have no beauty.—Native of the south of Europe. A few of this, and of the eleventh species, which will come up of themselves, may be transplanted in the spring into pots filled with kitchen-garden earth, to be preserved through the winter; and the others may be planted in the common borders, where they will flower and perfect their seeds.

11. *Chenopodium Amhrosioides*; *Mexican Goosefoot*, or *Oak of Cappadocia*. Leaves lanceolate, toothed; racemes leafy, simple. Stem from twelve to eighteen inches high, sometimes reddish, round, striated, with fine scattered hairs; leaves pale green, oblong, sinuated.—Native of Mexico. The leaves and flowery heads have a strong and not unpleasant smell, and a moderately aromatic taste, somewhat bitterish; on much handling them, an unctuous juice adheres to the fingers. The proper menstruum of their active matter is rectified spirit; but boiling water will also extract it. The infusions, which are not unpalatable, are said to be of service in humoral asthmas and coughs, and other disorders of the breast: they are supposed also to be antispasmodic and antihysterical. The seed is reckoned among the anthelmintics, and the dried herb is put among clothes, to keep away moths.

12. *Chenopodium Multifidum*; *Buenos Ayres Goosefoot*. Leaves multifid; segments linear; flowers axillary, sessile. This rises with a shrubby stalk three or four feet high; with oblong leaves cut into many linear segments.—It grows naturally at Buenos Ayres. It is perennial; and, retaining its leaves through the year, will add to the variety in a green-

house, during the winter; but it has little other beauty to recommend it. It may be propagated by cuttings.

13. *Chenopodium Anthelminticum*; *Wormseed Goosefoot*. Leaves ovate-oblong, toothed; racemes leafless. Stems three cubits high, straight, stiff, grooved, hairy, dividing into few branches to the middle, but above that more branched.—Native of Buenos Ayres, of Pennsylvania, and New Jersey, where it is called *Worm-seed*, and *Jerusalem Oak*. It has a disagreeable scent; and the seeds are given to children against the worms.

14. *Chenopodium Glaucum*; *Oak-leaved Goosefoot*. Leaves ovate-oblong, repand; racemes naked, simple glomerate. Root annual; stems twelve to eighteen inches high, thickish, branched, and spreading, often prostrate, striated with green and white; leaves alternate, petioled, green, and smooth above, mealy and white beneath; flowers green, in small, axillary, and terminal racemes.—Native of several parts of Europe; and in England found chiefly in the neighbourhood of London; flowering in August.

15. *Chenopodium Quinoa*. Leaves triangularly egg-shaped, obsolete toothed, the younger ones mealy; racemes crowded, shorter than the petioles; root annual; stem three feet high, erect, branched.—Native of Chili. It is eaten in Peru as *Spinach* or *Sorrel*, and the seed as *Millet*.

** *With simple Leaves.*

16. *Chenopodium Vulvaria*; *Stinking Goosefoot*. Leaves quite entire, rhomboid-ovate; flowers conglomerate, axillary. The whole plant is sprinkled with a white pellucid meal; stems numerous, spreading, round, somewhat striated, and thinly beset with leaves, which are alternate, petioled.—This species is easily known by its decumbency, and its permanently disagreeable odour, both green and dried, resembling that of stale salt fish.—It is common on dry banks, and at the foot of walls and pailings. It is reckoned a useful antihysterical; some recommend a conserve of the leaves, others an infusion in water, and others a spirituous tincture of them: on some occasions it may perhaps be preferable to the fetids which have been more commonly made use of, as not being accompanied by any pungency or irritation, and seeming to act merely by virtue of its odorous principle. It is omitted in the last edition of the *London Pharmacopœia*, and, as *Alione* affirms, is not undeservedly neglected. The herb dyes a good strong greenish lemon-colour.

17. *Chenopodium Polyspermum*; *Round-leaved Goosefoot*, *Upright Blite*, or *Allseed*. Leaves quite entire, ovate; stem decumbent; cymes dichotomous, leafless, axillary. The stalk is generally of a bright red colour, with long extended branches, and reddish seeds, which are numerous and strikingly visible, from being only in part covered with the calix.—Mr. Curtis remarks, that it is a troublesome weed to the gardener, but scarcely injurious to the farmer. Woodward and Ray, however, affirm that it is generally found in Turnip-fields, and that it grows abundantly in Hop grounds, and among corn where the soil is good. It is a very grateful food to fish in ponds.

18. *Chenopodium Scoparia*; *Flax-leaved Goosefoot*, *Beldere*, or *Summer Cypress*. Leaves linear-lanceolate, flat, quite entire. Stem round, three feet high or more, slender, clothed with short hairs; leaves ciliated about the edge, nerved beneath; flowers greenish, in small sessile clusters. It is a beautiful plant, naturally disposed to grow very close and thick, and in as regular a pyramid as if cut by art. The leaves are of a pleasant green, and were it not for that, it so strongly resembles the *Cypress*, that at some distance it might be mistaken for it. According to Scopoli, this plant drives away bugs. It grows wild in Carniola, Greece, China, and Japan.

The seeds should be sown in autumn; and in the spring, when the plants are come up, they may be put into pots of good earth, and kept supplied with water in dry weather: these pots may be intermixed with other plants, to adorn court-yards, &c. where they will appear very handsome.

19. *Chenopodium Maritimum*; *Sea Goosefoot*, or *White Glasswort*. Leaves awl-shaped, semicylindrical. Root annual, fibrous, small; stem eight or nine inches high, erect, branched, round, leafy; leaves alternate, succulent, abounding with a salt juice; flowers green, sessile, two to four together in small clusters, with a pair of bractes to each.—Common on the sea-coast in various parts of Europe; and is collected for the manufacture of glass.

20. *Chenopodium Aristatem*. Leaves lanceolate, somewhat fleshy: corymbs dichotomous, awned, axillary; root annual; stem two to five inches high, much branched; flowers small, greenish.—Native of Siberia.

21. *Chenopodium Oppositifolium*. Leaves opposite, lanceolate, awl-shaped, very short; stem somewhat woody, cylindrical, much branched, nearly erect-spreading, opposite, striated with reddish lines; flowers in axillary leafy clusters.—Native of Siberia, about the river Jaick.

Cherleria; a genus of the class Decandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets lanceolate, concave, equal. *Corolla*: petals none, except the calix or nectary be so called; nectaries five, emarginate, placed in a circle, very small. *Stamina*: filamenta ten, subulate, of which the alternate ones are affixed to the back of the nectaries; antheræ simple. *Pistil*: germen ovate; styles three, spreading; stigmas simple. *Pericarp*: capsule ovate, three-celled, three-valved. *Seeds*: two or three, kidney-shaped. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Nectaries*: five, bifid, resembling petals. *Antheræ*: alternate, barren. *Capsule*: one-celled, three-valved, three-seeded.—The only known species is,

1. *Cherleria Sedoides*; *Stonecrop Cherleria*. Leaves opposite, linear, rugged about the edge, connate at the base into a sheath. When the leaves are fallen, the sheaths remain with the keel of the leaves, investing the lower part of the stem. It forms large green mossy tufts; stems about two inches high, closely matted; flowers from the summits of the branches, single, erect, on very short peduncles, yellowish green; leaflets of the calix streaked on the back with three lines; nectaries much shorter than the calix, fleshy, and connected.—Scopoli informs us, that in the garden the flower sometimes produces ten entire nectaries, and has all the stamina arising from the receptacle.—It flowers in July and August, and is found on the mountains of Dauphiny, Switzerland, Savoy, the Valais, Austria, Carniola, and the Highlands of Scotland: perennial.

Cherry Tree, Cherry Laurel. See *Prunus* and *Cordia*.

Chervil. See *Chærophyllum*, and *Scandix*.

Chestnut. See *Fagus*.

Chestnut, Horse. See *Æsculus*.

Chickpea. See *Cicer*.

Chickweed. See *Alsine*, and *Arenaria*.

Chickweed, Bastard. See *Bufonia*.

Chickweed, Water. See *Callitriche*.

Chimarrhis; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth margin entire, crowning the germen, permanent. *Corolla*: one-petalled, funnel-form; tube very short; border five-cleft; segments lanceolate, concave, blunt, hirsute below, with a longitudinal line running along the middle, and spreading. *Stamina*: filamenta five, subulate, hirsute at the base, below the divisions of the border, the length of the corolla; antheræ

oval, erect. *Pistil*: germen roundish, inferior; style filiform, the length of the stamina; stigma bifid, obtuse. *Pericarp*: capsule sub-ovate, obtuse, crowned, two-celled, two-valved; the valves bifid at the tip. *Seeds*: solitary. ESSENTIAL CHARACTER. *Corolla*: funnel-form, with a very short tube. *Capsule*: inferior, obtuse, two-celled, two-valved the valves bifid at the tip. *Seed*: one in each cell.—The only species is,

1. *Chimarrhis Cymosa*. This is a lofty tree, with a handsome head, and the boughs spreading out horizontally; leaves ovate, acuminate at both ends, quite entire, shining, petioled, opposite, a foot long, commonly eight or ten at the end of each twig; flowers numerous, small, with white corollas, and without scent, disposed in cymose racemes, half a foot in diameter; those in the axils opposite and solitary, those at the end usually four together; capsules small. The wood is white, and serves for beams, rafters, &c.—Native of Martinico, where it is commonly called *bois de riviere*.

China Root. See *Smilax*.

China Rose. See *Hibiscus*.

Chiococca; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-toothed, superior, permanent. *Corolla*: monopetalous, funnel-form; tube long, spreading; border five-parted; divisions equal, acute, reflected. *Stamina*: filamenta five, filiform, length of the corolla; antheræ oblong, erect. *Pistil*: germen inferior, roundish, compressed; style filiform, length of the stamina; stigma simple, obtuse. *Pericarp*: berry roundish, compressed, crowned with the calix, one-celled. *Seeds*: two, roundish, compressed distant. ESSENTIAL CHARACTER. *Corolla*: funnel-form, equal. *Berry*: one-celled, two-seeded, inferior.—The species are,

1. *Chiococca Racemosa*; *Climbing Snowberry Tree*, or *David's Root*. Scandent: leaves broad-lanceolate; flowers lateral; panicle racemed, one stipular tooth. Stem a fathom or more in height, with smooth loose branches, spreading out horizontally; berry snow-white; seeds two, oblong, acuminate. The root of this plant has much the same bitter acrid taste with the Seneca Snake-root, and has been long used as a strong resolutive and attenuant; it is administered with great success in obstinate rheumatism, and old venereal taints; nor is it entirely useless in the *spina ventosa*: it is best given in decoction.—There is a variety of this, which grows to a considerable height, distinguished by large and pale-coloured corollas, which are purple at the corners.—Native of the West Indies, in woods, and on the lower mountains of Jamaica. It is propagated by seeds procured from the West Indies, which should be sown in pots, plunged in a moderate hot-bed, where they may remain till the autumn, and should then be removed into the stove for the winter, and placed on a fresh hot-bed in the following spring, in order to bring them up, for they rarely appear the first year. When they are fit to remove, plant them each in a separate small pot filled with light earth, and plunge them in a fresh hot-bed, shading them from the sun till they have taken new root, and then treating them as other tender plants from hot countries. As they obtain strength, the plants may be set abroad in a sheltered situation, for two months or ten weeks, in the warmest part of the summer; and in the winter should be placed in a moderately warm dry-stove, where they will thrive, and produce flowers in autumn.

2. *Chiococca Barbata*. Erect: leaves ovate; peduncles axillary, one-flowered; corollas bearded in the throat.—Native of the Marquesas, Society, and Friendly islands.

Chionanthus; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved,

four-parted, erect, acuminate, permanent. *Corolla*: monopetalous, funnel-form; tube very short, length of the calix, spreading; border of four divisions, which are linear, erect, acute, oblique, most extremely long. *Stamina*: filamenta two, very short, subulate, inserted into the tube; antheræ cordate, erect. *Pistil*: germen ovate; style simple, length of the calix; stigma obtuse, trifid. *Pericarp*: drupe round, one-celled. *Seed*: not striated. **ESSENTIAL CHARACTER.** *Corolla*: quadrifid, with the divisions extremely long. *Drupe*: with a striated nut.—The species are,

1. *Chionanthus Virginica*; *Virginian Fringe Tree*, or *Snowdrop Tree*. Peduncles three-cleft, three-flowered. It is a common shrub in South Carolina, where it grows by the sides of rivulets, and seldom is more than ten feet high; the leaves are as large as those of the Laurel, but of a much thinner substance; the flowers come out in May, hanging in long bunches, and are of a pure white, from whence it received the name of Snowdrop-tree; and, from the flowers being cut into narrow segments, it has received the appellation of Fringe-tree. After the flowers have fallen away, the fruit appears, which becomes a dark-coloured drupe, about the size of a sloe, having one hard seed in it.—The best way to obtain good plants is from the seeds, which must be procured from America, for they never have produced any fruit in this country: they should be sown soon after they arrive, in small pots filled with fresh loamy earth, which should be placed under a hot-bed frame till the beginning of May, when they must be removed to a situation exposed to the morning sun, but screened from the sun in the middle of the day: in dry weather the pots must be watered, and kept clean from weeds; for, as the seeds lie in the ground a whole year before the plants, will come up, they should not be exposed to the sun the first summer, but removed in the following autumn, and placed under a frame, to protect the seeds from being injured by the frost; and if the pots be plunged into a moderate hot-bed in the beginning of March, it will bring up the plants much sooner than they will otherwise rise; by which means they will acquire more strength the first summer, and be better able to resist the cold of the next winter. They are liable to suffer from severe frosts while young, but when they are grown strong, will endure without the greatest cold of our climate in the open air; they delight in a moist, soft, loamy soil.

2. *Chionanthus Zeylanica*; *Ceylon Snowdrop Tree*. Peduncles paniced, many-flowered. Leaves egg-shaped, villose underneath; drupes inversely egg-shaped.—Native of Ceylon.

3. *Chionanthus Compacta*. Panicles trichotomous, the last flowers subcapitate; calices villose; leaves lanceolate-oblong; antheræ acuminate. This tree is fifteen feet in height, with a dusky ash-coloured bark; petals snow-white, scarcely any tube, but the segments very long, and of a linear shape.—Native of the Caribbee Islands.

4. *Chionanthus Mayepea*. Panicles axillary, trichotomous, all the flowers distinct; antheræ obtuse. This is a middle-sized shrub, five or six feet high, and five inches in diameter, the wood and bark whitish; petals white, fragrant, concave, terminated by a thread three lines in length; fruit the size of an olive; rind violet, succulent, two lines thick, bitter.—Native of the forests of Guiana.

Chironia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, five-parted, erect, acute, permanent; leaflets oblong. *Corolla*: monopetalous, equal; tube narrower; border five-parted, spreading; divisions ovate, equal. *Stamina*: filamenta five, broad, short, growing from the tip of the tube; antheræ oblong, erect, large, converging, and (after having shed the pollen) spirally twisted. *Pistil*: germen ovate; style fili-

form, a little longer than the stamina, declinate; stigma headed, ascending. *Pericarp*: ovate, bilocular. *Seeds*: numerous, small. **ESSENTIAL CHARACTER.** *Corolla*: rotated. *Pistil*: declinate; stamina on the tube of the corolla. *Antheræ*: finally spiral. *Pericarp*: two-celled. The drooping stigma seems to constitute the essence of this genus.—The species are,

1. *Chironia Trinervia*. Herbaceous: leaflets of the calix membranaceous, keeled. Stem annual, quadrangular, acute; leaves opposite, lanceolate, acuminate at each end, smooth, entire, three-nerved; flowers elegant, blue.—Native of Ceylon and the Cape.

2. *Chironia Jasminoides*. Herbaceous: leaves lanceolate: stem four-cornered. Stem two feet high, glossy; leaves opposite, sessile, erect, smooth.—Native of the Cape.

3. *Chironia Lychnoides*. Stem simple; leaves linear-lanceolate. Stem entirely simple, round, stiff, and straight, two feet high; flowers purple, disposed three or four together, in a terminal panicle.

4. *Chironia Campanulata*. Herbaceous: leaves sublinear; calices the length of the corolla. Stem a foot high, round, with long branches; flowers terminal, solitary, wheel-shaped, purple, on a long peduncle.—Observed in Canada by Kalm.

5. *Chironia Angularis*. Herbaceous: stem acute-angled; leaves ovate, stem-clasping. This has the appearance of Lesser Centaury.—Found by Kalm in Virginia.

6. *Chironia Linoides*; *Flax-leaved Chironia*. Herbaceous: leaves linear. An undershrub, with filiform, round, smooth branches; leaves an inch long, narrow; flowers pale red, solitary at the top of the upper branches; tube of the corolla half the length of the calix.—Native of the Cape.

7. *Chironia Nudicaulis*. Herbaceous: leaves oblong, bluntish. Stems many, subdiphyllous, quite simple, one-flowered; calices with setaceous teeth. This species is singular for its oblong leaves frequently rooted into a tuft.—Discovered by Thunberg at the Cape.

8. *Chironia Tetragona*. Shrubby: leaves ovate, three-nerved, bluntish; leaflets of the calix bluntish, keeled; corolla yellow, large.—Native of the Cape.

9. *Chironia Baccifera*; *Berry-bearing Chironia*. Stem shrubby at the base, much branched, four-cornered; leaves linear, green; pericarp resembling a berry. Flowers pale red, small, terminal, on short peduncles. This plant grows to the height of a foot and a half or two feet, and becomes very bushy, and is rather more so than is consistent with ornament; it produces both flowers and fruit during most of the summer.—Native of Africa. The seeds of this, and of the tenth species, should be sown in small pots, filled with light sandy earth, soon after they are ripe, and plunged into a moderate hot-bed, and must be frequently but gently watered: sometimes the seeds will lie a long time in the ground, so that if the plants do not appear the same season, the pots should not be disturbed, but preserved in shelter till the following spring. When they are fit to remove, they should be transplanted into small pots, four or five in each pot; then plunge the pots into a moderate hot-bed, and sprinkle them with water, shading them from the sun till they have taken new root; after which they will require a large share of air in warm weather, to prevent them from being drawn up weak: when they have acquired some strength, they may be gradually inured to bear the open air, but must be screened from great or long rains: when their roots have filled the pots, they should be parted, and each put into a separate pot filled with light sandy earth, but not rich with dung, which must be shaded until they have taken fresh root, and then removed to some warm situation, among

plants that require little water ; where they may remain till autumn, and then have the protection of a glass-case, giving them but little water in winter, enjoying the sun as much as possible, and the air in mild weather. With this management, they will produce flowers the second year. The cuttings also will take root with proper management, but not very readily.

10. *Chironia Frutescens*. Shrubby : leaves linear-lanceolate, fleshy, subtomentose ; calices bell-shaped. Stem a foot and half high, woody ; branches round, tomentose, ash-coloured, mostly alternate, subdividing a little at top ; flowers bright red, at the summits of the branches.—Native of Africa.

Chlora ; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix* : perianth eight-leaved ; leaflets linear, spreading, permanent. *Corolla* : monopetalous, salver-shaped ; tube shorter than the calix, coating the germen ; border eight-parted ; divisions lanceolate, longer than the tube. *Stamina* : filamenta eight, very short, seated on the throat ; antheræ linear, erect, shorter than the divisions. *Pistil* : germen ovate-oblong ; style filiform, length of the tube ; stigmas four, oblong, cylindrical. *Pericarp* : capsule ovate-oblong, one-celled, somewhat compressed, furrowed, two-valved ; valves incurvated on the side. *Seeds* : numerous, minute. ESSENTIAL CHARACTER. *Calix* : eight-leaved. *Corolla* : one-petalled, eight-cleft. *Capsule* : one-celled, two-valved, many-seeded. *Stigma* : four-cleft.—All these plants may be easily propagated from seeds, and require only common care in the cultivation. Our common Yellow Centaury, however, does not thrive well in a garden.—The species are,

1. *Chlora Perfoliata* ; *Perfoliate Yellow Wort*, or *Yellow Centaury*. Leaves perfoliate. The whole plant generally very glaucous ; stem cylindrical, smooth, from three inches to three feet high ; corolla gold coloured, with a milky juice ; segments sometimes nine, slightly emarginate.—Annual ; found on chalky and limestone soils, flowering from June through the autumn. Haller says, that this plant is more bitter than the red, (*Gentiana Centaurium*) and that it seems to possess the same qualities.

2. *Chlora Imperfoliata*. Corollas six-cleft. Stem herbaceous, quite simple, erect, four-cornered, glossy, a hand in height ; the internodes longer than the leaves ; flowers yellow, terminal, peduncled.—Annual ; and a native of Italy.

3. *Chlora Quadrifolia*. Leaves in fours. Supposed to be a hybrid plant, produced from *Gentiana perfoliata* and *Linum quadrifolium*. Stem simple, a span in height, somewhat quadrangular, jointed.—Native of the south of Europe.

4. *Chlora Dodecandria*. Leaves opposite : corollas twelve-cleft. Flowers flesh-coloured. Native of Virginia.

Chloranthus ; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix* : none, but an ovate, acute, concave seale, on which the germen is placed. *Corolla* : one or three lobed convex petal, inserted into the outside of the germen. *Stamina* : filamenta none ; antheræ four, inserted into the lobes of the petal, on the edges towards the inside, and bivalve. *Pistil* : germen obovate, prominent in front, and bearing the petal ; style unequal, very short, angular ; stigmas three, very minute, erect. *Pericarp* : drupe, oblong. *Seed* : nut oblong, smooth. ESSENTIAL CHARACTER. *Calix* : none. *Corolla* : a petal three lobed by the side of the germen. *Antheræ* : growing to the petal. *Drupe* : one-seeded.—The only discovered species is,

1. *Chloranthus Inconspicuus*, or *Chu lan*. This is an herbaceous plant ; stems many, from the root, half a foot high, spreading, suberect, a little branching, round, striated, smooth ; leaves about two inches long, oblong-ovate, somewhat wrinkled, permanent ; flowers pale yellow, in a terminal

panicle.—This plant has been long introduced into the royal garden at Kew, as a native of China, where, we are told, it is cultivated in their gardens, though it seems not to have any qualities either palatable or odoriferous, nor any thing to recommend it in its appearance. Dr. Lind asserts, that the Chinese mix it with their tea, to give it a pleasant smell ; but this plant itself has no smell whatever. It is preserved in the stove, and may be readily increased by runners.

Chocolate-nut Tree. See *Theobroma*.

Chondrilla ; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix* : common calicled, cylindrical ; scales of the cylinder very many, parallel, linear, equal ; those of the base few, very short. *Corolla* : compound imbricate, uniform ; corollets hermaphrodite, very many, equal, in several rows ; proper monopetalous, strap-shaped, linear, truncated, four or five toothed. *Stamina* : filamenta five, capillary, very short ; antheræ cylindrical, tubular. *Pistil* : germen subovate ; style filiform, length of the stamina ; stigmas two, reflex. *Pericarp* : none ; calix cylindrical, oblong. *Seeds* : solitary, ovate, compressed, mucated ; pappus hairy ; stripe long, attenuated above. *Receptacle* : naked. ESSENTIAL CHARACTER. *Calix* : calicled. *Florescens* : in many rows. *Seeds* : mucated. *Pappus* : simple, stipitated.—The species are,

1. *Chondrilla Juncea* ; *Rushy Gum Succory*. Radical leaves runcinate ; stem leaves linear, entire. Root perennial ; stem much branched, from two to three feet high, erect ; at bottom strigose, towards the top smooth, bright green ; corollas slender, yellow, like those of Lettuce. The juice of the whole plant is extremely bitter ; although the Spaniards use it as a salad herb. It flowers in July, and ripens its seed in September.—Native of France, Switzerland, Germany, Austria, Italy, and Spain. It is seldom preserved in gardens, because the roots are very apt to spread, and become troublesome weeds ; the downy seeds are also carried by the wind to a considerable distance, and fill the ground with plants ; the roots strike deep and spread out with thick fibres on every side : each of these when cut or broken, will shoot up ; so that, when this plant has once got possession of the ground, it is very difficult to root it up.

2. *Chondrilla Crepioides*. Leaves sagittate, stem-clasping ; flowers subsessile, lateral. Stem simple, a foot and a half high, purple at the base, striated, set with a few white bristles ; corolla yellow, purplish underneath ; calix striated, beset with black tubercles, and a white bristle.

3. *Chondrilla Nudicaulis*. Scape naked ; flowers panicled. Radical leaves runcinate, obtuse at the end, glossy ; toothlet ciliated ; corolla pale yellow, consisting of about twenty-four corollules, all forming the ray, and obtusely five-toothed.—Native of the East Indies.

Christmas Rose, Christmas Flower. See *Helleborus*.

Christ's Thorn. See *Rhamnus Palustris*.

Chrysanthemum ; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix* : common hemispherical, imbricate ; scales close, incumbent, the interior ones larger by degrees, the innermost terminated by a parched scale. *Corolla* : compound radiated ; corollets hermaphrodite, tubular, numerous in the disk ; females more than twelve in the ray ; proper of the hermaphrodites funnel-form, five-cleft, patulous, length of the calix ; of the females strap-shaped, oblong, three-toothed. *Stamina*, in the hermaphrodites : filamenta five, capillary, very short ; antheræ cylindrical, tubular, shorter than the corolla. *Pistil*, in the hermaphrodites : germen ovate ; style filiform, longer than the stamina ; stigmas two, revolute. In the females : germen ovate ; style filiform, equal with the hermaphro-

dites; stigmas two, obtuse, revolute. *Pericarp*: none; calix unchanged. *Seed*: solitary, oblong, without any pappus; receptacle naked, dotted, convex. **ESSENTIAL CHARACTER.** *Calix*: hemispherical, imbricated, the marginal scales membranaceous. *Pappus*: margined. *Receptacle*: naked.—The species are,

* *With white Corollas.*

1. *Chrysanthemum Frutescens*; *Canary Oxeye*. Shrubby: leaves fleshy, linear, pinnate-toothed, trifid at the end. Stem shrubby, nearly two feet high, dividing into many branches; leaves of a greyish colour, cut into many narrow segments; flowers axillary, greatly resembling those of common Chamomile; there is a succession of them during great part of the year, for which this plant is chiefly esteemed.—Native of the Canary islands. It will perfect its seed in England when the seasons are favourable; but as the cuttings take root very easily during any of the summer months, the seeds are rarely sown. It will not endure our winters in the open air, therefore when the cuttings have made good roots, they should be each planted into a separate pot, and placed in the shade until they have taken fresh root, then remove them to a sheltered situation till autumn; and thence into the green house, giving them free air in mild weather, and frequently refreshing them with gentle waterings in winter; in summer they will require more moisture, and should receive the same treatment as other bardy exotics.

2. *Chrysanthemum Serotinum*; *Creeping-rooted Chrysanthemum*. Leaves lanceolate, serrate at top, acuminate at both ends. Roots perennial, creeping far under the surface: the stems are strong, and three or four feet high; the flowers appear in September.—It multiplies very fast by its creeping roots, and will thrive in any soil or situation.

3. *Chrysanthemum Atratum*; *Fleshy-leaved Chrysanthemum*. All the leaves wedge-shaped, oblong, gashed, fleshy, stem one-flowered.—It is a perennial; and frequents the pastures of the Alps in Switzerland, Savoy, and Austria.

4. *Chrysanthemum Alpinum*; *Alpine Oxeye*. Leaves wedge-shaped, pinnatifid; segments entire; stems one-flowered. Stems stoloniferous. It is perennial; and found in the south of France, Switzerland, the Valais, Savoy, about Tubingen, on the Pyrenees, and in Arragon.

5. *Chrysanthemum Leucanthemum*; *Common Oxeye*, or *Great Daisy*. Leaves stem-clasping, oblong, the upper serrate, the lower toothed. Root perennial, somewhat creeping; stem from twelve to eighteen inches high, erect, rigid, angular, at bottom often purplish and hairy, above naked, simple, or little branched; flowers terminal, solitary, large, and showy.—It is very common in dry meadows and pastures, sometimes on walls, and in corn-fields, flowering from May to July, and increasing greatly by seed. The fresh leaves chewed, have a sweetish, but unpleasant and slightly aromatic taste, somewhat like Parsley, but not hot or biting; they have been recommended in disorders of the breast, both asthmatical and phthisical, and as diuretics. Allioni commends it; and John Bauhin observes, that the young leaves are eaten for salads at Padua, as well as in other places. According to Linneus, horses, sheep, and goats eat it, but cows and swine refuse it. Mr. Curtis remarks, that it is singular, while so many beautiful varieties of the common Daisy are met with in almost every garden, we never see this plant in a similar state; he has, however, been credibly informed, that two double varieties of this species are found near Ayr in Scotland. Haller asserts, that the varieties of this plant are innumerable, and he mentions several, among others, one in which the florets of the ray are fistulous: it is highly probable, therefore, that culture would produce as

many varieties of this as the common Daisy has afforded: Parkinson mentions it with double flowers. The country people give a decoction of the fresh herb in ale for the jaundice, which operates by urine. Besides the common names of *Great and Oxeye Daisy*, Dr. Withering says it is called *Moonflower*. Gerarde calls this plant *Maudlinwort*.

6. *Chrysanthemum Montanum*; *Mountain Oxeye*. Bottom leaves spatulate-lanceolate, serrate, upper linear. Perennial: stems many, erect, very hirsute at bottom, and somewhat villose at top, simple, and one-flowered, but becoming branched in a state of cultivation; leaves smooth.—Said, by Mr. Miller, to have been imported from Verona, near which place it grows in great plenty. Sow the seeds in a shady border; they will come up in about six weeks; transplant them, when fit to remove, into another shady border, where they may remain, and keep them clean from weeds.

7. *Chrysanthemum Graminifolium*; *Grass-leaved Oxeye*. Leaves linear, toothed at the end, or the whole length. Perennial; ray of the corolla white.—This and the twelfth species rarely perfect their seeds in England, but being perennials, may easily be increased by parting the roots; the best time for this is in autumn.

8. *Chrysanthemum Mospeliense*; *Montpellier Oxeye*. Lower leaves palmate; leaflets linear, pinnatifid. An elegant plant, without scent; perennial; very smooth and slightly villose, with erect branching stems.—This species ripens seed every year in England, by which the plant is easily propagated, for if they are sown in the spring on a common border, they will come up in six weeks; when these are fit to remove, they may be transplanted into a nursery bed, at about a foot distance every way, and kept clean from weeds till autumn, when they may be removed to the places where they are designed to remain. As these plants extend their branches pretty far on every side, they should be allowed at least two feet room; if planted upon poor dry land, or upon lime rubbish, they will not grow so vigorously as in good ground, but will endure the cold better, and continue longer: when very succulent, they are apt to rot in winter; but where they grow from the joints of old walls, they continue in vigour several years.

9. *Chrysanthemum Balsamita*. Leaves ovate-oblong, serrate, eared. Perennial; stems many, erect, roundish, very slightly villose; the ray of the flower is white; disk yellow.—It was found by Tournefort in the Levant.

10. *Chrysanthemum Inodorum*. Leaves pinnate, multifid; stem branching, diffused; flowers large, terminating.—It is an annual; found in corn-fields and by road-sides, flowering from July to September. Old authors usually rank this plant with the Chamomiles.

11. *Chrysanthemum Achillæa*; *Milfoil-leaved Chrysanthemum*. Leaves bipinnate; pinnae imbricate; stem stiff and straight, many-flowered. Stem erect, somewhat angular, a foot high. Perennial.—Native of Italy.

12. *Chrysanthemum Corymbosum*; *Corymbed Chrysanthemum*. Leaves pinnate, gash-serrate; stem many-flowered. Stem erect, from eighteen inches to two or three feet high or more; florets of the ray about twenty in number, white, three-toothed; disk flat. The whole plant is void of taste and smell. It is a perennial; flowering in July and August.—Native of the mountainous woods of the south of France, Switzerland, Germany, Austria, Carniola, Hungary, and Siberia.

** *With Yellow Corollas.*

13. *Chrysanthemum Indicum*. Leaves simple, ovate, sinuate, angular, serrate, acute. Root perennial; stem herbaceous, annual, four feet high, upright, round; branches

oblique, subdivided, smooth and even; flowers subterminating, on long peduncles, commonly one-flowered, and solitary; all the florets ligulate; their colours are white, red, purple, violet, yellow, orange. They are three inches and more in diameter, but are not remarkable for the pleasantness of their odour. The many varieties of this species differ not only in colour, but in size and doubleness.—These are cultivated through the whole empire of Japan, as well as in China and Cochinchina, for the beauty of their flowers, which display themselves during the summer and autumnal months.

14. *Chrysanthemum Pinnatifidum*; *Cut-leaved Chrysanthemum*. Shrubby; leaves smooth, drawn to a point at the base, pinnatifid; segments gashed.—Found by Masson near torrents on the highest rocks in the island of Madeira.

15. *Chrysanthemum Arcticum*. Leaves simple, wedge-form, subpalmate, multifid, obtuse; stems weak, diffused, herbaceous, branching at bottom.—Native of Kamtschatka and Siberia.

16. *Chrysanthemum Pectinatum*. Leaves pinnate, linear, parallel, acute, quite entire; peduncles solitary, one-flowered. Stems very short, thickish, prostrate, creeping. Perennial.—Native of Spain and Italy.

17. *Chrysanthemum Segetum*; *Corn Marigold*. Leaves stem-clasping, the upper lacinate, the lower tooth-serrate. The whole plant is smooth; stem a foot or more in height, upright, striated, branched, each branch terminated by one large yellow flower. Besides the names of *corn marigold*, and *yellow or golden corn-flower*, it is called *yellow bottle*, in Kent; *buddle*, which is a corruption of bottle, in Norfolk; *golds*, or, as it is more generally pronounced, *goulds*, or *gows*, in the midland counties; *goulans* or *goldins*, in the north of England; and *gules*, *gools*, *guills*, or *yellow gowans*, in Scotland, from the golden colour of the flowers, which, however they may give a brilliancy to the fields in tillage, and please the eye of the passing traveller, are, as Linneus observes, no very agreeable sight to the farmer, as it is a very troublesome weed in sandy soils. Linneus informs us, that it was imported into Sweden along with corn from Jutland, about the end of the last century, and that there is a law in Denmark obliging the farmers to extirpate it. A large quantity which grew on arable land, was cut when in flower, dried, and eaten by horses as a substitute for hay. The Germans use it for dying yellow. Linneus observes, that the flowers, which appear from June to October, follow the sun remarkably. The plant is annual. The method which Linneus prescribes for destroying this weed, is, to dung the ground in autumn, then to give the land a summer fallow, and to harrow it about five days after sowing.

18. *Chrysanthemum Myconis*; *Tongue-leaved Chrysanthemum*. Leaves tongue-shaped, obtuse, serrate; scales of the calix equal; calix with scales scariose at the tip; corolla deep yellow; ray short, three toothed; crown of the seed membranaceous.—It is annual; and a native of Portugal, Spain, and Italy.

19. *Chrysanthemum Italicum*. Leaves bipinnate, serrate; rays of the flowers the length of the disk; stem procumbent. This resembles the next species very much, but the stem is more branched, many-flowered, and more erect. The ray of the flower is white, the length of the disk.—Observed by Arduini in Italy.

20. *Chrysanthemum Millefoliatum*. Leaves bipinnate, toothed; stem decumbent; rays of the corolla shorter than the disk. It is low and bushy, but the flower-stems rise nearly two feet high. It begins to flower in June, and continues till September.—Tournefort first discovered it in the Levant. Being very hardy, it will endure the open air, and may be

easily increased by slips; but does not perfect seeds in England, unless in warm dry seasons.

21. *Chrysanthemum Bipinnatum*. Leaves bipinnate, serrate, villose; rays shorter than the disk; peduncles axillary, naked, one-flowered, pubescent, the length of the leaves.—Observed by Gmelin in Siberia.

22. *Chrysanthemum Coronarium*; *Garden Chrysanthemum*, or *Cretan Corn Marigold*. Leaves pinnate, gashed, broader outwards. Stem furrowed, leafy, branching, three feet high: florets of the ray very large, broad, and short, obtusely three-toothed; in the wild plant yellow: of this plant there are single and double flowers, both white and yellow. There is also a variety with fistular florets, called *Quill-leaved Chrysanthemum*; but the seeds of this degenerate to the common sort.—Native of Sicily, Crete, the Lower Valais, &c. These plants are always esteemed as annual, so the seeds are usually sown upon a slender hot-bed in the spring, and the plants treated in the same manner as the African Marigold, for the culture of which the reader is referred to the genus *Tagetes*: but as the plants which are produced from seeds frequently produce single flowers, even if the seeds were saved from the best double flowers, on that account, many persons now propagate these plants from cuttings, whereby they continue the double sorts only. The cuttings are taken from the plants in the beginning of September, and planted in pots. They take root readily, and if placed under a hot-bed frame to screen them from the frost in winter, admitting free air in mild weather, they will survive the severity of that season, and may be transplanted into the border of the flower-garden in the spring: here they will flower in June, and continue in succession, until the first frosts set in. By the above method all the varieties may be continued without variation; but the plants which are thus propagated by cuttings will soon become entirely barren and will not produce any seed.

23. *Chrysanthemum Flosculosum*; *Bastard Chrysanthemum*. All the florets uniform, hermaphrodite. A procumbent evergreen undershrub: flowers small, solitary, terminating, of a deep yellow colour.—Native of the Cape.

24. *Chrysanthemum Japonicum*. Leaves petioled, gashed at the tip, and toothed. Stem simple, erect, striated, villose; leaves alternate, oblong, smooth, pale above, green underneath.—Native of Japan.

25. *Chrysanthemum Ceratophylloides*. Stem one-flowered; pinnas deeply cut. The whole plant is extremely smooth; stem simple, one-flowered, leafy, straight, growing to a foot in height; florets of the ray marked with lines, and gashed.—It is perennial; and found upon the mountains Tende and Briga.

26. *Chrysanthemum Arragonense*. Stem one-flowered; root-leaves heaped, linear, silky, slightly three-toothed at the tip; upper stem-leaves quite entire, acute. Stems low and shrubby, about a foot high: from the end of each of the slender woody branches of the stem, a naked peduncle is produced six inches long, sustaining one flower of a sulphur-colour, which appears in June and July, but seldom ripens seed in England.—Found in la Sierra de Villaroya, near Purujosa in Arragon.

27. *Chrysanthemum Procumbens*. Leaves sinuate-gashed, blunt; stem procumbent. Stem perennial, three feet long, frequently creeping, slender, and very much branched; peduncles many-flowered, terminating. There are many varieties, but the flowers of all are small.—It is found both wild and cultivated, in China and Cochinchina.

Chrysitrix; a genus of the class Polygamia, order Diœcia. —GENERIC CHARACTER. *Hermaphrodite Plant*. Calix; glumes bivalve, many, imbricate; valvelets ovate-oblong,

close, cartilaginous, permanent. *Corolla*: chaffs extremely numerous, heaped into a fascicle, setaceous, membranaceous, coloured, bright, longer than the calix, permanent. *Stamina*: filamenta solitary, between the chaffs capillary, the length of the chaffs; antheræ linear, growing on each filamentum, except the tip of the filamentum. *Pistil*: germen oblong, obtuse; style filiform, length of the stamina: stigmas simple. *Male*, in a distinct plant, differing in nothing from the hermaphrodite but the want of a pistil. **ESSENTIAL CHARACTER.** *Glume*: bivalve. *Corolla* of numerous setaceous chaffs. *Stamina*: many, solitary, between the chaffs. *Pistil*: one.—The only known species is,

1. *Chrysitrix Cœpensis*: *Cape Golden Hair*. Root perennial; leaves ensiform, equitant, even, a palm or foot in length. The flower comes forth from the upper edge of the scape, like a fastigiate fascicle of golden bristles, straightened by a cartilaginous perianth. Jussieu remarks, that this herb has grassy-rooted leaves; a compressed ancipital scape towards the top, cloven on one side at the edge, putting forth a single sessile head, with one-valved coriaceous spathe below it, and that the germen is sometimes abortive.—Native of the Cape.

Chrysoalanus; a genus of the class Icosandria, order Monogynia.—**GENERIC CHARACTER** *Calix*: perianth one-leaved, bell-shaped, five-cleft; divisions expanding, withering. *Corolla*: petals five, oblong, flat, spreading, inserted by their claws into the calix. *Stamina*: filamenta very numerous, placed in a circle, erect, inserted into the calix: antheræ small, twin. *Pistil*: germen ovate; style of the shape and length of the stamina, inserted laterally at the base of the germen; stigma obtuse. *Pericarp*: drupe ovate, large, one-celled. *Seed*: nut ovate, marked with five furrows, wrinkled, five-valved. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Petals*: five. *Style*: lateral. *Drupe*: with a five-furrowed, five-valved nut.—The only species is,

1. *Chrysoalanus Ieaco*; *Cocoa Plum*. It is an irregular shrub, from three to ten feet high, covered with a ferruginous bark, with pale spots; leaves ovate-roundish, obtuse, on short petioles, two inches long, alternate; racemes branched, corymbed, lax, terminating and axillary; flowers inodorous, small, with white petals, having almost the character of the Plum. Fruits roundish, about an inch in diameter, red, purple, yellow, whitish, or variegated: the skin is very thin, and the pulp small, white, with very little smell, adhering very firmly to the nut: it is of the consistence of a baked apple; the taste austere, but rather sweet, and not unpleasant: they are sold in the markets in the West Indies, and are eaten both raw and preserved: the nut or stone varies in form, but approaches to the ovate-acuminate, and sometimes has six or seven angles. It is a native of the Caribbean islands, and the neighbouring continent, near the sea. There are several varieties. As these trees are natives of the hot regions of America, they will not thrive in England, unless protected by a warm stove. They are propagated by seeds, which must be imported from their native country, and sown in the spring, in small pots filled with light earth, and plunged into a hot-bed of tanner's bark, observing to water them frequently in small quantities at each time. In six weeks the plants will come up, and, if properly managed, will be fit to remove in a month after, when they should be carefully separated, and each planted into a small pot filled with light kitchen-garden earth, and then plunged into the hot-bed again, observing to shade them from the sun till they have taken fresh root; after which they must have air every day in proportion to the warmth of the season, and their waterings should be frequent, but sparing, during the summer. In autumn remove them into the bark-stove, and plunge them into the tan-bed.

In summer they must have a good share of air, and be treated as other tender plants from the same countries.

Chrysocoma; a genus of the class Syngenesia, order Polygamia Æqualis.—**GENERIC CHARACTER.** *Calix*: common hemispherical, imbricate; scales linear, outwardly convex, acuminate. *Corolla*: compound, tubular, longer than the calix; corollets hermaphrodite, tubular, numerous, equal; proper funnel-form; border five-cleft, revolute. *Stamina*: filamenta five, filiform, very short; antheræ cylindric, tubular. *Pistil*: germen oblong, crowned; style filiform, scarcely longer than the florets, stigmas two, oblong, depressed, involute. *Pericarp*: none. *Calix*: scarcely changed. *Seeds*: solitary, ovate-oblong, compressed; pappus hairy. *Receptacle*: naked, flat. **ESSENTIAL CHARACTER.** *Calix*: hemispherical, imbricate. *Style*: scarcely longer than the florets. *Pappus*: simple; receptacle naked.—Most of these plants are perennial, and natives of the Cape of Good Hope. They may be increased by cuttings, which if planted in a common border in any of the summer months, and covered with hand-glasses, will easily take root, provided they be shaded from the sun, and duly watered: when these have gotten good roots, they should be carefully taken up, and each planted in a separate pot, filled with light earth, placing them in the shade till they have taken new root; they may then be exposed with other hardy exotic plants till autumn, when they must be removed into the green-house during the winter season; and should have a large share of fresh air in mild weather, for they only require a protection from frost, and must not be too tenderly treated.—The species are,

* *Shrubby.*

1. *Chrysocoma Oppositifolia*; *Opposite-leaved Goldylocks*. Leaves opposite, obovate; flowers fascieled, peduncled. A shrub with brachiated distorted branches; flowers yellow, terminating.—Native of the Cape of Good Hope.

2. *Chrysocoma Comaurea*; *Great Shrubby Goldylocks*. Leaves linear, straight, smooth, decurrent by the back. This rises with a ligneous stalk, about a foot high, dividing into many small branches, which are garnished with deep green narrow leaves. The flowers are produced at the end of the branches, on slender naked foot-stalks, and are of a pale yellow. It is chiefly esteemed for flowering during the greater part of the year; and the seeds ripen very well in autumn.—Native of the Cape. Both it and the sixth species may be increased by sowing them in spring, on a border of light earth: but the mode of raising them by cuttings is most expeditious, and therefore most common.

3. *Chrysocoma Sericea*. Shrubby, silky white: leaves linear, channelled; small branches panicled at top. This is easily distinguished by its very white silky leaves, branches, and peduncles, and by its yellow flowers. The bark and wood have an acrid pungent taste.—Native of Spain; where it is used as a remedy for the tooth-ache.

4. *Chrysocoma Montana*. Leaves oblong, quite entire; flowers solitary. Stem shrubby, with round villose branches; leaves acute, villose; flowers single at the ends of the branches.—Found upon Mount Horeb, in Palestine.

5. *Chrysocoma Patula*. Undershrubby: leaves linear, smooth; branches divaricate; flowers terminating, solitary, scarcely peduncled.—Native of the Cape.

6. *Chrysocoma Cernua*; *Small Shrubby Goldylocks*. Leaves linear, recurved, subscabrous; flowers, during impregnation, dropping, of a brown sulphur colour, nodding on one side before they are blown. It flowers the greater part of the year, and ripens seed very well.—Native of the Cape of Good Hope. See the second species.

7. *Chrysocoma Ciliata*; *Heath-leaved Goldylocks*. Un-

dershrubby: leaves linear, straight, ciliate; branches pubescent.—Native of the Cape.

8. *Chrysocoma Tomentosa*. Undershrubby: leaves and branches tomentose. Leaves linear, straight.

9. *Chrysocoma Scabra*. Undershrubby: leaves lanceolate-ovate, recurved, tooth-serrate; peduncles pubescent. Height nine or twelve inches, dividing into many woody branches covered with a brown bark, and these into smaller green ones, on which are very narrow subhirsute alternate leaves; corollas very small, yellow.—It flowers in August and September, and is a native of the Cape.

**Herbaceous*.

10. *Chrysocoma Linosyris*; *German Goldlocks*. Leaves linear, smooth; calices lax. Root perennial; stalks two feet and a half high: the upper part of the stalk divides into many slender peduncles, each sustaining a single head of flowers, of a bright yellow, and disposed in the form of an umbel. The plant, when handled, sends forth a fine aromatic smell.—Native of Germany, Switzerland, France, and Italy. The seeds will ripen in September, in favourable seasons; but the seedling plants do not flower till the second or third year, and hence the most general method of increasing it is by parting the roots. The best time for this, and for removing the plants, is soon after the stalks decay in autumn, that they may have time to strike fresh root before winter. It will increase very fast by the roots in a dry loose soil, and in the open air; but the roots often rot upon strong wet lands in winter.

11. *Chrysocoma Biflora*; *Two-flowered Goldlocks*. Panicked: leaves lanceolate, three-nerved, dotted, naked. Root perennial, creeping, spreading on every side to a considerable distance, sending up many erect stalks, with flat spear-shaped leaves, ending in points: these are rough, and have three longitudinal veins. The upper part of the stalks branch out and form loose panicles of yellow flowers, which are larger than those of the former sort.—Native of Siberia. It propagates too fast by its creeping roots, to be admitted into the flower-garden; but as they will grow in any soil or situation, a few roots may be planted on the side of extensive rural walks, round the borders of fields, where they will require no care, and their flowers will make a good appearance, and continue long in beauty.

12. *Chrysocoma Villosa*. Leaves lanceolate, villose; calices close. Stem a foot and a half high, upright, round, hoary, branched; flowers yellow.—Native of Siberia, &c.

13. *Chrysocoma Purpurea*. Leaves elliptic-lanceolate, subserrate, pubescent; panicle terminating, corymbed.—Found in the Isle of Tanna.

Chrysogonum; a genus of the class Syngenesia, order Polygamia Necessaria.—**GENERIC CHARACTER.** *Calix*: common five-leaved, flat, spreading; leaflets lanceolate, nearly the length of the flower. *Corolla*: compound radiate; corollets, hermaphrodite, very many in the disk; females five in the ray: proper, in the hermaphrodites, funnel-form, five-toothed, erect; in the females ligulate, oblong, truncate, three-toothed. *Stamina*: in the hermaphrodites, filamenta five, very small; antheræ cylindrical, tubular. *Pistil*: in the hermaphrodites; germen very small; style setaceous, length of the corollet; stigma obscure. In the females; germen larger, covered with its proper perianth; style shorter; stigmas two, revolute. *Pericarp*: none; calix unchanged. *Seeds*: of the hermaphrodites, none; of the females, solitary, inverse, heart-shaped, depressed-quadrangular, with the sides widish, crowned with a three-toothed scale, gaping inwards, contracted towards the base: each seed lies concealed within its proper four-leaved glume, the outward scale being ovate,

VOL. I.—25.

and wider, the three remaining ones very narrow, closely converging, and gaping when the seed is ripe. *Receptacle*: chaffy, flat; chaffs linear, obtuse. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Seed*: involved in a four-leaved calicle. *Pappus*: one-leaved, three-toothed. *Receptacle*: chaffy.—The only species is,

1. *Chrysogonum Virginianum*. Leaves moderately hairy opposite, on long petioles, resembling common *Baum*; flower golden-coloured, terminal; seeds obovate, convex without, concave within, having two obscure grooves on them, and of a pale bay colour.—Native of Virginia.

Chrysophyllum; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, small; leaflets roundish, obtuse, permanent. *Corolla*: monopetalous, bell-shaped; border five-cleft; segments roundish, very much expanded, shorter than the tube. *Stamina*: filamenta five, subulate, placed on the tube, converging; antheræ roundish, twin, incumbent. *Pistil*: germen roundish; style very short; stigma obtuse, subquinquefid. *Pericarp*: berry globular, ten-celled, large. *Seeds*: solitary, bony, compressed, marked with a scar, shifting. **ESSENTIAL CHARACTER.** *Corolla*: bell-shaped, ten-cleft; segments alternate, spreading. *Berry*: ten-seeded.—These trees being natives of the hottest parts of the world, they cannot be preserved in this country without being kept in the warmest stoves: and should always remain in a hot-bed of tanner's bark, otherwise they will make but little progress. They are propagated by seeds, which must be procured from the places of their growth, for they do not produce them in Europe. These seeds must be fresh, otherwise they will not grow; and if they be sent over in sand, it will preserve them from drying too much: when they arrive, they must be sown as soon as possible, in small pots filled with light fresh earth, and plunged into a good hot-bed of tanner's bark. If the seeds be good, and the bed in a proper temperature of warmth, the plants will appear in five or six weeks, and in two months after will be strong enough to transplant; in doing which, the plants with all the earth should be shaken out of the pots very carefully, and separated with their roots entire, and each replanted into a small pot filled with light fresh earth, and plunged again into a hot-bed of tanner's bark, watering and shading them until they have taken fresh root. The chief care they require is, to keep them in a proper degree of heat, and never to put them into too large pots. In winter they should be watered twice a week, in small quantities.—The species are,

1. *Chrysophyllum Cainito*; *Broad-leaved Star Apple*. Leaves ovate, striated in parallel lines, tomentose, and shining underneath. Leaves alternate, petioled, quite entire; peduncles lateral, one-flowered, numerous, very short.—Brown has two species of *Chrysophyllum*, which he calls, 1. *Star Apple Tree*, and 2. *Damson Plum*. Both have the leaves ferruginous underneath. The fruit of the first is larger and globular; of the second smaller and smooth. The last, he says, is found wild in many parts of Jamaica, but seldom grows to any considerable size: the first is cultivated all over the country, and thrives with very little care; it rises commonly to a very considerable size, and spreads much; but its branches, like those of the other sort, are very slender and flexile, and hang down when charged with fruit. This is full of milk, and the fruit retains it even in the most perfect state; but though this juice be rough and astringent in the bark, and even in the unripe fruit, yet when the fruit is in full perfection it becomes sweet and gelatinous, with an agreeable clamminess, and is very much esteemed. The juice of this fruit, a little before it is perfectly ripe, when mixed with a

small quantity of orange juice, will occasion extreme costiveness, and would undoubtedly prove a very powerful remedy in some disorders. Perhaps the action of the fire might take off much of the native roughness of the juice, if it were to be inspissated by that means. The Americans are fond of this fruit, but it is rarely eaten by the Europeans.—Native of Martinico and Domingo. This, as well as the rest of the plants in this genus, is preserved in several curious gardens for the beauty of the leaves, for which this species is very remarkable; the under sides of its leaves shining like satin; the upper sides are of a deep green. They continue all the year, and make a very pretty appearance in the stove.

2. *Chrysophyllum Argenteum*; *Narrow-leaved Star Apple*. Leaves sickle-ovate, shining, and tomentose underneath. The leaves are green, and smooth on the upper surface, without the parallel lines which mark the foregoing species; underneath they are of a silvery-shining green. The fruit is roundish, of a dirty blue purple colour, the size of a middling plum, and eatable; the pulp is soft, blueish, and slightly milky, tasting like the others.—Native of Martinico.

3. *Chrysophyllum Glabrum*; *Smooth-leaved Star Apple*. Leaves quite smooth on both sides. This tree grows fifteen feet in height, erect, and branching; leaves alternate, petioled, quite entire, a little coriaceous; fruit blue, the form and size of a small olive, with a sweetish viscid flavour; but seldom eaten, except by slaves and children.—Native of Martinico.

4. *Chrysophyllum Monopyrenum*. Leaves elliptic, acuminate, golden-tomentose beneath; fruit ovate, one-seeded.—Native of the West Indies.

5. *Chrysophyllum Microcarpum*. Leaves ovate, smooth, pubescent beneath; berries oblique, oblong, one-seeded. Fruit very sweet.—Native of Hispaniola.

6. *Chrysophyllum Rugosum*. Leaves oblong, acuminate, smooth on both sides; fruit acuminate, wrinkled.—Native of mountain-woods in Jamaica.

Chrysosplenium; a genus of the class Decandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth four or five-parted, spreading, coloured, permanent; divisions ovate the opposite ones narrower. *Corolla*: none, unless the coloured calix be called so. *Stamina*: filamenta eight or ten, subulate, erect, very short, placed in an angular receptacle; antheræ simple. *Pistil*: germen inferior, ending in two subulate styles, the length of the stamina; stigma obtuse. *Pericarp*: capsule two-beaked, two-parted, one-celled, two-valved, surrounded with the green calix. *Seeds*: very many, very small. ESSENTIAL CHARACTER. *Calix*: four or five cleft, coloured. *Corolla*: none. *Capsule*: two-beaked, one-celled, many-seeded.—If any curious person feel disposed to cultivate the plants of this genus in a garden, they must be planted in very moist shady places, otherwise they will not thrive. They succeed best in pots filled with bog earth, set in a pan of water, and placed under the shelter of a wall or hedge.—The species are,

1. *Chrysosplenium Alternifolium*; *Alternate-leaved Golden Saxifrage*. Leaves alternate. The root has offsets, but no creeping suckers; leaves all deeply notched; root-leaves two or three, kidney-shaped, bluntly notched, on long hairy petioles; stem-leaves alternate, one of them solitary, about the middle of the stem, the rest clustered, partly about the root, and partly near the flowers; flowers gold-coloured, in a terminating dichotomous leafy corymb. Stem three-cornered, with imperfect angles, hairy below, smooth upwards, near the top forked, the forks bare of leaves.—It is found in moist shady places, and by the sides of rivulets, in Lapland, Sweden, Denmark, Germany, Switzerland, Carniola, Italy, Siberia, Japan, and in Great Britain, though less commonly,

as near Bingley, and about Esholt, eight miles from Leeds in Yorkshire; Porland Heath, near Norwich; in Worcestershire, and in Scotland. A black boggy soil, by rills in wet woods, is the favourite situation of this plant.

2. *Chrysosplenium Oppositifolium*; *Opposite-leaved Golden Saxifrage*. Leaves opposite. Stems creeping at bottom, square, very tender, about four inches in height, beset with a few stiffish white hairs, branched and forked at top; leaves petioled, somewhat fleshy, yellowish green, whitish underneath; flowers yellow, in a sessile fastigiate corymb; segments of the calix nearly equal; seeds of an orange colour.—This is found in the same soil and situation as the other, in Denmark, Holland, Switzerland, and Germany. It is more common in England than the first species, and may be found on Hampstead Heath; in the boggy part of Charlton Wood; Polingland Heath, near Norwich; and at Selborne in Hampshire: it flowers in April, or early in May, and ripens seed soon after. Perennial.

Cicca; a genus of the class Monœcia, order Tetrandria.—GENERIC CHARACTER. *Male Flowers*, scattered. *Calix*: perianth four-leaved; leaflets roundish, concave. *Corolla*: none. *Stamina*: filamenta four, setaceous; antheræ subglobose, the length of the calix. *Female Flowers*, scattered on the same plant. *Calix*: as in the males. *Corolla*: none. *Pistil*: germen roundish; styles four, two-parted, subulate, the length of the germen; stigmas acute, permanent. *Pericarp*: capsule subglobose, tetracoccos, elastic. *Seeds*: solitary. ESSENTIAL CHARACTER. *Male Calix*: four-leaved. *Female Calix*: three-leaved. *Styles*: four. *Capsule*: tetracoccos.—The species are,

1. *Cicca Disticha*. Male and female flowers in separate racemes on the naked part of the branches. A tree with long simple branches; leaves alternate, petioled, distich, ovate, acuminate, glossy.—Native of the East Indies.

2. *Cicca Nodiflora*. Flowers aggregate, axillary. A shrub; leaves on short petioles, egg-shaped, acute, smooth, entire; flowers very small; fruit a globose berry.—Native of Java.

Cicely. See *Cherophyllum*.

Cicer; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth five-parted, length of the corolla; segments four, incumbent on the banner, the two middle converging longitudinally, the lower underneath the keel. *Corolla*: papilionaceous; banner flat, roundish, larger, bent in on the sides; wings obtuse, half the length of the banner; keel shorter than the wings, sharpish. *Stamina*: filamenta ten, diadelphous, rising; antheræ simple. *Pistil*: germen ovate; style simple, rising; stigma obtuse. *Pericarp*: legume rhomboid, turgid, inflated. *Seeds*: two, roundish, gibbous, with knots on the sides, crooked, and bent in at top. ESSENTIAL CHARACTER. *Calix*: five-parted, length of the corolla; the four upper segments incumbent on the banner. *Legume*: rhomboid, turgid, two-seeded.—The only species at present known is,

1. *Cicer Arietinum*; *Chickpea*. Annual; stem from a foot to eighteen inches in height, erect, leafy, branched; corolla purple or white; calix hirsute.—Native of the south of Europe, the Levant, and Africa, where it is frequently eaten both raw and boiled. Gerarde says it is sown in our London gardens, but not commonly, and is in English named *common cich*, or *ciches*, *red cich* or *sheep's cich*, or *peason*. Parkinson adds the names of *cicers* and *rammes ciches*. Hill informs us that the seeds are eaten, and are found to be gentle diuretics. They are sometimes used as a substitute for coffee when roasted. The seeds may be sown in the spring, in the same manner as peas, making drills with an hoe about an inch and a half deep, in which the seeds should be sown at

about two inches asunder, and the earth drawn with a rake into the drill to cover them. The drills should be made at three feet distance from each other, that there may be room for their branches to spread, when the plants are fully grown, as also to hoe the ground between them, to keep it clean from weeds, which is all the culture these plants require. It flowers in June, and the seeds ripen in August; but unless the season prove warm and dry, the plants decay in this country before the seeds are ripe.

Cichorium; a genus of the class Syngenesia, order Polygamia Aequalis.—GENERIC CHARACTER. *Calix*: common calicled, cylindric; scales eight, narrow-lanceolate, equal, forming a cylinder, and five others incumbent and shorter. *Corolla*: compound, flat, uniform; corollules hermaphrodite, twenty in a ring; proper monopetalous, ligulate, truncate, deeply five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindric-pentagon, tubulous. *Pistil*: germen oblong; style filiform, the length of the stamina; stigmas two, revolute. *Pericarp*: none. *Calix*: cylindric, converging at top. *Seeds*: solitary, compressed, with sharp angles; pappus obscurely hairy, slightly five-toothed. *Receptacle*: somewhat chaffy. ESSENTIAL CHARACTER. *Calix*: calicled. *Pappus*: slightly five-toothed, obscurely hairy. *Receptacle*: somewhat chaffy.—The species are,

1. *Cichorium Intybus*; *Garden and Wild Succory*. Flowers twin, sessile; leaves runcinate. Root perennial, yellow on the outside, tapering, branched, the thickness of the finger, from a span to a foot in length, milky; stem from one to three feet in height, upright, rigid, crooked, angular, roughish to the touch, and generally very much branched, leaves radical, numerous, roughish; flowers generally in pairs, sessile in the bosom of the upper leaves; florets of a fine blue, frequently white, and sometimes red; tube white, dilated, and hairy at top; border ribbed on the under side, and villose; antheræ deep blue. The fine blue colour of the florets is convertible into a brilliant red by the acid of ants. The flowers open at eight, and close at four.—It is common in the borders of corn-fields, flowering from July to September, and increasing itself much by seed. This plant has generally been considered as a noxious weed, although for several years past the French have cultivated it as food for cattle. Arthur Young, Esq. introduced it into England for the same purpose in 1788, and has since cultivated it to a considerable extent with great success. In Lombardy it is sown mixed with other herbs of pasture, and cut three or four feet high; it is there reputed to increase both the milk and flesh of cattle, and to be very nutritious when made into hay: horses eat it greedily, and it is an important object for summer soiling both for them and cattle; sheep also eat it freely. It defies drought, being of early growth, and the first large and spreading leaves covering the ground so as to retain the moisture: the thick stiff stalks will support themselves against winds and the heaviest rains, nor does the severest cold at all injure it. Its quick growth increases its value, because it furnishes abundance of salutary fodder, at the season when green food is scarce. It has been known to grow seven inches in three weeks, whilst Saintfoin and Burnet grew only four inches; two cuttings may be made of it in the first year, and three or four, according to the season, every year after, in April, June, August, and October, or in May, July, and October, never letting it stand till it becomes hard and sticky; or it may be cut continually, by beginning again when the whole piece is gone over, and thus yield a constant supply of fresh food during seven or eight months. The produce is said to be superior, on the whole, to that of Lucerne, in the proportion of three to one. A piece of ground sown with Succory, was found to yield

by the acre the year of sowing, at two cuttings, July the 24th and October the 17th, *nineteen tons four hundred-weight*; second year, at three cuttings, May 21st, July 24th, and December 3d, *thirty-eight tons nine hundred-weight*; and the whole average produce of four years was nearly *thirty tons*. The quantity of seed produced on an acre has been, the first year, a hundred and a half; the second, two hundred-weight; and the third, from three hundred and a half, to four hundred-weight and a half. After allowing for the partiality which commonly attends novelties, and notwithstanding this succulent plant seldom dries well for hay in our climate, except in very dry seasons, yet, as far as our experience has hitherto gone, it must be conceded that Succory seems to be a valuable object of culture, as fresh feed for horses, cows, and sheep.—The leaves, when blanched, are eaten early in the spring as salads; and the roots, gathered before the stems shoot up, are eatable, and when dried may be made into bread. The Germans dry and pulverize them to mix with their coffee, to two parts of which they add one of Succory roots, which is said to increase its strength and salubrity, as well as improve the taste. Hill informs us, that an infusion of the root opens obstructions, and is good against the jaundice. A decoction of the whole plant, fresh gathered, works powerfully by urine, is good for the gravel, and promotes the menses. Succory is an useful detergent, aperient, and attenuating medicine, acting without much irritation, tending rather to cool than heat the body, and at the same time corroborating the tone of the intestines: the juice, taken in large quantities, so as to keep up a diarrhœa, and continued for some weeks, has been found rather to produce excellent effects in scorbutic and other chronic disorders.—It is the common Succory, (or *Cichoris*, as agriculturists affect to call it from the French name *Chicorée*,) or rather a highly improved variety of it, that is now introduced into field culture with great advantage. The proper quantity of seed to be sown upon an acre, either alone or with spring corn, is twelve pounds; but if it be sown with various other seeds, the quantity of Succory seed must be less, in proportion to the quantity of such seeds. When sown with Barley or Oats, with either of which it succeeds very well, it must be sown of course at the usual time of sowing these grains; but alone it may be put into the ground with safety at any time between March and September. It should not be mixed with Clover, unless the latter be expected to fail. Chicory does not stool, tiller, or thicken on the ground: it flourishes best where it has most room and air; it should seem therefore that the drill husbandry would be most suitable to it: thus cultivated, after the first year it may be mown four times a year. If sown for seed only, it should be drilled alone, or at least drilled across corn before it be up; but it is better sown by itself.

2. *Cichorium Endivia*; *Broad-leaved Succory*, or *Common Endive*. Flowers solitary, peduncled; leaves entire, crenate. Stem herbaceous, annual, two feet high, upright, round, thick branched; root-leaves many, large, subcuneiform, sinuate-toothed, smooth on both sides; the uppermost lanceolate, small; flowers pale blue, solitary, peduncled.—Native of China and Japan. There is a variety with *curled leaves*, which is almost exclusively cultivated in the south of England, as an early salad; but no kind of Endive is much cultivated in the north. The first season for sowing is in May, for those which are sown earlier generally run up to seed before they have arrived at a proper size for blanching, and it frequently happens that the seeds sown in May in the rich grounds near London, will run to seed the same autumn, but this seldom happens in colder situations, therefore there should be some sown about the middle or end of the month. The next

sowing should be about the middle of June; and the last in the middle of July: these three crops will furnish a supply for the whole season, as there will be plants from each sowing very different in their growth, so that there will be three different crops from the same beds. When the plants appear, they must be weeded, and watered in dry weather, to keep them growing until they be fit to transplant, and should then be removed to a rich spot of open ground, well dug, levelled, and, if very dry, it must be well watered, to prepare it to receive the plants, the largest of which should then be drawn carefully out of the seed-bed, so as not to break their roots, leaving the smaller ones to acquire more strength. As the plants are drawn up, they should be placed with their roots even, all the same way, and every handful as they are drawn should have the tops of their leaves shortened, to make them of equal length; then the ground should be marked out in rows at one foot asunder, and the plants set ten inches distant in the rows, closing the earth well to the roots: they should be well watered every other evening, till the plants have taken good root, and afterwards should be kept clean from weeds. When the plants of the seed-bed have been thus thinned, they also should be well cleaned and watered, which will encourage the growth of the remaining plants, so that in ten days or a fortnight after, there may be another thinning made by removing some more plants, which should be transplanted as above described; and about the same distance of time, the third and last drawing of plants may be transplanted. Those plants which were first transplanted will be fit to blanch by the latter end of July at farthest; and if they be properly managed, in three weeks or a month will be fit for use, which will be as soon as these salads are commonly required; for during the continuance of good Cos-lettuce, few persons care for Endive in their salads; nor indeed, is it so proper for warm weather. If any of the plants should put out flower-stems, they must be immediately pulled up, and carried away as good for nothing. As the quantity of roots necessary for the supply of a middling family is not very great, there should not be too many plants tied up to blanch at the same time; therefore the largest should be first tied, and in a week after those of the next size, so that there may be three different times of blanching the plants, on the same spot of ground: but as in some large families there is a great consumption of this herb for soups, the quantity of plants should be proportionably greater, at each time of planting and blanching.—In order to blanch Endive, provide a parcel of small osier twigs or bass-mats, to tie up some of the largest heads, which should be done in a dry afternoon, when there is neither dew nor rain to moisten the leaves in the middle of the plants, which would occasion their rotting soon after their being tied up; the manner of doing it is as follows: First gather up all the inner leaves of the plant in a regular order, into one hand, and then take up those on the outside which are sound, pulling off and throwing away all the rotten and decayed leaves which lie next the ground, observing to place the outside leaves all round the middle ones, as nearly as possible in the natural order of their growth, so as not to cross each other; then having grasped the whole plant close up in your hand, tie it up with the twig, bass, &c. at about two inches below the top, very close, and about a week after go over the plants again, and give them another tie about the middle, to prevent the heart-leaves from bursting out on one side, which they are subject to do as the plants grow, if not thus prevented; in doing this, you need only tie up the largest plants first, and so go over the piece once a week, as the plants increase in their growth, by which means you will continue the crop longer than if they were all tied up at one

time; for when they are quite blanched, which will be in about three weeks or a month after tying, they will not hold sound and good above ten days or a fortnight, especially if the season prove wet, and it is on this account that I would advise sowing at three or four different seasons, that you may have a supply as long as the weather will permit; but in order to this, you must transplant all the plants of the last sowing under warm walls, pales, or hedges, to screen the plants from frost; and if the winter should prove very sharp, you should cover them with some pease-haulm, or such other light covering, which should be constantly taken off in mild weather: these borders should also be as dry as possible, for the plants are very subject to rot, if planted in a moist soil in winter. Although it has been before directed that the plants should be tied up in order to blanch them, yet this is only to be understood for the two first sowings; for after October, when the nights begin to be frosty, those plants which are so far above ground will be liable to be much injured thereby, especially if they remain uncovered in frosty weather; therefore the best method is, to take up your plants of the latter sowings in a very dry day, and with a large flat-pointed dibble plant them into the sides of trenches of earth, which should be laid very upright, planting them sideways on the south side of the trenches, towards the sun, with the tops of the plants only out of the ground, so that the hasty rains may run off, and the plants be kept dry, and secured from frosts. The plants thus planted will be blanched fit for use in a month or five weeks' time, after which they will not keep good more than three weeks before they will decay; you should therefore continue planting some fresh ones into trenches every fortnight or three weeks, that you may have a supply for the table; and those which were last transplanted out of the seed-beds should be preserved till February, before they are planted to blanch, so that from this you may be supplied until the beginning of April, or later; for at this last planting into the trenches it will keep longer than in winter; the days growing longer, and the sun advancing with more strength, dries up the moisture much sooner than in winter, which will prevent the rotting of these plants; but if the weather should prove frosty, these latter plantations of Endive should be covered with mats and straw to preserve them, otherwise the frost will destroy them, but the coverings must always be taken off when the weather is favourable. When your Endive is blanched enough for use, dig it up with a spade, and, after having cleared it from all the outside green and decayed leaves, wash it well in two or three different waters, to clean it the better from slugs, and other vermin, which commonly shelter themselves among the leaves. But in order to have a supply of good seeds for the next season, you must look over those borders where the last crop was transplanted, before you put them into the trenches to blanch, and make choice of some of the largest, soundest, and most curled plants, in number according to the quantity of seeds required: a dozen of plants will produce seeds enough for a small family; and for a large one, two dozen or thirty plants will be sufficient. These plants should be taken up, and transplanted under a hedge or pale, at about eighteen inches distance, in one row, about ten inches from the hedge or pale; this should be done in the beginning of March, if the season be mild, otherwise it may be deferred a fortnight longer: when the flower-stems begin to advance, they should be supported by packthread, which should be fastened to nails driven into the pale, or to the stakes of the hedge, and run along before the stems, to draw them upright close to the hedge or pale, otherwise they will be liable to break with the strong winds. Observe also to keep them clear from

weeds, and about the beginning of July your seeds will begin to ripen; as soon as you find the seeds quite ripe, you must cut off the stalks, and expose them to the sun upon a coarse cloth to dry, and then beat out the seeds, which must be dried and put in bags of paper, and preserved for use in some dry place: but be cautious not to wait for all the seeds ripening upon the same plant, for if so, all the first-ripe and best of the seeds will scatter and be lost before the others be nearly ripe, so great an inequality is there in the time of ripening the seeds of the same plant.

2. *Cichorium Spinosum*; *Prickly Succory*. Stems dichotomous; branches naked, spinescent; flowers axillary, solitary. This sends out many long leaves from the root, which are indented on their edges, spreading flat on the ground; flowers blue.—Native of the islands of the Archipelago, and of Sicily, in dry sandy places near the coast. In England the plant is biennial, but is frequently killed by cold winters; it flowers and seeds about the same time as the first sort, and may be treated in the same way as the Endive.

Cicuta; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel universal, roundish; rays very many, equal; partial roundish, with very many equal setaceous rays. *Involucre* universal, none; partial many leaved; leaflets bristly, short: perianth proper, scarcely visible. *Corolla*: universal uniform; floscules all fertile; proper of five ovate, inflected, nearly equal petals. *Stamina*: filamenta five, capillary, longer than the corolla; antheræ simple. *Pistil*: germen inferior; styles two, filiform, longer than the corolla, permanent; stigmas headed. *Pericarp*: none; fruit subovate, furrowed, bipartite. *Seeds*: two, subovate, convex, and striated on one side, flat on the other. **ESSENTIAL CHARACTER.** *Fruit*: subovate, furrowed.—The species are,

1. *Cicuta Virosa*; *Long-leaved Water Hemlock*. Umbels opposite-leaved; petioles margined, obtuse. Stem round, hollow, two to four feet high; leaves twice ternate, larger ones pinnate; leaflets lanceolate, acute, the serratures white at the tip; antheræ white or reddish purple; styles at first short and very close, after flowering much longer; stigmas white, obtuse.—This plant generally grows near the sides of large stagnant waters, or in shallow slow rivers, in England, and all the north of Europe, but not common with us. Towards the end of autumn, the root for the succeeding summer is formed out of the lower part of the stalk; this is divided transversely into many large unequal cells, so that it becomes specifically lighter than water, and in winter, when the rivers or pools swell, is buoyed up; the old root then rots, floats all the winter, and in rivers is frequently carried to great distances. In the spring the old root is washed away, and the new one, on coming near the soil, sends out many slender fibres, by which it is again fixed, grows, and flowers. This plant is one of the rankest of our vegetable poisons; numerous instances of the fatal effects of it are recorded in the Philosophical Transactions by Dr. Watson, upon the authority of Wepfer, Haller, and others. Linneus informs us that it is fatal to swine; and Withering observes, that early in the spring, cows often eat of it, and are killed by it; but that as summer advances, and its scent becomes stronger, they carefully avoid it: he adds, that horses and sheep are not affected by eating it, and that goats greedily devour it with impunity. Strong emetics, succeeded by vegetable acids or oils, are the most approved remedies for counteracting this poison.

2. *Cicuta Bulbifera*. Branches bulbiferous. The leaves are divided into very minute capillary segments; the flowers are white, with the smell of Cumin flowers.—Native of watery

places in Virginia and Canada. This, and the next species, may be propagated by seeds sown in autumn on a shady border; the plants will come up in the spring, and require no other care but to keep them clean.

3. *Cicuta Maculata*; *Spotted Water Hemlock*. Serratures of the leaves mucronate; petioles membranaceous, two-lobed at the end; stem thick, spotted with purple, three feet high and more; leaves black, shining, triply pinnate; flowers white; fruit middle-sized, ovate-globular, thick, gibbous, distantly ribbed. Root perennial.—Native of watery places in Virginia, Switzerland, &c.

Cimicifuga; a genus of the class Polyandria, order Tetragynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets roundish, concave, caducous. *Corolla*; nectaries four, petal-shaped, urceolate, cartilaginous. *Stamina*: filamenta twenty, filiform; antheræ twin. *Pistil*: germina four to seven; styles recurved; stigmas longitudinal on the style. *Pericarp*: capsules oblong, opening with a lateral suture. *Seeds*: many, covered with spreading scales. **ESSENTIAL CHARACTER.** *Calix*: four or five leaved. *Nectaries*: four, urceolate. *Capsules*: four to seven.—The only species is,

1. *Cimicifuga Fœtida*; *Stinking Bugbane*. Root perennial, thick, knotty, short, with many thickish fibres creeping transversely; stem sometimes two yards in height, red at the base, thence pale green, slightly hirsute, scarcely striated; leaves pinnate; leaflets egg-shaped, serrated; flowers in long terminating racemes, alternate, globular, on very short pedicels. The flowering-spike hangs down at first, but becomes erect as the flowers open. The whole plant has a strong virose smell, occasioning the head-ache: it flowers in the middle of July, ripens its seed in the middle of August; and is a native of the farther Siberia, from the river Jenisca.

Cinchona: a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, superior, short, five-toothed, permanent; teeth sharp. *Corolla*: monopetalous, funnel-shaped, five-cleft; tube long, obscurely angular; segments lanceolate or linear, equalling the tube. *Stamina*: filamenta five, in the middle of the tube; antheræ linear, erect. *Pistil*: germen inferior, turbinate, obscurely angular; style the length of the stamina; stigma thick, bifid or entire. *Pericarp*: capsule crowned with the calix, bipartite, opening into two parts inwardly, the partition parallel. *Seeds*: many, oblong, compressed, surrounded by a membranaceous wing. **ESSENTIAL CHARACTER.** *Capsule*: inferior, two-celled, bipartite; the valves parallel to the partitions, opening inwardly.—The Cinchonas are trees; the branches are round, except at the top, where they are obscurely four-cornered; the flowering branches are alternately compressed; the leaves are opposite, undivided, and quite entire; the inflorescence, in most of the species, is a brachiate panicle, with trifid peduncles.—The species are,

* *Flowers tomentose*; *Stamina included*.

1. *Cinchona Officinalis*; *Common Jesuit's bark*, or *Official Cinchona*. Leaves ovate-lanceolate, smooth; capsules oblong. This is a tall tree, with a trunk rather bigger than a man's thigh; the branches are covered with a purplish brown bark, frequently rugged, with obliquely transverse chinks, and scarred by the fallen leaves; leaves two to three inches long, and one broad, opposite, petioled, green above, pale underneath, smooth; corolla tomentose on the outside.—Native of Peru, growing abundantly on a long chain of mountains, extending to the north and south of Loxa, between two and five degrees of south latitude, where the trunks frequently exceed a man's body in size: they thrive best in a red clayey or rocky ground, especially on

the banks of small rivers or torrents, and the most proper season for cutting the bark is from September to November, which is the only period of some intermission from rain. Having made a road from the nearest plantation in the low lands to the spot where the trees abound, they build huts for the workmen, and a large hut for the bark : each Indian is provided with a large knife, and a bag that will hold about fifty pounds of green bark ; he cuts down the bark as high as he can reach from the ground, and then fastens a stick about half a yard long with tough withs to the tree, like the step of a ladder, and having sliced off the bark as high as he can reach with this, he fixes a new step, and thus ascends to the top, while another Indian below gathers up what he cuts down : this process they perform by turns, going from tree to tree, till the bag is filled. Care is taken not to cut the bark wet ; and if it should happen to be moist, they immediately carry it to the low country to dry, for otherwise it loses its colour, turns black, and rots ; which will also happen if it remain long in the hut without being spread, so that the Indians remove it as soon as the weather permits, and while they are cutting, the mules are employed in carrying the bark to the drying place, where it is spread in the open air, and frequently turned. As the trees are said to perish soon after they have been stripped of their bark, a scarcity of them has been apprehended ; but Condamine asserts, that the young trees do not die by losing their bark, but send out fresh roots from the base : and, as the trees which stand to any considerable age probably increase by seed, the fear that this valuable bark may be exhausted seems to be groundless. The bark of this tree is brought to us in pieces of different sizes, some of which are rolled up in thick short quills, and others are flat : the outside is brownish, and has sometimes a whitish moss on it ; the inside is of a yellowish, reddish, or rusty iron colour. Those who affect to be nice in the choice of their drugs, prefer such pieces as are rolled up about the size of a common quill. To the taste it is astringent and bitter, and has an advantage over other bitters, in being aromatic. To enumerate all its virtues, would require the extent of a volume. Morton, the contemporary of Sydenham, was one of the first who made considerable use of the bark. From us it was carried into France, where the dauphin was cured by it. Boerhaave restrains the use of the bark with almost innumerable cautions ; while Hoffman and others are boundless in its praise. All the prejudices with which it had at first to contend, are now done away, and its character has long been universally established : it gives out its virtues both to cold and boiling water ; but the decoction is thicker, and more powerfully tinctured with its taste : the bark, however, is generally given in substance, and may be taken in very considerable doses with the most perfect security : sometimes it is found necessary to join it with opiates, to prevent its passing off too suddenly as a purgative. A most excellent tincture of the bark, under the name of *Huzham's Tincture*, is sold in the shops, in which preparation the bark is rendered still more efficacious by the addition of orange-peel and snake-root. The best sort is bitter, resinous, breaks short and smooth, and is easily reduced to powder. The great number of complaints in which this medicine may be advantageously employed, seem to entitle it to the character of an universal one. In many disorders it is a sovereign specific ; and every practitioner finds by daily experience, that its use may still be carried to a greater extent of cases. Its first and principal operation appears to be the strengthening of the solids ; and however variously its salutary effects may appear, they are undoubtedly the consequences of this general property or power. In all disorders where the bark

is found serviceable, other medicines of an astringent or bitter nature may be used, and will be found serviceable, though not so effectual as that, when it is given in substance, which it always should be where the stomach will bear it, as none of its preparations contain all its parts, and none of its parts separately answers so well as the whole. Many are intimidated from the use of this medicine, though convinced of its salutary effects, through fear of its astringency ; but there is very little cause to be apprehensive on that account ; it is a prejudice for which there is in reality very little foundation, for the truth is, the bark is not of a very astringent nature : it may be given in almost all disorders, when once there is a fair remission of the fever, and the pain which attends it ; and in general while the pulse of a grown person does not exceed seventy strokes in a minute, it is safe and useful. So far from causing obstructions in any part of the body, it in many instances removes such as are already formed, as is frequently experienced in glandular swellings, and serofulous cases : it has been given to women two days after delivery with success, to the amount of a drachm every three hours, without lessening the lochia ; and during the natural flux of the menses, without in the least interrupting them ; and even in the confluent small-pox, the use of it does not lessen the spitting : whence it appears, that the astringency of this medicine is too slight to obstruct either any natural or critical discharge ; and, therefore, whenever its use is indicated on other accounts, it may be freely administered, without running any risk of doing mischief by its astringency. If ever any injury were sustained by its use in a case to which it is adapted, a too late, and not too early administration is generally to be blamed. It was first celebrated for its efficacy in fevers, and in this respect it still maintains its reputation : it is indeed the principal thing to be depended on in all kinds of fevers ; and if given in the ardent, when they are once brought to intermit, it generally effects a cure. In the low kinds of fevers its effects are equally salutary, but its use should be begun much earlier ; in agues, and all other intermitting complaints, it is almost a certain remedy. It is not, however, only in fevers of every kind that the bark is so potent a remedy, but also in numerous other cases, and particularly in mortifications. It has also of late been much used in cases of acute rheumatism, especially after the violence of the disease has been in some degree moderated by the antiphlogistic treatment, or when an evident remission has taken place. In the fluor albus, profluvia, and hæmorrhages of every kind, the decoction of the bark is of excellent use : and the tincture taken in water of various parts, as chalybeate, &c. is extremely useful in restoring lost appetite. If any medicine, in short, deserved the title of a panacea, the bark would prefer the fairest claim. Foul ulcers, by a free use of the bark, are soon reduced to a healing state : it resolves glandular tumors, and promotes a laudable suppuration in those of an inflammatory nature.—But it should be noticed, that as the judicious use of this medicine is so extensively beneficial, so an improper one may be productive of as ill consequences ; for though it is an excellent febrifuge, its use in ardent fevers is only in the time of their intermitting, for when the fibres are tense its use is not necessary ; its primary effect being to increase their firmness, must, in this case, render it highly improper to be administered. Cases sometimes occur in which its free use would be very hurtful, such as where symptoms of congestion or topical inflammation of the head appear, which are known by redness of the eyes, phrenetic delirium, &c. It has also been sometimes accused of producing a difficulty of respiration. Though it is one of the most potent antiseptics, or resisters

of putrefaction, yet in mortifications attended with a fulness of the pulse, or such as arise from too large a quantity of blood, its use should not be admitted; but in such mortifications as originate in a poverty of that vital fluid, it is truly excellent, and cannot well be used too freely.—Those who cannot take the bark in substance, may infuse an ounce of it reduced to a fine powder in three quarters of a pint of cold spring water for the space of an hour, and then pour it clear off: three or four ounces of this infusion is a moderate dose. We have no well-authenticated account at what time or by what means the medicinal efficacy of the Peruvian bark was first brought to light: most of the tales commonly related have too fabulous an air to be admitted here; but the following statement given by Geoffrey seems to be the most probable, and certainly is the best authenticated. A great number of the trees which surrounded a lake near a town in Peru, were torn up by an earthquake, and thrown into the water, which they rendered bitter. An Indian, urged by his thirst, during a fever under which he laboured, drank plentifully of this water, because he could procure no other; and observing that he soon recovered, he related the case to others, who laboured under similar circumstances, and on following his example were likewise cured: on this, inquiry was made, and it was soon discovered that the water derived its virtue from the trees; and presently after, that the medicinal virtues resided in the bark of them only. About the year 1638, a Spanish soldier being quartered in the house of an Indian, was seized with an ague, and he compassionating his case, told him of a remedy, which was no other than the bark, with which he cured himself, and afterwards many of his comrades. At length the vice-queen, wife of the count del Cinchon, then viceroy of Peru, was by this same soldier cured of an intermitting fever with the same medicine, which, on this occasion, received the name of *pulvis comitissa*, *cortex china-china* or *chinchina*, *kina-kina* or *kinkina*, *quina-quina* or *quinquina*. The countess is said to have distributed a large quantity of the bark, upon her recovery, among the Jesuits, in whose hands it acquired still greater reputation, and by whom it was first introduced into Europe, acquiring the name of *Jesuit's bark*, *cortex* and *pulvis Jesuiticus*, *pulvis patrum*, and also *cardinal de Lugo's powder*, that charitable prelate having bought a large quantity of it at a great expense for the use of the poor at Rome, whence it spread into France and England, and at length became general. For a more particular account of the bark and its various properties, read *Lewis, Newman, Motherby, and Percival*.—The other species of Cinchona approach in some degree to the virtues of the common officinal bark, but seem less efficacious, and their power less perfectly ascertained in practice. The red bark (see the seventh species) has indeed been often considered as of still higher efficacy than the common, and has been thought to be the bark, which, according to Arrot, the Spaniards call *Cascarilla colorada*, and was probably the kind brought originally to Europe, and which proved so successful in the hands of Sydenham, Morton, and Lister; as it appears, from the testimony of the oldest practitioners, that the bark first employed was of a much higher colour than the common bark.

2. *Cinchona Pubescens*; *Pubescent Cinchona*. Leaves ovate, elongated at the base, pubescent underneath; capsules cylindrical. The branches of this species are pubescent towards the end.—Native of Peru.

3. *Cinchona Macrocarpa*; *Long-fruited Cinchona*. Leaves oblong, pubescent underneath, ribbed. Branches jointed, the size of a swan's quill; leaves more than a hand in length; flowers subsessile.—Native of Santa Fé.

** *Corollas smooth*; *Stamina standing out*.

4. *Cinchona Caribbæa*; *Caribbean Cinchona*. Peduncles axillary, one-flowered. Jacquin says this is an erect branching shrub, ten feet high; or, from fifteen to twenty feet, according to Swartz. Jacquin informs us, that the leaves are from two to three inches long, and reflex at the end; that the flowers are of a very pale flesh-colour, exceedingly sweet-scented; and the capsules, before they become ripe, green, very bitter, and abound in a juice that excites heat and irritation on the lips and nostrils. Dr. Wright informs us, that the Jesuit's-bark tree of Jamaica and the Caribbees rises to twenty feet, with a trunk not thick in proportion, but hard, tough, and of a yellowish white colour in the inside; the leaves, he says, are of a rusty green, and the young buds of a blueish-green hue; the flowers are of a dusky yellow colour; and the pods black; when ripe they split in two, and are, with their flat brown seeds, in every respect similar to the first species. The bark in general is smooth, and gray on the outside, though in some rough and scabrous; when well dried, the inside is of a dark brown colour: its flavour at first is sweet, with a mixture of the taste of Horse-radish, and of the aromatics of the East, but when swallowed, of that bitterness and astringency which characterises the Peruvian bark. It grows near the sea-shore, and is called *sea-side beech* in Jamaica.—Native of the West Indies.

5. *Cinchona Corymbifera*; *Corymbiferous Cinchona*. Leaves oblong-lanceolate; corymbs axillary. Trunk upright, round, smoothish, a fathom or more in height, the thickness of the human arm; branches round, spreading, opposite, the upper ones herbaceous, compressed at the joints; leaves acuminate, spreading, smooth and even, a hand in length, deep green, with the midrib purple underneath: petioles round, spreading, longer than the interstices of the leaves, scarcely an inch in length; stipules membranaceous, acute: flowers white, red on the outside; before opening they appear of a dusky purple: the bark is extremely bitter, and subastringent, very like the common Jesuit's bark.—Native of the islands of Tongataboo and Eaoowe in the South Seas; where it is cultivated on account of the pleasantness of its odour, and the beauty of its flowers.

6. *Cinchona Lineata*. Panicle terminating; leaves ovate, acuminate, smooth; capsules five-cornered. Branches round at bottom, with an ash-coloured bark, purplish at top; germen five-cornered.—Native of the island of Dominica.

7. *Cinchona Floribunda*; *Tufted Cinchona*. Panicle terminating; capsules turbinate, smooth; leaves elliptic, acuminate. The whole of this species is very smooth: the branches are round at bottom, but obscurely four-cornered at top, and purplish; leaves resembling those of the Coffee shrub; frequently short, a span in length, spreading very much, lanceolate-elliptic, on the upper surface even, shining, with a groove along the middle, on the under paler, veined, nerved; the nerves oblique, and but little raised; petiole half an inch in length, convex beneath. This tree is nearly the size of a Cherry-tree, seldom thicker than the human thigh, and tolerably straight; the wood is light and porous, without any of the bitterness and astringency of the bark; the flowers, which appear in June, are in small tufts, at first white, purplish; the bark is of a lighter red than that which was sent to St. Lucia under the name of *red bark*, inclining more to the colour of cinnamon, notwithstanding which they are probably of the same species. This tree grows in a stiff red clay, delights in a shady situation, a north-west aspect, under larger trees, and is generally near the middle of a hill by some running water.—Native of St. Lucia, Martinico, and Hispaniola.

8. *Cinchona Brachycarpa*. Panicle terminating; capsules obovate, ribbed; leaves elliptic, obtuse.—Native of Jamaica.

9. *Cinchona Angustifolia*. Panicle terminating; capsules oblong, five-cornered; leaves linear-lanceolate, pubescent. This is a small tree, from ten to fifteen feet in height, with an upright smooth trunk, covered with a wrinkled ash-coloured bark, which becomes brown and striated near the root; corolla white and odorous; tube an inch long; segments of the border the length of the tube.—Native of Hispaniola.

10. *Cinchona Parvifolia*. Leaves egg-shaped, obtuse, smooth; flowers paniced, twice-trichotomous, villose; corolla very small. Branches smooth, upright, cylindrical; stamina not projecting; flowers white.—Native of Jamaica.

Cineraria; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common simple, many-leaved; leaflets equal. *Corolla*: compound, radiated; corollets hermaphrodite, equal, numerous in the disk; female ligulate, the same number with the leaves of the calix, in the ray; proper of the hermaphrodite funnel-shaped, with an erect five-cleft border; female ligulate, lanceolate, toothletted at top. *Stamina*: in the hermaphrodite, filamenta five, filiform, short; antheræ cylindric, tubulous, five-cleft at top. *Pistil*: in the hermaphrodite, germen, oblong; style filiform, the length of the stamina; stigmas two, almost erect. Females: germen oblong; style filiform, short; stigmas two, oblong, bluntish, revolute. *Pericarp*: none; calix unchanged. *Seeds*: solitary, linear, quadrangular; pappus hairy, copious. *Receptacle*: naked, flattish. ESSENTIAL CHARACTER. *Calix*: simple, many-leaved, equal. *Pappus*: simple. *Receptacle*: naked.—The leaves are commonly entire, but sometimes pinnatifid; most of the species are tomentose. Every species may be propagated by cuttings, planted in a shady border during the summer months, and duly watered: in a month or five weeks they will put out roots; soon after which it will be necessary to transplant them into pots, as their roots are very apt to spread in the full ground. They are generally natives of the Cape of Good Hope, and therefore too tender to bear the open air of our climate in winter; yet, if too tenderly nursed, they are liable to be drawn up weak: therefore the surest way to preserve them, is to make young plants annually from cuttings, and to place them in a common hot-bed frame in winter, where they may enjoy the full air in mild weather, but be screened from the frost: in summer they should be placed abroad with the hardier sorts of exotic plants.—The species are,

1. *Cineraria Geifolia*; *Kidney-leaved Cineraria*. Peduncles branching; leaves kidney-shaped, suborbiculate, sublobed, toothed, petioled. Stalks herbaceous, round, striated, with white hairs scattered over them; leaves alternate, smoothish above, subhirsute beneath, especially the more tender ones, two inches long; corolla yellow, shaped like that of common ragwort.—Native of the Cape.

2. *Cineraria Cymbalarifolia*. Leaves lyrate, the end leaf kidney-shaped, toothletted; upper stem-leaves clasping, lobed, quite entire. Root a solid bulb; stem herbaceous, simple, even; flowers peduncled, terminating, many; ray of the corolla purple.—Native of the Cape.

3. *Cineraria Sibirica*; *Siberian Cineraria*. Raceme simple; leaves cordate, obtuse, toothletted, even; stem entirely simple, one-leaved. Root perennial; stem undivided, the height of a man; stem-leaves with petioles, dilated at the base, and clasping.—Native of Siberia, the Levant, &c.

4. *Cineraria Glauea*. Raceme simple; leaves spatulate-cordate, quite entire; stem quite simple. The leaves are of a glaucous hue, rather fleshy; the petioles are edged in a spatulate form. Perennial; and a native of Siberia.

5. *Cineraria Sonchifolia*. Leaves stem-clasping, sinuate, difform; flowers large and purple.—Native of the Cape.

6. *Cineraria Cordifolia*; *Heart-leaved Cineraria*. Panicle few-flowered; stem-leaves petioled, cordate, sharply serrate, smooth; stem angular. Root perennial, fibrose, brown; stem from one to two feet high, straight, obscurely angular, a little striated at top, fistulose, simple, almost smooth and green; corollas yellow; florets of the ray about twenty; pappus toothletted when viewed with a magnifier.—Native of Austria and Switzerland.

7. *Cineraria Crispa*; *Curled Cineraria*. Flowers paniced; stem-leaves spatulate-oblong, serrate, obtuse, clasping, dilated and toothed at the base. Two feet high.—Native of Austria.

8. *Cineraria Integrifolia*; *Mountain Cineraria*, or *Flea-wort*. Leaves oblong, obscurely toothed, (or almost entire) shaggy; flowers in a simple involucred umbel, sometimes single. According to Linneus, this plant is extremely variable. The several varieties of it may be found on the Alps and Pyrenees, in Switzerland, Austria, about Montpellier, in Siberia, &c. The plant, which grows in high pastures or open chalky downs in some parts of England, as on Gogmagog hills, Bartlow hills, and Newmarket heath, and near Basingstoke and Andover, has the radical leaves numerous, spreading on the ground, ovate, obovate, or spatulate; stem three, and sometimes six and nine inches high, upright, woolly, angular, or furrowed; flowers yellow; peduncles unequal; calix furrowed, with scarious edges; seeds hirsute.—It is a perennial, and flowers in May and June.

9. *Cineraria Longifolia*. Leaves obscurely toothletted, all oblong.—Native of Austria.

10. *Cineraria Palustris*; *Marsh Cineraria*. Flowers corymbed; leaves broad-lanceolate, tooth-sinuated; stem villose. Leaves thick, tomentose, and almost clammy, covering the stem quite up to the flowers, the lower cut, and scarcely semipinnatifid; root perennial, large, fibrose, running deep in muddy ditches. Meyrick, Hill, and Culpeper, all agree in calling this plant *flea-wort*; while Mr. Miller, and others, whose botanical authority is at least more respectable, give it to the eighth species, to which the reader is referred. They say that a mucilage made of the seeds, is useful to cool the throat in fevers; that the juice of the leaves is esteemed a good remedy for disorders of the breasts, but that it is very unpalatable, and not absolutely to be depended upon.—This plant frequents marshes, in many parts of Europe. It is found in Lincolnshire, about Marsh and Chatteris in the Isle of Ely; near Norwich, Yarmouth, and Hadiscoe in Norfolk; about Pillin Moss in Lancashire; and Aberavon in Merionethshire. There are several varieties of this species, but none worth enumerating.

11. *Cineraria Aurea*. Flowers corymbed; leaves lanceolate, serrate, tomentose underneath. Stem villose; flowers yellow, with a large ray.—Perennial; and a native of Siberia.

12. *Cineraria Maritima*; *Sea Cineraria*. Flowers paniced; leaves pinnatifid; tomentose; divisions sinuated; stem shrubby. Stems many, woody, two or three feet high, divided in many branches, which have a white downy bark; leaves very woolly, six or eight inches long, deeply sinuated and jagged on their border. The stems which support the flowers are a foot or more in length, having two or three small leaves on each, shaped like those below, and terminated by many yellow flowers, growing in panicles, or rather corymbs, shaped like those of common Ragwort: they appear from June till August, and ripen seed in the beginning of October.—Ray says this plant is very common every where on the coast of the Mediterranean, but that it cannot be found in England, nor any of the northern countries of Europe: yet Mr. Miller

affirms that it grows naturally on the coast of England and Wales.—There is a less hardy variety of this species, the stems of which are more woody, rise higher, and do not branch so much; the leaves are broader, not so much sinuated, and of a very dark green on their upper side; the flowers are produced in smaller bunches, and rarely produce seeds in England.—Native of the sea-coasts of Dauphiny, Italy, and Sicily. When the cuttings or slips are well rooted, they should be planted in a dry rubbishy soil, where they will resist the cold of our ordinary winters very well, and continue many years; but in rich moist ground, the plants are often so very luxuriant in summer, as to be killed in winter when there is much frost.

13. *Cineraria Canadensis*. Flowers paniced; leaves pinnatifid, subvillose; divisions sinuated; stem herbaceous. Stem annual, not perennial; the ray of the corolla spreading, but not revolute.—Found in Canada, by Kalm.

14. *Cineraria Capillacea*. Leaves pinnate; pinnas capillaceous, entire. Observed by Thunberg at the Cape.

15. *Cineraria Linifolia*. Peduncles one-flowered; leaves scattered; stem shrubby. Flowers small, yellow.—Native of the Cape.

16. *Cineraria Purpurata*. Stem subbiflorous; leaves obovate, subtomentose. Root perennial; stem a foot high, herbaceous; ray of the flower purple; pappus plumose.—Native of the Cape.

17. *Cineraria Amelloides*; *Blue-flowered Cineraria*, or *Cape Aster*. Peduncles one-flowered; leaves opposite, ovate, naked; stem undershrubby. Root perennial; stem purplish, rough, dividing into many branches near the root, so as to form a low bushy plant, seldom rising more than two feet high; but the branches extending more than a foot on every side. Leaves about an inch long, and one-third broad, thick, succulent, sessile, generally two, but sometimes three or four at a joint; flower with a yellow disk, and sky-blue ray. The whole plant is a little acrid to the taste, and it is never without flowers throughout the year.—Native of the Cape. This, and some of the others, may be propagated by seeds, sown on a bed of light earth in the beginning of April; and when the plants are fit to remove, part of them should be planted in pots, to be sheltered in winter under a hot-bed frame; and the remainder under a warm wall in poor ground, where, if the winter prove favourable, they will live.

18. *Cineraria Americana*. Shrubby; panicles axillary; leaves alternate, petioled, broad-lanceolate, serrate, smooth above, and hoary underneath. The entire plant is clothed with an epidermis of very fine wool, which may easily be rubbed off, like a thin membrane; the branches, petioles, peduncles, and lower surface of the leaves, are white with it: stems woody.—Observed by Mutis in South America.

19. *Cineraria Alata*. Stem herbaceous; leaves obovate, decurrent; flowers corymbed. Stem erect, two feet high, sparingly branched; florets about sixteen, some of the marginal ones naked, and female.—Native of the Cape.

20. *Cineraria Elongata*. Leaves subcordate, gnawn; peduncles very long, subulate, scaly. Stem erect, branched, a foot and a half high, reddish, at the ramifications tomentose; corolla yellow, without any ray. Native of the Cape.

21. *Cineraria Cacalioides*. Leaves columnar, oblong, fleshy; panicle terminal, elongated, few-flowered; peduncles alternate.—Native of the Cape.

22. *Cineraria Denticulata*. Leaves lanceolate, smooth, toothletted: flowers paniced. Almost all the leaves are radical and long; it has scarcely any stem-leaves, except some small ones at the ramifications.—Native of the Cape.

23. *Cineraria Perfoliata*. Leaves ovate, cordate, stem-

clasp; peduncles one-flowered, elongated. The whole plant somewhat fleshy and glaucous.—Native of the Cape.

24. *Cineraria Lineata*. Leaves lanceolate, tomentose underneath, serrated at the end, toothed at the base. Stem herbaceous, a foot high or more, erect, striated, hoary; calices small; ray of the corolla yellow.—Native of the Cape.

25. *Cineraria Hastifolia*. Leaves hastate; divisions lateral, bifid, divaricated. Stem erect, more than a span high; calix with about ten leaves; flowers yellow.—Discovered by Sparrman, at the Cape.

26. *Cineraria Japonica*. Leaves sword-shaped, toothed, tomentose; flowers terminal. Stem round, simple, erect, tomentose, a span high; leaves alternate, acute, attenuated at both ends, erect; flowers solitary or tern, yellow.—Native of Japan.

27. *Cineraria Rotundifolia*. Panicles few-flowered; leaves petioled, ovate-roundish, quite entire, tomentose underneath; stem arboreous.—Native of New Zealand.

28. *Cineraria Repanda*. Panicles compound, racemed, diffused; leaves petioled, ovate, repand-sinuate, tomentose underneath; stem arboreous.—Native of New Zealand.

29. *Cineraria Lanata*; *Woolly Cineraria*. Peduncles one-flowered; leaves cordate-roundish, seven-angled, lanuginous underneath. In the beauty of its blossoms, this species of *Cineraria*, lately introduced from Africa, by far eclipses all the others cultivated in our gardens. The interior of the petals is white, and the exterior of the most vivid purple. It flowers early in the spring, and, by proper management, may be made to flower the whole year through.—Found in the Canary islands by Masson. Some persons keep it in the stove, by which means they make it flower earlier; but it succeeds better in a common green-house, with no more heat than is just necessary to keep out the frost; it may indeed be kept in a common hot-bed frame, unless the weather prove severe. The hardiness of this plant renders it a most valuable acquisition to the green-house, and its value is still further enhanced by its readiness to flower, and the facility by which it may be cultivated by cuttings. As this plant, like many others, is obliged to be confined, it becomes liable to be infested with *aphides*, or, in vulgar phrase, to turn lousy: however, the best way to have handsome, strong-flowering, healthy plants, is to procure a constant succession by cuttings, which strike very readily, if placed in a pot, and plunged into a bed of tan.

30. *Cineraria Humifusa*; *Trailing Cineraria*. Peduncles one-flowered; leaves kidney-form, somewhat angular; petioles eared, or naked at the end. The flowers are yellow; and both they and the calices are villose, and somewhat rugged.—Native of the Cape.

31. *Cineraria Viscosa*; *Clammy Cineraria*. Peduncles one-flowered; leaves pinnatifid-lobed, acute, viscid, somewhat fleshy.—Native of the Cape.

32. *Cineraria Populifolia*; *Poplar-leaved Cineraria*. Flowers corymbed; leaves cordate, somewhat angular, tomentose underneath; petioles having several pairs of appendices at the end. This is a shrub, with an angular tomentose hoary stem; panicles terminating; pedicels bracted; flowers yellow.—Found in the Canary Islands by Masson.

33. *Cineraria Aurita*; *Purple-flowered Cineraria*. Flowers corymbed; leaves cordate, somewhat angular, tomentose underneath; petioles two, eared at the base. Flowers purple; leaves resembling those of the Poplar.—Native of Madeira.

34. *Cineraria Malvæfolia*; *Mallow-leaved Cineraria*. Flowers cymed; leaves cordate, angular, somewhat tomentose underneath; petioles simple.—Native of the Canary Islands, and of St. Miguel, one of the Azores.

35. *Cineraria Cruenta*; *Purple-leaved Cineraria*. Flowers cymed; leaves cordate, angular, purple underneath; petioles eared at the base. Root perennial; stem two or three feet high; flowers purple.—Native of the Canary islands.

36. *Cineraria Lobata*; *Lobed Cineraria*. Flower subcorymbed; leaves roundish, many-lobed, smooth; petioles eared at the base; calices subcalicled. This resembles a *Senecio*.—Found by Masson at the Cape.

37. *Cineraria Sinensis*. Panicle, diffused; leaves ovate-lanceolate, serrate-repand, smooth. Stem suffruticose, erect, round, smooth, four feet high, branched; leaves alternate; flowers yellow, terminating.—Native of China, near Canton.

38. *Cineraria Minuta*. Leaves pinnatifid; stem one-flowered, capillary. Root annual; stems often two, capillary, two inches high, at first woolly, but afterwards almost smooth, one-flowered; leaves alternate, sessile, violet-coloured underneath; flowers terminating, solitary; corolla yellow; corollas in the ray ten, trifid at the end; seeds ovate, oblong, very small, with a sessile plumose pappus.—It flowers in May; and is a native of Spain near Aranjuez.

39. *Cineraria Glabra*. Flowers corymbed; calices cylindrical; leaves oblong, acute, somewhat toothletted, nerveless, smooth on both sides, and a little succulent; stem shrubby.—Native of Jamaica.

40. *Cineraria Discolor*. Flowers corymbed; leaves oblong-lanceolate, acuminate, somewhat toothletted, smooth; beneath white tomentose; stem shrubby. Root perennial.—Native of Jamaica.

Cinna; a genus of the class Monandria, order Digenia.—**GENERIC CHARACTER.** *Calix*: glume one-flowered, two-valved, compressed, linear, keeled, acuminate; one valve shorter, mucronated. *Corolla*: glume bivalve, compressed, linear; outer valve within the smaller valve of the calix, longer, with somewhat of an awn below the tip; inner slender, shorter. *Stamina*: filamenta one, capillary; anther oblong, forked at each end. *Pistil*: germen turbinated; styles two, capillary very short; stigmas longer, plumose. *Pericarp*: none; glume involving. *Seed*: one, cylindrical. **ESSENTIAL CHARACTER.** *Calix*: glume two-valve, one-flowered. *Corolla*: glume two-valve. *Seed*: one.—The only known species is,

1. *Cinna Arundinacea*. A grass the size of Oats; root perennial; culms many; leaves broadish, smooth, many-nerved, rugged about the edge; panicle glaucous, oblong, attenuated, somewhat compressed, composed of imbricate racemes; keel of the calix rough, one of the valves having an awn-like point; anther purple; styles hirsute.—Native of Canada, whence the seeds were sent by Kalm. See *Agrostis Cinna*.

Cinnamon, Cinnamomum. See *Laurus*.

Cinquefoil. See *Potentilla*.

Cinquefoil, Bastard. See *Sibbaldia*.

Cinquefoil, Marsh. See *Comarum*.

Circæa; a genus of the class Diandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth two-leaved; leaflets ovate, concave, deflected, deciduous. *Corolla*: petals two, orbiculate, generally shorter than the calix, spreading, equal. *Stamina*: filamenta two, capillary, erect, the length of the calix; antheræ roundish. *Pistil*: germen turbinate, inferior; style filiform, the length of the stamina; stigma obtuse, emarginate. *Pericarp*: capsule turbinate-ovate, hispid, two-celled, two-valved, opening from the base towards the top. *Seeds*: solitary, oblong, narrower at bottom. **ESSENTIAL CHARACTER.** *Corolla*: two-petalled. *Calix*: two-leaved, superior. *Seed*: one, two-celled.—These plants multiply exceedingly by their creeping roots, and are therefore seldom kept in gardens. If the roots be planted in any

shady moist part of a garden, they will increase fast enough without any care.—The species are,

1. *Circæa Lutetiana*; *Common Enchanter's Nightshade*. Stem erect; racemes many; leaves ovate. Root perennial, creeping, toothed; the whole plant pubescent; stems from twelve to eighteen inches and more in height, erect, round, villose or smooth, seldom hairy; the joints swelled, and sometimes purplish, branching; leaves opposite, dark green, flowers in simple racemes on the top of the branches, both terminating and lateral; frequently solitary; sometimes more than forty flowers in a raceme; corolla small, whitish, reddish-white, or flesh-coloured; petals the length of the calix, and alternate with its leaflets.—It is not uncommon in shady lanes and orchards, under moist hedges and walls; and in woods, flowering in July and August. It frequently infests gardens, and is not easily destroyed, the roots being creeping: sheep are said to eat it: and although it has not been admitted into the dispensaries, yet it is esteemed very detersive, and is recommended by Chomel against the piles, applied outwardly as a cataplasm, and inwardly as an infusion. The seeds of this plant stick by their little hooks to any thing that passes; and Boerhaave informs us, that this peculiarity gave occasion to the name; the fruit laying hold on the clothes of passengers, and drawing them to it, as Circe was fabled to attack by her enchantments.

2. *Circæa Alpina*; *Mounting Enchanter's Nightshade*. Stem ascending; leaves heart-shaped, shining; calix membranaceous; root creeping. The whole plant less pubescent than the preceding species. Stems low, diffused at the base, with red joints; leaves tender, petioled, tooth-serrated, of a pleasant yellowish green colour; flowers of a vivid red colour.—It is found in rocky woods, in Lapland, Sweden, Carniola, Piedmont, Silesia, and Denmark. It was gathered, in the month of August, upon Mount Scheidegg in Switzerland; and Mr. Miller found it growing wild in the wood near the Hague. In Great Britain it is found near Leeds and Halifax in Yorkshire; by the river side at Matlock in Derbyshire; in Lancashire, Westmoreland, Cumberland, and Scotland.

Cissampelos; a genus of the class Diœcia, order Monadelphia.—**GENERIC CHARACTER.** *Male. Calix*: none, unless the corolla be so called. *Corolla*: petals four, ovate flat, expanded; nectary, the membranaceous disk of the flower, wheel-shaped. *Stamina*: filamenta four, very small, coalescent; antheræ broad, flat. *Female. Calix*: none, except the bractæ. *Corolla*: none; nectary, the membranaceous lateral edge of the germen, dilated outwards. *Pistil*: germen roundish; styles three; stigmas three, erect, acute. *Pericarp*: berry globular, one-celled. *Seed*: solitary, wrinkled, somewhat compressed. **ESSENTIAL CHARACTER.** *Male. Calix*: four-leaved. *Corolla*: none. *Nectary*: wheel-shaped. *Stamina*: four, with connate filamenta. *Female. Calix*: one-leaved, ligulate, roundish. *Corolla*: none. *Styles*: three. *Berry*: one-seeded.—These plants are propagated by seeds, which should be sown upon a hot-bed in the spring, and the plants must afterwards be treated in the same way as other tender exotics, keeping them constantly in the bark-stove, otherwise they will not live in this country.—The species are,

1. *Cissampelos Pareira*. Leaves peltate, cordate, emarginate, and entire. Stem climbing and twining, from ten to fifteen feet in height, lax, round, striated, smooth, or hirsute; flowers numerous, dusky yellow, minute. The fruit is a roundish, compressed, scarlet drupe, containing a single nut or very hard seed, compressed, triply echinate, wrinkled at the edge, two-celled. In mountainous coppices it is smooth, with cordate entire leaves, hoary underneath; in champaign calcare-

ous situations it is hirsute, with cordate-roundish, emarginate leaves, which are tomentose.—Native of the West Indies. The leaf, applied whole or bruised to a wound, cures it effectually; it is also a remedy against the bite of poisonous animals: the root is excellent for the stone, and is looked upon as an excellent diuretic, which the negroes constantly use in all obstructions of the urinary passages. The root, which is the part chiefly used, has a pleasant bitterish taste, and answers well in decoctions.—It thrives best in a rich shady soil; grows well both on the high and low lands of Jamaica, and is very easy propagated there.

2. *Cissampelos Caapcaba*. Leaves petioled at the base, entire. This has round or heart-shaped leaves, which are extremely woolly and soft to the touch. The stalks and every part of the plant is covered with a soft woolly down.—Grows in Jamaica.

3. *Cissampelos Smilacina*. Leaves cordate, acute, angular. The stalks are slender, running up walls, and twining about posts and trees. The leaves resemble those of common Ivy. The berries are red, of the size of small peas, and grow in clusters.—Native of Carolina.

4. *Cissampelos Fruticosa*. Stem erect, shrubby; leaves ovate, petioled, entire.—Found by Thunberg at the Cape.

5. *Cissampelos Capensis*. Stem twining; leaves ovate, obtuse, petioled, entire.—Found by Thunberg at the Cape.

6. *Cissampelos Ovata*. Leaves egg-shaped, obtuse, almost entirely smooth; racemes slender, elongated, pubescent. Stems woody, cylindrical, slightly striated: branches numerous, alternate, climbing, slightly villose; leaves about two inches long, alternate, petioled, finely veined, green, with a few short hairs underneath along the veins; flowers small; fruit a dry berry or drupe about the size of a lentil.—Native of the East Indies.

Cissus: a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre many-leaved, very small; perianth one-leafed, flat, short, obscurely four-cornered. *Corolla*: petals four, concave; nectary a rim surrounding the germen. *Stamina*: filamenta four, the length of the corolla, inserted into the nectary; antheræ roundish. *Pistil*: germen roundish, obtusely four-cornered, retuse; style filiform, the length of the stamina; stigma simple, acute. *Pericarp*: berry round, shining, umbilicate. *Seed*: a roundish stone. ESSENTIAL CHARACTER. Berry one-seeded, surrounded by the calix and four-parted corolla.—These plants are preserved in some of the European gardens, more for the sake of variety than for use or beauty, as they rarely produce either fruit or flowers in temperate climates. They are propagated either by laying their flexible branches down in pots of earth, where they will put out roots in four or five months: or by planting cuttings in pots filled with light earth, which should be plunged into a moderate hot-bed of tanner's bark, covering the pots closely with hand-glasses to exclude the outer air: they must be frequently refreshed with small quantities of water. When these, or the layers are well rooted, they should be carefully taken up, and each planted in a small pot filled with light earth, and plunged into the hot-bed of tan, where they must constantly remain. They should be shifted into large pots when it is necessary, and their branches must be supported with stakes, to prevent them from trailing over the neighbouring plants; and in warm weather the plants should have free air admitted to them daily.—The species are,

1. *Cissus Vitiginea*; *Vine-leaved Cissus*. Leaves cordate, with about five lobes, tomentose. Linneus observes, that this species of *Cissus* has the appearance of a vine, but differs in the calix, corolla, number of stamina, and in having a style.

The stem is tomentose; the branches villose, hoary at top, and subquadrangular; leaves alternate, two inches long, entire; flowers hoary, most of them deciduous; fruitful pedicels commonly in pairs, and divaricating; berries pear-shaped, the size of peas, of a blueish glaucous colour.—Native of the East Indies.

2. *Cissus Repanda*. Leaves cordate, entire, or sublobed, repand, smooth on both sides. The branches of this are round, flexuose, jointed, tomentose, but become smooth by age; leaves petioled, two to three inches long, and still more in breadth; peduncles opposite to the leaves; rays of the umbel three, dichotomously branched; berries pear-shaped, the size of peas, mucronate with the permanent style.—Native of the East Indies.

3. *Cissus Latifolia*. Leaves cordate-ovate, villose, acuminate, setaceous, serrate; branches four-cornered. Branches jointed, woody, as are also the petioles and peduncles, ferruginous-tomentose, especially at top, becoming smooth at bottom by age; berries black, smooth and shining, succulent.—Native of the East Indies.

4. *Cissus Cordifolia*. Leaves cordate, quite entire; branches simple, knotty; berries large, oblong; tendrils large, bifid, retrograde.—Native of South America.

5. *Cissus Rotundifolia*. Leaves cordate, roundish, serrate; leaves smooth, setaceous, serrate; umbels racemed, opposite, many-flowered, about four on each common peduncle, and simple; peduncles nearly the length of the leaves.—Native of Arabia.

6. *Cissus Sicyoides*. Leaves subcordate, naked, bristly, serrate. Root perennial; stem somewhat woody, herbaceous at top, climbing, branched, marked with red spots; leaves petioled, alternate, nerved, somewhat succulent; flowers yellow; petals broader at the base, egg-shaped, reflexed, deciduous; antheræ orange; berry oblong, black.—Native of Jamaica, in waste places, by walls, and on rocks. Jacquin informs us, that it is found in all the Caribbee islands, and the neighbouring continent, differing in habit according to the situation in which it grows. The berries of this, and some of the other sorts, are sometimes eaten by the negroes, but they are chiefly food for birds.

7. *Cissus Quadrangularis*. Leaves cordate, fleshy, serrate-toothed; stem four-cornered, somewhat swelling. Stem very long, climbing, smooth, and even. The root is tuberous.—Native of Arabia, and the East Indies; found also by Loureiro near Mosambique in Africa.

8. *Cissus Acida*; *Three-leaved Cissus*. Leaves ternate, obovate, smooth, fleshy, gashed. Stem scandent, flexuose, round, tinged with purple, succulent, jointed; branches short; corolla four-parted, the parts reflex and deciduous; germen truncate; berry black, surrounded by the calix. The whole of this plant is acid.—Native of Jamaica, in woods near the coast.

9. *Cissus Trifoliata*. Leaves ternate, roundish, hirsute, with a few teeth; branches angular and membranaceous. Stem suffrutescent, scandent, having five or six angles, knotted, rooting, branched, green, the angles slightly winged; branches herbaceous, lax; flowers umbelled, blood-red: calix or rim of the germen entire and four-cornered; berry roundish, one-seeded.—Native of the West Indies, climbing high above the branches of the trees, in the hedges, upon the mountains.

10. *Cissus Crenata*. Leaves ternate; leaflets roundish, crenate. The branches, petioles, younger leaves, and peduncles, villose; tendrils opposite to the leaves, compound; petals arched; filamenta shorter than the corolla.—Native of the East Indies.

11. *Cissus Carnosa*. Leaves ternate, ovate, obtuse, serrate, smooth; branches and petioles round. The whole plant is smooth; universal umbel of three rays, partial with dichotomous divaricating branches; general peduncle longer than the leaf.—Native of the East Indies.

12. *Cissus Obovata*. Leaves ternate; leaflets obovate, quite entire, smooth. Stem scandent, smooth; tendrils opposite to the leaves, of the same length, and bifid; peduncles axillary, solitary, longer than the leaves, smooth, trichotomous; the branchlets three-flowered; the flowers pedicelled.—Native of America.

13. *Cissus Pedata*. Leaves pedate; leaflets lanceolate, serrate, tomentose underneath. Branches tomentose, hoary; leaves petioled, five, six, or seven; leaflets also petioled, three or four inches long, unequal, attenuated, unequally serrate, but with the point quite entire, on the upper surface slightly villose, beneath villose, tomentose, hoary, nerved; flowers small; calix obscurely four-toothed, runcinate.—Native of the East Indies.

14. *Cissus Heptaphylla*. Leaves in sevens, serrate, hispid. This is a sarmentose scandent shrub; branches pubescent; tendrils opposite to the leaves, bifid; panicles fastigate, brachiate, peduncled, opposite to the leaves; flowers small.—Native of the East Indies.

15. *Cissus Umbellata*. Leaves ovate, quite entire; flowers umbelled; stem shrubby, twining, long, branched; leaves opposite, smooth; flowers white, in compound terminating umbels; corolla bell-shaped, four-cleft, woolly within; calix truncate, surrounding the berry.—Native of China, near Canton.

16. *Cissus Ovata*. Leaves egg-shaped, acuminate, sparingly toothed, smooth and even on both sides.—Native of Gaudaloupe.

17. *Cissus Orientalis*. Leaves somewhat bipinnate; leaflets egg-shaped, serrated; stem rather shrubby. This has the habit of *Vitis Arborea*, but is larger, and the leaves less compound.—Native of the East.

Cistus; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; permanent; leaflets roundish, concave, of which two alternate ones are lower and smaller. *Corolla*: petals five, roundish, flat, spreading, very large. *Stamina*: filamenta numerous, capillary, shorter than the corolla; antheræ roundish, small. *Pistil*: germen roundish; style simple, the length of the stamina; stigma flat, orbiculate. *Pericarp*: capsule roundish, covered with the calix. *Seeds*: numerous, roundish, small. ESSENTIAL CHARACTER. *Corolla*: five-petalled. *Calix*: five-leaved, with two of the leaflets smaller. *Capsule*: superior, angular, many-seeded.—The history of this genus is extremely obscure, on account of the multitude of varieties which occur in it. Linneus says, that the species may be much elucidated, if botanists will attend to the following circumstances, in their native places of growth: 1. Whether the trunk be shrubby, undershrubby, annual, or perennial; 2. whether the stem be erect or decumbent; 3. whether the leaves be opposite or alternate, and what is their form; 4. whether there be two stipules or none; 5. whether the peduncles be one-flowered or many-flowered, naked or with a bracte; 6. what is the form of the petals; 7. whether the capsules have five or three valves; 8. whether the calix be equal or unequal. The form of the leaves in the greater part is ovate or lanceolate, or some modification of these two forms; but the principal difference attending these plants is in the capsule, which in some is five or ten celled, with as many valves; in others one-celled, and three-valved: hence this great genus might very commodiously be divided into two,

as Tournefort, Miller, Jussieu, Gärtner, and others, have divided it, at least in the artificial arrangement, for undoubtedly they all constitute one natural genus. They may be distinguished thus: *Cistus*, or *Rock-rose*, has a five or ten celled capsule, with as many valves; seeds fixed to the axis; embryo spiral. These are shrubs, or undershrubs; the leaves opposite, and naked; the flowers in umbels, with unequal calicine leaflets; and the corolla either purple or white, commonly large and specious. *Helianthemum*, or *Dwarf Sunflower*, has a one-celled, three-valved capsule, with the seeds fixed to the valves; embryo uncinately-inflexed. These are suffruticose or herbaceous; the leaves opposite, or sometimes alternate, stipuled or naked; the flowers in spikes or racemes, with two of the calicine leaflets minute; and a corolla commonly yellow, seldom purple or white, smaller than that of the *Cistus*, very deciduous in both.—All the various kinds of *Cistus* are very great ornaments to a garden; their flowers, though of short duration, are succeeded by fresh ones almost every day, for above two successive months: they are generally about the size of a middling rose, but single, and of different colours: their leaves continue all the year; they are most of them hardy enough to bear the open air in England, unless in very severe winters, which often destroy many of them, so that a plant or two of each sort may be kept in pots, and sheltered in winter to preserve the kinds; the rest may be intermixed with other shrubs, where they will make a pretty diversity; and in such places where they are sheltered by other plants, they will endure cold much better than where they are scattered singly in the borders. Many of these plants will reach five or six feet in height, and, if permitted to grow uncut, will have large spreading heads; but if they be trimmed at all, it should be only to prevent their heads from becoming too large for their stems, for whenever this happens they are liable to fall to the ground, which spoils their appearance. They are propagated both from seeds and cuttings, but the latter method is seldom resorted to except for such species as do not produce seeds in England; these are the twelfth and the fifty-fifth sorts; all the others generally produce plenty of seeds, especially those plants which came from seeds, for those which are propagated by cuttings are liable to become barren. The seeds should be sown in the spring, upon a common border of light earth, where the plants will come up in six or seven weeks; and, if they be kept clean from weeds, and thinned where they are too close, they will grow eight or ten inches high the same year; but as these plants are liable to be injured by hard frost when young, they should be transplanted, when they are about an inch high, into some small pots filled with light earth, that they may be removed into shelter in winter, and the others into a warm border, at about six inches' distance each way: those which are potted must be set in a shady situation till they have taken fresh root; and those planted in the border also must be shaded every day till they are rooted, after which the latter will require no other care but to keep them clean from weeds till autumn, when they should have hoops placed over them, that they may be covered in frosty weather; those in the pots may be removed into an open situation as soon as they have taken new root, where they may remain till the end of October, but must be shifted into larger pots, and frequently watered during the summer; at the end of October they should be placed under a hot-bed frame, to screen them from the cold in winter, but at all times when the weather is mild they should be fully exposed to the open air, and only covered in frosts. The above is the method which the gardeners generally practise; but those who desire to have their plants come forward, should sow the seeds on a moderate hot-bed in the spring,

which will bring up the plants very soon; but these must have plenty of air when they appear, otherwise they will draw up very weak: when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into a very moderate hot-bed, observing not to shade them until they have taken fresh root, when they must have plenty of air admitted to them every day in good weather, to prevent them drawing up weak; and they must be hardened by degrees, so as to bear removing into the open air in the beginning of June, after which they may be treated in the same manner as is before directed for the other seedling plants. By this method of bringing the plants forward in the spring, they will grow to the height of two feet or more the first summer, and have many lateral branches, so that they will be strong enough to endure planting abroad in the succeeding spring, and most of them will flower the same summer; whereas those which are sown in the full ground rarely flower till the year after, nor will they be so strong, or able to resist the cold of the second winter, as those which have been thus brought forward. In the spring following these plants may be turned out of the pots, with all the earth preserved to their roots, and planted in the places where they are to remain, (for they are bad plants to remove when grown old) observing to give them now and then a little water, until they have taken fresh root, after which time they will require no farther care, than to train them upright in the manner you would wish them to grow; but those plants which were at first planted into a border in the open ground, should be arched over with hoops, and covered with mats in frosty weather, during the first winter, but may be transplanted abroad in the following spring. In removing these plants, care should be taken to preserve as much earth as possible about their roots; and if the season be hot and dry they must be carefully watered and shaded until they have again struck root, after which they will only require the treatment above directed.—If they be propagated by cuttings, they should be planted in May or June, upon a bed of light earth, keeping them shaded with mats, and frequently refreshed with water until they have taken root, which will be in about two months' time; they may then be transplanted into pots filled with good fresh light earth, and should be set in a shady place until they have again taken root, after which they may be exposed to the open air till October, when they should be removed to pass the first winter under shelter, but in the succeeding spring should be brought forth and planted abroad, as has been directed for the seedling plants.—Most of the perennial sorts of *Dwarf Cistus* or *Sunflower*, will thrive in the open air in England; they are propagated by seeds, sown where they are intended to remain, and will require no care, except to keep them clear from weeds, and to thin them where they are too close, always observing to leave those sorts at a greater distance, the stalks of which trail on the ground to the greatest length. These plants will continue several years in a poor dry soil; but in rich ground, or in moist situations, they seldom last long; but as the seeds ripen in plenty, they may be easily renewed. For the annual sorts the seeds may be sown in April, upon a bed of common earth; the plants will come up in May, and flower in July.—The species are,

* Without *Stipules*, shrubby.

1. *Cistus Capensis*; *Cape Cistus*. Leaves ovate-lanceolate, petioled, three-nerved, toothletted, naked on both sides. Branches round, purplish, having hairs thinly scattered over them; petioles distinct; leaves three inches long; corolla yellow.—Linneus remarks, that this differs from the other species in the toothlets of the leaves.—Native of the Cape.

VOL. I.—26.

2. *Cistus Villosus*; *Hairy Rock-Rose*, or *Shrubby Cistus*. Leaves ovate, petioled, rough with hairs. Corolla purple. It has a strong woody stem, covered with a rough bark, and three or four feet high, dividing into many branches, so as to form a large bushy head. The flowers are produced at the ends of the branches, four or five together; the petals, which are purple and large, spread open like a rose, but are of short duration, generally falling off on the same day they expand; but there is a succession of fresh flowers every day for a considerable time, in May and June, and again in September and October, if the autumn be favourable; and even in the winter, if the plants be protected from frost.—Native of Italy and Spain. It requires the protection of a stove in winter.

3. *Cistus Populifolius*; *Poplar-leaved Cistus*, or *Rock-Rose*. Leaves cordate, even, acuminate, petioled. This has a stiff, slender, woody stem, six or seven feet high, sending out many branches the whole length; branches and leaves hairy; leaves large, of a light green colour, with many nerves; corolla white, and soon dropping off. Linneus adds, that the petals are tinged with purple on their edges; that the stamina are yellow; and that the calices appear three-cornered before they unfold. It flowers in June and July.—Native of Portugal. This is a very handsome plant.

4. *Cistus Laurifolius*; *Bay-leaved Gum Cistus*. Leaves oblong-ovate, petioled, three-nerved, the upper surface smooth; petioles connate at the base. It rises five or six feet high, with a strong woody stem, sending out many erect hairy branches; leaves lanceolate, acute, thick, dark green above, and white beneath, very glutinous in warm weather. According to Linneus, they are wrinkled, green on both sides, and scarce visibly hairy: the petioles become purple at the base. The flowers, which appear in June and July, are produced at the ends of the branches, upon long naked peduncles, branching on their sides into smaller ones, each sustaining one large white flower with a hairy calix. It is a beautiful plant.—Native of Spain.

5. *Cistus Ladaniferus*; *Spanish Gum Cistus*. Leaves lanceolate, even on the upper surface; petioles united at the base, and sheathing. Stem strong and woody, five or six feet high, sending out many hairy branches; leaves smooth on their upper side, veined on their under, on short footstalks which join at their base, where they form a sort of sheath to their branch; corolla white, the size of the officinal Poppy.—Native of the hills of Spain and Portugal. There is a variety which Mr. Miller considers a distinct species; it has smooth branches, covered with a reddish brown bark; the leaves are narrow-lanceolate, whitish on their under side, of a dark green above, having three longitudinal veins; the petals are very large, roundish, white, with a large purple spot at their base. The whole plant exudes a sweet glutinous substance in warm weather, which has a very strong balsamic scent, and perfumes the air to a great distance. It flowers from June to August. There is another variety, with white flowers, having no purple spots, which is in every other respect similar to this. They are all remarkable for their great beauty.

6. *Cistus Monspelienis*; *Montpellier Gum Cistus*. Leaves linear-lanceolate, sessile, villose on both sides, three-nerved. Stem slender, from three to four feet high, sending out many hairy branches, from the bottom upwards; leaves very dark green, in warm weather covered with a glutinous sweet-scented substance; the peduncles, which come out at the branches, are long, naked, and sustain many white flowers, rising above each other; their calices are bordered, and end in sharp points. It flowers from June till August.—Native of Narbonne, and the kingdom of Valentia.—The variety, or Olive-leaved Rock-Rose, of Miller, has, according to him, the stem

4 K

about four feet high, with hairy, glutinous, erect branches; and long, narrow, hairy leaves, ending in points, deep green on both sides, having a deep furrow made by the midrib on their upper side; the flowers are on long peduncles at the ends of the branches, of a pale sulphur colour, and have an acute bordered calix. It flowers at the same time with the other; and both plants are very handsome.

7. *Cistus Salvifolius*; *Sage-leaved Cistus*. Leaves ovate, petioled, hirsute on both sides; stem slender, smooth, covered with a brown bark, never rising more than three feet high, and sending out many weak branches spreading horizontally; leaves obtuse, without veins, not so soft as in many other species; peduncles lateral, solitary, one-flowered, longer than the leaves; corolla white, and somewhat smaller than that of the other *Rock-Roses*. It flowers from June to August.—Native of Italy, Sicily, Narbonne, Switzerland, and Carniola.

8. *Cistus Incanus*; *Hoary Rock-Rose*, or *Rose-Cistus*. Leaves spatulate, tomentose, wrinkled, the lower connate at the base and sheathing. Branches villose, whitish towards the summit; leaves opposite, sessile, oblong, a little cottony on both sides, with three nerves at the base; flowers purple, on simple peduncles; petals heart-shaped.—Native of Spain and Narbonne. This also is a beautiful plant.

9. *Cistus Creticus*; *Cretan Ladaniferous Cistus*. Leaves spatulate-ovate, petioled, nerveless, rugged; calices lanceolate. A foot and half high, sometimes more, branching, diffused; stem and branches round, and somewhat villose; leaves from broad stem-clasping, petioled, first spatulate, then ovate or lanceolate, somewhat acute, wrinkled, sometimes waved, roughish, thickish, quite entire, viscid, closely set on both sides and round the edge with white hairs of different lengths, some simple, others branched or headed, scarcely visible to the naked eye; peduncles one-flowered, terminating the last leafy twigs, erect, and villose; calix villose, with ovate acuminate leaflets, nearly equal; petals rose-purple, without smell, very obscurely crenate, forming a corolla an inch and half in diameter; the whole of the stamina are yellow; germen hirsute, green; capsule ovate, obtuse, brown, hirsute with ash-coloured hairs, five-celled and five-valved; seeds smooth, rufous, angular.—It flowers copiously in June and July, and ripens seeds in September. Native of the Levant, and remarkably handsome. It is from this species of *Cistus* that the drug *ladanum* (or, as it is sometimes spelt, *labdanum*) is procured; it is a kind of resin, which is secreted from the leaves and other parts of the shrub, and is scraped off by means of a kind of rake, which has numerous leather thongs instead of teeth: this being drawn backwards and forwards over the plant, collects the resin, which differs in degrees of purity; the best is in dark-coloured masses, of the consistence of a soft plaster, growing still softer on being handled; it is, however, subject to many sophistications from the more or less careful manner in which it is at first collected, and from the fraudulent practices of those through whose hands it afterwards passes. In England it is now wholly confined to external use; it is an ingredient in the stomachic plaster of the London Pharmacopœia: it is also used in modern practice in fumigations, its fragrant smell having always introduced it into such preparations: sometimes it is used in troches, and in the Paris Pharmacopœia there is a pectoral troche in which a considerable quantity of *ladanum* is united with musk and amber; in the old German shops, a tincture of this drug is reserved for female weaknesses, but it is unknown to us. *Ladanum* being entirely resinous, is not soluble in water, but readily gives out its active matter to spirit of wine.

10. *Cistus Albidus*; *White-leaved Cistus*. Leaves ovate-

lanceolate, tomentose, hoary, sessile, mostly three-nerved; calix not rough with hairs, the outer leaflets longer, the sides reflex; peduncles from the tops of the branches, many, scarcely longer than the leaves; petals purple, not emarginate, somewhat crenate, flattish.—Native of Narbonne and Spain. This plant is very handsome.

11. *Cistus Crispus*; *Curl-leaved Cistus*. Leaves lanceolate, pubescent, three-nerved, waved; branches weak, slender, woody, spreading horizontally. This shrub is seldom more than two or three feet in height; the peduncles and calices are covered with a thin wool; the calices are lanceolate. The corollas purple; but, according to Mr. Miller, (who cultivated it in 1731) white, coming out upon naked peduncles from the wings of the leaves, in June and July, and succeeded by ripe seeds in August and September.—Native of Portugal.

12. *Cistus Halimifolius*; *Sea Purslane-leaved Cistus*. Leaves lanceolate, hoary; peduncles wand-like. It is an upright shrub, three or four feet high; branches round, ash coloured, angular at top, the younger ones dotted with yellow; leaves petioled, opposite, lanceolate, very white, scarcely soft, without veins, obtuse, flat, about an inch in length; peduncle terminating, compound, white; partial peduncles, below opposite, above alternate: there is a sessile leaflet, narrower than those on the stem, at the base of the peduncles and pedicels; calices erect, ovate, acute, somewhat rugged, having two outer leaflets minute and linear at the base of the larger ones. Mr. Miller describes it as rising four or five feet high, and branching from the ground so as to form a large bush. The leaves on the lower part of the branches have footstalks, but those at the top coalesce at their base, and surround the stalk; the peduncles are a foot in length, naked, hairy, and put out two or four shorter peduncles on the side, each supporting three or four flowers, which are large, of a bright yellow colour, but of short duration, appearing in June and July.—Native of Portugal. There are two varieties, one with a slender stem, woody, and three or four feet high, with many slender branches, and loose bunches of a dirty sulphur-coloured flower, upon slender peduncles, and appearing in June and July; another three feet in height; peduncles naked; flowers solitary, on naked opposite pedicels; corolla bright yellow, with a purple spot near its base, appearing in June and July.—This very beautiful plant is the tenderest of all the European species, and will hardly survive an English winter in the open air, unless protected by other shrubs planted near it.

13. *Cistus Libanotis*; *Rosemary-leaved Cistus*. Leaves linear, revolute; flowers umbelled, yellow. This shrub resembles *Rosemary*; stem naked, purplish; peduncles terminal, longer than the leaves, with a few yellow flowers.—Found in Spain.

** Without *Stipules*, undershrubby.

14. *Cistus Umbellatus*; *Umbelled Cistus*. Procumbent: leaves opposite, linear; flowers umbelled. Stems low, trailing, woody, seldom branching, and not more than four or five inches long; leaves narrow and hoary; flowers white, in small clusters at the end of the stalks. It seldom continues beyond two years. There are two varieties, one having erect stems.—Native of the south of France, and Spain.

15. *Cistus Lævipes*; *Cluster-leaved Cistus*. Ascending: leaves alternate, fascieled, filiform, smooth; peduncles; racemed; root woody, creeping very much; stems many, round, becoming woody; when young herbaceous, glaucous, branched, diffused, spreading horizontally or ascending, very few, erect. The flowers are inodorous, in thin villose racemes at the ends of the branches, on long smooth pedicels; petals ovate, yellow, obscurely crenulate at the end, a little longer than

the calix; the outer stamina are barren.—Native of the south of France, in the neighbourhood of Montpellier.

16. *Cistus Calycinus*. Erect: leaves linear; peduncles one-flowered; calices three-leaved. Stem a foot high; branches opposite, reddish; leaves opposite, even, underneath obtusely keeled, crowded; leaflets from the axils; peduncles terminating, solitary, scarcely longer than the leaves; calix three-leaved, even, equal: corolla yellow, with scarcely the edge red; stamina very short, yellow, all fertile; pistil white; style very short; stigma warted.—Native of the south of Europe.

17. *Cistus Syriacus*; *Syrian Cistus*. Erect: leaves lanceolate, revolute; flowers racemed: petals yellow.—Native of the Levant.

18. *Cistus Fumana*; *Heath-leaved Cistus*. Procumbent: leaves alternate, linear, rugged about the edge; peduncles one-flowered. Stem five to eight inches high, woody, more or less upright, twisted, branched; branches slender, diffuse, lower ones often procumbent; leaves resembling those of *Antirrhinum Linaria*, but smaller, greenish; lower ones shorter and stiffer; flowers yellow, on a solitary peduncle; calix smooth or clothed with a very short down, sometimes with a purple tint, five-leaved; capsule three-celled, three-valved. In the autumn this species is often covered with tufts of leaves, in shape of roses, so as to resemble a *Ledum* more than a *Cistus*.—Native of Gothland, France, Switzerland, Austria, and Carniola.

19. *Cistus Canus*; *Myrtle-leaved Dwarf Cistus*. Procumbent: leaves opposite, obovate, villose, tomentose underneath; flowers subumbelled; peduncles from the upper axils, and those almost naked; petals deep yellow. There is a Portuguese variety, which is larger; the leaves oval or obovate-obtuse, pale ash-coloured above, tomentose-hoary underneath; umbel terminating, four-flowered.—Native of the south of France, Spain, Portugal, Austria, Carniola, and Piedmont.

20. *Cistus Italicus*; *Italian Cistus*. Leaves opposite, hispid, lower ovate, upper lanceolate; branches spreading. Stem erect, a span high; branches opposite, longer, spreading, somewhat deflected, rufous; leaves with a few strigose hairs, mostly twin and subciliate, the lower petioled and ovate, the upper subsessile; raceme terminal; calices hispid; corolla pale, with the petals scarcely emarginate.—It inhabits mountains near the sea, and alpine places not much exposed to the sun.

21. *Cistus Marifolius*; *Marum-leaved Cistus*. Leaves opposite, oblong, petioled, flat, hoary underneath. Stems upright, shrubby, a foot and a half high, sending out branches the whole length; leaves small, silvery, opposite, smooth. The flower-stalks branch; and the flowers, which are white, are produced in short spikes at the ends of the branches.—Native of the south of Europe.

22. *Cistus Roseus*; *Rose-flowered Cistus*. Procumbent: leaves opposite, oblong, rolled back at the edge, somewhat hoary on both sides. Stem branched, diffused, shrubby at the base, as are also the branches, woody, perennial, round; younger branches racemed; leaves and calices roughish; somewhat villose, and hoary; leaves on short petioles, and quite entire; racemes terminating, many-flowered, erect; fruit-pedicels reflex; three leaflets of the calix ovate, obtuse, concave, the two others shorter, and very narrow; petals flesh-coloured, with a yellow base, very entire; and spreading; filamenta as well as antheræ yellow; pistil green; seeds few, brown.—Native of the county of Nice and Unelia. Mr. Miller informs us, that Dr. William Sherard found it growing near Smyrna, and was the first who sent the seeds to England.

23. *Cistus Anglicus*; *English Cistus*. Procumbent: leaves opposite, oblong, revolute, hairy; flowers racemed. Stem scarcely six inches high, oblique, all rugged; leaves lanceolate, like those of *Hyssop*, roughish, not even, green on both sides; flowers white, nodding, but erect when in bloom. There is a variety with stems many, slender; leaves resembling those of wild thyme, but thicker, more hirsute, and hoary, dark green above, paler underneath, but hoary on both sides, without any younger ones arising from the axils: on the tops of the branches grow three or four, and sometimes more, small, yellow flowers.—This species was first observed by Mr. Newton, on some rocks near Kendal in Westmoreland: it has since been found at Buck-barrow Bank Scar, between Brigsteer and Conswick, and about Cartmel Wells, in Lancashire; at Betram-Beuke, about a mile west of Kendal; and also in Carnarvonshire and Anglesea. It flowers in May.

24. *Cistus Celandicus*. Procumbent: leaves opposite, oblong, smooth on both sides. Petioles ciliate; petals emarginate; racemes terminating, few-flowered, villose, erect; flowers sweet-scented; leaflets of the calix very hairy, the two outermost linear, the three inner ones ovate; petals yellow, from roundish obovate, entire or slightly crenulate, scarce emarginate; stamina and pistil all yellow; stigma large, subquadrifid, muricate; capsule hirsute, nodding; seeds ovate, minute.

*** *Without Stipules, herbaceous.*

25. *Cistus Tuberaria*; *Plantain-leaved Cistus*. Perennial: root-leaves ovate, three-nerved, tomentose; stem-leaves smooth, lanceolate, the upper alternate. Root hard, perennial, gradually narrower as it descends; stem a foot high, simple, villose at the bottom; root-leaves spreading on the ground, narrowed towards the base, white underneath; stem-leaves sessile, distant, opposite, except the uppermost which are alternate; flowers on the top of the stem in a sort of corymb; the two outer leaflets of the calix shorter, and lanceolate, the three inner ovate, acuminate, concave; corolla yellow; capsule globular, three-valved.—Native of Spain, in Catalonia, and near Benicasi, in Valencia, also of the south of France, and about Pisa.

26. *Cistus Guttatus*; *Annual Spotted-flowered Cistus*. Leaves opposite, lanceolate, three-nerved; racemes without bractes. Root annual; stem upright, five or six inches high; that, and the rest of the plant, covered with spreading hairs; leaves sessile, three or four pairs; raceme filiform, terminating; peduncles longer, slender, often without bractes; flowers erect, but when just out of bloom pendent; two-leaflets of the calix spreading; petals yellow, with a very dark purple spot approaching to black at the base.—Native of the south of Europe, in sandy soils. Columna and Ray remarked it at the foot of Mount Vesuvius, without any spots in the corolla. It was observed by Brewer, in sandy pastures, on Llechddue, near Holyhead, Anglesea, flowering in June; and by Dr. William Sherard on the west side of the Isle of Jersey, near Grosnez Castle.

27. *Cistus Canadensis*; *Canadian Cistus*. All the leaves alternate, lanceolate; stem ascending; perennial.—Found in Canada, by Kalm.

**** *With Stipules, herbaceous.*

28. *Cistus Ledifolius*; *Ledum-leaved Cistus*. Erect, smooth: flowers solitary, subsessile, opposite to a ternate leaf; calix longer than the corolla, which is of a pale yellow; seeds angular, of a ferruginous red colour, not mucilaginous. This plant assumes different appearances, according to the soil and situation. In a good soil, if the plants stand single, and are not injured by weeds, they will rise nearly a foot and a half high, the leaves will be two inches and a half long,

and nearly half an inch broad in the middle; but in a poorer soil they do not attain to half that height; the leaves are much narrower, and the seed-vessels not half so large. When cultivated in a garden, they are not found to differ.—It is annual: native of the south of France and Italy; and also found near Smyrna by Dr. William Sherard.

29. *Cistus Salicifolius*; *Willow-leaved Annual Cistus*. Spreading, villose: flowers racemed, erect; pedicels horizontal; capsules longer than the calix; petals yellow, smaller than the calix, and extremely fugacious. It varies with apetalous flowers.—Native of Spain and Portugal, Monte Baldo, near Verona, and in the county of Nice. It is also found in sandy pastures, near Bream downs in Somersetshire. Annual; flowering in June and July.

30. *Cistus Niloticus*. Erect, subtomentose: flowers racemed, solitary, sessile, opposite-leaved. Stem somewhat woody, a foot high, round; branches next the root ascending, shorter on the stem towards the top, alternate, erect, few;—flowers alternate, accompanied with a leaf, and two stipules, like the stem-leaves; petals yellow.—Annual; and a native of Egypt.

31. *Cistus Aegyptiacus*; *Egyptian Cistus*. Erect: leaves linear-lanceolate, petioled: calices inflated, larger than the corolla. Root annual, putting out one stem only, which is erect, but not able to support the weight of the fruits; leaves shining, thickish, furrowed on the upper surface, where the nerve is below, sublinear, drawing to a point at each end; on each side the petiole is a subulate stipule; peduncles solitary; flowers drooping, and without scent; petals lanceolate, yellow, very short, included.—Native of Egypt.

***** *With Stipules, undershrubby.*

32. *Cistus Squamatus*. Leaves covered with orbiculate scales. Branches rather erect, at bottom four-cornered; leaves oval-lanceolate, thickish, petioled, opposite, or else three on each side; stipules very minute, racemose, marcescent, sessile; peduncles round, crowded. The whole plant is covered with orbiculate scales, depressed in the centre.—Observed by Loeffling, in Spain.

33. *Cistus Lippii*. Erect: leaves alternate and opposite, lanceolate, rugged; spikes directed one way. Stem round, pubescent, whitish, bifid or sparingly branched; branches below the forking of the stem, lateral, simple, white; leaves petioled, bluntish, spreading, hoary underneath; flowers sessile, crowded; petals obovate, yellow, scarcely larger than the calix; stamina usually ten, shorter than the petals; germen pubescent; fruits obtuse, covered with the calix, sessile, roundish: The wild plant has the branches and leaves hoary on both sides. The younger leaves of the axils are revolute; stipules bristle-shaped; calices hairy, silky.—Native of Egypt, near Alexandria, &c.

34. *Cistus Sarrcianus*; *Small-flowered Cistus*. Procumbent: leaves ovate-oblong, somewhat hairy; petals lanceolate. Mr. Hudson and others consider this as a mere variety of the common sort; the only material difference being in the shape of the petals. Dillenius, on the contrary, who cultivated it at Eltham, and observed it in many other gardens, and Miller, who cultivated it above thirty years, and never found it to vary from seed, do not hesitate to pronounce it a distinct species.—It was first discovered near Croydon in Surry.

35. *Cistus Nummularius*. Lower leaves orbiculate, upper ovate. Stems long, trailing, and dividing into many branches; leaves veined, of a light green on their upper side, but of a greyish colour beneath, with three narrow erect stipules at their base. The flowers are pretty large, white, and grow in clusters at the ends of the branches.—Found by Magnol, on Mount Capouladon, near Montpellier.

36. *Cistus Canariensis*; *Canary Cistus*. Procumbent: leaves subovate, alternate, and opposite; racemes erect. Root perennial; stems shrubby, erect, or ascending, round, scabrous, a span high, branched; leaves quite entire, glaucous, thickish, villose, and somewhat scabrous, flat, obtuse, petioled; stipules linear, lanceolate, erect; racemes opposite to the leaves, and terminating with many flowers pointing one way; bractes linear; stamina entirely yellow; petals roundish, yellow, obtuse, spreading very much, a little longer than the calix. It flowers from June to August; the blossoms expand only in the morning.—Native of Fuertaventura, one of the Canary Islands.

37. *Cistus Fœtidus*. Procumbent: stipules lanceolate, leaves oblong, rugged. Root perennial; stems somewhat shrubby at bottom, but the branches annual. The branches leaves, racemes, and calices, are beset with scabrous villose hairs; the petals are rounded, white, or sometimes very pale yellow, with a yellow base; stamina yellow. It has a strong smell like Bryony.

38. *Cistus Serpyllifolius*; *Wild Thyme-leaved Cistus*. Leaves oblong; calices even. Stems shrubby and crooked, covered with a purplish brown bark, like common heath; branches slender; leaves narrow and stiff, like those of Thyme, they are opposite, and have no stipule at their base. The flowers, which are of a pale yellow colour, are produced on naked peduncles, terminating the branches in a sort of umbel.—Native of the Alps, and of Austria. It flowers from May to September.

39. *Cistus Glutinosus*; *Clammy Cistus*. Leaves linear, opposite, and alternate; peduncles villose, glutinose. Root woody, small, creeping much; stems many, a long span in height, straightish, at bottom woody and branched, but at length solitary, more slender, round, green, naked at top, villose, and glutinous, with very short spreading hairs; racemes few-flowered; peduncles longer than the flower, glutinous, villose; corolla yellow, a little longer than the calix.—Native of the south of Europe.

40. *Cistus Thymifolius*; *Thyme-leaved Cistus*. Procumbent: leaves oval-linear, opposite, very short, heaped. The leaves much resemble those of Thyme, but they are harder, and a little whiter.—Native of the south of France, and Spain.

41. *Cistus Pilosus*; *Hairy Cistus*. Almost upright: leaves linear, with two grooves underneath, hoary; calices even. Stems somewhat erect; bractes solitary, at the side of the pedicels. The white colour of the corolla varies exceedingly; and, in the garden, the same plant will have white, sulphureous, and rose-coloured flowers. It is also not uncommon on the maritime hills of the county of Nice, with rose-coloured flowers.—Native of the south of France, Spain, and Piedmont.

42. *Cistus Racemosus*. Leaves linear; calices racemed, pointing one way, nerved, angular, smooth. This is a weak shrub, half a foot in height; the branches numerous, remotely muricated from the fallen leaves, tomentose and hoary at top; leaves opposite, on very short petioles, narrow, about an inch long, revolute, tomentose and whitish underneath, green above; the flowers in terminating, solitary, very long, pendulous racemes, all directed one way; without any bractes.—Native of Spain.

43. *Cistus Angustifolius*. Diffused: leaves lanceolate; calices hirsute. Root perennial, branched; stem round, branched from the base, woody; the younger branches, with the leaves, stipules, and racemes, slightly villose and hoary; stipules four, subulate, sharp; petals yellow, with an orange-coloured base, either quite entire, or crenulate about the edge; capsule hirsute, ovate.

44. *Cistus Helianthemum*; *Dwarf Cistus*, or *Little Sun-*

flower. Procumbent: stipules lanceolate; leaves oblong, revolute, somewhat hairy. According to Linneus, the petals are suborbiculate, quite entire, yellow, generally with a tawny ring surrounding the receptacle. The racemes nod before they flower, and the leaves have a few hairs scattered over them; germen hirsute, ovate. The usual colour of the corolla is a full yellow, but it varies to lemon-colour, white, and even rose-colour: it is also said to be found with a double corolla: it varies likewise something in the leaves.—Found in dry pastures in many parts of Europe, with us generally in calcareous soils. Perennial: flowering from June to August. Though, says Mr. Curtis, our common Dwarf Cistus cannot vie with those which are the produce of warmer climates, yet it is one of the most ornamental of our native plants, and admirably well calculated to decorate a rock or dry bank, especially if its several varieties, with white, rose, and lemon-coloured flowers, be intermixed. It is hardy, and easily propagated, either by seeds or cuttings, and continues during the greater part of the summer to put forth daily a multitude of new blossoms. Haller mentions a variety with double flowers, which would be a valuable acquisition to our gardens, if it could be obtained.

45. *Cistus Mutabilis*; *Changeable Cistus*. Procumbent: stipules lanceolate; leaves oblong, smooth, flat. Stems several, branching very much, woody at bottom, and the size of a common quill, procumbent and brown: from these spring annually numerous, smooth, ascending branches, about a foot in length; petals obovate, sharp at the base, pale yellow, or rose-coloured; stamina entirely yellow; seeds few, brown. It flowers in May and June, and the seeds ripen in July.

46. *Cistus Hirtus*; *Rosemary-leaved Cistus*. Leaves ovate; calices hispid. Stem erect, sending out many side-branches, with the joints pretty close; leaves very narrow, opposite, revolute, the upper surface of a lucid green, and the under hoary; flowers large, white, in small clusters at the ends of the branches. Allioni observes, that the calix is whitish; that it has nothing rough or hairy about it; and that it is a very distinct species.—Native of the south of France, and near Villafranca in Spain.

47. *Cistus Apenninus*; *Apennine Cistus*. Spreading: leaves lanceolate, rough with hairs. It is a foot in height, branching, and spreading; leaves green, and rough with hairs on the upper surface, on the lower hoary. Mr. Miller makes two species of this, and describes them: 1. with stalks much longer than those of the 44th species; the leaves longer and hoary; the racemes much longer; the calix hairy and whitish; and the corollas white and larger: 2. the stems more erect; the leaves not so long; the stipules very small; and the whole plant very hoary; the flowers are white, the spikes shorter and more compact.—Native of the Apennines, and of Italy.

48. *Cistus Polifolius*; *Mountain Cistus*. Procumbent: leaves oblong-ovate, hoary; calices even; petals serrate. Branches many, spreading on the ground, hoary towards the end, towards the base brownish, with frequent joints, and naked, most of them a hand in length, but the inner and younger branches much shorter; leaves thickish, somewhat stiff, revolute, having a prominent rib underneath, hoary frequently, with others much smaller growing from the axils; flowers few, terminal, of the same form and size with those of the common sort, or Dwarf Cistus, but white; petals slightly crenate, generally cordate. In a garden, the leaves become larger, lose their hoariness, and turn green and hairy; flowering branches ascending, white; leaves opposite.—First remarked by Plukenet, on Brent-down in Somersetshire, near the Severn sea; and found by Dillenius in the same place, on the middle of the hill.—Native also of the south of Europe.

49. *Cistus Arabicus*; *Arabian Cistus*. Procumbent: leaves linear, those on the peduncles alternate, those on the branches lets crowded. This plant is a foot high, suffruticose, and diffused.—Native of Spain.

***** *Species not in the Systema Vegetabilium.*

50. *Cistus Medius*. Leaves ovate, lanceolate, wrinkled, petioled, toothletted. Stems reddish, viscid; leaves green; peduncles solitary, axillary, and terminal; corolla pale yellow; no stipules; shrubby.—Grows in the county of Nice.

51. *Cistus Grandiflorus*; *Great-flowered Cistus*. Stipuled, suffruticose: leaves lanceolate, villose on both sides, acuminate; stipules longer than the calix. Stem villose, about six inches high; leaves an inch long; flowers in racemes; peduncles and calices villose; the smaller leaflets of the calix linear, the others twice as long; petals yellow, rounded, almost half an inch in length.—Found in Carniola and Piedmont.

52. *Cistus Breviorifolius*; *Short-leaved Cistus*. Shrubby, without stipules: leaves ovate-lanceolate, connate, hirsute, wrinkled; peduncles longer. This species differs from the second and eighth species, in having shorter and greener leaves, which are joined at the base, and hairy; the peduncles are much longer, and the flowers smaller, but of a deeper purple. It flowers and seeds at the same time with them, and the shrubs grow as large as those of the second species.—Native of Portugal.

53. *Cistus Lusitanicus*. Shrubby, without stipules: leaves ovate, obtuse, villose, nerved, and wrinkled underneath; flowers larger; the branches are white and hairy; and the flowers of a light purple colour, and very large.

54. *Cistus Hispanicus*. Shrubby, without stipules, villose: leaves lanceolate, green, connate; flowers sessile; calices acute. The flowers are of a deep purple colour.

55. *Cistus Cordifolius*. Shrubby, without stipules: leaves oblong-ovate, smooth; petioles longer. It rises with a smooth shrubby stalk four or five feet high, sending out many slender woody branches, covered with a smooth brown bark, with oblong heart-shaped leaves, which are smooth, and have long footstalks. The flowers are produced at the ends of the branches, standing upon pretty long peduncles; they are white, and appear in June, July, and August, but rarely produce any seeds in England.

56. *Cistus Fasciculatus*. Leaves in bundles. Stem shrubby, about nine inches high; leaves very narrow and fine, growing in clusters. The flowers come out from the sides and at the ends of the branches, on slender peduncles; they are of a pale straw-colour, and it is seldom longer than two hours before the petals fall off. This plant seldom continues more than two years.—Native of the Cape.

57. *Cistus Vaginatus*; *Oblong-leaved Cistus*. Arborescent, without stipules: leaves oblong, hairy underneath, netted-wrinkled; petioles united at the base, sheathing, furrowed. It flowers from April to June.—Found in the island of Tenerife by Masson.

58. *Cistus Laxus*; *Broad Waved-leaved Cistus*. Arborescent, without stipules; leaves ovate-lanceolate, waved, toothletted, smooth, the upper rough with hairs; calicine leaflets roundish-ovate. It flowers in June and July.—Native of Spain and Portugal.

59. *Cistus Seabrosus*; *Rough Cistus*. Undershrubby, without stipules; leaves opposite, ovate, hairy and rugged, three-nerved; calices three-leaved. Stems decumbent, round, closely beset with short stellated hairs, and rugged; branches short; leaves subpetioled, an inch in length; flowers terminating, subpanicled. It flowers in June and July.—Native of Italy and Portugal.

60. *Cistus Sericeus*. Arborescent, without stipules: leaves ovate, tomentose, three-nerved, the lower petioled, the uppermost sessile; peduncles rough with hairs. Stem two or three feet high; branches round, densely tomentose, hoary-white; leaves opposite, hoary, very soft, flat, bluntish, about an inch in length; the four uppermost sessile, subcordate at the base, the rest ending in a short petiole; peduncle from the top of the branches, solitary, erect, a short span in length, hoary, wholly beset, as are the pedicels also, with long purplish hairs; petals purple, with a yellow spot at the base; filamenta purple; antheræ yellow.—Native of Spain and Portugal.

61. *Cistus Hybridus*. Arborescent, without stipules: leaves ovate, petioled, hoary; branches scaly; peduncles elongated, rough with hairs. This is a shrub, with all the leaves petioled, flat, the younger ones waved, hoary on both sides, appearing very minutely dotted when viewed with a magnifier, nerved, brittle, half an inch in length. It is distinguished from the foregoing species, by having all the leaves petioled and whiter, with the branches covered with yellow scales.—Native of Spain.

62. *Cistus Elongatus*. Arborescent, without stipules: leaves lanceolate, hoary; peduncle elongated, two-leaved; that and the racemed calices hirsute. An upright and very branching shrub, a foot or more in height; branches short, the younger ones tomentose, hoary, with yellowish scales scattered over them; flowers racemed; peduncle terminating, half a foot long, erect, by no means hoary, hairy, especially at bottom; flowers nodding before they open; petals yellow, with a dusky spot at the base a little longer than the calix.—Native of Spain.

63. *Cistus Alternifolius*. Suffruticose, without stipules: leaves alternate; peduncles lateral and terminating, solitary, one-flowered. An erect little shrub, with slender villose branches, and a brown bark.—Native of Brazil.

64. *Cistus Lavandulifolius*; *Lavender-leaved Cistus*. Suffruticose, stipuled: leaves lanceolate-linear, tomentose; calices racemed, tomentose, pointing one way, pendulous. This shrub is a palm and sometimes a foot in height, branched at bottom; branches round, upright, tomentose, hoary; leaves opposite, hoary; flowers copious, without bractes; corolla yellow.—Native of Spain, south of France, Barbary, and of the dry hills of Tunis.

65. *Cistus Lanceolatus*. Suffruticose, without stipules: leaves lanceolate, three-nerved, hairy. Stem suffruticose, branched at the base; branches quite simple, a short span in length, ascending, leafy, smooth at bottom, tomentose at top, hoary, as they are also at the base.—Found by Vahl on the heaths near Bizerta in Barbary.

66. *Cistus Ocymoides*. Shrubby, without stipules: leaves obovate, three-nerved, those of the branchlets hoary on both sides, reflex at the tip; calices racemed, both they and the peduncles quite smooth. A small upright shrub, a span high; branches opposite, purple at bottom, clothed at the base, as are also the branchlets, with long thinly scattered hairs; stipules none; petals white, with a purple spot at the base.—Native of Spain.

Citharexylum; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-form, five-toothed, acute, permanent. *Corolla*: one-petalled; funnel-wheel-form; tube twice as long as the perianth, thicker at the top; border five-parted, two-lipped; segments above villose, oblong, truncate, flat, very spreading. *Stamina*: filamenta four, with the rudiment of a fifth from the middle of the tube, filiform, two of them somewhat longer; antheræ oblong, twin, erect. *Pistil*: germen roundish; style filiform, the length of the stamina; stigma

obtuse-headed. *Pericarp*: berry roundish, somewhat compressed, one-celled. *Seeds*: two, ovate, two-celled, convex on one side, concave at the other, emarginate at the end. ESSENTIAL CHARACTER. *Calix*: five-toothed, bell-form. *Corolla*: funnel-wheel-form; segments above villose, equal. *Berry*: two-seeded. *Seeds*: two-celled.—The species are,

1. *Citharexylum Cinereum*; *Ash-coloured Fiddlewood*. Branches round; calices toothed. This is a tree rising with a round upright trunk, not more than a foot in diameter, to the height of fifteen or twenty feet, with a handsome branching head; leaves oblong-oval, entire, shining, about six inches long; flowers small, numerous, odoriferous, on short pedicels; corolla white; berries succulent, shining, soft, roundish, first green, next red, and finally black. Browne says, that it rises not above eight or nine feet in height; that the veins of the leaves, and all the tender buds, are of a brown colour; the bark of the trunk and lower branches of a whitish ash-colour.—It is very common in all the savannas of Jamaica, and is called *old woman's bitter*; also in the woods of Martinique, where the French have named it *bois cotelet*.

2. *Citharexylum Caudatum*; *Oval-leaved or Long-spiked Fiddlewood*. Branches round; calices truncate. The leaves are obovate, and, like the racemes, erect. According to Browne, it is a shrub which seldom exceeds ten or twelve feet in height, and bears a great number of small berries, disposed on divided spikes at the extremities of the branches.—It is pretty common about Sixteen-mile Walk in Jamaica.

3. *Citharexylum Quadrangulare*; *Square-stalked Fiddlewood*. Branches quadrangular. The bark is ash-coloured. Mr. Miller describes it with an upright trunk, fifty or sixty feet high, sending out branches on every side, which have several angles or ribs, running longitudinally, garnished by three oval spear-shaped leaves at every joint, standing in a triangle upon short footstalks; leaves four inches long, and one to two broad, of a lively green colour, notched on their edges, and veined. The flowers come out from the sides, and also at the ends of the branches, in loose bunches, which are succeeded by small pulpy berries inclosing two seeds in each. The French call it *bois cotelet carré*.—Native of Jamaica, Martinique, &c. This species has been long preserved in some of the curious gardens in England, for the sake of variety; the leaves continuing through the year, and being of a fine green colour, make a pretty variety in the stove during the winter season. It may be propagated either by seeds or by cuttings; the latter of which is the usual method in England, where the seeds are not produced; but when seeds can be obtained from abroad, the plants raised from them should be preferred. They should be sown in small pots early in the spring, and plunged into a fresh hot-bed of tanner's bark, and treated in the same manner as other exotic seeds which are brought from hot countries. If the seeds be fresh, the plants will appear in five or six weeks; and in a month after that, will be ready to transplant: when this is done, care should be taken not to tear or break the roots in separating them. They should each be planted in a small pot filled with light fresh earth, and plunged into the hot-bed again, observing to shade them till they have taken fresh root; after which they should have a large share of air admitted to them in warm weather, and must be frequently watered. In autumn they should be removed into the bark-stove, where it will be proper to keep them during the first winter until they have obtained strength. They may afterwards be kept in a dry-stove in winter, and be exposed in the middle of summer for two or three months to the open air, in a warm situation, which will cause them to flourish better than when they are more tenderly treated.

4. *Citharexylum Villosum*; *Hairy-leaved Fiddlewood*. Leaves villose. This is a small tree, about ten feet in height. The trunk and older branches are round and ash-coloured, the younger ones four-cornered and green; the young shoots are villose; racemes half a foot long, hanging down at the ends of the branchlets; flowers numerous, on short pedicels, villose all over, and smelling extremely sweet; calix truncate; corolla white.—Native of St. Domingo.

5. *Citharexylum Melanocardium*; *Black-heart Fiddlewood*. Branches quadrangular; racemes terminating, compound; flowers four-stamined. This tree frequently rises to the height of forty or fifty feet, and is generally looked upon as one of the hardest and best timber-trees; the body grows to a considerable thickness, and is covered with a thick whitish bark, which, like the grain of the wood, winds in a loose spiral form; the leaves are pretty long, rugged, and slightly serrate; the flowers are disposed in bunches at the extremities of the branches; the berries are small and yellow, and are sometimes eaten by the negroes; they contain each two hemispheric shells with two kernels, and the nuts may easily be parted into two lobes or segments.—Native of Jamaica, chiefly in the low lands and savannas. Mr. Miller informs us, that the French call this tree *fidèle*, from its faithfulness or durability in building; and that the English have corrupted the name to *fiddlewood*, as if it were used for making musical instruments, which is a mistake.

Citrus; a genus of the class Polyadelphia, order Icosandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, flat at the base, very small, withering. *Corolla*: petals five, oblong, flat, spreading. *Stamina*: filaments usually twenty, subulate, compressed, erect, placed in a ring or cylinder, united generally into fewer or more bunches; anthera oblong. *Pistil*: germen superior, roundish; style cylindrical, the length of the stamina; stigma globular, nine-celled within. *Pericarp*: berry with a fleshy rind, the pulp bladdery, many-celled. *Seeds*: in couples, subovate, callous. *Observe*. Orange has a *cordate petiole*: Citron, Lemon, and Lime, have a *naked and simple petiole*. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: five. *Stamina*: about twenty, polyadelphous. *Berry*: many-celled. All the species of Citrus are either trees of small growth, or shrubs; leaves evergreen, ovate, or ovate-lanceolate, entire or serrate, pellucid, dotted, the petiole frequently margined: on the natural trees there are often solitary axillary spines: peduncles axillary or terminating, one-flowered, or many-flowered. The species seem best distinguished by the petiole, which, in the Orange and Shaddock, is winged; in the Citron, Lemon, and Lime, naked: the form of the fruit, although not quite constant, may also serve for a distinction: in the Orange and Shaddock it is spherical, or rather an oblate spheroid, with a red or orange-coloured rind; in the Lime spherical, with a pale rind; in the Lemon oblong with a nipple-like protuberance at the end; in the Citron oblong, with a very thick rind. Mr. Miller distinguishes the Citron from the Orange, because in all the varieties of Citron which he has examined, he found but ten stamina in the flowers, whereas those of the Orange always have more. It is very difficult to determine what is a variety, and what a species, in this genus. The trees in the eastern countries, their natural place of growth, vary not only in the size and shape of their fruit, but also in their leaves; many of those which are only esteemed to be varieties in Europe, and are given here as such, preserve their differences in their native woods.—The species are,

1. *Citrus Medica*. Petioles linear; leaves egg-shaped, acuminate.—In its wild state this tree grows to the height of

about eight feet, erect, and prickly, with long reclining branches; leaves ovate-oblong, alternate, subserrate, smooth, pale green; flowers white, odoriferous; fruit esculent, both raw and preserved. Miller mentions two kinds of the proper Citron; one sweet, with a thick rough-rinded fruit; the other sour, with a rough knobbed-rinded fruit. The other varieties are, the *Common Lemon*; the *Sour Lemon*, or *Lime*; and the *Clustered Lemon*. Genoa supplied the English gardens with several varieties of the Citron, that country being the great nursery of this, as well as of Lemons and Oranges; and the gardeners who cultivate them are as proud of introducing a new variety into their collection, as the nursery-men in England are of obtaining a new Pear, Apple, or Peach. The fruit of the Citron is seldom eaten raw, but is generally preserved, and made into sweetmeats, which being kept till winter and spring, when there is a scarcity of fruit to furnish out the dessert, is the more valuable; but unless the season be warm, and the trees well managed, the fruit rarely ripens in England. The best fruit will be produced where the trees are trained against a south wall, through which there are flues for warming the air in winter; and glass covers, to protect the plants when the weather begins to be cold.—The Citron is a native of all the warm regions of Asia; it was introduced into Europe from Media, and had the name of *Malus Medica*, and seems to have been brought into Italy after the age of Virgil and Pliny, but before that of Palladius, who appears to be the first who cultivated it there with any success. According to Haller, the Median Apple described by Theophrastus, and which, Athenæus asserts, first came from Persia into Greece, is certainly a sort of Orange; and if Haller be correct, the *tristes succi* of Virgil, and the *acres medulla* of Palladius, must have been much corrected by culture, for the latter, together with Theophrastus and Pliny, agree in describing it as not eatable, though they celebrate its medical qualities far above its desert. *Citrus Medica*, or Citron, has medical virtues similar to those of the Orange and Lemon; the fruit is more flavoured than the latter, and the rind acts more as an emetic; the yellow rind is used, and from it the perfume called *bergamot* is extracted. Citrons are very rarely kept in the shops, though formerly much used in the materia medica. Whether the Median apple were the Citron or the Orange, it was anciently celebrated as a cure for the asthma, and for expelling poison.

Media fert tristes succos tardumque saporem
 Filicis mali, quo non præsentius ullum
 (Pocula si quando sævæ infecere noceræ
 Miscueruntque herbas, et non innoxia verba)
 Auxilium venit, ac membris agit atra venena.
 Ipsa ingens arbor, faciemque simillima lauro:
 Et, si non alium latè jactaret odorem,
 Laurus erat: folia haud ullis labentia ventis:
 Flos apprime tenax; animas et olentia Medi
 Ora fovent illo, et senibus medicantur anhelis.
 VIRGIL, Georgic. lib. ii. v. 126—135.

The Median fields rich citron fruits produce,
 Tho' harsh the taste, and clammy be the juice;
 Blest antidote! which when in evil hour,
 The step-dame mixes herbs of pois'nous pow'r,
 And crowns the bowl with many a mutter'd spell,
 Will from the veins the direful draught expel.
 Large is the trunk, and laurel-like its frame,
 And 'twere a laurel, were its scent the same:
 Its lasting leaf each roaring blast defies,
 Tenacious of the stem its flow'rets rise;
 Hence a more wholesome breath the Medes receive,
 And of their sires the lab'ring lungs relieve.

Pitt & Wharton.

—The *Common Lemon*; leaves ovate-lanceolate, acuminate, subserrate. This differs materially from the Orange-tree, both in the naked footstalks of the leaves, and in the shape and colour of the fruit; but there is scarcely any distinction between this and the Citron, except it be that the rind of the fruit is generally thicker and more knobbed in the Citron than in the Lemon, and the fruit itself longer and more irregular; to which Mr. Miller adds, that the bark of the Citron-tree is smoother, and the wood less knotty. Many varieties of the Lemon are preserved in some of the Italian gardens, and in both the Indies there are several which have not yet been introduced to the European gardens; but these may be multiplied without end from seeds. The most remarkable varieties in the English gardens are: 1. The sweet Lemon, plain and variegated; 2. the pear-shaped Lemon; 3. the Imperial Lemon; 4. the Lemon called Adam's apple; 5. the furrowed Lemon; 6. the childing Lemon; 7. the Lemon with double flowers; 8. Browne mentions the St. Helena Lemon, as having been then lately introduced to Jamaica, and much cultivated there, on account of its fruit, which frequently yields above half a pint of juice: 9. in China, and other parts of the East, they have a remarkable variety of Lemon or Citron, which has a solid fruit without any cells or pulp, and divided above the middle into five or more long round parts a little crooked, and having the appearance of the human hand with the fingers a little bent, whence the Chinese call it *phat-thu*, or fingered Lemon; it is a monstrous fruit, a mere curiosity without any use. The common and sweet Lemon are brought to England from Spain and Portugal in great plenty, but the later is not much esteemed; the pear-shaped Lemon is a small fruit with very little juice; the fruit of the imperial Lemon is sometimes imported from Italy, but not from Spain or Portugal; probably therefore it is not propagated in either of those countries. The Portuguese had many of the most curious sorts of Orange, Lemon, and Citron trees, brought from the Indies formerly, which seemed to thrive almost as well there as in their native soil, and yet they have not been increased. There are a few trees still remaining in some neglected gardens near Lisbon, which are almost unnoticed by the inhabitants.—The *Sour Lemon* or *Lime*: leaves ovate, entire; branches somewhat thorny. It grows to the height of about eight feet in its native country, with a crooked trunk, and many diffused branches, which have prickles on them; leaves ovate-lanceolate, almost quite entire; the petioles usually linear; flowers few together, on terminating peduncles; corolla oblong, white, with a purplish spot; stamina twenty, in several parcels; berry an inch and half in diameter, almost globular, with a protuberance at the tip, the surface regular, shining, greenish-yellow, with a very odorous rind, nine-celled, abounding in a very acid juice, but having very few subovate seeds: it is a native of Asia, but has long been common and much esteemed in the West Indies. Browne says, that it is a bushy shrub in Jamaica, where it is much cultivated for the sake of its fruit, and not unfrequently planted for fences; that when it grows luxuriantly it is seldom under twelve or fourteen feet in height, and spreads gently about the top, but that it is often stunted, and of a smaller stature. They have also a sweet Lime, which is generally a more upright tree, and bears a fruit which in size as well as form seems to hold a mean between the Lime and the Lemon; the juice is very insipid, but the bark and the fibres of the root have much of that bitter so peculiar to the Lime. There can be no doubt that any one investigating the subject in the native climates of these fruits, would detect varieties connecting all that are here described as species, not only the Citron with the Lemon and Lime, which certainly are no

more than varieties, but these also with the Shaddock and the Orange, which are hardly to be considered as specifically distinct. Mr. Miller declares, that he has never known the common Lemon vary to the Lime when raised from seeds, nor the Lime vary to the Lemon; but that he has always found them continue their difference in leaf and branch; and therefore supposes them to be specifically distinct. The Lime is not often brought to England, nor is it much cultivated in Europe; but in the West Indies the fruit is preferred to the Lemon, the juice being more wholesome, and the acid more agreeable to the palate.—The *Clustered Lemon*: leaves ovate-lanceolate, subserrate; fruits in clusters. All these varieties have linear petioles, and are therefore referred to one species by all botanists.—The medical virtues are very considerable: the juice of the Lemon is very generally carried by sailors going on long voyages, as an antiscorbutic; it has been found to cure the jaundice, when taken to the quantity of four or six ounces per day; Dr. Whytt says, that it allays hysterical palpitations of the heart: the rind is a very grateful aromatic bitter, not so hot as Orange-peel, and yields, in distillation, less quantity of the oil, which is nevertheless similar in quality to that of the Orange, and employed for the same purposes. For their propagation and culture, see the next species.

2. *Citrus Aurantium*; *Orange*. Petioles winged; leaves acuminate. The Orange is a middle-sized evergreen tree, with a greenish brown bark; in its native country the branches are prickly; leaves broad-lanceolate, almost quite entire, smooth, with the petioles commonly winged; peduncles many-flowered, terminating; corolla white; stamina twenty, connected in several parcels; berry subglobular, flattened (an oblate spheroid) of a golden colour, shining, odorous, three inches in diameter, divided within into about nine cells, filled with a bladdery pulp, having a sweet acid juice in it; rind fleshy, of a middling thickness, covered with a pellicle which is somewhat biting and bitter to the taste. Loureiro, the author of the above description says, that it agrees particularly with that sort of Orange which is most common all over the world, and is known in Europe by the name of Portugal or China Orange, because it was brought from China by the Portuguese, and by them dispersed over Europe.—It is a native of India, China, &c. There are innumerable varieties in China, as well as in other countries of Asia, in South America, in the West Indies, and even in Europe. Loureiro describes the most grateful of all the Oranges as a distinct species, under the title of *Citrus Nobilis*: the branches are less spreading than those of the common Orange, but are rather ascending, and without prickles; leaves lanceolate, quite entire, dark green, on linear petioles; berry red within and without, twice as large as the common sort, being five inches in diameter: the skin thick, juicy, sweet, eatable, and irregularly tubercled; it abounds in Cochin-china. The most esteemed fruit in China, according to Grosier, is very small, with a smooth soft skin, of a reddish yellow colour; they have also the four-season or everlasting Orange, so called from its being always in fruit and blossom; this also bears a very small fruit: the large clove or mandarine, and the small clove or mandarine; the soft cushion Orange, the gold Orange, &c. The Chinese Oranges are generally firmer than those of Europe, their skin does not easily peel off, and the pulp will not separate into small divisions; they commonly give them to the sick, softening them a little at the fire, and mixing sugar with them. The Seville Orange differs little from that of China in the tree, except that it is more hardy, and that the leaves are longer and handsomer; the fruit, however, is very different in the colour of the peel, and in the taste both of that and of the juice, as is well known. The varieties of

the Orange most known in the English gardens are, in addition to the Seville and China, already named, 1. The willow-leaved or Turkey Orange; 2. the yellow and white-striped leaved; 3. the curled-leaved; 4. the horned Orange; 5. the double-flowering; 6. the hermaphrodite; 7. the dwarf, or nutmeg Orange. The horned Orange divides into parts, spreading out in form of horns; this and the distorted Orange are preserved merely for variety, not being so beautiful as the common sort. The leaves of the dwarf Orange are very small, and grow in clusters; the joints of the branches are very near each other; the flowers grow very close together, and appear like a nosegay, the branches being covered with them; this, when in flower, is proper to be placed for ornament in a room or gallery, which it will perfume with its flowers; but it requires care, and is seldom in health. The first China Orange, says Evelyn, that appeared in Europe, was sent for a present to the old Condé Mellor, then prime minister to the king of Portugal; but of that whole case which came to Lisbon, there was but one only plant which escaped the being so spoiled and tainted, that with great care it hardly recovered to be since become the parent of all those flourishing trees of that name cultivated by our gardeners, though not without sensibly degenerating. Receiving this account, adds our famous planter, from the illustrious son of the Condé, I thought fit to record it as an instance of what industry may produce in less than half an age. South America and the West Indies have been furnished from Spain and Portugal with this fruit, so salutary and agreeable to the palates of the people, and so congenial to those hot climates. Mr. Miller informs us, that he sent two small trees of the true Seville Orange to Jamaica, where this sort was then unknown, and that from these many other trees were budded, which produced plenty of fruit, some of which was sent to England, and, although they were long on their passage, yet they were greatly superior to any of the fruit imported from Spain and Portugal, affording three times the quantity of juice. The Orange-tree has been cultivated in England ever since the year 1629, and the first shifts made to preserve it may not be uninteresting to the reader. "The Orange-tree," says Parkinson, "hath abiden with some extraordinary looking and tending of it, when as neither Citron or Lemon-trees would by any means be preserved any long time; some keep them in great square boxes, and lift them to and fro by iron hooks on the sides, or cause them to be rolled by trundles, or small wheels under them, to place them in an open house, or close gallery, for the winter time; others plant them against a brick wall in the ground, and defend them by a shed of boards, covered over with sear-cloth in the winter, and by the warmth of a stove, or other such thing, give them comfort in the colder times; but no tent or mean provision will preserve them." But notwithstanding what Parkinson here advances, bishop Gibson, in his additions to *Camden's Britannia*, probably from Aubrey, says, that the Orange-trees at Beddington in Surry, introduced from Italy by a knight of the noble family of the Carews, were the first that were brought into England; that they were planted in the open ground, under a moveable covert during the winter months; and that they had been growing there more than a hundred years, that is, before 1595; the first edition of *Camden*, by bishop Gibson, being printed in 1695. The editors of the *Biographia Britannica*, article *Raleigh*, reciting a tradition preserved in that family, tells us, that these Orange-trees were raised by sir Francis Carew from the seeds of the first Oranges which were imported into England by sir Walter Raleigh, who had married his niece, the daughter of sir Nicholas Throckmorton; but this is improbable, since the plants

raised from these seeds would have required to be inoculated, in order to produce fruit, and it is therefore more likely that they were plants brought from Italy. Professor Bradley reports, that they always bore fruit in great perfection, that they grew on the south side of a wall, not nailed against it, but at full liberty to spread. And by the account of Mr. Henry Day, the gardener, they were fourteen feet high; the girth of the stem twenty-nine inches; and the spreading of the branches one way nine feet, and twelve feet another; these trees were all killed by the great frost of 1739-40. They had been inclosed the year before by a permanent building, after the manner of a green-house; so that it is uncertain whether the dampness of new walls, and the want of so much air and light as the trees had been accustomed to, might not have destroyed them, if the frost had not happened. The Orange has long maintained a very respectable place in the materia medica. The sort principally employed in medicine is the Seville Orange, the juice of which is well known to be a grateful acid liquor, which, by allaying heat, quenching thirst, and promoting various excretions, proves of considerable use in febrile and inflammatory disorders: it is also considered as a powerful antiseptic, and of great efficacy in preventing and curing the scurvy: the juice of the China or common Orange possesses the same qualities in an inferior degree. The acid of Oranges, by uniting with the bile, is said to take off its bitterness; and hence Dr. Cullen thinks it probable, that acid fruits taken in, are often useful in obviating the disorders that might arise from the redundancy of bile, and perhaps from the acrid quality of it; he adds, on the other hand, however, if the acids be in greater quantity than can be properly corrected by the bile present, they seem by some union with that fluid, to acquire a purgative quality that gives a diarrhoea, and the colic pains that are ready to accompany the operation of every purgative. Not only the juice, but the rind or peel, of the Seville Orange, is of considerable medical efficacy; since, besides its use as a stomachic, it has been much celebrated in intermittent fevers; and in testimony of its efficacy in the most obstinate agues, we find several authorities cited by professor Murray: it has also been experienced as a powerful remedy in menorrhagia, and in immoderate uterine evacuations; and for its good effects in these disorders, we have not only the assertions of foreign physicians, but also those of Drs. Whytt and Hamilton. It gives out its taste and flavour readily to water, is useful in all flatulencies, in whatever form it be given, and also sits better on the stomach than most other corroborants. The leaves of the Orange are not without their virtues, and have, like the flowers, been particularly celebrated in convulsive disorders, and successfully given in the dose of a drachm at a time, in nervous and hysterical cases.—*Propagation and Culture of the Citron, Lemon, and Orange.* Where the trees are to be raised for stocks to bud Oranges, some Citron seeds, duly ripened, should be procured, because their stocks are preferable to any other, not only for quick growth, but as they will take buds of either Orange, Lemon, or Citron; and next to these are the Seville Orange seeds. The best seeds are from rotten fruits, which may be easily obtained in the spring of the year. Prepare a good hot-bed of tanner's bark, which is preferable to horse-dung, and when this bed is in a moderate heat, sow your seeds in pots of good rich earth, and plunge them into the hot-bed, observing to give them water frequently, and raise the glasses in the great heat of the day, to give a sufficiency of air, lest the seeds should be injured by too much heat: the seeds will soon come up, and if the young plants be not stunted either of proper heat or moisture, they will be fit to transplant into

single pots in a month's time after their appearance: you must therefore renew your hot-beds, and having prepared a quantity of small halfpenny pots, which are about five inches over at the top; fill these half full of good fresh earth, mixed with very rotten cow-dung, and then shake out the young plants from the large pots, with all the earth about them, that you may the better separate the plants without tearing their roots: half fill the pots with earth, and put a single plant into each of the small pots, and fill them up as before directed, plunging the pots into the new hot-bed, giving them a good watering to fix the earth to their roots, observing to repeat the same very often, for this plant requires much water when in a hot-bed, and must be screened from the sun in the heat of the day; by pursuing this method, your plants will be two feet high in July, at which time you must begin to harden them by degrees, raising your glasses very high, and altogether removing them in fine weather. The plants must not, however, be exposed to the mid-day sun, especially while they are young; they must be housed towards the end of September, observing to place them near the windows of the green-house to prevent the damps from moulding their tender shoots: they should be often refreshed with water during the winter season, and should have their heads and stems washed in March or April, to clear them from the filth that may have settled thereon, during their being in the house; they must also have a moderate hot-bed in the spring, which will greatly forward them. Towards the beginning of June, however, they ought to be hardened, that they may be in right order to bud in August, when you should choose cuttings from trees that are healthy and fruitful, of whatever kind you please, observing that the shoots are round, their buds being much better and easier to part from the wood, than such as are flat. When you have budded the stocks, you should remove them into a green-house, to defend them from wet, turning the buds from the sun; but let them have as much free air as possible, and often be refreshed with water. It will be evident which have taken, in a month's time after budding; they must then be untied, that the binding may not pinch the buds, and let them remain in the green-house all the winter; then in the spring prepare a moderate hot-bed of tanner's bark, and after having cut off the stocks about three inches above the buds, plunge their pots into the hot-bed, observing to give them air and water as the weather shall require, and screening them from the sun in the heat of the day. If the buds shoot kindly, they will grow to the height of two feet or more by the end of July, at which time you must begin to harden them before the cold weather comes on, that they may the better stand the green-house during the following winter. In the first winter after their shooting they must be kept very warm, for they will be rather tender by forcing them in the bark bed; but it is very necessary to raise them to their height in one season, that their stems may be straight; for in trees which are two or more years growing to their heading height, the stems are always crooked. In the succeeding years their management will be the same as in full-grown trees, which will be hereafter noticed.—We shall now proceed to treat of the management of such trees as are brought over every year in chests from Italy, which is, in fact, by far the most expeditious way of furnishing a green-house with large trees, for those which are raised from seeds in England, will not grow so large in their stems in less than eighteen or twenty years, as these are when brought over; and although their heads be small when we receive them, yet in three years, with good management, they will produce large heads, and bring forth fruit. In the choice of these trees, observe first the differences of their

shoots and leaves, if any remain upon them, to distinguish their different sorts, for the Shaddock and Citron always make much stronger shoots than the Orange, for which reason the Italian gardeners, who raise these trees for sale, generally propagate those sorts, so that they bring few of the Seville Oranges over, which are well known to be the most valuable both for their flowers and fruit; prefer also those that have two good buds in each stock, for many of them have but one, which will always produce an irregular head: the straightness of the stem, freshness of the branches, and plumpness of the bark, are necessary considerations. When you have procured the trees, prepare a moderate hot-bed of tanner's bark, and let the length and breadth of it be proportioned to the number of trees which you intend to force; then put your trees about half way up their stems upright into a tub of water, leaving out the head and the upper part of the stem, that they may the better imbibe the moisture: after they have remained several days in this situation, take them out, clean their roots from all filth, cutting off all that are broken or bruised, and all the small fibres which are quite dried by being so long out of the earth; scrub the stems with a hard hair brush, wiping them afterwards with a cloth; then cut off the branches about six inches from the stem, and having prepared a quantity of good fresh earth, mixed with very rotten cow-dung, plant your trees therein, observing never to put them into large pots, for if they be big enough to contain their roots it is sufficient at first planting. Potsherds and large stones must be placed in the bottom of each pot, to enable the water to pass off freely: hay-bands should also be wrapped round their stems from bottom to top, to prevent the sun from drying their bark; then plunge these pots into the bark-bed, watering them well to settle the earth to their roots, frequently repeating the same all over their heads and stems, yet being very careful not to over-water them, especially before they have made good roots; and particularly observing to screen the glasses of the hot-bed from the sun in the heat of the day. If the trees grow kindly, they will have sent out strong shoots, which should be stopped by the beginning of June, in order to obtain lateral branches to furnish their heads; at this time plenty of air must be admitted to begin to harden them, so that by the middle of July they may be removed into the open air in some warm situation, defended from the great heat of the sun, and from winds, that they may be hardened before winter. They should be housed about the end of September, setting them at first in front of the green-house near the glasses, opening the windows whenever the weather will permit; and about the latter end of October, when the Myrtle and other less tender trees are brought in, let the Oranges be set in the warmest and best part of the house, placing lower plants or trees in front to hide their stems; water them frequently during the winter, but in small quantities at a time, for now their heads are but small, and therefore incapable of discharging a large quantity of moisture; they must also be particularly guarded from frost. When you thin the green-house, by taking out some of the hardiest sorts of plants in the spring, it will be well to cleanse the stems and leaves of the Orange-trees, taking out the upper part of the earth in the pots, filling them up again with good fresh rich earth, laying thereon a little rotten cow-dung round the outside of the pots, but not near the stems of the trees; after this remove them farther apart in the house, that the air may circulate round their heads, giving them air discretionally, as the weather grows warm: they should not be placed out in the open air until the latter end of May, when the weather is settled, for many times, when they are taken out too soon, the cold mornings give them a great check, at

least changing the colour of their leaves, and often kill the extreme weak part of the shoots: during the summer season, let them be as much as possible defuded from the sun, by tall trees or hedges, during the heat of the day, and also from strong winds, both of which are exceedingly injurious to them. As the trees advance in the summer, it will be necessary to stop strong shoots wherever they grow irregularly, in order to force out lateral branches to fill the head, but do not pinch off the tops from all the shoots, as is the practice of some, which will fill the tree with small shoots, too weak to support fruit: the best plan is, to aim at forming a regular head, and obtaining strong shoots, taking away weak trifling branches whenever they are too close: they must be frequently watered in dry weather, especially if they be large, and on this account it is advisable to have the water as near the trees as possible, in order to save the trouble of carrying it, which will take up too much time where the number of trees is great; the water should be soft, and exposed to the air, but should never have dung of any sort added to it, which, although recommended by many, has always been found to operate upon these and upon all other trees, like spirituous liquors upon the human body, seeming at first to communicate vigour, but afterwards leaving it weaker than before.—Orange-trees require to be shifted and new-potted every other year, therefore you must prepare a quantity of good earth, at least twelve months beforehand, that it may be well mixed and perfectly rotten; the best season for this is about the end of April, that they may have taken fresh root before they are removed from the green-house; and when this work is performed, it will be necessary to let them remain in the house a fortnight longer than usual, in order to be well settled. In performing this work, after the trees are drawn out of the pots, all the roots round the outside of the ball of earth must be cut off, and the mouldy roots taken away; then with a sharp iron instrument take away as much of the old earth from between the roots as can be removed without breaking or tearing them: then set the root of the tree into a large tub of water for about a quarter of an hour, to soak the under part of the ball of earth; afterwards scrub the stems of the trees with a hard hair brush, cleaning them and the heads with water and a soft woollen cloth: when the pots are prepared, with some potsherds and large stones at the bottom, put some fresh earth into each pot about three or four inches thick, place the trees thereon in the middle of the pots, upright, filling them up with the same rich earth, pressed down hard with your hands; then water the tree all over the head, with a watering-pot that has a rose upon the spout, to let the water fall light and thick, as in a shower of rain, observing to water them in the same manner during the time they remain in the house after shifting; this will greatly refresh their heads, and promote their taking fresh roots. When these trees are first placed abroad after shifting, they should be placed near the shelter of hedges, and have their stems fastened to strong stakes, to sustain them against strong winds.—If old Orange-trees have been so ill managed that their heads have become ragged and decayed, the best means of restoring them is to cut off the greatest part of their heads early in March, and draw them out of the tubs or pots, shaking off the earth from their roots, casting away all those which are mouldy, together with all small fibres, and then soaking and cleaning their roots, stems, and branches, and afterwards resetting them into a hot-bed of tanner's bark, as above directed for such trees as came from abroad, managing them in the same manner; by this method they will produce new heads, and in two years' time become good trees again: but if they be large trees, that have grown

in tubs for several years, the best way will be to prepare a parcel of rough baskets, such as are used for evergreens, when sent to a distant place: let them be somewhat smaller than the tubs into which it is intended to plant the trees; and set the trees in them, plunging them into the hot-bed; and in the beginning of July, when they have made good shoots remove them into the tubs with their baskets still about them, filling the empty space with the same good earth, which will preserve the tubs from rotting in the bark; and the trees will do equally well as if planted into tubs at first, provided care be taken, in removing the baskets, not to disturb their roots; and also to let them remain in the green-house a fortnight or three weeks after planting, before you set them abroad. Orange-trees are new-potted or tubbed every other year, in the month of April: in the years wherein they are not shifted, as much old earth as possible must be taken out from the tops of the pots and tubs, and also round the sides, as can be removed without injuring the roots: this must be replaced with fresh earth: you must also wash and clean their stems and leaves from filth, which will greatly strengthen their flowering, and cause them to shoot vigorously in the following summer.—In the management of Orange-trees which are in good health, the chief care should be to supply them with water duly, instead of starving them in winter, as is sometimes practised, whereby their fibres are dried, and become mouldy, to the great prejudice of the trees. But they certainly must not have much water at once, but should often have small quantities. Care must be taken to secure a free passage for the water to drain off, for if it be detained in the tubs or pots it will rot the tender fibres of the trees. During winter they require a large share of air when the weather is favourable, for nothing can injure these trees more than stifling them: hence they ought not to be placed too near each other in the green-house, but set at such a distance that their branches may be clear of each other, and that the air may circulate freely round their heads. In summer they should be placed where the wind is not violent, and be exposed to the morning and evening sun; but if they be too much exposed to it in the middle of the day, they will not thrive. The best situation for them is near some large plantation of trees, which will break the force of the winds, and screen them from the violent heat of the sun. In this situation they may remain until the beginning of October, or later, according as the season proves favourable; for if they be carried into the green-house early, and the autumn should prove warm, it will compel the trees to send forth fresh shoots, which will be weak and tender, and so liable to perish in winter; and sometimes it will occasion their flowering in winter, which greatly weakens them; nor should they remain so long abroad as to be injured by morning frosts.—The best compost for Orange-trees is two-thirds of fresh earth from a good pasture, which should not be too light nor over stiff, but rather a hazel loam. It should be taken along with the sward to the depth of ten inches, and mixed with one-third of cow-dung twelve months before, to rot. It should be turned over every month, to mix it well, and to dissolve the sward, which will at the same time break the clods, and produce finer mould. Before this mixture be used, it should pass through a rough screen, to separate the great stones and the roots of the sward from it; but the earth should on no account be too finely sifted, for that is very prejudicial to most plants, particularly to Orange-trees. Of late years many of these trees have been planted against walls, where frames of glass have been constructed to protect them in the winter; and some curious individuals have planted them in the full ground, erecting moveable covers, which entirely enclose them in winter, and in the summer are with-

drawn; and where these have been well executed, the trees have made great progress in their growth, and have also produced a much larger quantity of fruit, which have ripened so well as to be extremely good for eating. If these be planted either with a design of training the branches to the walls, or in borders at a small distance, so as to train them up as standards, there should be a contrivance of a fire-place or two, in proportion to the length of the wall, through the whole of which flues should be carried to warm the air in very cold weather, otherwise it will be extremely difficult to preserve the trees in very hard winters, for if they do not die, they may be so weakened by the cold as not to recover their strength for bearing in the following summer; so that wherever the trees are intended to be placed against or near old walls, the flues should be built up against the front, allowing four inches' thickness of the brick-work on each side of the flues, observing to fasten this with iron at proper distances, to secure it against separating from the old wall. Where this contrivance is carefully used, there will be no hazard of losing the trees, be the winter ever so severe; whereas if this be wanting, it will require endless trouble to cover and uncover the glasses every day, when there is any sun: and if the wall be not thicker than walls are usually built, the frost will penetrate it in severe winters; so that covering and securing the glasses of the front will not be sufficient to preserve the trees, though done with ever so much care; and hence the first expense of the walls will save great trouble and charge, and be the surest method. If the ground be wet, or a strong clay which detains the moisture, the borders should be raised above the level of the ground, in proportion to the situation of the place, for where the wet lies in winter near the surface, it will greatly prejudice, if not totally destroy the trees; so that lime rubbish should be laid at least two feet thick in the bottom of the border, to drain off the wet, with the earth two and a half or three feet thick thereon, which will be a sufficient depth for the roots of the trees. In these borders a few roots of the Guernsey and Belladonna Lilies, and *Hæmanthus*, may be planted, or indeed any other exotic bulbous-rooted flowers, which do not grow high, or draw too much nourishment from the borders; and these producing their flowers in autumn and winter, will make a good appearance, and thrive much better than if kept in pots. The management of Orange-trees in these places is nearly the same as has been directed for those in pots or tubs, excepting that the borders in these places should be dug, and refreshed every year with some very rotten dung.—It is commonly said that the Maltese red Oranges are budded on the Pomegranate; and that the Orange, budded or grafted on Mulberry stocks in Sicily, produces fruit with a blood-coloured pulp; but these accounts of travellers are not to be depended upon. The China dwarf Orange, Shaddock, and those with striped leaves, are all more tender than the Seville Orange, and therefore must be treated with more care, and placed in a warmer part of the green-house in winter. The China Orange rarely produces good fruit in England, nor are the leaves of the trees near so large or beautiful as those of the Seville Orange; the latter therefore should be preferred, and only a tree or two of the China sort kept for variety. The varieties with striped leaves never produce good fruit, nor do they even produce flowers in so great plenty as the plain varieties.

3. *Citrus Decumana*; *Shaddock*. Petioles winged; leaves obtuse, emarginate. Linnæus originally regarded this merely as a variety of the Orange, to which it certainly makes very near approaches. It is a tree above the middle size, with spreading prickly branches; leaves ovate, subacute, seldom

obtuse, very seldom emarginate, smooth, scattered; petioles cordate-winged, the wings as broad as the leaves; flowers white, very sweet-scented, in copious upright terminating bunches; corolla reflex; stamina about twenty, nearly equal to the petals, collected into a many-cleft tube; berry spheroidal, frequently retuse at each end, eight inches in diameter, of an even surface, greenish-yellow, divided into twelve or more cells, containing some a red, others a white pulp, the juice in some sweet, in others acid. The rind is very thick, white, fungous, bitter, useless; seeds ovate, subacute, two or three in each cell. There are many varieties of this tree, one of which is superior to the rest in the smell and flavour of the fruit, and may be distinguished by having a smaller trunk, and subglobular fruit, five inches in diameter, yellow on the outside, white and very sweet within. In China it is called *hiam yuen*, in Cochinchina *huongien*, which signifies *sweet ball*. Thunberg describes the first in Japan as being the size of a child's head; and says, that it may be kept many weeks on ship-board, if it be hung up; that the juice of it is subacid and sweet, and excellent for allaying thirst.—It was brought from Batavia to Japan, and is also found in the Friendly Islands. Captain Shaddock, after whom it has been named, first brought it from the East to the West Indies. The Dutch call it *pompelmoes*. The fruit has degenerated greatly since its importation into the West Indies, owing to raising the trees from seeds, the greatest part of which produce harsh sour fruit, with a pale yellow pulp; whereas, if they would have budded from a good sort, they might have continued it in perfection; but there are few persons there who understand the method of grafting or budding fruit-trees; and they are so negligent of their fruits as to leave the whole to nature, seldom giving themselves any farther trouble than to put the seeds into the ground, and leave the rest to chance.

4. *Citrus Japonica*. Petioles winged; leaves acute; stem shrubby. This is a small shrub, with fruit no larger than a cherry; it ripens in December and January, and is very sweet and pleasant. It approaches to the Citron in having the flowers axillary, but it has winged petioles like the Orange, from which, however, it differs in having only one or two axillary flowers, not paniced, as in that which is native of Japan.

5. *Citrus Trifoliata*. Leaves ternate. A shrub; stem nearly two yards in height; branches alternate, flattened, and angular, flexuose, spreading very much, stiff, very smooth, thorny; thorns alternate, dilated, and compressed at the base, spreading very much, acute, smooth, yellow at the end, an inch in length; corolla white; stamina double the length of the petals; fruit globular, the size of a small orange.—It forms strong hedges in Japan, with its long, stiff, sharp thorns. It flowers in April, with leafless branches, to May, when the leaves burst forth. Thunberg says, the fruit is bad, and has a glutinous pulp; and Linnæus adds, that it is laxative.

Cives. See *Allium*.

Clary. See *Salvia*.

Clathrus: a genus of Fungi, the essential characteristic of which, according to Dr. Withering's Botanical Arrangement, containing eleven species, is, that it grows in clusters, mostly fixed to a membranaceous base; capsules globular or oblong; seeds escaping from its whole surface, through openings made by the separations of the fibres.—They are found chiefly on rotten wood.

Clavaria; a genus of Fungi, one of the lowest order in the scale of vegetation, differing sometimes very little in substance from the rotten wood out of which it issues. It is a smooth oblong body, of one uniform substance. Withering's Botanical

Arrangement contains twenty species, besides many varieties, the essential character of which he thus states:—Fungus oblong, upright, club-shaped; seeds emitted from every part of its surface.

Claytonia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth bivalve, ovate, transverse at the base. *Corolla*: petals five, obcordate, with claws emarginate. *Stamina*: filamenta five, subulate, recurve, a little shorter than the corolla, each inserted into the claw of each petal; antheræ oblong, incumbent. *Pistil*: germen roundish; style simple, the length of the stamina; stigma trifid. *Pericarp*: capsule roundish, three-celled, three-valved, elastic. *Seeds*: three, round. ESSENTIAL CHARACTER. *Calix*: two-valved. *Corolla*: five-petalled. *Stigma*: trifid. *Capsule*: three-valved, one-celled, three-seeded.—The species are,

1. *Claytonia Virginica*. Leaves linear-lanceolate; petals entire. It has a small tuberous root, which sends out slender stalks three inches high in the spring, having each two or three succulent narrow leaves, two or three inches long, of a deep green colour. Four or five flowers are produced at the top of the stalk in a loose bunch; petals spreading, white, spotted with red on their inside. The flowers appear in April, and the seeds ripen in June.—Found in Virginia. This and the next species are propagated by seeds, and also from offsets sent out from the roots: the seeds should be sown upon a shady border of light earth, or in pots filled with the like mould, soon after they are ripe; for if they be kept out of the ground till spring, the plants will not come up till the next year; whereas those which are sown early in the autumn will grow the following spring; so that a whole year is gained: when the plants appear, they will require no other care but to keep them clean from weeds; and in the autumn, if some old tanner's bark be spread over the surface of the ground, it will secure the roots from being injured by frost; but in mild winters they will not require protection. The best time to transplant the roots is about Michaelmas.

2. *Claytonia Sibirica*. Leaves ovate. This is a low plant, seldom rising more than two or three inches high; flowers red, root tuberous.—Native of Siberia.

3. *Claytonia Perfoliata*. Leaves nerveless, root ones rhomb-egg-shaped, stem ones somewhat connate; flowers umbel-verticillate; petals entire. Root annual; stem four or five inches high; flowers white.—Native of North America.

Cleavers, or *Clivers*. See *Gallium Aparine*.

Clematis; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals four, oblong, lax. *Stamina*: filamenta very many, subulate, shorter than the corolla: antheræ growing to the side of the filamenta. *Pistil*: germina very many, roundish, compressed, ending in subulate styles, longer than the stamina; stigmas simple. *Pericarp*: none; receptacle headed, small; seeds very many, roundish, compressed, furnished with the style, in various forms. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: four, sometimes five, or even six. *Seeds*: having a tail.—The Virgin's Bowers are chiefly climbing shrubs, though some of them are erect; leaves opposite, simple, ternate, or unequally pinnate; flowers axillary, but more frequently terminating; solitary, but more frequently in corymbs; in some species dioecous, and in others furnished with a turbinate bifid calicle, removed a little from the petals.—The species are,

1. *Clematis Cirrhosa*; *Evergreen Virgin's Bower*. Leaves simple; stem climbing by opposite tendrils; peduncles one-flowered, lateral. This has a climbing stalk, rising to the height of eight or ten feet, sending out branches from every

joint, whereby it becomes a very thick bushy plant. The leaves retain their verdure throughout the year: they are sometimes single, sometimes double, frequently ternate, serrate. The flowers are produced from the sides of the branches, are large, and of an herbaceous colour: they appear at the end of December or beginning of January.—Native of Spain, and Candia. Gerard calls it *Traveller's Joy of Candia*; Johnson, *Spanish Traveller's Joy*; and Parkinson, *Spanish Wild Climber*. This species is valuable on account of retaining its leaves all the year, and was formerly preserved in green-houses in the winter, having been supposed too tender to endure the open air in England; but now it is generally planted in the full ground, where the plants thrive much better than in pots, and produce plenty of flowers, which they never bore when tenderly treated. They do not suffer from severe frosts, even when left uncovered. It does not produce seeds in England, and therefore is propagated by layers and from cuttings; if by the former, they should be planted in the beginning of October, when the shoots of the same year only should be chosen for this purpose; for the older branches do not put out shoots in less than two years, whereas the tender shoots will make good roots in one year; these must be pegged down; if the shoots have two inches of earth over them, it will be better than a greater depth; but then a little old tanner's bark should be spread over the surface of the ground, to keep out the frost, for the plants generally begin flowering about Christmas, and at the same time are putting out roots, which being but just formed, may be injured by severe frosts: these layers will have strong roots by the following autumn, when they may be taken from the old plant, and transplanted where they are designed to remain.—If it be propagated by cuttings, they should be planted in March, in pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, observing to shade them from the sun in the day-time, and to water them gently twice or thrice a week, and in less than two months they will have taken root, and should be gradually inured to the open air. In the following summer they may be placed in any part of the garden till Michaelmas, and then they should be turned out of the pots and planted in the full ground, either where they are designed to remain, or into the nursery-bed, to grow a year longer, to get strength before they are placed out for good.

2. *Clematis Viticella*; *Purple Virgin's Bower*. Leaves compound and twice compound; leaflets ovate, sublobed, quite entire. Root perennial; stems very slender and weak, having many joints, whence come out side-branches which are again divided into smaller; leaflets from nine to fifteen, ovate acute, smooth, entire. If these be supported, they will rise to the height of eight or ten feet. The petals are of a dark worn-out purple or blue, or bright purple or red.—It grows naturally in the woods and hedges of Spain and Italy. Gerard calls it "blue or red-flowering Ladies-Bower," from its aptness to make bowers or harbours in gardens. There are four varieties cultivated in the nurseries: 1. the single blue; 2. single purple; 3. single red; 4. double purple. They flower in June and July, but the seeds seldom ripen in England; the last continues to the end of August.—All the varieties of Purple Virgin's Bower are propagated by laying down their branches; for although the single flowers sometimes produce seeds in England, yet as these seeds when sown, generally remain a whole year in the ground before they vegetate, the other, being the more expeditious method of increasing these plants is generally preferred: in order to succeed, these layers should be laid down at different seasons from the former sort; for when they are laid in the autumn, their

shoots are become tough, so as rarely to put out roots under two years; and after being so long in the ground, not one in three of them will have made good roots; so that many have supposed that these plants were difficult to propagate, but since they have altered the season of performing it, they have found that these layers succeed as well as those of other plants. The best time for laying down the branches is in the beginning of July, soon after they have made their first shoots, for it is these young branches of the same year which freely take root; but as they are very tender, great care must be taken not to break them in the operation; therefore those branches from which these shoots were produced, should be brought down to the ground, and fastened, to prevent their rising; then the young shoots should be laid into the earth, with their tops raised upright three or four inches above ground; and after the layers are placed down, if the surface of the ground be covered with moss, rotten tanner's bark, or other decayed mulch, it will prevent the ground from drying, so that the layers will not require watering above three or four times, which should not be at less than five or six days' interval; for when the layers have too much wet, the tender shoots frequently rot. Where the method here directed is practised, the layers will be more sure to take root, than by any other way of treating them. Most of these plants have climbing branches, and should therefore always be planted where they may be supported, otherwise the branches will fall to the ground, and appear unsightly; so that unless they be properly disposed, they will cease to be ornamental, and become the reverse: where there are arbours or seats with trellis-work round them, or where any walls or other fences require to be covered from the sight, these plants are very proper for the purpose; but they are by no means proper for open borders, nor do they answer the expectation when they are intermixed with shrubs; for unless their branches have room to extend, they will not be productive of many flowers. The sort with double flowers is the most beautiful, and that should be preferred to those with only single flowers, of which a few should be planted for the sake of variety: they are all equally hardy, and are seldom injured by frost, except in very severe winters, when sometimes the very tender shoots are killed; but if these be cut off in the spring, the stems will put out new shoots.

3. *Clematis Viorna*; *Leathery flowered Virgin's Bower*. Leaves compound and decomposed; some of the leaflets trifid. Stems many, slender, sarmentose, round, striated, prostrate, or climbing; flowers purple or blueish violet, axillary, solitary; petals with a whitish cotony border.—Native of Carolina and Virginia. It flowers from June to September, and if the autumn prove warm the seeds will ripen. This, as well as the fourth and fifth species, is a very hardy plant, and having climbing branches, may be disposed in the same manner as the first and second species: they are also propagated by layers, which will succeed, if performed at the same time, and in the same manner, as is directed for them.

4. *Clematis Crispa*; *Curled Virgin's Bower*. Leaves simple and ternate; leaflets entire, and three-lobed. This has weak stalks, which rise nearly four feet high, and by their clasps fasten themselves to neighbouring plants: the corolla is purple, the inside curled, and has many longitudinal furrows. The flowers appear in July, and the seeds ripen in September.—Native of Carolina, Florida, and Japan.

5. *Clematis Orientalis*, *Oriental Virgin's Bower*. Leaves compound; leaflets gashed, angular, lobed, wedge-form; petals villous on the inside. This also has weak climbing stalks, rising to the height of seven or eight feet when supported; flowers drooping; petals bent back, finally flat, villous within,

of a yellowish green colour, with a tinge of russet on the upper part or outside; stamina collected into an oblong purple head, with oblong purple antheræ, yellow at the edge.—It flowers from July to October; and was discovered by Tournefort in the Levant.

6. *Clematis Hexapetala*; *Six-petalled Virgin's Bower*. Leaves compound; leaflets ovate, serrate; peduncles two-leaved; corolla spreading; six-petalled; flowers yellowish, diœcous; peduncles branching, dichotomous.—Native of New Zealand.

7. *Clematis Virginiana*; *Virginian Virgin's Bower*. Leaves ternate; leaflets heart-shaped, somewhat lobed and angular; flowers diœcous. Root perennial; stems numerous, six feet high or more; flowers white, in short panicles resembling umbels; petals villous on the outside, naked and veined within.—Native of North America.

8. *Clematis Florida*; *Large-flowered Virgin's Bower*. Leaves decomposed; leaflets binate and ternate; petals ovate. Stem striated, purple, smooth; corolla large, handsome, spreading; petals acuminate, yellowish; stamina unequal, purplish.—It flowers most part of the year; and is a native of Japan.

9. *Clematis Japonica*; *Japan Virgin's Bower*. Leaves ternate; leaflets elliptic-ovate, serrate; flowers cylindric. Stem filiform, striated, purple, villous; petiole capillary, loose; flowers from the joints, peduncled, solitary, purple.—Native of Japan.

10. *Clematis Dioica*; *Trifoliate Virgin's Bower*, or *Climber*. Leaves ternate, quite entire; flowers diœcous. Root perennial; stems slender, tough, climbing ten or twelve feet high; flowers white; peduncles on the joints close to the petioles, one on each side, long, naked, horizontal; petals narrow, reflexed; stamina erect.—Native of South America. Both this, and the seventeenth species, are unable to endure the open air in this country, unless they are preserved in stoves: but as they are great ramblers, and not remarkable for beauty, they are seldom preserved in Europe, except for the sake of variety in botanic gardens: they may be propagated by layers in the same manner as the other sorts, or may be raised from the seeds imported from the country where they naturally grow, but must receive the same treatment as other exotic plants from that country.

11. *Clematis Vitalba*; *Common Virgin's Bower*, *Wild Climber*, or *Traveller's Joy*. Leaves pinnate; leaflets cordate; petioles twining. Root perennial; stems branched, leafy, furrowed, twining round other plants by means of the twisted petioles of the fallen leaves; leaves opposite, unequally pinnated; leaflets in fives, petioled, egg-shaped; flowers white, sweet-scented; seeds with long plumose tails, which adorn the hedges in autumn, and great part of the winter. The recent leaves, when rubbed on the skin, produce blisters.—Native of England, and the south of Europe, chiefly on a calcareous soil.

12. *Clematis Flammula*; *Sweet-scented Virgin's Bower*. Lower leaves pinnate, lacinate; upper simple, quite entire, lanceolate. Flowers white, small, sweet-scented. This is rather creeping than climbing: it flowers from July to October.—Native of the south of France, Italy, and the Grisons.

13. *Clematis Maritima*. Leaves pinnate, linear; stems simple, hexagonal, erect. Perennial: leaves opposite.—Found near Montpellier, Nice, and Venice.

14. *Clematis Recta*; *Upright Virgin's Bower*. Leaves pinnate; leaflets ovate-lanceolate, quite entire; stem erect; flowers four and five petalled. Perennial: stems herbaceous, annual, round, scarcely branched, from three to five feet high, firm, ending in a panicle at top; petals white, oblong, four in number, obtuse, somewhat villous, a little longer than

the stamina. The flowers come out in June, and the seeds ripen in September.—Native of France, Switzerland, Silesia, Austria, Carniola, Hungary, and Tartary. This, like some of the other species of this genus, is extremely acrid, on which account it was called *fammula* by the old botanists, and has obtained a place in the Edinburgh dispensatory. It is recommended by Baron Stoerck in inveterate syphilitic diseases, in ulcers, cancers, and severe head-aches: it acts as a diuretic or diaphoretic, and rests its character wholly upon Baron Stoerck's authority: he used an extract of the leaves; but he chiefly recommends an infusion of them fresh, two or three drachms to a pint of boiling water, four ounces to be taken three times a day, whilst the powdered leaves are applied as an escharotic to the ulcers. It may also be employed to raise blisters, where cantharides cannot be obtained. This, and the next sort, have perennial roots, which multiply pretty fast, but their stalks die down every autumn, and new ones arise in the spring: they are propagated either by seeds or by parting their roots, but the latter is generally preferred. The best season for parting these roots is in October or February, either just before their branches decay, or before they rise again in the spring; they will grow almost in any soil or situation; but if the soil be very dry, they should always be new planted in the autumn, otherwise their flowers will not be so strong; but if the soil be wet, it is better to defer it until the spring: the roots may be cut through their crowns with a sharp knife, observing to preserve to every offset some good buds or eyes, and then it matters not how small you divide them, for their roots increase very fast; but if they be parted very small, it will be three or four years before they will be fit to be again removed, for their flowers cannot become strong, and their roots multiplied in eyes, in less time. These plants are extremely hardy, enduring the cold of our severest winters in the open air. They are very proper ornaments for large gardens, either to be planted in extensive borders, or intermixed with other hardy flowers in the quarters of flowering shrubs, where, by being placed promiscuously in little open places, they fill up small vacancies agreeably enough. They begin to flower about the beginning of June, and often continue to produce fresh flowers until August.

15. *Clematis Integrifolia*; *Entire-leaved Virgin's Bower*, or *Hungarian Climber*. Leaves simple, ovate-lanceolate; flowers drooping. Perennial. Stems several, annual, a foot and a half high or more, striated, erect, a little fistulous, somewhat pubescent at top, terminated by a nodding flower, and sometimes branched in the upper axils; peduncles erect, pubescent, sustaining one elegant scentless flower; petals large, lanceolate, blue, nerved, acute, wavy, thick, spreading very much; filamenta very pale yellow, villose all over, and twice as long as the petals.—Native of Germany, Austria, Carniola, and Hungary. It flowers in July, or from June till August, and is not uncommon in the nurseries about London.

16. *Clematis Calycina*; *Minorca Virgin's Bower*. Calycine involucre approximating; leaves ternate and intermediate one three-parted. Stem climbing, smooth, striated.—It flowers in February; and is a native of Minorca.

17. *Clematis Americana*; *South American Virgin's Bower*, or *Climber*. Leaves ternate; leaflets cordate-acuminate, quite entire; flowers corymbed. It has strong climbing stalks, which fasten themselves by their clasps to the neighbouring trees, whereby they are supported, and rise to the height of twenty feet or more; at each joint are trifoliate leaves, heart-shaped, pointed, and entire. The flowers are white.—Native of Campeachy. See the tenth species.

18. *Clematis Sincensis*; *Chinese Virgin's Bower*. Leaves quinately-pinnate; leaflets lanceolate. Stems four-cornered,

weak, so as to want support, scarcely climbing; flowers small; petals linear-lanceolate, dark purple, the inner edge painted with a tomentose line; tail of the seeds scarcely shorter than the antheræ.—Native of China.

19. *Clematis Ochroleuca*; *Yellow-flowered Virgin's Bower*. Leaves simple, ovate, pubescent, quite entire; flowers erect. A low unbranched plant; stem pubescent; leaves opposite, sessile, strongly nerved; flower single, terminating, pale yellow.—Native of North America, flowering in June and July.

20. *Clematis Trifolia*. Leaves ternate; leaflets ovate, serrate; serratures mucronate; peduncles three-flowered. Branches striated, smooth; seeds purple, villose, with a long plumose tail.—Native of the Isle of Bourbon.

21. *Clematis Minor*; *Small Virgin's Bower*. Leaves quinately; leaflets conical, three-nerved; peduncles very long. Stem suffruticose, round, slender, not very long, scandent, branched; flowers white, axillary, several together; petals oblong, striated; stamina about forty, unequal; styles four, hairy, a little longer than the corolla.—Native of the suburbs of Canton in China.

Cleome; a genus of the class Tetradynamia, order Siliquosa. GENERIC CHARACTER. *Calix*: perianth four-leaved, very small, spreading, the lower leaflets gaping more than the rest, deciduous. *Corolla*: four-petalled, all the petals ascending, spreading, the intermediate one smaller than the others; nectareous glands three, roundish, one at each division, except one at the calix. *Stamina*: filamenta six (sometimes twelve or twenty-four) subulate, declining; antheræ lateral, ascending. *Pistil*: style simple; germen oblong, declining, the length of the stamina; stigmas thickish, rising. *Pericarp*: silique long, cylindrical, placed on the style, one-celled, two-valved. *Seeds*: very many, roundish.

ESSENTIAL CHARACTER. Nectareous glands three, at each sinus of the calix, except the lowest. Petals all ascending. Silique one-celled, two-valved.—Most of these plants are natives of very warm countries, and will not thrive in England without artificial heat. Therefore their seeds must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be planted in separate small pots, filled with fresh light earth, and plunged into a fresh hot-bed, observing to shade them until they have taken fresh root; after which they should have air admitted to them every day, in proportion to the warmth of the season, and their waterings should be frequently repeated, but not given in too great plenty. When the plants have filled the small pots with their roots, they should be put into larger, and plunged again into a hot-bed to bring them forward; and in July, when they are too tall to remain longer in the hot-bed, they should be removed into an airy glass-case, where they may be screened from cold and wet. With this management they will soon after flower, and perfect their seeds in autumn.—The species are,

1. *Cleome Fruticosa*; *Shrubby Cleome*. Flowers gynandrous, four-stamined; leaves simple; stem shrubby, round, frutescent; racemes terminating, simple. Native of India.

2. *Cleome Heptaphylla*; *Seven-leaved Cleome*. Flowers gynandrous; leaves with about seven leaflets; stem prickly. The stem is herbaceous, from three to five feet high, branched, upright, angularly grooved; branches subdivided, spreading, grooved, hirsute, viscid; leaves alternate, scattered; flowers white, or flesh-coloured, terminating, in long loose spikes; siliques five inches long, thick, tapering, pendulous.—It is an annual, flowering in June and July, growing plentifully in Jamaica, and also supposed to be a native of Egypt and the East Indies.

3. *Cleome Pentaphylla*; *Five-leaved Cleome*. Flowers gynandrous; leaves ternate; stem unurned. This is an annual,

elegant, but fetid plant, upright, either wholly smooth, or with a few hairs at bottom: the stem is round and branching, two feet high, of a dusky red colour; the germen is placed on a long, slender, purple pedicel, round which are six stamina, of the same colour, and equal.—It flowers in June and July; and is a native of both Indies, &c.

4. *Cleome Triphylla*; *Three-leaved Cleome*. Flowers gynandrous; leaves ternate; stem unarmed. An annual plant, rising two feet high, sending out many side-branches, with leaves having one large spear-shaped lobe in the middle, and two very small ones on the side; these sit close to the branches: the flowers come out singly from the sides of the branches, upon long peduncles; they have four large flesh-coloured petals, and six stamina, which stand out beyond the petals.—Native of Jamaica.

5. *Cleome Juncea*; *Rushy Cleome*. Leafless; flowers gynandrous, eight-stamined; corymbs lateral; genitals elongated; silique linear, tomentose; stem shrubby. The stem is from a foot to two feet in height, hardly the thickness of a goose-quill; branches rigid, like spines, commonly ending sharply, greenish, round, spreading, smoothish; flowers dirty yellow.—Native of the Cape of Good Hope.

6. *Cleome Polygama*. Upper flowers four-stamined, male: leaves ternate; leaflets sessile, somewhat prickly on the edge. Stem erect, somewhat glossy, and a little branched. It seldom rises above twenty or twenty-five inches.—Native of moist bottoms in Jamaica.

7. *Cleome Chelidonii*. Flowers many stamined; leaflets in fives or sevens, wedge-form, rugged; racemes terminating; siliques filiform. Leaves on long petioles, digitate; leaflets acute; corolla red; petals five; stamina yellow; seeds hispid.—Found in the East Indies.

8. *Cleome Felina*: *Cat's-tongue Cleome*. Flowers many-stamined, axillary, solitary, peduncled; leaves ternate, wedge-form, strigose; siliques linear, compressed. The whole herb, together with the calix, is strigose; corolla angular, small, red; siliques short, smooth. Found by Kœnig in Ceylon. The leaves are singular, being hispid; the hairs very much dilated at the base, very stiff, pressed close to the leaves, pointing towards the extremity, so as exactly to resemble a cat's tongue.—Found in Ceylon by Kœnig.

9. *Cleome Icosandra*. Flowers icosi-tetrandrous; leaves quinate. Stem herbaceous, annual, two feet high, erect, round, unarmed, striated, viscid, hairy; branches ascending; petiole long.—Native of the East Indies, and Cochinchina.

10. *Cleome Viscosa*; *Viscous Cleome*. Flowers twelve-stamined; leaves quinate and ternate. Stem erect, two feet high, simple, round, striated, villose, viscid, (often red) leaves alternate, on long petioles; leaflets unequal, subrhomboid, quite entire, nerved underneath; flowers axillary and solitary along the branches, with a terminal raceme; petals yellow, lanceolate-ovate, from erect spreading, and sometimes revolute, equal, two more distant than the others; stamina eight or nine to thirteen, from the receptacle, not from the germen, unequal; silique about two inches long, very villose, terminated by a stigma on a short style.—Annual: native of Ceylon.

11. *Cleome Dodcandra*; *Twelve-stamined Cleome*. Flowers twelve-stamined; leaves ternate. Stem and siliques viscid, pubescent; petals white, emarginate; stamina ten to fourteen; siliques sessile, erect, fusiform, somewhat inflated.—Annual: native of both Indies.

12. *Cleome Gigantea*; *Gigantic Cleome*. Flowers six-stamined; leaves in sevens; stem unarmed. The stem is two and even four yards in height, round, pubescent, erect, evergreen. Branches few, irregular with scars; petioles longer than the leaves; flowers greenish; racemes terminating, erect,

stiff, two feet in length; pedicels remote, standing out, glutinous, longer than the flower, without bractes. This beautiful plant has a very burning taste and stinking smell.—Native of South America.

13. *Cleome Aculeata*; *Prickley Cleome*. Flowers six-stamined; leaves ternate, quite entire; stipules spinescent. Stem herbaceous; stipules in pairs, very short, recurved; flowers solitary, peduncled, small; silique cylindrical, beset with fine white hairs.—Observed by Zœga in America.

14. *Cleome Spinosa*: *Thorny Cleome*. Flowers six-stamined; leaves in sevens and fives; stem thorny; siliques peduncled. Root annual; stems five or six feet high, erect, villose, branched; flowers large, white, on solitary one-flowered peduncles, longer than the bractes; leaflets of the calix lanceolate, linear, concave; petals oblong, entire, with elongated claws, and a roundish gland at the base of each; filamenta six, unequally inserted into the receptacle, almost of the same length, spreading, filiform, three times the length of the corolla, purple; anthera erect, long, two-celled, yellow; germen pedicelled, round, curved; style none; seeds oblong.—Native of the West Indies.

15. *Cleome Serrata*; *Serrate-leaved Cleome*. Flowers six-stamined; leaves ternate; leaflets linear-lanceolate, serrate. An annual upright plant, two feet in height; racemes loose, simple, terminating; corolla white; stamina tetradynamous; silique cylindrical, three inches long.—Native of the moist woods of Carthage in South America.

16. *Cleome Ornithopodioides*; *Bird's-foot Cleome*. Flowers six-stamined; leaves ternate, leaflets oval-lanceolate. Stem round, straight, from a foot to two feet in height, pale green, with short, stiffish, rough hairs; leaves strong-smelling, on a rough petiole half an inch in length; leaflets commonly bent back, of a pale glaucous hue on both sides, smooth in appearance, but roughish to the touch, having numerous short hairs along the edge, scarcely perceptible, except in the younger leaves: from the upper axils come out singly small yellow flowers, on slender peduncles, spreading horizontally; siliques two inches long, slightly hirsute. Annual; flowering in June and July.—Native of the Levant.

17. *Cleome Violaacea*; *Violet-coloured Cleome*. Flowers six-stamined; leaves ternate and solitary; leaflets lanceolate-linear, quite entire. This is a viscid and pubescent plant; stem erect, sometimes crooked; branches diffuse; leaves on long petioles; leaflets nearly equal; floral-leaves simple; peduncles even; calix yellow, with purplish tips; the two upper petals purple-violet, with yellow dots; the two lateral cordate, clawed, crenate, concolor.—Annual; flowers in June and July.—Native of Portugal.

18. *Cleome Arabica*.—Flowers six-stamined; leaves ternate, lanceolate, obtuse; siliques fusiform, viscid, scabrous. Root annual; stem two feet high, viscid, rough with hairs; branches diffuse; floral-leaves simple; petals yellow, with purple tips; seeds hirsute.—Native of Arabia.

19. *Cleome Monophylla*. Flowers six-stamined; leaves simple, ovate-lanceolate, petioled. Root annual; stem eighteen inches high, herbaceous, erect, striated, villose, branched near the top; flowers yellow, solitary, peduncled at the extremity of the branches.—Native of the East Indies.

20. *Cleome Capensis*. Flowers six-stamined; leaves simple, sessile, linear-lanceolate; stem angular, simple, stiff, and upright; flowers yellow.—Native of India and the Cape.

21. *Cleome Procumbens*. Flowers six-stamined; leaves simple, lanceolate, petioled; stems procumbent, herbaceous, six inches high, suffrutescent, branched, smooth; flowers axillary, peduncled, solitary; peduncles longer than the petioles, one-flowered, purple; corolla yellow, turning to orange

or red.—It flowers in November, and is a native of dry sands in Jamaica and Hispaniola.

22. *Cleome Tenella*. Flowers six-stamined; leaves ternate; leaflets filiform, linear. Root annual; stem a span high, branching, erect; leaflets sessile, the length of the petals; siliques linear; corolla yellow.—Found by Kœnig, in abundance, in dry sandy soil in the East Indies.

23. *Cleome Filifolia*. Flowers six-stamined; leaves lower septenate, upper ternate. Stem erect, weak, herbaceous, a foot high, branched, striated towards the top, dotted, with raised minute scattered dots; leaves petioled; petioles shorter than the leaves; flowers yellow, with a violet base, in terminal racemes; siliques two inches long, at first erect, afterwards pendulous.—Native of Egypt and Arabia.

Cleonia: a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, angular, two-lipped, upper lip flattish, broad, three-toothed, lower two-parted, short. *Corolla*: one-petalled, ringent; upper lip straight, bifid, keeled, lower trifid; the middle segments two-lobed, the side ones spreading. *Stamina*: filamenta four, forked at the end, the two lower longest; antheræ sitting on the outer apex of the filamenta, crossed in pairs. *Pistil*: germen four-parted. *Style*: filiform, the length of the stamina; stigmas four, setaceous, equal. *Pericarp*: none. *Calix*: closed with hairs. *Seeds*: four, nearly columnar, smooth. ESSENTIAL CHARACTER. *Filamenta*: forked, with an anthera at one of the tips. *Stigma*: four-cleft.—The only known species is,

1. *Cleonia Lusitanica*; *Sweet-scented Cleonia*. Root annual; stem erect, six to eight inches high, brachiate, in the lower part hairy; flowers violet-coloured; upper lip of the calix large, the segments reflected at the end; lower one obcordate, complicate, spreading, gibbous on the upper side of the base; all the filamenta thorny; antheræ crested at the back; seeds roundish, turgidly lens-shaped, mucronate at the base, rufescent, with a white umbilicus, shaped like the letter *y*.—Native of Spain and Portugal.

Clerodendrum: a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted, bell-shaped; segments ovate-acute, broader than the tube of the corolla, permanent. *Corolla*: one-petalled, irregular; tube slender, long; border five-parted, equal, the upper segments more deeply separated. *Stamina*: filamenta four, filiform, much longer than the corolla, ascending through the upper fissure of the corolla, two of them shorter; antheræ simple. *Pistil*: germen roundish; style the form, length, and situation of the stamina; stigma simple. *Pericarp*: drupe roundish, placed on a large calix, one-celled, with four stones, often splitting into four parts; each stone contains one seed. ESSENTIAL CHARACTER. *Calix*: five-cleft, bell-shaped. *Corolla*: with a filiform tube, and a funnel-shaped, five-parted, equal border. *Stamina*: very long, gaping very much between the segments. *Berry*: one-celled, with four stones, and a single seed in each.—The species are,

1. *Clerodendrum Infortunatum*. Leaves cordate, tomentose. This is a tree, or rather shrub, with subtomentose branches; leaves opposite, acute, veined, somewhat scabrous, large, quite entire; petioles the length of the leaves; border of the corolla short; segments obovate; antheræ oblong; stigma bifid.—Loureiro describes it as upright, seven feet high, with quadrangular, four-grooved branches; flowers in a vast terminating racemed corymb; the peduncle, and all the parts of the flower, are of a bright scarlet colour.—Native of the East Indies, and China.

2. *Clerodendrum Fortunatum*; *Entire-leaved Cleroden-*

drum. Leaves lanceolate, quite entire. A shrub, the stem cylindrical, and slightly hoary.—Native of the East Indies.

3. *Clerodendrum Phlomoïdes*. Leaves ovate, toothed, and angular; peduncles axillary, subtriflorous. This is a hoary shrub.—Found by Kœnig in the East Indies.

4. *Clerodendrum Calamitosum*. Leaves oval, somewhat toothed, naked; leaves opposite, petioled; panicle brachiate.—Observed by Baster, in Java.

5. *Clerodendrum Paniculatum*. Leaves five-lobed, tooth-letted, smooth; panicle brachiate; axils woolly; branches quadrangular, smooth, purple, with a groove along the sides; leaves five or six inches long, opposite, petioled, heart-shaped; flowers in a vast expanding panicle, about six inches long; calix smooth, with lanceolate segments; corolla an inch over; tube filiform; segments of the border oblong.—Native of the East Indies.

6. *Clerodendrum Trichotomum*. Leaves lobed and undivided, broad-ovate, entire; panicle trichotomous. Stem shrubby; branches four-cornered, four-furrowed, smooth; leaves opposite, petioled; panicle very large, superdecapound, naked; peduncles and pedicels smooth, compressed at the division; tube of the corolla a little bent; segments of the border oblong, obtuse, spreading, white; germen four-cornered, smooth. The fruit is an almost globular capsule, which is four-furrowed, smooth, inclosed within the large calix, four-celled, and four-valved; there is one smooth seed in each. The leaves have a strong poisonous smell, like *Mandragora*.—It flowers in August and September; and is found near Nagasaki in Japan.

7. *Clerodendrum Squamatum*. Leaves cordate, obscurely angular; branches of the panicle dichotomous, smooth. Stem frutescent, erect; branches smooth, tetragonous, with a groove on each side; leaves three to five inches long; panicle terminating, spreading, smooth; peduncles thrice dichotomous; pedicels not racemed, but one-flowered; leaflets of the calix ovate, acute, coloured, smooth.—Native of the East Indies.

8. *Clerodendrum Diversifolium*. Leaves entire, and three-lobed, ovate; branches of the panicle dichotomous, villose; pedicels racemed. Panicle terminating, half a foot long; partial peduncles opposite, spreading, twice or thrice dichotomous; flowers pedicelled, alternate, distant; tube of the corolla pubescent, an inch long; upper bifid, with erect linear segments, the lower three-lobed, spreading very much; the lobes oblong, the side ones shorter; the lobes of the corolla are scarcely equal.—Native of the East Indies.

Clethra: a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted; leaflets ovate, concave, erect, permanent. *Corolla*: petals five, oblong, broader on the outside, from erect spreading, a little longer than the calix, the upper one broadest. *Stamina*: filamenta ten, subulate, the length of the corolla; antheræ oblong, erect, gaping at the top. *Pistil*: germen roundish; style filiform, erect, permanent, increasing; stigma trifid. *Pericarp*: capsule roundish, involved in the calix, three-celled, three-valved. *Seeds*: six or eight in each cell, angular. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Stigma*: trifid. *Capsule*: three-celled, three-valved.—The species are,

1. *Clethra Alnifolia*; *Alder-leaved Clethra*. Shrubby; leaves obovate, lanceolate, serrate, smooth; racemes simple, in form of spikes. The roots spread far on every side, and send up many stems, from eight or ten to fourteen feet high, which are covered with a grayish bark, and divide into small round alternate branches; the leaves are three inches long, deep green on their upper side, and whitish green underneath, alternate, on short petioles. The flowers are on loose spikes.

from four or five inches to a span long; the petals are white.—Native of moist places, and by rivulets, in North America. It is sufficiently hardy to endure the open air of our climate, and at the season of its flowering is a most beautiful shrub: it will commonly flower here by the beginning of July; and if the season be not very hot, there will be part of the spikes in beauty till the beginning of August; and as most of the branches are terminated by these spikes of flowers, they make an elegant appearance when the shrubs are strong. They will thrive much better in moist than in dry ground, and require a sheltered situation, to defend them from strong winds, which frequently break off the branches, where they are too much exposed to their violence. It is propagated by layers, but they are generally two years before they get root, so that it is now rare in England. They may also be propagated by suckers, sent out from their roots; these should be taken off carefully together with fibres, in the autumn, and planted in a nursery-bed, whence at the end of two years, they may be transplanted wherever they may be intended to remain. It may also be propagated by seeds imported from its native country, for they are never produced in Great Britain; but as the seeds seldom arrive here till spring, when they are sown in that season, the plants will not come up till the following spring; therefore the seeds should be sown in pots and placed in a shady situation till autumn, and then under a frame during winter: the plants will come up in the following spring, and may be transplanted to a nursery-bed in autumn, to acquire strength, before they are finally removed to the spot where they are to remain.

2. *Clethra Paniculata*; *Panicled Clethra*. Shrubby: leaves lanceolate, naked on both sides; flowers paniced.—It flowers from August to October, and is a native of North America.

3. *Clethra Arborea*; *Tree Clethra*. A tree: leaves oblong-lanceolate, smooth on both sides; racemes in form of spikes; calices obtuse.—Native of Madeira.

4. *Clethra Tinifolia*. A tree: leaves oblong, lanceolate, quite entire, hoary underneath; racemes paniced, spike-shaped, tomentose. It generally rises to the height of twelve or fourteen feet, with a thick trunk, covered with a smooth clay-coloured bark; the branches spread equally round, and towards their ends are beset with leaves five inches long, dark-green and smooth, on petioles; each flower is on a pedicel, with a subulate bracte at the base; fruit smooth, green, roundish bigger than peas, containing a sweet white mealy pulp, and a hard brownish-black stone, larger than a pepper-corn, and much like it; they are sometimes eaten in Jamaica, where it is a native. Sloane calls it the Bastard Locust tree.

Clibadium; a genus of the class Monœcia, order Pentandria.—GENERIC CHARACTER. *Calix*: common, imbricate; scales ovate, acute. *Corolla*: compound; corollules tubular, funnel-form; border five-cleft. *Corollules*: of the disk many, pedicelled, hermaphrodite; of the ray, three or four, sessile, female. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; antheræ oblong, approximating. *Pistil*: in the hermaphrodites; germen very small, superior; style filiform; stigma simple: in the females, germen roundish, inferior; style filiform; stigma two-parted. *Pericarp*: common, none. *Calix*: ventricose, coloured. Proper to the hermaphrodites, none: to the females, a roundish, succulent, umbilicate drupe. *Seed*: one, cordate, compressed. ESSENTIAL CHARACTER. *Male*: common calix imbricate; corolla of the disk five-cleft. *Female*: common calix the same; corolla of the ray female, three or four; seeds an umbilicate drupe.—The only known species is,

1. *Clibadium Surinamense*. Leaves opposite, petioled, ovate, acuminate, acutely crenate, scabrous; peduncles opposite; common calix violet-coloured when ripe; corolla white; drupe green, with a yellow viscid juice.—Native of Surinam.

Cliffortia; a genus of the class Diœcia, order Polyandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth three-leaved; leaflets ovate, acute, coriaceous, spreading, deciduous. *Corolla*: none. *Stamina*: filamenta about thirty, capillary, erect, the length of the calix; antheræ twin, oblong, obtuse, erect, compressed. *Female*: *Calix*: perianth three-leaved, equal, erect, superior, permanent; leaflets acute, lanceolate. *Corolla*: none. *Pistil*: germen oblong, inferior; styles two, filiform, long, plumose; stigmas simple. *Pericarp*: capsule oblong, nearly columnar, two-celled, crowned with the calix. *Seeds*: solitary, nearly columnar, linear. ESSENTIAL CHARACTER. *Male*. *Calix*: three-leaved. *Corolla*: none. *Stamina*: about thirty. *Female*. *Calix*: three-leaved, superior. *Corolla*: none. *Styles*: two. *Cap-sules*: two-celled. *Seed*: one in each cell.—This genus consists of shrubs from the Cape of Good Hope. Leaves simple or ternate, sheathing at the base; flowers axillary, subsessile.—The species are,

**With simple Leaves.*

1. *Cliffortia Odorata*; *Sweet-smelling Cliffortia*. Leaves ovate, serrate, ribbed, villose underneath. This is an erect shrub, three feet high, little branching; branches simple, pubescent; leaves alternate, about an inch in length and breadth, resembling those of Mint; flowers axillary, sessile.

2. *Cliffortia Ilieifolia*; *Ilex-leaved Cliffortia*. Leaves subcordate, toothed. This is a shrub about three feet high, with alternate declining branches, clothed with truncated membranes and stipules; leaves small, alternate, biennial, cartilaginous about the edge, a little embracing the stem, heart-shaped; flowers lateral, axillary, sessile, solitary, green; filamenta white; antheræ yellow. The flowers appear in June, July, and August, but the leaves continue in verdure throughout the year. All the plants of this and of the following species, now in European gardens, are males.—It is easily propagated by cuttings, which may be planted in any of the summer months; if these be planted in small pots filled with light earth, and plunged into a very moderate hot-bed, they will soon take root, provided they be screened from the sun and duly watered: they must be gradually inured to bear the open air when they have taken root, or they will be drawn up weak; they should therefore be placed abroad till they have acquired some strength, and may afterwards be each transplanted into a separate small pot, and placed in the shade until they have taken fresh root; after which they may be planted with other hardy exotics in a sheltered situation till October, when they should be removed into the green-house, or placed under a common hot-bed frame, where they may be screened from the hard frost, but enjoy the free air at all times when the weather is mild. The stems and branches will require support as the plants advance in height, or they will trail upon the ground. In summer they must be placed in the open air, with Myrtles and other hardy green-house plants; and in winter the plants may be treated in the same manner as those, but must not have much water.

3. *Cliffortia Ruscifolia*; *Butcher's Broom-leaved Cliffortia*. Leaves lanceolate, quite entire. A shrub about two feet high, thickly branched; branches alternate, ascending, ash-coloured, and smooth near the bottom, brown, and tomentose above; branchlets alternate, very frequent, short, covered with lanceolate, acuminate, imbricate scales, in other respects naked, except at the end, where they are leafy; spikes of flowers

roundish, at the ends of the branchlets, intrenched in the leaves; bracts smaller than the leaves, involving each flower, trifid, hirsute on the outside, spiny, with a sharp membranaceous, hairy leaflet, near the base on each side.—This is not so hardy as the preceding species, which see; it will therefore require more tender treatment.

4. *Cliffortia Ferruginea*. Leaves lanceolate, setaceous, serrate. The stems are like those of knotgrass, filiform, usually prostrate, even, branching; branches short, ferruginous, herbaceous; flowers axillary, sessile, trifid.

5. *Cliffortia Graminea*. Leaves ensiform, serrulate; petioles dilated, terminated by two stipule-shaped awns. Stems many together, two feet high, scarcely branching, striated, covered with leaves; which are approximating, erect, convolute, smooth, striated, acute; petioles broad, connected with the leaves by a joint.

6. *Cliffortia Polygonifolia*. Leaves linear, hairy. An undershrub, about a foot high, much branched, villose; leaves very small, apparently in alternate fascicles, but growing three together upon each small sheath; capsules smaller than a grain of wheat.

7. *Cliffortia Filifolia*. Leaves filiform, triquetrous, smooth, quite entire. Branches naked, upright, alternate, gray, pubescent, round.

** *With compound Leaves.*

8. *Cliffortia Crenata*. Leaves binate, orbiculate, crenulate. An erect shrub, rather large; leaves alternate, sessile, smooth, size of a finger-nail; flowers axillary, solitary, trifid.

9. *Cliffortia Pulchella*. Leaves binate, orbiculate, quite entire. The leaves are converging, and guarding the flowers in the cavity which they form, beautifully adorned on the outside with radiating nerves.

10. *Cliffortia Trifoliata*. Leaves ternate, the middle three-toothed. Stems slender, woody, procumbent, silky with hairs, and sending out slender branches on every side; flowers axillary, on very short peduncles, shaped like those of the second species, but smaller: they appear in July and August.—It requires the same management as the second species, and is equally hardy. As there are only male plants in Europe, it can only be propagated by layers, and these are two years before they take root: the leaves continue green all the year, and being singularly shaped, make a good variety in the green-house during winter.

11. *Cliffortia Sarmetosa*. Leaves ternate, linear, villose. Stem shrubby, sarmentose, filiform, four feet high; branches alternate, short, simple, round, pubescent; flowers lateral, axillary, sessile, solitary, white.

12. *Cliffortia Strobilifera*. Leaves ternate, linear, acute, even. A shrub, with round smooth branches; stipules sheathing, scariose, subovate, having two teeth, smooth, permanent; leaves sessile, carinated or keeled, on a very short sheathing petiole.

13. *Cliffortia Obcordata*. Leaves ternate; leaflets roundish, the middle one obcordate. An erect lowly shrub, with distich branches; leaves small, sessile, obovate, nerveless, very obtuse, quite entire, smooth; flowers in the axils of the leaves sessile, not longer than the leaves.

14. *Cliffortia Ternata*. Leaves ternate; leaflets entire, hairy. A shrub, with small, ovate, lanceolate, hairy leaflets; very different from the rest of the genus.

15. *Cliffortia Juniperina*. Leaves ternate, triquetrous, subulate, crowded. A shrub, resembling Juniper, erect, three feet in height, branching very much; leaves on a broadish, short, scarcely perceptible peduncle; leaflets acerose, linear, channelled, mucronate, slightly serrated; flowers axillary, sessile.

16. *Cliffortia Falcata*. Leaves ternate, linear, falcated, smooth. A shrub, a foot in height, erect, branching strict; leaves often three from each bud: leaflets sharpish, incurved.

17. *Cliffortia Teretifolia*. Leaves fascicled, columnar, subulate, incurved, smooth, entire.

18. *Cliffortia Ericæfolia*. Leaves fascicled, columnar, furrowed, smooth.

19. *Cliffortia Cuneata*. Leaves wedge-shaped, serrated at the end.—All the species are natives of the Cape.

Clinopodium; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: involucre many-bristled, length of the perianth, placed beneath the whorl; perianth one-leafed, cylindrical, very slightly incurved, with a two-lipped mouth; upper lip wider, trifid, acute, reflected; lower lip divided, slender, inflexed. *Corolla*: one-petalled, ringent; tube short, gradually widened into the throat; upper lip erect, concave, obtuse, emarginate; lower lip trifid, obtuse; middle segments wider, emarginate. *Stamina*: filaments four, under the upper lip of which two are shorter than the others; antheræ roundish. *Pistil*: germen four-parted; style filiform, the same situation and length with the stamina; stigma simple, acute, compressed. *Pericarp*: none; calix contracted round the neck, gibbous round the body, containing the seeds. *Seeds*: four, ovate.

ESSENTIAL CHARACTER. *Involucre*, many-bristled, under the whorl.—These plants may be propagated by seeds, and also by parting their roots; the latter is the mode generally adopted in England, because the foreign sorts do not perfect their seeds here. The best time to transplant and part their roots is in autumn, that they may strike root again before winter: if planted in a dry soil, they are all, except the third species, sufficiently hardy to thrive in the open air in England, and require no other care but to keep them clean from weeds; and every other year they may be transplanted and parted.—The species are,

1. *Clinopodium Vulgare*; *Wild Basil*. Whorls hairy; bracts bristle-shaped; pedicels branched; leaves slightly serrated. Root perennial, fibrous; stems somewhat undulated, but not regularly zig-zag; flowers purplish, rose-coloured, whorled, the whorls terminal and axillary; calix ribbed, hairy; corolla twice the length of the calix, handsome, with two hairy knobs at the orifice. The whole herb is aromatic, with a faint Thyme-like odour.—Native of England, and other parts of Europe, on the borders of woods and in dry hilly situations, flowering in June. There are three varieties; one from Canada, differing in the flowers being much smaller; two from Carolina, one which Miller calls *humile*, only half the size of the European sort; the other *Carolinianum*, with round stems, the joints four or five inches asunder, with two oblong leaves at each, hairy on their under side, having white flowers in small whorls.

2. *Clinopodium Incanum*; *Hoary Clinopodium*. Leaves tomentose underneath; whorls flattened; bracts lanceolate. Root perennial; stems about two feet high, putting out a few short side-branches towards the upper part; leaves oblong, oval, the size of those of Water Mint, opposite, sessile, soft to the touch, with a strong odour between that of Marjoram and Basil, the upper surface pale green, the under hoary and woolly; the edges are slightly indented; whorls flat, smooth, generally three; flowers pale purple, the stamina standing out beyond the corolla; the bracts large, lanceolate, indented.—Native of North America, where in some parts it is called snake-weed, being accounted a remedy for the bite of the rattlesnake. It flowers in England in July.

3. *Clinopodium Rugosum*; *Wrinkled Clinopodium*. Leaves wrinkled: heads axillary, peduncled, flattened, radiated; root

perennial; stems closely covered with brownish hairs, and between two and three feet high; leaves very unequal in size, serrate, rough on their upper side, hairy on the under; peduncles slender, hairy, about three feet long, sustaining small heads of flowers shaped like those of the scabious; corolla white, smaller than that of the foregoing; bractes radiate. It flowers in September, but never ripens its seeds in England.—Native of Carolina.

4. *Clinopodium Capitatum*. Leaves flat, smooth; head axillary, peduncled. Stems suffruticose, two or three feet high. The whole plant is inodorous.—Native of the West Indies. See *Hyptis Capitata*.

5. *Clinopodium Asiaticum*. Leaves oblong, nerved, wrinkled, tomentose underneath; spike whorled, terminating. Stem suffruticose, two feet and a half high, erect, quadrangular, four-furrowed, simple, villose; flowers violet-coloured in interrupted whorls, forming an oblong spike, with sharp hirsute involucre.—Native of Cochin-china.

Clitoria; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, erect, tubular, five-toothed, permanent. *Corolla*: papilionaceous; standard very large, straight, emarginate, waved at the margin, spreading, and overshadowing the other petals; wings oblong, straight, obtuse, shorter than the standard; keel shorter than the wings, falcated, somewhat roundly. *Stamina*: in two-brotherhoods, (simple and nine-elft) antheræ simple. *Pistil*: germen oblong; style ascending; stigma obtuse. *Pericarp*: legume very long, linear, compressed, one-celled, two-valved, with the tip subulate. *Seeds*: many, reniform. ESSENTIAL CHARACTER. *Corolla*: inverted. *Standard*: very large, spreading, overshadowing the wings.—The seeds of these plants should be sown upon a good hot-bed early in the spring, and when the plants are two inches high, they should be carefully taken up, and each planted in a small pot filled with light fresh earth, and plunged into a hot-bed of tanner's bark, observing to shade them until they have taken fresh root, and refresh them with water as they may require it: after they are well rooted in the pots, they must have air every day in proportion to the warmth of the season, to prevent their drawing up weak; their waterings should be repeated sparingly two or three times a week. As these plants have climbing stalks, they will soon grow too tall to remain under common frames, therefore they must then be removed into the stove, and plunged into the bark-bed; but if their roots have filled the pots, they should then be removed into larger, and afterwards they must be treated in the same manner as other plants from their native countries.—The species are,

1. *Clitoria Ternata*; *Winged-leaved Clitoria*. Leaves pinnate. It rises with a twining herbaceous stalk, to the height of four or five feet, in the same manner as the Kidney-bean, and requires the like support, for in the places where it grows naturally, it twists itself about the neighbouring plants: the leaves are winged, composed of two or three pair of leaflets, terminated by an odd one; these are of a beautiful green colour, and are placed alternate on the stalks: from the appendages of the leaves come out the peduncles, each of which is encompassed by two very fine leaves about the middle, where they are bent, sustaining a very large gaping beautiful flower, the bottom part of which appears as if it grew to the top: legumes three or four inches long, narrow, lenticular-compressed, without knots or risings above the seeds, terminated by the longish awl-shaped style; seeds solitary, from seven to twelve, ovate-kidney-shaped, of a chestnut-brown colour. The flowers have a green membranaceous calix; the corolla is blue, and stains paper like Indigo, but

the dye is not permanent.—Native of the East Indies and Cochin-china. There is a variety with white flowers, and another with blue flowers, very double; which is a singularity in the leguminous class of plants.

2. *Clitoria Brasiliana*; *Brasilian Clitoria*. Leaves ternate; calices solitary, bell-form. It has a twining stem, which rises five or six feet high, having at each joint one ternate leaf on a long petiole: the flowers come out singly from the axils, on long peduncles, encompassed about the middle with two small oval leaves; they are very large, of a fine blue colour, and make an elegant appearance in July.—Native of Brazil. There is a variety with double flowers, which was imported from India.

3. *Clitoria Virginiana*; *Small-flowered Clitoria*. Leaves ternate; calices geminate, bell-form. Root perennial; stem about three feet high, twining, slender, hairy; leaflets egg-shaped, hairy; flowers in short spikes or racemes; standard externally of a dull yellow colour, pubescent; wings and keel pale lilac; legume narrow, with prominent sutures. This species being tender, and flowering with difficulty in our climate, the flowers frequently come out singly in our stoves; which accounts for the difference between Mr. Miller's description and the Linnean character. Dillenius also observes, that the flowers are very apt to fall off.—Native of Virginia, Jamaica, and generally of the West Indies.

4. *Clitoria Mariana*; *Maryland Clitoria*. Leaves ternate, calices cylindric. The seeds of this species were imported from Carolina, where they grow naturally: it rises with a twining weak stalk about five feet high, having trifoliate leaves; the flowers come out by pairs, they are small, and of a pale blue colour within, but of a dirty white on the outside.—Native of Carolina: it flowers in August, but seldom ripens any seed in England.

5. *Clitoria Galactica*; *Milky Clitoria*: Leaves ternate; raceme erect; flowers pendulous. Stem about six feet high, twining, weak; leaflet elliptic-oblong, obtuse; flowers reddish; calix four-toothed, short, campanulate; corolla a little papilionaceous.—Native of Jamaica, found chiefly in the lower hills: it is easily distinguished by its long reddish flowers, milky branches, and smooth leaves.

Club-Rush. See *Scirpus*.

Cusia; a genus of the class Polygamia, order Monœcia.

—GENERIC CHARACTER. *Calix*: perianth four, five, or six leaved, imbricate; leaflets concave, permanent, the interior ones gradually smaller. *Corolla*: petals four, five, or six, roundish, spreading, concave, large. *Stamina*: filamenta many, simple, shorter than the corolla; antheræ simple, growing to the side of the tip. *Pistil*: germen ovate-oblong; style none; stigma starred, flat, obtuse, permanent. *Pericarp*: capsule ovate, marked with furrows, celled, the valves bursting in a radiate manner. *Seeds*: numerous, ovate, covered with pulp, affixed to a columnar angulated receptacle. *Observe*. The number in the fruit differs from four to twelve, according to the proportion observed in the stigma, valves, cells, &c.: some of the flowers are sterile with respect to the male organs, and others with respect to the female. In the female flowers a nectary is formed by the coalition of the antheræ, including the germen. ESSENTIAL CHARACTER. *Male*. *Calix*: four or six leaved; leaflets

opposite, imbricate. *Corolla*: four or six petalled. *Stamina*: numerous. *Female*. *Calix* and *Corolla* as in the males. *Nectary*: formed by the coalition of the antheræ, including the germen. *Capsule*: five-celled, five-valved, stuffed with pulp.—This is a genus of trees, abounding in a tenacious glutinous juice, which becomes red when exposed to the air, and hardens into a gum or resin. As the seeds seldom succeed in England; and the young plants grow so slowly as not to make any figure for some years, the best method of having these plants, is to procure them from the West Indies, to be brought over in tubs: they are tender, and must be kept constantly in the stove, otherwise they will not live through the winter in England, in which season they must have very little water. They may be propagated by cuttings, which must be laid to dry for a fortnight or three weeks when they are cut off from the plants, that the wounded part may be healed over, otherwise they will rot. When the cuttings are planted, the pots should be plunged into a hot-bed of tanner's bark, and now and then gently refreshed with water: June or July is the best time for planting these cuttings, that they may be well rooted before the cold weather comes on in autumn: they must be placed upon stands in the dry-stove in winter, but if in summer they be plunged into the tan-bed, they will make great progress, and their leaves will be large, in which the principal beauty of these plants consists.—The species are,

1. *Clusia Rosea*; *Rose-coloured Balsam Tree*. Leaves veinless; corollas six-petalled. Height from twenty to thirty feet; flowers large, rose-coloured, and very handsome, but without smell; fruit green, the size of a middling apple, with eight lines running like meridians on a globe, from the stalk to the crown of it: when the fruit becomes ripe, it opens at these lines; and divides into eight parts, disclosing many mucilaginous scarlet seeds, resembling those of a Pomegranate; the mucilage being washed off, the seeds appear white and hard, and contain a kernel; they are found in the hollow furrows of an octagonal cove. The whole tree is exceedingly beautiful, and the structure of the fruit itself is a most exquisite piece of mechanism.—Native of the Bahama Islands, of St. Domingo, and also of other American islands between the tropics. It is found among rocks, and frequently upon the limbs and trunks of trees, occasioned by birds scattering or voiding the seeds, which being glutinous like those of Mistletoe, take root in the same manner; but the roots not finding sufficient nutriment, spread on the surface of the tree till they find a decayed hole or other lodgment, wherein is some small portion of soil: the fertility of this being exhausted, a root is discharged out of the hole till it reaches the ground, though at forty feet distance, where it again fixes itself and becomes a much larger tree. The resin it produces is used to cure sores in horses, and instead of tallow for paying the bottoms of boats, in order to accelerate their motion through the water.

2. *Clusia Alba*; *White-flowered Balsam Tree*. Leaves veinless; corollas five-petalled. Height thirty feet; an elegant tree, parasitical, or growing on other very large trees like the first species: the trunk is frequently a foot in diameter, and supports a spreading head. The whole abounds in a very tenacious balsamic juice, of a green colour, but turning to a brownish red when exposed to the air; leaves obovate, quite entire, obtuse, shining, coriaceous, firm, marked with obliquely transverse parallel nerves, without any connecting veins, on short petioles, opposite, placed chiefly at the extremities of the smaller branches; peduncles short, thick, commonly three-flowered, and terminating; flowers inelegant and without scent, white, all hermaphrodite, but with the

antheræ more or less polliniferous; fruits when ripe scarlet; seeds white, involved in a scarlet pulp; the birds are very fond of them, and when the capsules burst open, hang over them upon the wing, and pluck out the seeds with the pulp adhering.—It is common in the woods of Martinico, where it is called *arabic*. The Caribs used the juice of it for paying their boats.

3. *Clusia Flava*; *Yellow-flowered Balsam Tree*. Leaves veinless; corollas four-petalled.—It is pretty common in the British islands of America, where the trees grow to the height of twenty feet, and shoot out many branches on every side, with thick, round, succulent leaves, placed opposite: the flowers are produced at the ends of the branches, each having a thick succulent cover; they are of different colours in different plants, some being red, others yellow, some white, and some green. After the flowers are past, they are succeeded by oval fruit, which are also of different colours in different plants. According to Jacquin, wherever the trunk or larger branches are wounded, they throw out a thick resinous gum, which the inhabitants of Jamaica sometimes use as a vulnerary; but it has neither an extraordinary smell nor a pungent taste.

4. *Clusia Venosa*; *Vein-leaved Balsam Tree*. Leaves veined. This tree rises to the height of twenty or thirty feet; it has very large oval spear-shaped leaves, ending in points, placed alternate on the branches, and having several ribs, which go off from the mid-rib alternately, rising upward to the side of the leaves, and also a great number of small veins running horizontally between these ribs: the borders of the leaves are serrate, and their under surfaces of a brown colour: the branches are covered with a woolly down; and the flowers are produced in loose spikes at the end of the shoots. Jacquin describes the corolla as white, and an inch and a half in diameter.—Native of the moist mountainous woods of Martinico. Where it is called *paletuvier de montagne*.

5. *Clusia Pedicillata*. Leaves opposite, obovate and elliptic, quite entire, veined; cymes axillary; flowers four-petalled.—Native of New Caledonia.

6. *Clusia Sessilis*. Leaves opposite, obovate and elliptic, quite entire, veined; flowers axillary, solitary, subsessile, four-petalled—Native of Tongataboo.

Cluytia; a genus of the class Diœcia, order Gynandria.—**GENERIC CHARACTER.** *Male*. *Calix*: perianth five-leaved, size of the corolla; leaflets ovate, obtuse, concave, spreading. *Corolla*: petals five, spreading very much, cordate; claws flat, shorter than the calix; nectaries exterior five, three-parted, oblong, spreading, length of the claws of the petals, placed in a circle within the petals; nectaries interior five, glandiform, small, melliferous at the tip. *Stamina*: filamenta five, placed on the middle of the style, remote from the corolla, spreading horizontally; antheræ roundish, versatile. *Pistil*: germen none; style cylindric, truncate, very long, bearing the stamina on its middle. *Female*. *Calix*: perianth as in the male, permanent. *Corolla*: petals as in the male, permanent; nectaries exterior five, twin, roundish, of the same size and situation as in the male; nectaries interior, none. *Pistil*: germen roundish; styles three, bifid, reflex, length of the corolla; stigmas obtuse. *Pericarp*: capsule globular, six-furrowed, rough, three-celled. *Seeds*: solitary, roundish, even, appendiculated at the tip. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled. *Styles*: in the female flowers three. *Capsule*: three-celled. *Seed*: one.—The species are,

1. *Cluytia Alaternoides*; *Narrow-leaved Cluytia*. Leaves subsessile, linear-lanceolate; flowers solitary, erect. Stem shrubby, six or eight feet high, putting out many side-branches which grow erect; leaves of a grayish colour, and

entire. The flowers come out from the joints, at the setting on of the leaves, towards the upper part of the branches : they are small, and of a greenish white, flourishing from June till August, but not remarkable for their beauty.—Native of Africa. This, and the third species, are easily propagated by cuttings during any of the summer months : the cuttings, if planted in small pots, and plunged into a very moderate hot-bed, shaded from the heat of the sun in the middle of the day, will soon take root, and should afterwards be inured to the open air, to prevent them from being drawn up weak ; afterwards these plants may be each put into a separate small pot, and placed in a sheltered situation till the middle of October, or later, if the weather continue mild. They should afterwards be removed into the green-house, and so placed that they may enjoy the free air in mild weather, for they do not require much warmth, but merely to be protected from frost ; and if the green-house be too closely shut up, or the plants too much shaded by others, the tender shoots will grow mouldy, which destroys more of these plants than the cold. They must be placed abroad in summer among other hardy exotics, in a sheltered situation. As these plants are always green, they look well in the green-house during the winter season ; and in summer, when they are placed in the open air, make a pleasing contrast with the other exotics.

2. *Cluytia Polygonoides*. Leaves lanceolate ; flowers axillary, very many. The flowers are usually two together, pendulous, and small.—Native of the Cape.

3. *Cluytia Pulchella* ; *Broad-leaved Cluytia*. Leaves ovate, quite entire ; flowers lateral. This rises about three or four feet high, has a stronger stem than the first species ; the leaves are much larger, sea-green, and on petioles an inch long ; flowers greenish-white, axillary.—Native of Africa.

4. *Cluytia Hirta*. Leaves wedge-shaped, smooth ; flowers lateral, glomerate, hirsute. It is a very branching shrub : the flowers come out towards the ends of the branches and branchlets, and are subsessile ; petals oblong, minute, smooth.—Found at the Cape.

5. *Cluytia Tomentosa*. Leaves elliptic, tomentose on both sides. A shrub three feet in height, very branching, erect, tubercled with the scars of fallen leaves ; branches round, pubescent ; flowers lateral, solitary, sessile, longer than the leaves, white ; calix five-toothed, tomentose on the outside. It flowers in May.—Found on the sandy shores of the Cape.

6. *Cluytia Retusa*. Leaves oval, retuse ; flowers racemed, axillary. Leaves on short petioles, alternate ; petals three-toothed ; flowers very small ; racemes axillary ; no nectaries, but a ring surrounding the receptacle.—Native of the East Indies.

7. *Cluytia Eluteria* ; *Maritime Cluytia*, or *Sea-side Balsam*. Leaves cordate-lanceolate. This is a tree with round branches ; according to Miller, it rises with an upright shrubby stalk, not more than three or four feet high in England ; but in places where it grows naturally it reaches more than twenty feet in height, with branches forming a large spreading head. The leaves are shaded like those of the black Poplar. On breaking the more tender branches, a large drop of thick balsamic liquor oozes from the wound : whence it has the appellation of Balsam-tree. The leaves and tender tops are said to heal sores, and are frequently used in baths and fomentations. The *cortex cascarilla* is supposed to be the produce of this tree. Stisser recommended it, at the end of the last century, as a powerful diuretic and carminative ; and he used it with success in calculous, asthmatic, pthysical, scorbutic, and arthritic complaints : since that, it has been used in Germany for the Peruvian bark, in intermittent fevers ; and the German physicians have given it much credit as an astringent, having employed it in hæmorrhages

and various alvine fluxes.—Native of both Indies. This plant will live through our winters in an airy glass-case. If the *Cluytias* be placed when young in a very moderate warmth in winter, it will greatly forward their growth ; but they must not be forced with too much heat, and may be treated more hardly when they have acquired strength. The seventh species may be propagated by cuttings during the summer season, but the cuttings should be laid in a dry place for a few days, after they are taken from the old plants, that their wounded parts may dry and be healed over before they are planted. These must be planted in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark : if the season prove very warm, the glasses should be shaded in the heat of the day, and raised up to admit the fresh air, but they must be sparingly watered : when they begin to shoot, they should be gradually inured to the open air ; and when their roots have filled the pots, they should be carefully parted, and each planted in a separate pot of the same light sandy earth ; they then should be placed on the back part of the stove, behind the other plants, where they may be screened from the sun until they have taken fresh root, after which they may be brought forward, and exposed gradually to the open air. In the summer they should have free air constantly in warm weather, but must be screened from heavy rain, and placed in winter in an airy glass-case, where they may enjoy the sun, and during that season have very little moisture admitted to them.

8. *Cluytia Stipularis*. Leaves oval, tomentose underneath. Branches flexuose, tomentose ; flowers axillary, subsessile, not longer than the stipules, dark purple ; style columnar, scarcely trifid at the end.—Native of the East Indies.

9. *Cluytia Acuminata*. Herbaceous : leaves ovate, smooth, obtuse, with a point ; flowers axillary, solitary.—Native of the Cape.

10. *Cluytia Lanceolata*. Leaves elliptic-lanceolate ; flowers lateral, tomentose ; leaves broad lanceolate, above two inches long, without any dots beneath, few above, and visible only with a magnifier ; calices villose-tomentose ; capsules not dotted.—Native of Egypt.

Clypeola ; a genus of the class Tetradynamia, order Siliculosa.—GENERIC CHARACTER. *Calix* : perianth four-leaved ; leaflets ovate-oblong, permanent. *Corolla* : four-petalled, cruciform ; petals oblong, entire ; claws rather longer than the calix. *Stamina* : filamenta six, shorter than the corolla, the two opposite ones still shorter ; antheræ simple. *Pistil* : germen roundish, compressed ; style simple ; stigma obtuse. *Pericarp* : silicle orbiculate, emarginate, flat, compressed, erect, deciduous, bivalve ; valves orbiculate. *Seeds* : orbiculate in the centre of the pericarp. ESSENTIAL CHARACTER. *Silicle* : emarginate, orbiculate, compressed, flat, deciduous.—This genus consists of low plants of little beauty, which are preserved chiefly in botanic gardens.—The species are,

1. *Clypeola Jonthlasi* ; *Annual Treacle-Mustard*, or *Buckler-Mustard*. Annual : silicles orbiculate, one-celled, one-seeded. A low annual plant, seldom exceeding four inches high ; stem slender, hardish, upright, branched at the bottom, tinged with red, covered with short whitish hairs ; leaves spatulate, alternate, sessile, glaucous, with minute stars of hairs over the surface ; flowers in terminating spikes, and very minute ; corolla yellow, the size of the calix ; style scarcely visible with a magnifying glass.—Native of the south of France, Spain, and Italy, flowering there from March to May, but in England from May to July. If the seeds be scattered on a border of light earth, the plants will thrive without further care.

2. *Clypeola Tomentosa*; *Hoary Treacle-Mustard*. Perennial: silicles orbiculate, two-celled, two-seeded; leaves subtomentose. Root perennial, woody, branched; stems shrubby, diffused, leafy at the end; leaves hirsutely hoary; the lower ovate-oblong, sinuate, three inches long, and half an inch broad; the stem-leaves alternate, sessile, linear-lanceolate, entire or finely toothletted; flowers terminating and axillary, at first in a sort of umbel, but afterwards panicle; calix very small, hairy on the outside; petals yellow, emarginate, longer than the calix.—First observed by Tournefort in the Levant.

3. *Clypeola Maritima*; *Sea Treacle-Mustard*, or *Clown's Mustard*. Stems much branching, diffused, evergreen; leaves linear-lanceolate, whitish, not stiff; racemes striated; calix deciduous; petals white, obovate, the claws and filaments dark purple; antheræ yellow. It has the appearance of wall-flower, but the branches are weaker, and both they and the leaves much smaller.—Native of the south of France, Spain, and Italy; common on the coast of the Mediterranean. It should be sown upon a warm border in a dry soil, and does not bear transplanting well.

Cneorum; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth very small, three-toothed, permanent. *Corolla*: petals three, oblong, lanceolate-linear, concave, erect, equal, deciduous. *Stamina*: filamenta three, subulate, shorter than the corolla; antheræ small. *Pistil*: germen obtuse, triangular; style erect, firm, length of the stamina; stigma trifid, spreading. *Pericarp*: berry dry, globose, three-lobed, three-celled. *Seed*: solitary, round, in a two-celled shell. **ESSENTIAL CHARACTER.** *Calix*: three-toothed. *Petals*: three, equal. *Berry*: tricoccus.—The only species is,

1. *Cneorum Tricocum*; *Widow-wail*, or *Spurge-Olive*. A humble shrub, which seldom rises more than two feet and a half high in this country, but spreads out on every side with many lateral branches, so as to form a thick bush; the stems are ligneous, and almost as hard as those of the Box-tree, and the wood is of a pale yellow colour under the bark; the branches are garnished with thick stiff leaves, of an oblong oval shape, about an inch and a half long, and a quarter of an inch broad, of a dark green colour, having a strong vein or rib through the middle: the flowers are produced singly from the wings of the leaves, toward the extremity of the branches; they are of a pale yellow colour: after the flowers are fallen, the germen becomes a fruit, composed of three seeds joined together, in the same manner as those of *Euphorbia* or *Spurge*; they are green at first, afterwards of a brown colour, and black when ripe. The flowers begin to appear in May, and are succeeded by others during the summer months; and when the autumn proves favourable, they will continue in flower till the end of October. As this is a low evergreen shrub, it may be very ornamental, if placed in the front of plantations or evergreen trees or shrubs; for as the branches grow compactly, and are well garnished with leaves, it will conceal the ground between the taller shrubs better than most other plants, and being durable, will not want to be removed.—Native of the south of France, Italy, and Spain, in hot, dry, barren and rocky soils. It was formerly preserved in green-houses, being thought too tender to bear the open air in English winters, which it has since borne very well, being rarely killed, except by extremely hard frosts; nor do these destroy those plants which grow upon dry, rocky, or rubbishy soils, where their shoots are generally short and firm. It is propagated by sowing the seed in autumn, soon after they are ripe, which ensures the appearance of the plants in the following spring; whereas those

which are not sown till the spring, will remain a year in the ground, and often miscarry. The seeds may be sown in a bed of common earth, covering them half an inch deep, and will require nothing but weeding during the following summer, and may be transplanted in the succeeding autumn wherever they are intended to remain.—The leaves and fruit are acrid, caustic, and violently purgative.

Cnicus; a genus of the class Syngenesia, order Polygamia *Æqualis*.—**GENERIC CHARACTER.** *Calix*: compound ovate, guarded with bractes, imbricate; scales ovate, close, branched, thorny. *Corolla*: compound, tubular, uniform; corollets hermaphrodite, equal; proper, funnel-form, oblong; border five-cleft, erect, nearly equal. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: germen short; style filiform, length of the stamina; stigma oblong, emarginate. *Pericarp*: none; calix closed. *Seed*: solitary; down plumose. *Receptacle*: flat, villose. **ESSENTIAL CHARACTER.** *Calix*: ovate, imbricate with branch-thorny scales, guarded with bractes. *Corollets*: equal.—These are perennial plants, and may be propagated by parting the roots; the best time for doing which is in autumn, that the plants may get good root in winter, for those which are transplanted in the spring, do not flower well in the first year, unless they be planted in a moist soil. As these plants grow very large, they are not proper furniture for small gardens, where they will take up too much room; for if they be nearer to each other, or to other plants, than four feet apart, they will deprive them and each other of their nourishment, for their roots extend to so great a distance, that two or three for variety's sake are sufficient for any garden, where they should be planted at a distance from choicer plants. They are also propagated by seeds, which may be sown in the spring, on a bed of common ground, and will merely require to be thinned, and kept clean from weeds till autumn, when they may be transplanted to wherever they are intended to remain.—The species are,

1. *Cnicus Oleraceus*; *Pale-flowered Cnicus*. Leaves pinnatifid, keeled, naked; bractes concave, entire, somewhat coloured; calices lateral, sessile, usually two together, with one between on a short peduncle; a white line runs along the keel of the calycine scales; leaves smooth, stem-clasping; flowers pale yellow.—It is found near brooks in the woods of Switzerland, and grows to the height of six feet: it is also a native of most countries of Europe, except the southernmost, in moist woods, meadows, and marshes, flowering in the autumnal months. The Russians boil the leaves in the spring, and eat them as coleworts, although, according to Schreber, no cattle will eat it.

2. *Cnicus Erisithales*; *Clammy Cnicus*. Leaves stem-clasping, pinnatifid, awn serrated; peduncles drooping; calices glutinous. Stem three feet high and more, angular, sometimes a little tomentose, not branched, unless at the top, naked far under the flowers; flowers three or four, frequently two opposite, sessile, never guarded with leaves, seldom solitary, nodding in a state of maturity; florets purple, yellow, or white, with purple stamens and pistil.—Native of France, Switzerland, Austria, Carniola, and Silesia. It begins to flower in June, and is perennial.

3. *Cnicus Ferox*; *Prickly Cnicus*. Leaves decurrent, ligulate, tooth-thorny; stem branching, erect. The stem is firm, deeply grooved, covered with a cobweb-like pubescence: a large head of white or purple floscules terminates the branches, and is guarded with linear strigose bractes, having small spines about the edge. Biennial; flowering in July and August.—Native of the south of France, and Piedmont.

4. *Cnicus Pigmæus*; *Pigmy Cnicus*. Leaves sessile, sub-

linear, very much crowded; calix unarmed. Root perennial, black; stem upright, hollow, from two to five inches high, thickened at top, very closely covered with white hairs; leaves many, both at the root and on the stem, sharp, three inches long, some quite entire, others toothlétted, unarmed, the sides rolled back: flower solitary, terminating, erect, very large in proportion to the plant, sessile in the uppermost shorter leaves: corollets purple; antheræ violet coloured. It flowers in July and August. Native of the mountains of Austria.

5. *Cnicus Acarna*; *Yellow Cnicus*. Leaves decurrent, lanceolate, undivided; calices pinnate, thorny. Stem herbaceous, winged by the leaves running down it, hoary, a foot high, but sometimes much smaller; leaves sessile, scattered, extremely acute, hoary, keeled, having a few teeth about the edge, with two or three yellow spines in each; calix woolly; corollets purple; flowers terminating, afterwards axillary, sessile; corollas small, purplish.—Native of the south of France and of Spain.

6. *Cnicus Spinossissimus*; *Thorny Cnicus*. Leaves stem-clasping, sinuate, pinnate, thorny; head simple; flowers sessile. Stem unbranched, twelve to eighteen inches high; the top entirely covered with leaves, angular, not winged; stem-leaves most fiercely thorned; pinnas angular, many-lobed, the nerves continued into strong thorns; the leaves on the top of the stem form a nest for the flower, broader, ovate-lanceolate, pinnate, whitish yellow, pubescent; floscules pale yellow.—It rises to the height of four feet in gardens, and is perennial.—Native of Switzerland, Austria, and Carniola.

7. *Cnicus Centauroides*; *Artichoke-leaved Cnicus*. Leaves pinnatifid; calices scarioso; scales acuminate. Stem three feet high, angular, putting forth few branches, and having at the top heads the size of a small artichoke, of a tawny colour; leaves like those of the artichoke; corollas purple. It flowers in July and August.—Native of the Pyrenees.

8. *Cnicus Uniflorous*; *Single-flowered Cnicus*. Leaves pinnatifid; calix scarioso, villose. Stem two feet high, erect, subangular, the thickness of the little finger, scarcely lanuginose, one-flowered; flower terminating, sessile; corolla large, violet; floscules six-cleft, with linear acute segments; stamina and style longer than the corolla, the former white, the latter violet.—Perennial; and a native of Siberia.

9. *Cnicus Cernuus*; *Siberian Cnicus*. Leaves cordate; petioles curled, thorny, stem-clasping; flowers drooping; calices scarioso. Root perennial, large, and rough, sending out many thick black fibres, which strike deep in the ground; the stalks rise six or seven feet high, sending out a few small branches: they are striated, of a brown colour, and at bottom have heart-shaped leaves half stem-clasping; the leaves towards the top of the stalk are long and narrow, ending in acute points. Each branch is terminated by one large head of flowers; calycine scales imbricate, ending in a sharp spine; floscules pale yellow, with an agreeable scent.—It flowers in the second year after the seed has been sown, in July, and the seeds ripen in the autumn, when the plant decays. The inhabitants of Siberia, of whose country it is a native, eat the tender stalks boiled.

Coccocypselum; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, four-parted, superior; segments acute, erect. *Corolla*: one-petalled, funnel-form; tube longer than the calix, gradually widening toward the border, which is four-parted, the parts ovate, erect. *Stamina*: filamenta four, the length of the tube, inserted into the base, filiform, erect; antheræ erect. *Pistil*: germen ovate, inferior; style the length of the stamina, bifid at the tip; stigmas simple. *Pericarp*: berry roundish, inflated, two-celled, crowned. *Seeds*: nume-

rous, minute. ESSENTIAL CHARACTER. *Calix*: four-parted, superior. *Corolla*: funnel-form. *Berry*: inflated, two-celled, many-seeded.—The species are,

1. *Coccocypselum Repens*. Stems creeping at the base; leaves egg-shaped; cymes axillary, nearly sessile. It grows in spreading tufts, each stalk creeping eighteen or twenty inches from the root, and shooting out a few lateral branches as it runs; the flowers and fruit rise on short divided peduncles from alternate axils.—Native of Jamaica, frequent in the cooler mountains of Liguanea, and Mont Diable.

2. *Coccocypselum Virgatum*. Stems rod-like; leaves acuminate; cymes lateral, peduncled; peduncles longer than the petiole.—Native of South America.

Coccoloba; a genus of the class Octandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted; divisions oblong, obtuse, concave, spreading most widely, coloured, permanent. *Corolla*: none. *Stamina*: filamenta eight, subulate, patulous, shorter than the calix; antheræ roundish, twin. *Pistil*: germen ovate, trigonal; styles three, short, filiform, spreading; stigma simple. *Pericarp*: none. *Calix*: berried, thickened, converging, involving the seed. *Seed*: nut ovate, acute, one-celled. ESSENTIAL CHARACTER. *Calix*: five-parted, coloured. *Corolla*: none. *Berry*: calycine, one-seeded.—The plants of this genus are all easily propagated by seeds, whenever they can be obtained fresh from the places where they naturally grow, for none of them have hitherto produced seeds in England. The seeds should be sown in small pots of kitchen-garden earth, and plunged into a hot-bed; if they be fresh and good, and the bed be of a proper temperature, the plants will appear in five or six weeks, and will be fit to transplant in about a month after: they should then be shaken out of their pots, carefully separating their roots, and each replanted in a separate small pot of the same kind of earth, plunging them into a hot-bed of tanner's bark, taking care to shade them in the day-time until they have taken new root, after which they should be treated like other tender exotic plants, which require to be constantly kept in the bark-stove.—The species are,

1. *Coccoloba Uvifera*; *Round-leaved Sea-side Grape*, or *Mangrove Grape Tree*. Leaves cordate-roundish, shining. This is a lofty, spreading, branched, irregular, inelegantly formed tree, but rendered handsome by its leaves and fruits; bark cinereous, thin, in the younger trees smooth, in the older ones full of chinks; timber hard, ponderous, red, but fit for little except as fire-wood, on account of its fibrous texture, unless it should turn out to be serviceable in dying; flowers small, whitish, smelling like those of the cherry; racemes about a foot long, simple, terminal, solitary. Gærtner calls the fruit a superior drupe, formed of the berried calix, obovate, of a purple colour, with a bloom, becoming black when ripe, and wrinkled; pulp soft, drying into a thin crust. The fruit is very astringent, and may be used in emulsions, boluses, or electuaries, but its action is not of long continuance; it has the exact taste of Bistort; the berries possess an agreeable flavour, but the pulp is not considerable. This tree is common in the sugar colonies, and is generally found near the sea. It frequently grows to a considerable size, and is then looked upon as a beautiful wood for all sorts of cabinet ware, but it seldom rises straight or regular. The Spaniards call it *uvero*, and the French *raisinier du bord de la mer*.

2. *Coccoloba Pubescens*; *Great-leaved Sea-side Grape*. Leaves orbiculate, pubescent. This is an upright tree, sixty or eighty feet high: the head has frequently no more than two or three thick branches, but little divided and irregular: the bole is sometimes forty feet in length, and puts forth a

branch or two about the middle. The timber is deep red, heavy, very hard, and also incorruptible, but brittle; when used for posts, the part placed in the ground becomes as hard as stone.—It is common in the thick mountainous woods of Martinico, where the French call it *bois à grandes feuilles*. The fruit is said to be eatable.

3. *Coccoloba Excoriata*; *Oval-leaved Sea-side Grape*, or *Mountain Grape Tree*. Leaves ovate; branches as it were barked. This grows to a very large size, and the leaves, flowers, and fruits, are all large; the leaves are very smooth, and of a fine lucid green colour. Browne informs us, that it grows to a considerable size in Jamaica, and is looked upon there as a fine timber wood.

4. *Coccoloba Nivea*; *White Sea-side Grape*. Leaves elliptic, acuminate, veined, shining above; racemes almost upright. It grows to the height of twenty feet, is upright, and the boughs form a head; flowers small, yellowish. The calix becomes thick, succulent, and snow-white, covering to the middle a three-sided black shining nut; fruit sweet and pleasant. The French call it *raisinier de coude*.—Native of St. Domingo, Jamaica, and Martinico.

5. *Coccoloba Leoganensis*. Leaves roundish, quite entire, shining, flat; racemes of the fruit erect. This is a small upright branching tree, ten feet high; leaves veined, coriaceous.—Native of Port-au-Prince, and Leogane, in St. Domingo.

6. *Coccoloba Obtusifolia*. Leaves oblong, very obtuse. This is a small, very branching, irregular tree, about twelve feet high, with smooth ash-coloured branches; leaves quite entire, shining; flowers small white; fruit astringent.—It flowers in August; and is a native of Carthage.

7. *Coccoloba Flavescens*. Leaves lanceolate-oblong, blunt, with a point. A small branching tree, twelve feet high; leaves quite entire, coriaceous, shining, somewhat rigid; racemes simple, terminating, erect; drupes roundish, dark purple, the size of a large pea; the pulp sweet and eatable.—Native of St. Domingo at Port-au-Prince.

8. *Coccoloba Punctata*. Leaves lanceolate, ovate. A small, upright, branched tree, fifteen feet in height; leaves quite entire, subcoriaceous, veined, shining; flowers white: almost the whole receptacle, with a small part only of the calix, becomes a roundish drupe of a dark red colour, and a sweetish but austere taste.—Native of Carthage.

9. *Coccoloba Emarginata*. Leaves coriaceous, roundish, gash-emarginated.—Native of the West Indies.

10. *Coccoloba Barbadosensis*. Leaves cordate-ovate, waved. Bark of the branches cinereous; leaves very coriaceous, five inches long: wood red.—Native of Barbadoes.

11. *Coccoloba Tenuifolia*; *Small Sea-side Grape*. Leaves ovate, membranaceous. This is of a humbler growth than any of the preceding species, having also smaller fruits and flowers; flowers scattered and pedicelled, in simple terminal racemes.—Native of Jamaica.

12. *Coccoloba Australis*. Leaves cordate-ovate, acute; flowers polygamous.—Native of New Zealand.

13. *Coccoloba Asiatica*. Scandent: leaves oblong-ovate, veined; racemes terminating. Stem suffruticose, branching; leaves subacuminate, quite entire, coriaceous, alternate; flowers white, in loose racemes; fruit a roundish five-lobed berry, formed from the five segments of the calix, blackish, pellucid, small.—Native of Cochin-china, where it is found in bushes and hedges.

14. *Coccoloba Cymosa*. Scandent: leaves oblong-ovate, veined; flowers axillary and terminal, in sessile cymes.—Found also in the hedges of Cochin-china.

Cocculus Indicus. See *Menispermum Cocculus*.

Cochlearia: a genus of the class Tetradynamia, order Sili-

culosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets ovate, concave, gaping, deciduous. *Corolla*: four-petalled, cruciform; petals obovate, spreading, twice the size of the calix; claws narrow, shorter than the calix, patulous. *Stamina*: filamenta six, subulate, length of the calix, the opposite ones shorter; antheræ obtuse, compressed. *Pistil*: germen heart-shaped; style simple, very short, permanent; stigma obtuse. *Pericarp*: silicle heart-shaped, gibbous, turgid, emarginate, furnished with a style, two-celled, scabrous; valves gibbous, obtuse. *Seeds*: about four in each cell. ESSENTIAL CHARACTER. *Silicle*: emarginate, turgid, scabrous; valves gibbous, obtuse.—The species are,

1. *Cochlearia Officinalis*; *Common Scurvy Grass*. Root-leaves roundish; stem ones oblong, somewhat sinuated; fruit globular; root annual or biennial, white, rather thick, elongated, with hairy fibres; stems angular, branched in a corymbose manner, leafy; root-leaves petioled, roundish, kidney-shaped; stem-leaves alternate, sessile, embracing the stem; flowers white, in terminal corymbs, afterwards lengthening into racemes; petals inversely egg-shaped, entire; siliques globular, slightly veined, crowned with a short style. The whole herb smooth, somewhat fleshy, various in size. The common Scurvy-grass has been long held in very high estimation, as an antiscorbutic and purifier of the blood; it has a somewhat unpleasant smell, and a warm bitter taste. Its active matter is extracted by maceration both in watery and spirituous menstrua, and accompanies the juice obtained by expression. The most considerable part of it is of a very volatile kind, the peculiar penetrating pungency totally exhaling in the drying of the herb, and in the evaporation of the liquors. Its principal virtue resides in an essential oil, separable in a very small quantity by distillation with water. Scurvy-grass is antiseptic, attenuant, aperient, and diuretic, and is said to open obstructions of the viscera and remoter glands, without heating or irritating the system: it has long been considered as the most effectual of all the antiscorbutic plants, for which we have the testimony of the most celebrated physicians: and it has been observed to grow naturally in those high latitudes where the scurvy is most prevalent. In rheumatic pains of long continuance, accompanied with fever, this plant, combined with arum and wood-sorrel, is highly recommended by Sydenham and Lewis. A remarkably volatile and pungent spirit, prepared from this herb, and called *spiritus antiscorbuticus*, was found by Werlhof to be a useful remedy in the palsy, and other disorders requiring an active stimulant; he gave it in the dose of thirty drops several times a day: but no preparation seems so beneficial, by way of an antiscorbutic, as the fresh plant eaten as a salad, or its expressed juice drank. If the green herb be infused in ale or beer, and put into a bottle well-corked, it will communicate to it all its antiscorbutic virtue, or volatile spirit, in three or four days' time. Mr. Ray recommends this ale, from his own experience, to be taken as the ordinary drink of those who are troubled with the scurvy: he says, it is not so good if the Scurvy-grass be long infused in it, for the earthy and fixed parts are thereby forced from the herb, and communicated to the ale, while the volatile parts either fly off, or, being jumbled with the more fixed parts, lose a great deal of their virtue. The juice of the Scurvy-grass, with the bruised herb, applied to the face or any other part, has been recommended as a cosmetic, but should be afterwards washed off with a decoction of bran. According to Withering, Scurvy-grass is a powerful remedy in the moist asthma, and also in what some authors call the scorbutic rheumatism. A distilled water and conserve are preserved from

the leaves, and kept in the shops, and its juice is frequently prescribed, when mixed with that of Seville oranges, under the name of antiscorbutic juices.—It is found on the mountains and sea-shores of the north of Europe: in England, it will be met with near Lynn and Yarmouth; near Hall, Boston, Whaplod, Holbeach; in Cornwall, Cumberland, Lancashire, and Wales; and at a great distance from the sea, near Castleton, in Derbyshire, Penigent, Ingleborough, Stanemore, and near Settle, in Yorkshire; and on the Highlands of Scotland. It is propagated for its medicinal uses, and ought to be found in every garden: the seeds should be sown in July, soon after they are ripe, in a moist shady spot of ground, and when the plants come up they should be thinned, so as to be left at about four inches' distance each way; the plants which may be taken out in thinning, may be transplanted into other shady borders, if there be occasion for them; if not, they may be hoed out in the same manner as onions, carrots, &c. taking care at the same time to hoe down all the weeds together with them, that the remaining plants may have room to grow strong: in the spring the plants will be fit for use, while those which may be suffered to remain, will produce their seeds in May, and ripen them in June.

2. *Cochlearia Danica*; *Danish Scurvy Grass*. Leaves hastate-angular, all deltoid. Stems about five inches long, seldom branched, partly decumbent, striated, reddish; flowers white, small; silicle elliptical.—Found upon the sea-coasts of Denmark and Sweden; and in Great Britain, in the isle of Portland, and about Plymouth; also at Wells, in Norfolk; isle of Walney, and Blackpool, in Lancashire; near Llanbadrick church, Anglesea; and in Scotland.

3. *Cochlearia Anglica*; *English or Sea Scurvy Grass*. Root-leaves egg-shaped, entire; stem-leaves lanceolate, toothed; silicles elliptical, reticularly veined; root annual or biennial. The herb smooth, somewhat fleshy; flowers like those of the first species, of which, according to Hudson, it is only a variety. According to Mr. Woodward, it is undoubtedly a distinct species; and he affirms, that at Yarmouth, where it grows abundantly, as well as in other places, it is never known to vary. Hill recommends the leaves of this plant, or the juice of them, to be taken in the same manner as those of the first species, as he affirms their virtues to be the same, and even greater, although the taste be less agreeable.—It is found in muddy soils upon the sea-coasts, on the banks of the Thames, near Portsmouth, Bristol, in the salt-marshes of Kent and Essex, in the isle of Wight, near Kings-weston, and upon the rocks of Inch-columb, &c.

4. *Cochlearia Groenlandica*; *Greenland Scurvy Grass*. Leaves kidney-form, entire, fleshy. Root-leaves very small, underneath very convex and fleshy, veinless, very entire, on long petioles; stem-leaves hastate, angular, on short petioles. Not above two inches high.—It is found on the sea-coasts of Muscovy, and Davis's Straits; on the mountains of Caernarvonshire, and near Llanberys; near Settle; on the Highlands of Scotland; and in the Orkneys.

5. *Cochlearia Coronopus*; *Wild Scurvy Grass, or Swine's Cress*. Leaves pinnatifid; stem depressed. Stem and leaves smooth, lying flat upon the ground, all about the roots; the flowers grow in short axillary tufts, are very small, and have white petals. It is acrid, and tastes like garden-cress. The ashes were an ingredient in Mrs. Stephens's once celebrated medicine for the stone. The expressed juice of this plant is a safe but powerful diuretic, and is good for all inward obstructions, the jaundice, and scorbutic complaints; the leaves may be eaten as a salad, or dried and given in decoction.—It is an annual, and commonly found on road-sides, dung-hills, and among rubbish; flowering from June to August.

6. *Cochlearia Armoracia*; *Horse Radish*. Root-leaves lanceolate, crenate; stem-leaves gashed. Root perennial, creeping; leaves very large, varying much, sometimes deeply pinnatifid, sometimes entire, and only crenated; flowering-stem a foot or eighteen inches high, branching at top, almost naked; flowers white, in loose panicles; silicle nearly ovate.—Found on the sides of ditches, and it also grows among rubbish, and in pastures, flowering in May. Horse-radish, the scraped root of which is used for many culinary purposes, possesses a volatile and pungent quality, which evaporates in drying. It impregnates both water and spirit very richly with its active matter, whether it be extracted by infusion or distillation. It is a moderately stimulating, aperient, and antiseptic medicine, which sensibly promotes perspiration, urine, the expectoration of viscid phlegm, and excites appetite when the stomach is weakened or relaxed: it is principally used in paralytic and rheumatic complaints, in scurvy, and impurities of the humours, in cachectic disorders, and in dropsies, particularly those which often follow intermitting fevers: it provokes vomiting, if taken in considerable quantities. Thomas Bartholin extols the virtues of Horse-radish in the stone, from his own experience; he declares, that the juice of Horse-radish dissolved a calculous or stony concretion that was taken out of the human body. An infusion of it in cold milk is said to make one of the safest and best cosmetics. One dram of the root infused in four ounces of water for two hours in a close vessel, and made into a syrup with double its weight of sugar, a tea-spoonful of which to be taken occasionally, removes hoarseness. The Horse-radish is propagated by cuttings or buds, from the sides of the old roots; the best season for this work is in October or February; the former for dry lands, the latter for moist: the ground should be trenched at least two spits deep or more, if it will allow of it. The manner of planting is as follows: Provide yourself with a good quantity of offsets, which should have a bud upon their crowns, but it matters not how short they are, therefore the upper part of the roots which are taken up for use, may be cut off about two inches long, with the bud to it, which is esteemed the best for planting; then make a trench about ten inches deep, in which place the offsets, about four or five inches' distance each way, with the bud upward, covering them with the mould that was taken out of the trench; after this proceed to prepare other trenches, and plant them in the same manner, until the whole ground be filled; after this is done, level the surface of the ground even, observing to keep it clean from weeds, until the plants be so far advanced as to be strong enough to overbear and keep them down. Under this management, the roots of the Horse-radish will grow long and straight, and free from small lateral roots, and the second year after planting they will be fit for use. The ground in which they are planted ought to be very rich, otherwise they will not thrive. The roots may be preserved for some time in their juicy state, by putting them in dry sand.

7. *Cochlearia Glastifolia*; *Wood-leaved Scurvy Grass*. Stem-leaves cordate, sagittate, stem clasping. Root biennial; stem usually a foot and half high, with upright stalks; the flowers in loose spikes at the ends of the branches, very small, white; and are succeeded by short oval pointed swelling pods filled with round seeds.—Native of Germany and the south of France; flowering from May to July.

8. *Cochlearia Draba*. Leaves lanceolate, stem-clasping, toothed. Root perennial, striking deep; stems several, about a foot high, striated, leafy, almost simple, annual; leaves distantly toothed, pale green or hoary; flowers small, white, in several short racemes.—Native of Italy, Austria, &c.

9. *Cochlearia Acaulis*. Stemless: leaves cordate-kidney-shaped; scapes filiform, one-flowered, quite simple. The whole plant scarcely half an inch high, growing in smooth tufts; flowers blue or white; silicle inflated, thick, oblong, many-seeded.—Native of Portugal and Morocco.

10. *Cochlearia Auriculata*. Leaves oblong, arrow-shaped at the base, auricled, embracing the stem; racemes long, loose, simple. Stem six inches high; flowers white.—Found near Auvergne.

Cocos; a genus of the class Monœcia, order Hexandria; of the natural order of Palms.—**GENERIC CHARACTER.** *Male Flowers*, in the same spadix with the females. *Calix*: spathe universal, univalve; spadix branching; perianth three-parted, very small; divisions subtriquetrous, concave, coloured. *Corolla*: petals three, ovate, acute, patulous. *Stamina*: filamenta six, simple, length of the corolla; anthera sagittate. *Pistil*: germen scarce manifest; styles three, short; stigma obsolete. *Pericarp*: abortient. *Female Flowers*, on the same spadix with the males. *Calix*: spathe common with the hermaphrodites, as likewise the spadix; perianth three-parted; divisions roundish, concave, converging, coloured, permanent. *Corolla*: petals three, permanent, like the calix, but rather larger. *Pistil*: germen ovate; style none; stigma three-lobed. *Pericarp*: drupe coriaceous, very large, roundish, obscurely triangular. *Seed*: nut very large, subovate, acuminate, one-celled, valvless, obtusely three-cornered, the base perforated by three holes; kernel hollow. **ESSENTIAL CHARACTER.** *Male. Calix*: three-parted. *Corolla*: three-petalled. *Stamina*: six. *Female. Calix*: five-parted. *Corolla*: three-petalled. *Stigmas*: three. *Drupe*: coriaceous.—The species are,

1. *Cocos Nucifera*; *Cocoa-nut Tree*. Unarmed: fronds pinnate; leaflets folded back, ensiform. The roots are very slender, simple, and flexible; they arise separately from the bottom of the trunk, and spread in all directions, some running to a great depth, while others creep almost parallel to the surface. The trees grow to a great height; their stems are composed of strong fibres like net-work, which lie in several laminæ over each other, out of which come the branches, or rather leaves, which grow twelve or fourteen feet long, forming a terminal head; the upper ones erect, middle ones horizontal, lower ones rather drooping; leaflets numerous; petioles in two ranks; spathes oblong, acute, opening on one side. The flowers come out round the top of the trunk of the tree, in large clusters; they are inclosed in a large spathe or sheath; and the nuts also are afterwards formed in large clusters, ten or twelve together. The fruit is properly a berrid drupe, superior, very large, ovate, rounded-three-cornered; the shell itself is of a bony substance; the kernel adheres all round the inner wall of the shell, and the cavity is filled with a milky liquor. The kernel in some nuts is nearly an inch thick; and the hollow contains about a pint of sweet, delicate, wholesome, and refreshing liquor. While the nut is growing, it contains nothing but this liquor; but as it approaches towards maturity, the kernel begins to settle round the inside of the shell, like soft cream, which, as the nut ripens, increases in substance until it becomes hard. The ripe kernel is sweet, but difficult of digestion, and seldom eaten except by strangers; but while it is young and soft, some will eat it, scraping it out with a spoon after they have

drank the liquor. While the nuts are young, the liquor is very pleasant; as they grow old, it becomes more sharp and cooling, and far more agreeable to feverish habits. The kernel is certainly nourishing in a high degree, and is much used in making soups, curries, &c. and may be substituted for almonds, in emulsions and apozems, whenever it can be procured fresh: a pure sweet oil is extracted from it, which is fit both for medicinal and culinary uses: the inhabitants of the Society Isles scent this oil with sandal wood, and other perfumes, in order to anoint their hair and skin with it. Beside the liquor contained in the fruit, there is a sort of wine drawn from this tree, which looks like whey, and is called toddy: it is sweet and very pleasant, when fresh; but if not drank within twenty-four hours after it is drawn, will turn sour. From this wine, in its sour state, they who have a great many trees distil a spirit called arack. It is also distilled from rice, but none is so much esteemed for making punch, as this sort made from toddy, or the sap of the Cocoa-nut tree; although it requires a dash of brandy to hearten it, because it is not strong enough to make good punch of itself. This sort of liquor is principally used about Goa, and has thereby acquired the name of *Goa arack*. In order to make arack, the trees must be prevented from bearing fruit: and to accomplish this the sprout which produces the nut, and which shoots every month, is cut, and jars fastened to it to receive the liquor; or the body bored, and a plug put into the orifice, which is occasionally taken out when the liquor is wanted: this liquor is permitted to ferment, and is afterwards distilled into the spirit called arack, which is of a far better quality than that of the same name which is drawn from rice. If this liquor be exposed to the sun, it will soon turn to vinegar. The coat or husk of the shell is composed of strong fibres, and is two or three inches thick. With these fibres, after soaking them in water, sail cloth, cables, and cordage, are made for the largest ships; as also oakum, and a variety of yarn used in caulking ships, and for other nautical purposes. The shells answer a variety of purposes as household utensils; and when worn out, are burnt to make lamp-black, for painting, &c. The trunk of this tree is formed into gutters, and occasionally employed for enclosing and roofing outhouses; and being nailed close, is so hardy as to resist the weather for many years. The Indians make boats, rafters, and the whole frame of their houses, from the body of this tree; the leaves of which they use for thatching them, and are wrought into mats, baskets, and many other things, for which osiers are used in Europe. The tender shoots at the top afford a pleasant green or cabbage, which is dearly acquired by the destruction of the tree, which seldom survives their being cut off.—This useful tree is common almost every where within the tropics, and is cultivated in both Indies; but is supposed to be a native of Asia, and is found in a wild state in the Maldives and Ladrões, as well as in the islands of the South Seas. It is propagated by planting the nuts wherever they are intended to remain; for it will not bear transplanting unless the operation be performed while the trees are very young, for their roots shoot deep and wide, so that if they be cut or broken the plants seldom survive it, which is the case with most of the Palms. Where any persons desire to have a plant or two of this sort, they should procure some fresh nuts from the nearest place of their growth, which on their arrival should be buried, lying on one side in a warm bed of tanner's bark, that the young shoot which comes out from one of the three holes may not be injured by wet, covering them at the same time six inches deep with the tau. In this situation, if the nuts be good, they will put out shoots in six weeks or two months, when

they should be carefully taken up, and each planted in a separate pot filled with kitchen-garden earth, and plunged into the tan-bed in the stove, where the plants should always remain, as they are too tender to thrive in any other situation; but they should be shifted into larger pots as they advance in their growth, taking care not to cut or tear their roots in the removal. Very few of the nuts brought to England are ripe, being commonly gathered in an unripe state, that they may keep during their passage. The best way to bring them for planting is to put some that are fully ripe in dry sand in a tub, where vermin cannot get at them. These will often sprout upon the passage; which is an advantage, because they may be immediately planted into pots of earth, and plunged into the bark-bed. These trees make considerable progress in the West Indies, but they are many years before they attain to any considerable height in Europe: however, as the young leaves are rather large, they make a good appearance among tender exotics in the course of two or three years. The other species of this genus may be propagated by seeds in the same way: and for further information upon the subject, consult the article *Phanix*.

2. *Cocos Butyracea*. Unarmed: fronds pinnate; leaflets simple. A loftier tree than the preceding, with a larger head; universal spathe an oblong cylinder, drawn to a point at each end, woody, smooth within, marked on the outside with numerous woody parallel ribs uniting towards the end; it opens longitudinally, falls off after the bursting of the spadix, and is from four to six feet long; kernel cartilaginous, very hard, having the same taste as in the common Cocoa-nut. The pulp of the nut is very mucilaginous, and therefore used for fattening hogs: an oil or butter prepared from it is in constant use among the Indians in South America, both in food and medicine.

3. *Cocos Guinensis*; *Prickly Pole*. The whole spiny: spines bristle-shaped; fronds distant; root creeping. Root knotty, round, thicker than the trunk, short, horizontally bent in directly below the surface, creeping and presently putting out another trunk, so as to make a thicket, while it fixes itself firmly in the soil by slender fibrous roots: trunk erect, armed with very numerous prickles, seldom exceeding twelve feet in height, and one inch in diameter; flowers scentless, with a very slight tinge of yellow; corolla triquetrous, frequently three-parted almost to the base; fruits dark purple, the size of a common cherry, containing an acid juice, of which the Americans make a sort of wine: the fruit is eatable, but not pleasant, yet they furnish the wild hogs of Jamaica with abundant fare. Canes are made of the trunk when stripped of its bark; they are black, shining, jointed, and very light. The French call them *cannes de Tobago*, and they are sometimes brought to Europe. The outward part is extremely hard and elastic, looking like whalebone, and being very fit for bows and rammers.—Native of Carthage in South America.

4. *Cocos Aculeata*; *Great Macaw Tree*. Aculeate-spiny; trunk fusiform; fronds pinnate; stipes and spathes spiny. The trunk of this tree is about the thickness of the human body, and rises to the height of thirty feet, with an ash-coloured bark, very thickly set with sharp black prickles of different lengths, placed usually in rings. The fruit is as large as a crab, and of the same shape; under a green skin it has a thin sweetish astringent pulp, and within that, a nut full of a white sweet eatable kernel. Browne says, that the husks of this and of the small Macaw-tree are full of oil, and the nut black and shining. The negroes say, that it yields the true palm-oil. The outside of the trunk is made into laths, bows, and darts.—Native of the Caribbee islands.

5. *Cocos Nypa*. Unarmed: fronds pinnate; spadices to the male flowers round, to the females roundish; drupe grooved. This is a very thick palm, only four feet high, frequently shorter, or even without a stem; fronds fifteen feet long, almost upright, irregularly pinnate, with a subcylindric rachis or midrib.—It is very frequent in salt marshes, and at the muddy mouths of rivers in Cochinchina, Cambodia, the Philippine Islands, the streights of Malacca, &c. See *Nipa Fruticans*.

Codia; a genus of the class Octandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: common four-leaved; leaves reflected below the head; proper four-leaved; leaflets elliptic, erect. *Corolla*: petals four, linear. *Stamina*: filamenta eight, filiform, two, each growing to the base of a petal, longer than the corolla; antheræ ovate-angulate. *Pistil*: germen very small, superior, extremely villose; styles two, subulate, the length of the stamina; stigmas simple. *Receptacle*: common villose. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Petals*: four. *Common Receptacle*: involucred.—The only known species is,

1. *Codia Montana*. Leaves opposite, petioled, elliptic, very smooth, entire, obtuse; heads of flowers globular, terminating, and axillary, very short, peduncled. It is a shrub.—Native of New Caledonia.

Codlin Tree. See *Pyrus Malus*.

Codlins and Cream. See *Epilobium*.

Codon: a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, ten-parted; leaflets subulate, permanent, somewhat erect, alternately shorter. *Corolla*: one-petalled, bell-shaped, torulose at the base: border ten-parted, equal; nectary ten-celled, consisting of ten scales inserted into the claws of the stamina, converging, covering the receptacle. *Stamina*: filamenta ten, length of the corolla; antheræ thick. *Pistil*: germen superior, conic; style simple, length of the stamina; stigmas two, long, setaceous, divergent. *Pericarp*: two-celled. *Seeds*: several, roundish, echinate, with soft papillæ, situated in a juiceless coloured pulp. **ESSENTIAL CHARACTER.** *Calix*: ten-parted, permanent; leaflets alternately shorter. *Corolla*: bell-shaped, ten-cleft. *Nectary*: ten-celled, composed of ten scales. *Pericarp*: two-celled, containing several seeds.—The only known species is,

1. *Codon Royeni*. Stem herbaceous, firm, eighteen inches in height, round, with rising branches, cottony, and full of pith; leaves alternate, petioled, cordate-ovate, subrepand, undivided, acuminate, subcoriaceous, clothed with a short cottony down, and rough with small hard prickles; flowers supra-axillary, solitary, peduncled, having the appearance of the corolla of *Atropa Belladonna*, whitish, with ten purple streaks on the outside; fruit a capsule, contained within the segments of the calix, ovate-acuminate, two-valved, with numerous small seeds of a shining blood-red colour. The whole herb is striated.—Native country unknown.

Coli Rosa. See *Agrostemma*.

Coffea: a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-toothed, very small, superior. *Corolla*: one-petalled, salver-shaped; tube cylindric, slender, many times longer than the calix; border flat, five-parted, longer than the tube; divisions lance-shaped; sides rolled back. *Stamina*: filamenta five, subulate, placed on the tube of the corolla; antheræ linear, incumbent, length of the filamenta. *Pistil*: germen roundish, inferior; style simple, length of the corolla; stigmas two, reflected, subulate, thickish. *Pericarp*: berry roundish, umbilicated by a one or two celled puncture. *Seeds*: one or two, solitary, elliptically hemispherical, gibbous on one side, flat

COFFEA ARABICA — *Eastern Coffee Tree.*

on the other, where it is furrowed longitudinally, involved in an aril. **ESSENTIAL CHARACTER.** *Corolla*: salver-shaped. *Stamina*: upon the tube. *Berry*: inferior, two-seeded. *Seeds*: arilled.—The species are,

1. *Coffea Arabica*; *Eastern Coffee-Tree*. Flowers five-cleft; berries two-seeded. The Coffee-tree seldom rises more than sixteen or eighteen feet high in its native country, or more than ten or twelve in Europe. The main stem grows upright, and is covered with a light brown bark; branches horizontally opposite, brachiata at every joint; leaves opposite, four or five inches long when fully grown, an inch and a half broad in the middle, ovate-lanceolate, the borders waved, and the surface of a lucid green, but paler beneath. The flowers are produced in clusters at the base of the leaves, four or five together, sitting close to the branches; they are of a pure white, with a very grateful odour, but of short duration; and are succeeded by berries, which are at first green, but turn red when fully grown, and are black when ripe: they are of an oblong spheroidal form, with a little circular area at the top, within which is a callous dot; the pulp is pale, insipid, and gelatinous; within it is two-celled, each containing one seed, of an elliptical form, convex on one side, and flat on the other, with a longitudinal cleft.—Dr. Patrick Browne, who resided many years in Jamaica, informs us that the Coffee-tree thrives best in a rich soil, and cool shaded situation, where it produces so great a quantity of fruit, that the very trunk itself yields to the load. This fruit is large and succulent, and the berries lax and clammy; they are gathered when only half ripe; and instead of being stripped of their pulp, and carried down to the low lands to be dried, the seeds are left soaking in their clammy juices, to dry slowly in a damp air. This will sufficiently account for the inferiority of the Jamaica, when compared with the Arabian Coffee, which grows in a sandy, dry, hot soil, where the berries acquire but little pulp, and are soon dried by being spread upon mats, and exposed to the sun. The same accurate writer, however, consoles us by his opinion, founded upon repeated experiments, that the West India Islands might furnish Coffee equal in quality to the Turkish, if the following remarks were attended to: 1. New Coffee will never parch or mix well, from the natural clamminess of the juices: 2. the smaller the grain, the less pulp the berry has, the better the Coffee, and the sooner it will parch, mix, and acquire a flavour: 3. the drier the soil, and the warmer the situation, the better will be the Coffee it produces: 4. the larger and more succulent the grain, the worse the quality will prove: 5. the worst Coffee produced in America, will in the course of years, not exceeding ten or fourteen, be as good as the best we now receive from Turkey, if care be taken to keep it in a dry place, and to preserve it properly. Small-grained Coffee is the best. Mr. Miller advises those who cultivate the Coffee-tree in the West Indies; first, to prefer a dry before a moist soil; secondly, to permit the berries to remain upon the trees until the skin shrivels and turns black; thirdly, to gather, or rather shake them from the trees when they are perfectly dry, spreading them afterwards upon cloths or mats in the sun, and carrying them every evening under cover, until they are wholly dry, as is done in Arabia Felix: and when they are thus perfectly dried, deprived of their husks, and winnowed, he advises to pack them up carefully in bags, and not to ship them with rum or other goods, from which they may imbibe a disagreeable flavour. In addition to this, Dr. Browne recommends the possessors of large Coffee walks to have a convenient platform to dry the seeds on, and he thinks it would be a useful experiment to try whether sweating would remove the clamminess

of the large berries. They should, however, be pulped and dried as soon as possible, then husked, and cleared from all the outward coverings. This is generally done, in Jamaica, by pounding the dried berries lightly in a large wooden mortar; they are then winnowed, cleared, again exposed to the sun for some days, and then casked for the market. If it be not well dried, the Coffee is liable to heat on its way to Europe, and when that occurs it loses all its flavour. Long, in his history of Jamaica, observes, that the berries never ought to be gathered until the pulp is exhaled, and the coat suffered to become thoroughly dry and shrivelled, so that they may appear ready to drop off, and actually fall upon a slight touch. In confirmation of this, he affirms that he has experienced the best-flavoured Coffee to have been collected from under the trees, where it had recently fallen quite dry, black, and shrivelled: he adds that the trees should be planted at distances proportioned to their growth, which is five feet in the low lands, and ten or more in the mountains; and that the produce of a good tree is from one pound and a half to two pounds weight: he also thinks, that the mountain Coffee might be improved by sending the berries to the low lands, where the heat is greater, and the air more dry; and by having a drying house under a roof, with one or more platforms, admitting a free current of air, and excluding the rain and the beams of the sun: he further informs us, that the husks are no longer beaten off in mortars, but by rollers turned by mules; that wooden rollers are preferable to iron or stone; and that the most approved machine, invented by Mr. Latham, will clean one hundred hogsheads in a day. Dr. Fothergill very reasonably suggests, that the removal of the Coffee-tree from the dry sterile sandy soil of Arabia, into the rich deep staple of Batavia, where the quantity of water falling in the rainy season is excessive; its removal from thence into Holland and France; and its subsequent transportation to a climate much more abounding in moisture than that of which it was a native,—may so far have altered the quality of the fruit, as to make it difficult to restore it to its original perfection; which he nevertheless thinks may be accomplished by making the plantations in soils as similar as possible to that out of which it was originally taken: he also hints that the fruit of young trees is in general more insipid, or has a less refined taste, than the old, and that this probably applies to the Coffee-tree, the fruit of which he asserts to be smaller in the old than in the young trees. The French cultivate it with great attention in both Indies; and the consequence is, that their Coffee is much superior to ours, and by some is even accounted nearly equal to the best Turkey. They are also more careful in not shipping it among goods which destroy its flavour, and communicate an ill taste in its stead, as with rum and coarse sugars, the ill flavour arising from which can hardly be removed, even by roasting it in the fire. It is also probable, adds Dr. Fothergill, that our plantation Coffee is used too soon; and that one part of the excellence of the Mocha Coffee may arise from the intervention of two or three years between its growth and consumption. Mr. Miller, however, controverts this hypothesis. "It is (says he) contrary to all the experience I have had, and the information I have obtained from those who have been eye-witnesses to the whole process of managing Coffee in Arabia. Two gentlemen who have lived there some years assure me, that the berries, when first gathered, are much better than those which have been kept any time. And a curious observer, who resided two years in Barbadoes, also informs me, that he never drank better Coffee in any part of the world than what he made fresh from the berries he gathered himself, and roasted as he had occasion for them."

This account is further and fully confirmed, by trials with berries produced in our English stoves, which make a better flavour than the best Arabian Coffee-berries that can be procured in England. It is no misfortune to the planter that his Coffee is not improved by age, for if it were, it would be extremely difficult for him to keep it so long as is proposed; which would entirely deprive him of all profit whatever. Fuller, however, informs us, that after a multitude of experiments, the Jamaica planters have by the most laudable exertions, discovered the art of cultivating, picking, and curing the berries, so as to make their Coffee equal to the growth of Arabia. Some samples are said to have been produced which the London dealers pronounced superior to the best brought from the East. Two of them were equal to the best Mocha Coffee; and two more superior to any that could be procured at the grocers' shops in London, unless at the price of picked Coffee, which is two shillings per pound more than what they call the best Coffee; to which the remainder of the samples were little, if at all, inferior.—*Propagation and Culture.* As the Coffee-tree is an evergreen, it makes a beautiful appearance in the stove at every season, but particularly when it is in flower, and also when the berries are red, which is generally in winter; and as they continue a long time in that state, there is scarcely any plant that better deserves a place in the stove. It is propagated by the berries, which must be sown soon after they are gathered from the trees; for if not soon afterwards placed in the ground, they will not grow. They should be planted in small pots filled with light kitchen-garden earth, and plunged into a hot-bed of tanner's bark; they must be watered gently once or twice a week, but not so as to make the earth too moist, for that would rot the berries. If the bed be of a proper temperature of warmth, the plants will appear in a month or five weeks' time, and in about two months more will be fit to transplant: for as many of the berries will produce two plants, so the sooner they are parted, the better the roots will be formed; for when they grow double till they have made large roots, they will be so intermixed and entangled, as to render it difficult to separate them without tearing off their fibres, which will greatly prejudice the plants. When they are transplanted, they must be each put into a separate small pot filled with the same earth as before, and plunged into the tan-bed again, which should be stirred up to the bottom, and, if required, have new tan added, to increase or restore the heat. The plants should then be gently watered, and the glasses of the hot-bed must be shaded every day till they have taken fresh root, after which they must have free air daily admitted to them in proportion to the warmth of the season; and during the summer they will require to be refreshed with water, but it must be given sparingly, for if their roots be kept too moist, they are very subject to rot, which will cause the leaves to decay and drop off, leaving the plants naked, after which they are seldom recovered again. The first sign of the disorder in these plants, is their leaves sweating out a clammy juice, which attracts the small insects that too frequently infest the plants in stoves, when they are not in health; and these insects cannot be destroyed till the plants are recovered to vigour, for although they be ever so carefully washed and cleaned from them, yet they will soon be attacked again, if not fully restored; so that upon the first attack, the plants should be shifted into fresh earth, and all possible care taken to recover them. The disorders attending the Coffee-trees generally proceed either from being put into pots too large for them, nothing being worse than overpotting them, or from the earth being too stiff, or from their being overhung by other plants, or from being over-

watered. If these things be avoided, and the stove be always kept in a proper temperature, the plants will thrive, and produce plenty of fruit. The plants should not be too often transplanted, for that will greatly retard the growth; if they be new-potted twice a year at most, it will be sufficient; though, unless they make great progress, they will not require removing more than once a year, which should take place in summer, that they may have time to acquire good root again before winter. This tree has been propagated from layers and from cuttings; but these are long before they make roots, and the plants so raised are never so strong and thriving as those which arise from berries; the plants raised from which produce fruit in two years even in our climate, and much sooner in hot countries. In Arabia Felix the Coffee-tree is raised from seeds sown in nurseries, and planted out as there is occasion. The plantations are in moist shady situations, on small eminences at the foot of the mountains, whence little rills of water are conducted in small channels to the roots of the trees, to secure the production and ripening of the fruit. When they remove or transplant a tree, they make a trench three feet wide, and five feet deep, which they line or cover with stones, that the water may the more readily sink deep into the earth, and be thereby prevented from evaporating. When the fruit is nearly ripe, the water is turned off, lest it should become too succulent. In places that are much exposed to the south, the Coffee-trees are planted in regular lines, sheltered by a kind of Poplar-tree, which affords a thick shade. Without these precautions the Arabians suppose that the blossoms would be so parched by the excessive heat of the sun, as not to be succeeded by any fruit.—The liquor which we call *coffee*, or *coffea*, prepared from the berry of this tree, has been drank in Ethiopia from time immemorial. Du Thour recommends the following method of making this beverage: Pour into a Coffee-pot filled with boiling water, in the proportion of two ounces and a half of the powder, to two English pints of water. Let the mixture be stirred with a spoon, and the Coffee-pot be set on the fire, but soon taken off, and suffered to remain about two hours on the warm ashes, closely shut up; during this period it should be frequently agitated, and finally left a quarter of an hour to clear. Coffee thus prepared, he adds, is perfect. The Galla, a wandering nation of Africa, in their incursions on Abyssinia, being obliged to traverse immense deserts, and desirous also of falling upon the Abyssinians unawares; in order that they may be encumbered with as little baggage as possible, carry nothing with them to eat, but Coffee roasted till it can be pulverized, and then mixed with butter into balls, and put into a leathern bag. One of these, which is about the size of a billiard-ball, keeps them, according to their account, in better health and spirits, during a whole day's fatigue, than a loaf of bread or a meal of meat. The Coffee-tree was introduced into Aden in Arabia, from Persia, by Gemaleddin, only about the middle of the fifteenth century. Not long after it reached Mecca, Medina, and Grand Cairo, whence it continued its course to Damascus and Aleppo, and in 1554 became known at Constantinople, being introduced there by two persons, one from Damascus, and the other from Aleppo, each of whom opened a public Coffee-house in that city. The first European author who has mentioned Coffee, is Rauwolf, who was in the Levant in 1573; but the first who has particularly described it, is Prosper Alpinus, in his *Medicina Ægyptiorum*, 1591, and in his *History of Egyptian Plants*, 1592. The use of Coffee was known in London soon after the year 1652, for Mr. Daniel Edwards, a Turkey merchant, brought home with him a Ragusan Greek servant, who understood the roasting

and making of Coffee. This Greek was the first who sold Coffee, and kept a house for this purpose in George-yard, Lombard-street; or, according to Mr. Houghton, who wrote in 1701, in a shed in the church-yard of St. Michael's Cornhill, which is now, says he, a scrivener's brave house: he adds, that one Rastall, whom he knew, went to Leghorn in 1651, and there found a coffee-house; that he met Mr. Daniel Edwards there, with his Greek servant; and that Mr. Edwards was the first who brought the use of Coffee into England, except it were the famous Dr. Harvey, who, some say, did frequently use it. Pasqua, who first sold Coffee in London, being no freeman, the ale sellers petitioned the lord-mayor against him; which induced alderman Hodges, whose daughter Mr. Edwards had married, to join his coachman, Bowman, who was free, as Pasqua's partner; and thus Mr. Rastall found them in 1654. For some misdemeanor, Pasqua was forced to leave the country; and Bowman, by his trade, and a contribution of 1000 sixpences, turned the shed to a house. Bowman's apprentices were, first, John Painter, then Huniphry, from whose wife Mr. Houghton first obtained the above minute account of the introduction of Coffee into London. Two English travellers notice this beverage at the very beginning of the seventeenth century. Biddulph, in 1603, says, "The Turks have for their most common drink *coffa*, which is a black kind of drink, made of a kind of pulse like peas, called *coava*." and William Finch, in 1607, says, "that the people in the island of Socotora have for their best entertainment a china dish of *cobo*, a black bitterish drink, made of a berry like a bay-berry, brought from Mecca, supped off hot." Lord Bacon mentions Coffee in 1624; and Mr. Thevenot, the French traveller into the East, at his return in 1657, brought with him some Coffee to Paris for his own use. It was, however, known at Marseilles in 1644, although Mons. du Tour, who wrote upon Coffee in 1685, says, that the French knew nothing of it till 1645. The first mention of Coffee in the English statute-books, occurred in 1660. Monsieur la Roque, who published his Journey into Arabia Felix in 1715, contends, that his father, having been with Monsieur de la Haye, the French ambassador at Constantinople, did, when he returned to Marseilles in 1644, drink Coffee every day; but he allows, notwithstanding, that Thevenot was the first who taught the French to drink it: however, until the year 1660, it was drunk by those only who had been accustomed to it in the Levant; but in that year some bales were imported from Egypt, and in 1671 a Coffee-house was opened at Marseilles; and it was not known at Paris till two years before, except among Mr. Thevenot and his friends, but in that year it was effectually introduced by Solymán Aga, ambassador from sultan Mahomet; and, two years after, Pascal, an Armenian, sold it publicly in the Foire St. Germain, and afterwards set up a Coffee-house on the Quai de l'École; but meeting with little encouragement, he left Paris, and came to London. Not long after this, spacious rooms were fitted up in an elegant manner for selling Coffee and other refreshments at Paris, and in a short time the number of Coffee-houses was increased to three hundred. In 1688 the celebrated naturalist Mr. Ray affirms, that London might rival Grand Cairo in the number of its Coffee-houses, and that they were to be found not only in the capital, but in every town of note in England. Probably the ill-judged proclamation of Charles II. against Coffee-houses, in 1675, contributed much to establish them. In his history of plants, published also in the year 1688, Mr. Ray, speaking of Coffee as a drink very much in use, supposes that the Arabs destroyed the vegetable quality of the seeds, in order to confine their commodity to themselves, and adds, that he

wondered the neighbouring nations did not contrive to bring away some sound seeds or living plants, in order to share in so lucrative a trade: this was soon done, for Nicholas Witsen, burgomaster of Amsterdam, and governor of the East India company, desired Van Hoorn, governor of Batavia, to procure from Mocha, in Arabia Felix, some berries of the Coffee-tree, to be sown at Batavia, which was accordingly done about the year 1690: and Van Hoorn having raised many plants from the seeds, sent one over to governor Witsen, who presented it to the garden at Amsterdam, where it bore fruit, which in a short time produced many young plants. From these, the East Indies, and most of the European gardens, have been supplied; and even in the year 1696 it had reached Fulham, where it was cultivated by Bishop Compton. In 1714 the magistrates of Amsterdam presented Louis XIV. with a Coffee-tree, which was placed in the royal garden at Marli, under the care of the celebrated Jussieu, who had written a memoir, printed in the History of the Academy of Sciences for 1713, describing the characters of the genus, with a figure of it from a smaller tree, which he had received from the burgomaster of Amsterdam, and director of the botanic garden there. In 1718, the Dutch colony of Surinam began first to plant Coffee; and in 1722, M. de la Motte Aignon, governor of Cayenne, contrived by an artifice to bring away a plant from Surinam, which in the year 1725 had produced many thousands. Rochon, in his account of Madagascar, asserts, that in 1718 the inhabitants of the Isle of Bourbon sent to Mocha and Aden for some young plants of the Coffee-tree, which being carefully cultivated, in a few years became very productive, and soon afforded the French East India company a very important article of trade, until 1727, when perceiving that this acquisition might be of great advantage to their other colonies, they conveyed some of the plants to Martinico, whence it most probably spread to the neighbouring islands; for in the year 1732, it was cultivated in Jamaica, and an act was passed to encourage its growth in that island. The first plant that appeared in that island was carried thither by Sir Nicholas Laws, and placed in the garden of Townwell, at present called Temple Hall, the property of Mr. Lutterel; but he dying in 1731, did not see the cultivation of it make any considerable progress. In the year 1752, the exportation of Coffee from Jamaica was rated at 60,000 pounds weight; in 1775, at 440,000; and in 1790, at 1,783,740. The abbé Raynal says, that 12,550,000 pounds weight is annually exported from Arabia Felix.

2. *Coffea Occidentalis*; *Western Coffee Tree*. Flowers four-cleft; berries one-seeded. It is upright, branching, and six feet high; leaves lanceolate-ovate, ending in a blunt point, quite entire, shining, petioled, opposite, only on the young twigs, four inches long; corolla white, very sweet-scented; the flowers appear in December.—It is found near Cape François in St. Domingo, and is pretty common in the lower woods of Jamaica, where Brown calls it the *wild jessamine*, the flowers having much of the shape and smell of our white jessamine.

3. *Coffea Racemosa*. Very much branched; leaves rugged; racemes terminating. This is a small tree, only four feet high, with many diffused round branches; leaves ovate-lanceolate, quite entire, beset with many tubercles, opposite, on short petioles; flowers subterminating, in erect brachiate racemes; berry roundish, small, red, watery, one-celled, with two hemispherical seeds.—Native of the island of Mosambique.

4. *Coffea Zanguebariæ*. Corollas six-cleft; fruit angular, nerved. This is a small upright tree, six feet high, with thick short spreading branches; flowers white, axillary, several together on short one-flowered peduncles; border

six or seven parted ; berries red, oblong, ovate.—Native of Africa, on the coast of Zanguebar, and cultivated near Mosambique, with the preceding species.

5. *Coffea Guianensis*. Flowers four-cleft ; berries small, violet-coloured, two-seeded. Stem branching, from one to two feet in height ; branchlets quadrangular, knotty ; flowers axillary, several together, small and white ; berry spherical, and violet coloured.—It flowers and fruits in September ; and is a native of the great forests of Orapu in Guiana.

6. *Coffea Paniculata*. Branches quadrangular ; leaves ovate-oblong, acute ; corollas four-cleft ; berries two-seeded. Trunk seven or eight feet high, and five or six inches in diameter, covered with a gray, wrinkled, cloven bark ; boughs opposite, branched, knotty, quadrangular ; flowers terminating, panicled ; corolla white, very sweet-scented.—Native of Guiana ; flowering and fruiting in April.

7. *Coffea Sambucina*. Leaves oblong-lanceolate, acute ; cymes corymbed, terminating. — Native of the Friendly Islands in the South Seas.

8. *Coffea Opulina*. Leaves ovate-lanceolate ; cymes contracted, globular, terminating.—Native of New Caledonia.

9. *Coffea Odorata*. Leaves ovate, acute ; cymes corymbed, axillary.—Native of Tanna, and the Friendly Islands.

10. *Coffea Triflora*. Leaves ovate-lanceolate, acuminate ; peduncles terminating, three together, one-flowered.—Native of Otahite.

Coix ; a genus of the class Monœcia, order Triandria.—**GENERIC CHARACTER.** *Male Flowers*, disposed in a loose spike. *Calix* : glume two-flowered, two-valved ; valves oblong-ovate, obtuse, awnless, the outer thicker. *Corolla* : two-valved ; valves ovate-lanceolate, length of the calix, very thin, awnless. *Stamina* : filamenta three, capillary ; antheræ oblong, four-cornered. *Female Flowers*, fewer, at the base of the male spike, on the same plant. *Calix* : glume two-flowered, two-valved ; valves rounded, thick, shining, hard ; the outer larger, shining. *Corolla* : glume two-valved ; outer valve ovate, larger ; inner narrower, smaller ; both awnless. *Pistil* : germen ovate, very small ; style short, two-parted ; stigmas two, horned, longer than the flower, pubescent on every side. *Pericarp* : none : the outward calycine glume grows closely to the seed, it increases, grows shining, falls, does not gape. *Seed* : solitary, roundish, covered by the ossified calix. **ESSENTIAL CHARACTER.** *Males*, in remote spikes. *Calix* : glume two-flowered, awnless. *Corolla* : glume awnless. *Female. Calix* : glume two-flowered. *Corolla* : glume awnless. *Style* : two-parted. *Seed* : covered by the calix, ossified.—The species are,

1. *Coix Lachryma* ; *Job's Tears*. Seeds ovate. Culm six feet high, perennial, subcylindric, solid, jointed, erect, branched ; leaves lanceolate, quite entire, long, wrinkled underneath, reflex, clasping ; flowers axillary, on a long slender, suberect, common peduncle ; at the top many males, in a subovate spikelet, and at the base a solitary female ; the two styles are capillary, and entirely distinct, with long villose stigmas ; seed bluish-white, very hard, shining like pearls. Annual.—Native of the East Indies ; cultivated in Spain and Portugal, where, in times of scarcity, a coarse kind of bread is made of its seeds, and eaten by the poor. It is applied to the same use in China and the Levant. The seeds are sometimes bored and threaded for necklaces, and other female ornaments. Those who wish to cultivate this plant in England, may procure the seeds from Portugal, and should sow them upon a moderate hot-bed in the spring, to bring the plants forward, and afterwards transplant them on a warm border, allowing each two feet room apart ; when they have taken root, they only require to be kept clean from weeds ;

they will flower about midsummer, and in warm seasons ripen seed, at Michaelmas. There is a variety of this with much broader leaves, which was imported from Smyrna.

2. *Coix Angulata* ; *Large Job's Tears*. Seeds angular. This grows to the height of seven or eight feet ; the stems become hard, like the reed, or Indian corn, branching out ; and producing several spikes of flowers.—Native of America ; and a perennial. This species will not bear the open air in England, but must be plunged into the bark-bed, where it will flourish, and produce ripe seeds the second year, and may be continued longer if desired.

3. *Coix Agrestis* ; *Small Job's Tears*. Culm entirely simple ; leaves smooth and even ; seeds roundish. Root perennial, creeping ; culm three feet high ; leaves lanceolate-linear, acuminate, quite entire, suberect, alternate, clasping ; peduncles long, erect, axillary, many-flowered ; males and females from the same axil ; seed roundish, brown, shining, small.—Native of Amboyna, Ceylon, and Cochin-china.

Colchicum ; a genus of the class Hexandria, order Trigynia.—**GENERIC CHARACTER.** *Calix* : none, except scattered spathes. *Corolla* : six-parted ; tube angulated, rooted ; divisions of the border lance-ovate, concave, erect. *Stamina* : filamenta six, subulate, shorter than the corolla ; antheræ oblong, four-valved, incumbent. *Pistil* : germen buried within the root ; styles three, thread-form, length of the stamina ; stigmas reflex, channelled. *Pericarp* : capsule three-lobed, connected internally by a suture, obtuse, three-celled ; sutures gaping inwardly. *Seeds* : many, nearly globular, wrinkled. **ESSENTIAL CHARACTER.** *Calix* : a spathe. *Corolla* : six-parted, with a rooted tube. *Capsule* : three, connected, inflated.—All the plants of this genus form a very suitable variety for a flower garden, as they flower in autumn, when few other plants are in beauty. In May the leaves begin to decay, soon after which time the roots should be transplanted, for if they be suffered to stay in the ground till August, they will send forth fresh fibres, and after that it will be too late to remove them ; the roots may be kept above ground till the beginning of August, and if not then planted, will produce their flowers as they lie out of the ground ; but this will greatly weaken their roots. For the manner of planting these roots, see *Tulipa*. Whoever desires to obtain varieties in the flowers, must propagate them from seeds.—The species are,

1. *Colchicum Autumnale* ; *Common Meadow Saffron*. Leaves flat, lanceolate, erect. It has a bulbous root, about the size and shape of the Tulip, but not so sharp pointed at the top ; the skin or cover is also of a darker colour : these bulbs are renewed every year, for those which produce the flowers decay, and new roots are formed above. The flowers come out in autumn, and rise, with long slender tubes about four inches high, from the root ; these tubes are shaped like those of the Saffron, but larger ; and the number of flowers is generally in proportion to the size of the roots, from two to seven or eight. The green leaves appear in March, and are generally four in number to a full-grown root ; they are folded over each other below, but spread open above ground, standing crossways ; their colour is a deep green, and when fully grown they are five or six inches long, and one and a half broad. The seed-vessel comes out between the leaves in April, and the seeds ripen in May, soon after which the leaves decay. The seeds lie buried all the winter within the bulb ; in spring they grow up on a fruitstalk, and are ripe about the time of hay-harvest. May not the very great length of the styles account in some measure for the delay in the ripening of the seeds ? As this plant blossoms late in the year, and would not probably have time to ripen its seeds

before winter, Providence has so constructed it that they may ripen at a considerable depth in the earth, out of the reach of the usual effects of frost; and, as seeds buried at a certain depth are known not to vegetate, a no less admirable provision is made to raise them above the surface when they are perfected, and to sow them at a proper season.—This plant is a native of most parts of Europe. Mr. Miller observed it in great plenty in the meadows near Castle Bromwich in Warwickshire, in the beginning of September; and says, that the country people call the flowers *naked ladies*, because they come up without any leaves; a name they also apply to the *Hepatica*, and indiscriminately to any plant which has flowers on naked scapes, appearing at different times from the leaves. It is also found near Derby and Northampton; Bury in Suffolk; in orchards on the borders of Malvern Chase, and the meadows under Malvern Hills, in Worcestershire; near Wallington and Hales-Owen, Shropshire; about Bath, Bristol Warminster, Shepton Mallet, Southgate, and also near Comb in Oxfordshire, with a double flower, and some varieties of colour; besides some parts of Scotland, where however it is not very common. The following are the varieties most cultivated by the florists: 1. The Meadow Saffron, with white flowers; 2. Meadow Saffron, with striped flowers; 3. Broad-leaved Meadow Saffron; 4. Striped-leaved Meadow Saffron; 5. Many-flowered Meadow Saffron; 6. Meadow Saffron with double purplish flowers; 7. Meadow Saffron with double white flowers; and 8. Meadow Saffron with many white flowers. Cattle will not eat it: in a pasture where there were several horses, and which was eaten down rather bare, not a leaf of the Meadow Saffron was bitten, although the grass was closely cropped even under the leaves. Notwithstanding the concurrent testimony of ages has condemned this plant as poisonous, Dr. Stoerck, of Vienna, has taught us that it is a useful medicine: the roots are very acrimonious; and an infusion of them in vinegar, formed into a syrup with the addition of sugar or honey, is found to be a very useful pectoral and diuretic. It seems to resemble Squill very much in its virtues, but is less acrid and nauseous, though more sedative. Allioni, however, relates, that he has found the Squill to be more safe and efficacious than the Meadow Saffron; and Meyrick also informs us, “that, indiscreetly used, this root is poisonous, two drachms having killed a large dog after twelve hours of excessive torment: it operated violently by vomit, stool, and urine. A single grain only, being swallowed by a person in health, by way of experiment, produced heat in the stomach, and soon after flushings in various parts of the body, with frequent shiverings, which were followed by colic-like pains, after which he felt an itching in the loins and urinary passages, and soon after that a continual inclination to make water, with a tremor and pain in the head, great thirst, a very quick pulse, and other disagreeable symptoms. Yet, notwithstanding these effects, it is, when properly prepared, a safe but powerful medicine. The best way of preparing it is, to make it into a kind of syrup, by digesting an ounce of the fresh roots, sliced in a pint of white-wine-vinegar, over a gentle fire, for the space of forty-eight hours, and then mixing twice its weight of honey with the strained liquor, and letting it afterwards boil gently until it becomes of a proper consistence: this syrup is agreeably acid, gently vellicates or bites the tongue, is moderately astringent, and excellent for cleansing the tongue from mucus: in an increased dose, it vomits and sometimes purges, but its most common operation is by urine, for which it is a remarkably powerful medicine: the dose at first should be but small, half a tea-spoonful twice or thrice a day is enough to begin with, and the quantity may afterwards be gradually

increased, as the stomach will bear it, or the case may require. It has been given with the most astonishing success in dropsies, and tertian agues, and it frequently succeeds as an expectorant when all other means fail.

2. *Colchicum Montanum*. Leaves linear, spreading very much. The leaves of this species come up soon after the flowers decay, and continue green all the winter, like the Saffron; they are long, narrow, and spread on the ground, decaying in June; the flowers, which appear earlier than the common sort, are of a reddish purple colour, and come forth in August and September.—Native of Spain, Portugal, Italy, the south of France, and Switzerland.

3. *Colchicum Variegatum*; *Variegated Meadow Saffron*. Leaves waved, spreading. The leaves of this are smaller than those of the common sort, for the most part three in number, and of a paler and fresher green colour, broad at the bottom, a little pointed at the end, waved about the edges, and lying close upon the ground; root not so large as that of the common sort; flowers smaller, but very beautiful, whitish, with deep blue or purple spots. It flowers late, frequently not till October or November, and is somewhat tender.—Native of the Greek islands.

Coldenia; a genus of the class Tetrandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets lanceolate, erect, length of the corolla. *Corolla*: one-petalled, funnel-form, with the opening pervious; border patulous, obtuse, four-cleft. *Stamina*: filamenta four, inserted into the tube; antheræ roundish. *Pistil*: germina four, ovate; styles as many, capillary, length of the stamina; stigma simple, permanent. *Pericarp*: none; fruit ovate, compressed, scabrous, acuminate, terminated by four beaks. *Seeds*: two, muricate, two-celled. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Corolla*: funnel-form. *Styles*: four. *Seeds*: two-celled.—One species only is known,

1. *Coldenia Procumbens*. An annual plant, the branches of which trail on the ground, extending nearly a foot from the root, and dividing into many smaller branches; leaves alternate, egg-shaped, roundish at the summits, deeply crenated, clothed with white hairs; corolla of a pale blue colour, and very small.—Native of the East Indies. This plant is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each put into a separate small pot, plunged into a hot-bed of tanner's bark, observing to shade them until they have taken fresh root, after which they should have air admitted to them every day in proportion to the warmth of the season, and gently watered two or three times a week in warm weather, but they must not have too much moisture; they require always to remain in the hot-bed, where they will flower in June, and ripen seed in September.

Coleworts, *Coleseed*, *Colliflower*. See *Brassica*.

Collinsonia: a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, two-lipped; upper lip three-cleft, reflex, wider; lower lip two-parted, more erect, subulate, permanent. *Corolla*: one-petalled, unequal; tube funnel-form, many times longer than the calix; borders five-cleft; upper divisions obtuse, very short, the two upper ones reflex; lower lip longer, many-cleft, capillary. *Stamina*: filamenta two, bristle form, erect, very long; anthera simple, incumbent, compressed, obtuse. *Pistil*: germen four-cleft, obtuse, with a larger glandule lying below the germen; style bristle-form, length of the stamina, inclined to one side; stigma bifid, acute. *Pericarp*: none; calix cherishes the seeds in its bottom, and is ringent, with an irregular mouth. *Seed*: single, globose.

ESSENTIAL CHARACTER. *Corolla*: unequal. *Calix*: of the fruit one-leaved, toothed; of the flower, bifid. *Seed*: one under the calix of the flower.—The species are,

1. *Collinsonia Canadensis*; *Nettle-leaved Collinsonia*. Leaves ovate, both they and the stems smooth. It has a perennial root, and attains to the height of four or five feet in America, but seldom grows above three feet high in England: the stalks decay in the autumn, and fresh shoots come out in the spring; they are square, with heart-shaped leaves, opposite, and serrate; the flowers are produced at the extremity of the stalks, in loose spikes; they are of a purplish yellow, and appear in July: the seeds ripen in autumn; one seed only in general attains to maturity, the others being almost always abortive; this is globose, ash-coloured, obscurely reticulated with dusky veins.—Native of North America, in Pennsylvania, and that latitude, in little woods, and among bushes, in a rich soil. Mr. Barton was the first who discovered and sent it to Europe: it has a peculiar and very strong, but agreeable scent, and is reputed to be an excellent remedy against pains in the limbs, and a cold, if the affected parts be rubbed with it: a decoction of it is also said to have cured the bite of the rattlesnake. The Americans call it *horseweed*, because the horses eat it in the spring before any other plant comes up.—It may easily be propagated by parting the roots in October: they should be planted at three feet distance, for they require much nourishment to make them thrive, which they will do in the open ground, if planted in a sheltered situation: unless, however, it be kept warm and duly watered, it seldom flowers well; therefore many persons keep them in large pots; but these very rarely produce good seeds: whereas those which stand in the full ground, and are regularly watered, will ripen seeds very well in good seasons.

2. *Collinsonia Scabriuscula*; *Rough-stalked Collinsonia*. Leaves ovate, subcordate, somewhat hairy; stem somewhat hairy, scabrous.—Native of East Florida: perennial. This species is more tender than the first, and requires the protection of the green-house.

Columbine. See *Aquilegia*.

Columnnea; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-parted, subventriose at the base; divisions erect, equal, lanceolate, permanent. *Corolla*: one-petalled, ringent, villose; tube long, gibbous above at the base; border two-lipped; upper lip straight, emarginate; lower lip three-parted; lateral divisions lanceolate, the intermediate longer and more deeply separated, lanceolate. *Stamina*: filamenta four, of which the two longer are hid under the upper lip; antheræ simple, connected into a little crown. *Pistil*: germen ovate; style filiform, length of the upper lip; stigma bifid, obtuse. *Pericarp*: capsule two-celled, ovate. *Seeds*: numerous, small, lying on a very large receptacle. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Corolla*: ringent, upper lip three-parted, the middle-part vaulted, emarginate, gibbous above at the base. *Antheræ*: connected. *Capsule*: two-celled. *Seeds*: nestling.—As all these plants are natives of hot countries, and in general of the West Indies, they are too tender to live in England out of the stove. They are propagated by seeds sown in a good hot-bed; and when the plants come up they must be treated in the same way as other tender exotics which are kept in the bark-stove.—The species are,

1. *Columnnea Scandens*; *Climbing Columnnea*. Leaves ovate, acute, entire, subvillose; leaflets of the calix entire; corollas and calices pubescent, upper lip undivided. Stem scandent, rooting, angular, striated, succulent, brittle, somewhat hir-

sute; leaves petioled, opposite, small, scarcely nerved; flowers peduncled, solitary, axillary, blood-red, somewhat villose. It is said to be subparasitical.—Native of the Caribbee islands, Martinico, and Guiana, in moist parts of woods at the foot of mountains. The *Columnnea* with a yellowish flower is only a seminal variation.

2. *Columnnea Longifolia*; *Long-leaved Columnnea*. Leaves lanceolate, very long, somewhat serrated, smooth. Stem two feet high, herbaceous, quadrangular, smooth, branched; leaves three inches long, opposite; flowers red, opposite, in simple, long, erect, terminal racemes. Native of the East Indies.

3. *Columnnea Hirsuta*; *Hairy Columnnea*. Leaves ovate, acuminate, serrate, roughly hairy on the upper surface; calycine leaflets toothletted, lanceolate; they and the corollas hirsute, the upper lip bifid. This beautiful vegetable is a native of the cooler mountains of Jamaica; it is very succulent, and grows luxuriantly in every rich and shady soil, throwing its branches frequently to the height of four or five feet, and higher when supported; the stem is moderately thick; the leaves opposite, and alternately larger; the flowers are large, beautifully variegated, and hairy on the outside, like the other parts of the plant; the divisions of the calix are pinnated, somewhat like those of the garden rose. It has an uncommon appearance, and it is highly worthy of cultivation: it flowers in November.

4. *Columnnea Hispida*. Leaves ovate, obtuse, toothletted, hispid-hirsute; leaflets of the calix lanceolate, entire, hairy; stem hairy, rugged.—Native of Jamaica.

5. *Columnnea Rutilans*. Leaves ovate-lanceolate, villose, toothletted; leaves of the calix jagged; corollas villose, the upper lip two-parted.—Native of Jamaica.

6. *Columnnea Stellata*; *Starry Columnnea*. Leaves stellate; flowers solitary; stem creeping. Stem herbaceous, perennial, round, slender, whitish; branches suberect, four inches long, very tender; flowers white, striped with red, hirsute, axillary, peduncled. It is an aquatic plant, of a very pleasing appearance and agreeable smell, and being emollient and cooling, it is used as a wash by the women.—Native of Cochin-china, where it is cultivated in pots and tubs filled with water, having earth at the bottom.

Colutea: a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-shaped, five-cleft, erect, nearly equal, permanent. *Corolla*: papilionaceous. *Standard*, *wings*, and *keel*, differ in figure and various proportion; the wings are pressed close together, lanceolate. *Stamina*: filamenta diadelphous, single, and nine-cleft, ascending; antheræ simple. *Pistil*: germen oblong, compressed, attenuated to each end; style ascending; stigma is a bearded line, extended from the middle of the style to its tip, from the upper part. *Pericarp*: legume very large, very broad, inflated, transparent and membranaceous, the upper suture erect, the lower gibbous, one-celled, gaping on the upper suture at the base. *Seeds*: several, kidney-shaped. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Legume*: inflated, gaping on the upper suture at the base.—The plants of this genus are, in general, easily distinguished by their membranaceous inflated pod.—The species are,

1. *Colutea Arborescens*; *Common Bladder-Senna*. Leaflets oval-obcordate; standard gibbous, abbreviated. This species has several woody stems, which attain to the height of twelve or fourteen feet, sending out many woody branches, with winged leaves, composed of four or five pairs of oval lobes, placed opposite, terminated by an odd one; these are indented at the top in form of a heart, and are of a grayish

colour. From the wings of the leaves come out slender peduncles, about two inches long, each sustaining two or three yellow flowers, whose standard is reflexed and large, with a dark-coloured mark on it. In England it flowers from June to August.—It is a native of the south of France, of Italy, and the warmer parts of Switzerland, and Carniola. Mr. Ray observed it about Montpellier, and in many parts of Italy, especially on Mount Vesuvius, even in the ascent to the crater itself, where there were scarcely any other plants. The leaves are recommended as answering all the purposes of Senna; and Allioni has given particular directions for the preparation of them, as a larger dose of them seems to be required to produce the same effect. The seeds, in the quantity of a drachm or two, occasion vomiting; but the plant itself is said to afford grateful food for cattle.—This, and the second and third species, are very hardy shrubs, which thrive extremely well in the open air, and are generally propagated for sale in the nursery gardens. They are all propagated by sowing their seeds any time in the spring, in a bed of common earth, keeping them clear from weeds when they come up, and transplanting them at the Michaelmas following, either into nursery rows, or into the places where they are intended to remain; for if they be suffered to grow too long in the seed-bed, they are very subject to have downright roots, which render them unfit for transplantation; nor should they be suffered to remain too long in the nursery before they are transplanted, for the same reason. The first sort growing to the height of twelve or fifteen feet, is very proper to intermix with trees of a middling growth in wilderness quarters, or in clumps of flowering trees, where the singularity of their flowers and pods will make a pretty variety, especially as these trees usually begin flowering by the end of May, and are seldom destitute of flowers until September. Mr. Curtis has learned by experience, that a very wet soil proves fatal to the common Bladder-senna. The earwigs also, finding a commodious retreat within the bladders, are very destructive to the seeds. Mr. Miller therefore recommends the hanging lobster-claws, or bowls of tobacco-pipes, on the shrubs, to entice the insects. The third species does not grow so tall as the common, but makes a more regular shrub, and is less liable to split: the flowers of this sort being of a dusky red colour, spotted with yellow, it makes a very pretty variety, and is as hardy as the common sort, and may be propagated by seeds in the same manner. It sends forth many suckers, by which it may also be increased; but the seeds are much to be preferred.

2. *Colutea Cruenta*; *Oriental Bladder-Senna*. Shrubby: leaflets wedge-form, obcordate; standard gibbous, obtuse, very small. This has a woody stem, which sends out many branches on every side, which does not rise above seven or eight feet high. The leaves are composed of five or six pairs of small heart-shaped leaflets, terminated by an odd one. The flowers proceed from the side of the branches, standing upon peduncles, each sustaining two or three flowers, of a dark-red colour, marked with yellow; which appear in June, and the seeds ripen in autumn.—Discovered by Tournefort in the Levant. See the first species.

3. *Colutea Pocockii*; *Pococke's Bladder-Senna*. Shrubby: leaflets ovate; standard gibbous, elongated, ascending. This shrub seldom exceeds six or seven feet high in England. The branches are very slender, and much more pliant than the common sort; the leaves are composed of nine pairs of leaflets, and are much smaller. The flowers also appear a month earlier, and are of a brighter yellow; and as there is a succession of them till late in the autumn, and they are not so liable to be destroyed by the strong winds in summer, the value of this species is much increased.—Native of the Levant.

Dr. Russel, who resided many years at Aleppo, reports, that this shrub is very common in the neighbourhood of that city. See the first species.

4. *Colutea Frutescens*; *Scarlet Bladder-Senna*. Shrubby: leaflets ovate-oblong. This is a hoary shrub, with tomentose leaflets, smooth on the upper surface: height from two to four feet: in favourable seasons and in a warm situation, plants of three years' standing will be six feet high, with large heads, and all the branches covered with flowers, making a very fine appearance. Those plants, however, which are exposed to the air, seldom last beyond two years, and are generally destroyed in severe winters; but they make much stronger plants while they last, and produce a greater number of flowers than those which are housed. The flowers appear in June, are of a fine scarlet colour, intermixed with silvery leaves, affording an agreeable variety.—Native of the Cape of Good Hope. This is tender, and cannot endure the open air in severe English winters. It is propagated by seed sown early in the spring, upon a warm border of light earth. The plants will flower in August, and ripen seeds very well in favourable autumns; but if the seeds be sown upon a moderate hot-bed in the spring, the flowers will appear as early as July, which gives them a fine opportunity of ripening their seed during the hot weather. They must never be transplanted, except while young, for when they are grown large they will not bear removing. In a well-sheltered situation, they will sometimes live in the open air for three or four years, growing to have large heads, which make a very fine appearance when they are in flower, and the flowers of which also continue much longer in beauty than those produced by plants which have been more tenderly treated.

5. *Colutea Perennans*; *Perennial Bladder-Senna*. Herbaceous: leaflets ovate-oblong, pubescent. Root perennial; stems erect, round, striated, pale green, annual, quite simple, or with almost barren branchlets; flowers small, and without scent; corolla flesh-coloured.—It flowers in August; and is a native of Africa.

6. *Colutea Herbacea*; *Annual Bladder-Senna*. Herbaceous: leaflets linear, smooth. Annual; corollas dark blood-red, with a striated standard, the length of the wings and keel; stem a foot and a half high, and slender, dividing at top into three or four branches.—Native of the Cape. It is a low annual plant, which seldom grows more than a foot and a half in height: the flowers are small, and having but little beauty, it is seldom preserved but in botanic gardens. The seeds of this sort must be sown upon a moderate hot-bed in the spring, and the plants put into small pots, and brought forward in another hot-bed. They flower in July; when they may be exposed in the open air in a warm situation, where the seeds will ripen in September, and the plants soon after decay.

7. *Colutea Fistulosa*. Herbaceous: leaflets ovate, complicate, pubescent underneath. Stems angular, striated, fistulous, flowering the second year; calix pubescent; corolla small, whitish or red, with blood-red streaks.—This appears to be only a variety of the fifth species.

8. *Colutea Americana*. Shrubby: leaflets ovate, emarginate; legumes oblong, compressed, acuminate. It has a shrubby stalk, rising to the height of fourteen feet; the leaves are composed of three pairs of oval leaflets, terminated by an odd one; the flowers are of a bright yellow.—Sent from Vera Cruz by Dr. Houston. It will not bear the open air in England; but is propagated by seeds sown on a hot-bed in the spring; and when the plants are two inches high, they should be each transplanted into a separate small pot filled with light earth, and plunged into a hot-bed of tanner's bark, observing to shade them till they have taken fresh root; after

which they must be treated in the same way as other plants from the same climate, always keeping them in a stove, which should be of a moderate temperature.

9. *Colutea Procumbens*. Stems trailing; leaflets ovate-oblong, tomentose; flowers axillary, on very long peduncles. This species has many slender woody stems, which trail on the ground, and are divided into many smaller branches; leaves composed of twelve or fourteen pairs of leaflets, terminated by an odd one. The flowers are very small, of a purple colour, and stand three or four together, upon very long slender peduncles: they appear in June and July, and ripen seeds in autumn.—Native of the Cape. This is a perennial plant, which, if sheltered in the winter, will continue several years. It is raised from seeds on a moderate hot-bed in the spring.

Comarum: a genus of the class Icosandria, order Polygynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, ten-cleft, very large, spreading, coloured; alternate divisions smaller, inferior, permanent. *Corolla*: petals five, oblong, acuminate, three times smaller than the calix on which they are inserted. *Stamina*: filamenta twenty, subulate, inserted into the calix, length of the corolla, permanent; antheræ lunular, deciduous. *Pistil*: germina numerous, roundish, very small, collected into a head; styles simple, short, from the sides of the germen; stigmas simple. *Pericarp*: none; common receptacle of the seeds ovate, fleshy, very large, permanent. *Seeds*: numerous, acuminate, covering the receptacle. ESSENTIAL CHARACTER. *Calix*: ten-cleft. *Petals*: five, smaller than the calix. *Receptacle* of the seeds: ovate, spongy, permanent.—The only species is,

1. *Comarum Palustre*; *Marsh Cinquefoil*. This plant has creeping woody roots, which send out many black fibres, penetrating deep into boggy ground; stems many, herbaceous, about two feet high, generally inclined to the ground; at each joint is one leaf, composed of five, six, or seven leaflets. The petals are not more than a third part of the size of the calix.—Native of most parts of Europe, on boggy ground. A few plants grow upon a bog at Hampstead; but the nearest place to London where it grows wild in plenty, is in the meadows near Guildford in Surry. It is found at Selburne in Hampshire, near Bromsgrove Lickey in Worcestershire, Gamlingay in Cambridgeshire, in Norfolk, near Colchester in Essex, Giggleswick Tarn near Settle, and also in Scotland and Ireland. It flowers in June. The roots dye wool of a dirty red colour; and have astringency enough, with other plants of the same order, to tan leather. The Irish rub their milk-pails with it, to make the milk appear thicker and richer. Goats eat it. Cows and sheep are not fond of it. Horses and swine refuse it.—There is a variety with thicker and more villose leaves, which grows plentifully in the north of England, and in Ireland; but after one year's growth in a garden, it cannot be distinguished from the common sort.—As this plant is a native of bogs, it cannot well be preserved in a garden, except it be planted in a soil resembling that in which it naturally grows. The roots may be removed from the place of their growth in October, and will be in no danger of failing, if they be planted in boggy ground.

Combretum; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, superior, bell-shaped, four or five toothed, deciduous. *Corolla*: petals four or five, ovate, acute, inserted into the calix, and scarcely longer than it. *Stamina*: filamenta eight or ten, bristle-form, erect, very long; antheræ a little oblong. *Pistil*: germen inferior, linear; style bristle-form, length of the stamina; stigma acute. *Pericarp*: none, except the crust of the seed. *Seed*: single, four or five angled;

angles membranaceous, acuminate. ESSENTIAL CHARACTER. *Calix*: four or five toothed, bell-shaped, superior. *Corolla*: four or five petalled, inserted into the calix. *Stamina*: very long. *Seed*: one, four or five angled; the angles membranaceous.—The species are,

1. *Combretum Laxum*. Spikes lax; leaves opposite. It is a shrub, with round scandent branches, the younger ones brachiate; leaves three inches long, petioled; spikes erect, three inches long, axillary, and terminating; flowers small, whitish on very short pedicels.—Native of the West Indies.

2. *Combretum Secundum*. Spikes in one row; leaves opposite. A small tree, twelve feet high, supporting itself on other trees by its round and very long branches; leaves four inches long, ovate-oblong; flowers very numerous, with scarcely any scent, yellowish-green colour, except the antheræ, which are red, all turned upwards and erect, altogether appearing like a crest. The broken branches and the bruised leaves have a fetid and very unpleasant smell.—Native of Carthage in South America, and also of Guiana.

3. *Combretum Purpureum*. Leaves ovate-oblong, both they and the calices naked; spikes simple, directed one way. This is a smooth shrub, with round brachiate branches; flowers copious, scattered; corolla purple; seed roundish, retuse, very smooth, of a shining golden colour.—Native of Madagascar, and the East Indies.

4. *Combretum Decandrum*. Leaves opposite, oblong, acuminate; racemes lax; bractes larger than the flower; flowers decandrous, in two rows, white.—Native of woody mountains in the East Indies.

5. *Combretum Alternifolium*. Leaves alternate; flowers ten stamined. This is a weak branching shrub, climbing to twenty feet in height, with prickles on the older branches; pedicels very short; flowers small and very numerous, coming out usually before the leaves.—Native of Carthage, flowering in May and June, and fruiting in July and August.

Cometes; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre three-flowered, (flowers sessile) four-leaved; leaflets oblong, equal, spreading, ciliate-hispid; perianth four-leaved; leaflets oblong, equal, length of the involucre. *Corolla*: none. *Stamina*: filamenta four, capillary, length of the perianth; antheræ roundish. *Pistil*: germen roundish; style filiform, length of the flower; stigma three-cleft. *Pericarp*: capsule trilocular. *Seed*: solitary. ESSENTIAL CHARACTER. *Involucre*: four-leaved, three-flowered. *Calix*: four-leaved. *Capsule*: trilocular.—The only known species is,

1. *Cometes Alterniflora*. Root annual; stem herbaceous, a foot high, round; leaves opposite, sessile, obovate, acuminate, very entire, smooth; peduncles in pairs, terminal and axillary.—Native of Surat.

Comfrey. See *Symphytum*.

Commelina; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: spathe cordate, converging, compressed, very large, permanent. *Corolla*: petals six, of which the three exterior are small, ovate, concave, resembling a perianth; the three inferior ones alternate, very large, roundish, coloured; nectaries three, resembling stamina, seated on their proper filamenta, cruciform, horizontal. *Stamina*: filamenta three, subulate, reclined, agreeing in figure and circuit with the filamenta of the nectary, but inferior to them; antheræ ovate. *Pistil*: germen superior, roundish; style subulate, revolute, length of the stamina; stigma simple. *Pericarp*: capsule naked, nearly globular, three-celled, three-valved. *Seeds*: two, angulated. ESSENTIAL CHARACTER. *Corolla*: six-petalled. *Nectaries*: three, cross-shaped, pedicelled.—Every species of this genus

is propagated by seeds, and the first will even grow if planted in the full ground. If the seeds be sown in a warm border of light earth in autumn, the plants will rise early in the spring, and will produce good seed, if the season be favourable; whereas those which are sown in the spring often lie long in the ground, and rarely ripen seed. These plants have but little beauty; so that two or three of each sort is all that are worth retaining. The seeds should be sown in autumn; where the plants are designed to remain, or else permitted to scatter, and the plants will require nothing but to be kept free from weeds.—The species are,

* *With two Petals larger.*

1. *Commelina Communis*; *Common American Commelina*. Corollas unequal; leaves ovate-lanceolate, acute; stem creeping, smooth. This is an annual plant, having several trailing stalks, that put out roots at the joints; at each joint is one leaf, smooth, dark green, nerved, embracing the stalk; flowers axillary, two or three together, on short peduncles; corolla composed of two large blue petals, and four small green ones; leaves resembling those of *Sopewort*. It flowers in June and July, and the seeds ripen in autumn.—Native of America, the West Indies, and Africa.

2. *Commelina Africana*; *African Commelina*. Corollas unequal; leaves lanceolate, smooth; stem prostrate. Root fibrous; stalks many, trailing, three feet long, putting out roots at every joint, so that it will cover a large surface, where it has room to spread; leaves like those of the first species; the flowers are larger, and of a deep yellow colour.—Native of Africa. It seldom ripens seed in England; but the roots send out offsets, by which it is easily propagated; but it is too tender to live in the full ground in winter, unless placed in a warm sheltered situation; it should therefore be planted in pots, and sheltered under a common frame in winter, and exposed abroad in summer. The best time to transplant and part these roots, is by the end of March. It flowers in July, and ripens seed in autumn.

3. *Commelina Benghalensis*; *East India Commelina*. Corollas unequal; leaves ovate, obtuse; stem creeping. Root annual; stems numerous, diffused, about a span high, hirsute, jointed; branches alternate; leaves, before they are open rolled in, from an inch to an inch and a half in length, nerved, pubescent, waved; peduncle within the spathe double, one slender, longer, one-flowered, the other thicker, channelled, bearing from two to four flowers, on jointed, round, inflex pedicels; the two inner petals very large, blue, the four outer pale blue; nectaries yellow.—Native of Bengal and Cochin-china. This, like all the other species of this genus, except the first, second, and sixth, are so tender that it will not grow unless sown upon a moderate hot-bed in the spring, and must be transplanted to a moderate hot-bed when they are two inches high, in order to bring them forward. When they have again taken root, a large share of fresh air should be admitted to them every day in warm weather, to prevent their growing weak. In June they may be taken up carefully, and transplanted into a border of warm light earth, observing to shade them until they have taken fresh root; after which they will require no further care but to keep them clean from weeds.

4. *Commelina Erecta*; *Upright Virginian Commelina*. Corollas unequal; leaves ovate-lanceolate; stem erect, sub-hirsute, entirely simple. Root perennial; stems a foot and a half high, having a single leaf at each joint, shaped like those of the first sort, and embracing the stem; flowers axillary, at the upper part of the stalk, on short peduncles; petals blue.—Native country unknown.

VOL. 1.—29.

** *With three Petals larger.*

5. *Commelina Virginica*. Corollas nearly equal; leaves lanceolate, subpetioled, bearded on the edge; stems upright, simple, glossy, two feet high; spathes terminating, subcordate; flowers blue, with the petals cordate, and very entire; the lower one on a short pedicel.—Perennial, and a native of Virginia.

6. *Commelina Tuberosa*; *Tuberous-rooted Commelina*. Corollas equal; leaves sessile, oval-lanceolate, subciliate. This has a thick fleshy root, composed of several tubers, somewhat like those of *Ranunculus*, several joining together at the top, where they form a head, and diminish gradually downward; thence arise one or two inclining stalks, which put out side-branches from their lower parts. The flowers are axillary towards the upper part of the stalk, on slender peduncles.—It is said to grow in the mountains of Mexico; and the natives apply it externally for discussing tumors, and internally in hot plethoric habits: it was also sent to Mr. Miller, by Dr. Houston, from Vera Cruz in New Spain. If the roots of this species be taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the spring, placing them on a hot-bed, to forward their shooting, whereby they will become stronger plants than those which rise from seeds.

7. *Commelina Zanonia*; *Gentian-leaved Commelina*. Corollas equal; peduncles thickened; leaves lanceolate; sheaths swelling, hirsute about the edge; bracts in pairs. This has trailing stalks, embraced by narrow grassy leaves. The flowers are produced at the ends of the stalks, upon thick peduncles, which generally have three on each. The corolla has three, equal, large, sky-blue petals, and three smaller which are green. It flowers from June to August, but does not perfect seeds in England.—Native of the West Indies. See the third species.

8. *Commelina Vaginata*; *Sheathed Commelina*. Corollas equal; leaves linear; flowers two-stamined, sheathed with an involucre. Annual; stems ascending, numerous, somewhat scabrous; anthers yellow; spotted with black.—Found by Kœnig in the East Indies.

9. *Commelina Nudiflora*. Corollas equal; peduncles capillary; leaves linear; involucre none; flowers two-stamined. Annual; stem somewhat erect, decumbent at the base, somewhat scabrous, a span in height; flowers from four to six, pedicelled, (without any involucre) nodding.—Found by Kœnig in dry pastures of the East Indies.

10. *Commelina Spirata*; *Spear-leaved Commelina*. Corollas equal; leaves lanceolate; flowers panicled. Annual; stem creeping, ascending, somewhat scabrous. The style and stigmas are spirally convolved, and evolved variously.—Observed near brooks, and in moist places, in the East Indies. It flowers in July and August.

11. *Commelina Cucullata*. Corolla unequal, two-petalled; leaves ovate; involucre cowl'd, turbinate. Stem erect, a span high, creeping at the base, with filiform roots; flowers panicled, minute; the two large petals blue.—It is a weed in the gardens of the East Indies, and Cochin-china.

12. *Commelina Japonica*. Leaves ovate-lanceolate waved; stem erect, angular, hairy; flowers panicled. Stem grooved, erect, hairy, panicled at top, a foot high; flowers on the panicled branches in racemes.—Native of Japan.

Commersonia: a genus of the class Pentandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, corolliferous; divisions ovate, acute. *Corolla*: five-petalled; petals linear, dilated at the base on both sides, with an inflected lobe, spreading; nectary five-parted, within the stamina; divisions lanceolate, erect,

shorter than the petals; corpuscles filiform, five, villose, from the divisions of the nectary. *Stamina*: filamenta five, very short at the bases of the petals; antheræ roundish, twin. *Pistil*: germen globular, villose, with five swellings; styles five, filiform, approximating, short; stigmas globular. *Pericarp*: capsule globular, five-celled, echinate, with long hairy bristles; cells two-seeded. *Seeds*: ovate. **ESSENTIAL CHARACTER.** *Calix*: one-leafed, bearing the corolla. *Petals*: five. *Nectary*: five-parted. *Capsule*: five-celled, echinate.—The only known species is,

1. *Commersonia Echinata*. A tree, with alternate, obliquely ovate, acuminate, serrate leaves, hoary underneath; flowers white, minute, panicle, hoary.—Native of Otaheite, the other Society Isles, and the Moluccas.

Comocladia; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, three-parted, spreading, coloured; divisions roundish. *Corolla*: petals three, ovate, acute, flat, very spreading. *Stamina*: filamenta three, subulate, shorter than the corolla; antheræ roundish, incumbent. *Pistil*: germen ovate; style none; stigma obtuse, simple. *Pericarp*: drupe oblong, crooked, marked above with three dots. *Seed*: nut membranaceous, the figure of the drupe. **ESSENTIAL CHARACTER.** *Calix*: three-parted. *Corolla*: three-parted. *Drupe*: oblong, with a two-lobed nucleus.—These plants are propagated by seeds, which can only be obtained from those countries where they naturally grow, and should be sown in pots, and plunged into a hot-bed; when they are fit to remove, they must be each planted in a small pot, and plunged into a tan-bed, and in the autumn into the bark-bed in the stove, where they must be treated as other tender plants.—The species are,

1. *Comocladia Integrifolia*. Leaflets entire. It seldom exceeds twenty feet in height; trunk erect, dividing into few branches, adorned at the end with pinnated smooth leaves, two feet long, like a frond; flowers very numerous, small, sessile, scentless, of a deep-red colour, in loose panicle racemes, a foot and a half long; many of them have the calix and corolla four-parted, with four stamina. The whole tree abounds in a watery and slightly glutinous sap, which grows black in the air, and stains the hands so deeply with black, that it can scarcely be washed out. The fruit is eatable, but not inviting; and the wood is hard, of a fine grain, and reddish colour.—Native of Domingo and Jamaica, where it flowers in December, January, and February.

2. *Comocladia Dentata*. Leaflets egg-shaped, neuter, toothed, somewhat prickly, veined, and villose underneath. A tree, much like the first; the trunk is upright, with few branches; and the leaves a foot and half long, in tufts at the ends of the branches. The juice is milky, glutinous, turning very black, not to be washed out from the skin or cloth. If the tree be ever so slightly wounded, it has a strong smell of dung.—Native of Cuba, where the inhabitants imagine it to be dangerous to sleep under it.

3. *Comocladia Illicifolia*. Leaflets roundish, angular-spiny, smooth on both sides.—Native of the West Indies.

Composts. See *Manures*, Vol. II. p. 86.

Comptonia; a genus of the class Monœcia, order Triandria.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: ament cylindrical, loosely imbricate all round with concave, kidney-form, acuminate, caducous, one-flowered scales; perianth two-leafed; leaflets equal, boat-shaped, shorter than the scale of the ament. *Corolla*: none. *Stamina*: filamenta three, shorter than the calix, forked; antheræ six, two-valved. *Female Flowers.* *Calix*: ament ovate, closely imbricate all round with one-flowered scales, as in the male;

perianth six-leafed; leaflets opposite, in pairs, filiform, membranaceous at the base, many times longer than the scales of the ament. *Corolla*: none. *Pistil*: germen roundish; styles two, capillary. *Pericarp*: none. *Seed*: nut oval, one-celled, valveless. **ESSENTIAL CHARACTER.** *Male*: ament. *Calix*: two-leafed. *Corolla*: none. *Antheræ*: two-parted. *Female*: ament. *Calix*: six-leafed. *Corolla*: none. *Styles*: two. *Nut*: oval.—The only known species is,

1. *Comptonia Asplenifolia*; *Fern-leaved Comptonia*. It rises with slender shrubby stalks, nearly to the height of three feet, which are hairy, and divided into several slender branches; leaves three inches long or more, dark green, hairy on the under side, and sitting close to the stalks. The aments of male flowers come out on the side of the branches between the leaves; they are oval, and stand erect. The fruit is a bony nut, the size of a hazel nut, inclosing a single seed. It flowers in England from March to May, and is a native of North America, among Firs, in the county of Lancaster, and on the banks of the Northampton river. When planted here in a loose moist soil, it thrives very well, sometimes creeping at the roots, and sending up suckers plentifully, as in its native country. It may be propagated by these suckers, and will endure English winters very well.

Conferva, or *River-weed*; a genus of the class Cryptogamia, order Algæ.—**GENERIC CHARACTER.** Simple, uniform, hair-like, thread-shaped fibres; which are either continuous or jointed. **ESSENTIAL CHARACTER.** Unequal tubercles, in very long capillary filamenta. Linneus specifies twenty-one species in his system of vegetables; these are all inhabitants of the water, some in fresh, but more in salt water. Dr. Withering has sixty species, which are natives of England, in his fourth volume of the *Botanical Arrangement of British Plants*, published in 1796. A singular instance of irritability has been observed by Major Vellely in the *Conferva Corollina*, upon its being immersed, when quite recent, into fresh water: after it had been in the water a few minutes, several fibres were observed to move in an horizontal direction, with a quick convulsive twitch, and to stop suddenly; this they continued to do for some length of time; and the same effect may be produced several times, provided the plant be fresh. The experiment does not succeed in salt water.

Conium; a genus of the class Pentandria, order Digenia.—**GENERIC CHARACTER.** *Calix*: umbel universal with many spreading rays; partial similar. Involucre universal, many-leafed, very short, unequal; partial halved, three-leafed; perianth proper, scarcely observable. *Corolla*: universal, uniform; proper of five petals, inflex, heart-shaped, unequal. *Stamina*: filamenta five, simple; antheræ roundish. *Pistil*: germen inferior; styles two, reflex; stigmas obtuse. *Pericarp*: none. *Fruit*: nearly globose, five-streaked, the streaks notched, bipartite. *Seeds*: two, convex on one side, almost hemispherical, striated, flat on the other side. **ESSENTIAL CHARACTER.** *Partial Involucre*: halved, three-leafed. *Fruit*: nearly globular, five-streaked, notched on each side. The species are,

1. *Conium Maculatum*; *Common Hemlock*. Seeds striated. Root biennial, resembling that of a small parsnip; stem from three to four feet and upwards in height, hollow, round, shining, smooth, covered with a bluish powder which easily wipes off, spotted and streaked with livid purple, branched and striated towards the top; bottom-leaves very large, two feet in length, of a dark green colour, but paler underneath, shining, superdecimipinnate, or several times pinnate; pinnules oblong, gashed, and serrate; petiole spotted, smooth, fistulous, succulent, round, being scarcely flattened at top; sheath grooved;

rays of the umbel ten to twelve, of the umbellule fifteen or sixteen; calix entire; corolla white: outer petals largest; fruits ovate, gibbous, with compressed ribs, waved before it is ripe, but becoming almost straight; seeds brownish, resembling those of aniseed, with five notched elevated ridges, three on the back and two on the side.—Hemlock is obviously distinguished by its large and spotted stalk, by the dark and shining green colour of its bottom leaves, and particularly by their disagreeable smell when bruised.—It is common by road and hedge sides, in cultivated ground, among rubbish, and on dunghills; flowering in June and July. According to Linneus, sheep eat the leaves, while horses, cows, and goats, refuse them. Ray informs us, that the thrush will feed upon the seeds, even when corn is to be had; and Mr. Curtis remarks, that scarcely any insects appear to touch it. The dried fistulous stalks of this and several other umbellate plants, are called by the country people *kaxes* or *kecksies*. This plant, which was stigmatized as one of the most noxious of vegetable poisons, has of late years been considered as a highly useful and powerful article of the materia medica; and it has been proved by indisputable experiments, that though highly deleterious when imprudently used, it has been productive of considerable benefit in cases which have resisted the usual methods. It has been particularly celebrated in cancerous cases; the leaves are frequently employed in poultices, fomentations, and plaisters, to discuss and disperse hard tumors: taken internally in any considerable quantity, they occasion disorders of the senses, convulsions, and sometimes death. The dried leaves, put into little bags, and boiled for a few minutes in water or milk, then squeezed from the superfluous moisture, and applied warm to gangrenous sores check the progress of the mortification; and procure a separation of the unsound parts: the same application being made to gouty members, immediately abates the pain, softens and dissolves the hard concretions which frequently are formed about the joints in this disorder, and occasions the next fit to be milder and of shorter continuance. In hard glandulous swellings, and cancerous ulcers, its effects are likewise very considerable: and though some have made a trial of it without receiving any benefit, there has hitherto no instance occurred of its proving prejudicial to any: Baron Stoerck recommends an extract made from the juice of the plant, to be taken internally at the same time, and for the same purposes; and relates a number of cases, wherein the worst kinds of ulcers, glandular swellings, fistulas, and cancers, were effectually cured by it. The manner in which he orders the extract to be taken, is, to begin with giving one pill of two grains twice a day, then three times, and after that gradually increase the number, till six or more of them are taken for a dose. Withering recommends the extract of Hemlock, when prepared with attention and accuracy, as a valuable addition to medicine. "Not" says he, "that I have been a witness to any cures performed by its use, either in occult or ulcerated cancers, but I have never given it without mitigating the pain, and producing an alteration for the better in the discharge. Fifteen or twenty grains of the powdered leaves, taken twice or three times a day, have been found of very great efficacy in obstinate rheumatic complaints, and several other disorders, which are usually supposed to arise from an acrimonious state of the fluids." The following is Dr. Withering's method of preparing this powder of the dried leaves: Gather them about the end of June, when the plant is in flower; pick off the little leaves, and throw the stalks away; dry these small leaves in a hot sunshine, or in a tin dripping-pan, or other convenient vessel, before the fire; preserve them in bags of

strong brown paper, or powder them and keep them in glass phials, and put them away in a drawer, or place where no light can come upon them, for the light not only takes away their fine green colour, but also their virtue. When administered with prudence, it agrees with all ages and constitutions; joined with pectoral medicines, it promotes perspiration, and has been of great utility in the falling sickness and convulsions: taken inwardly, and applied outwardly at the same time, it abates inflammations of the eyes, takes away pain, and occasions sleep; and though it has all the good properties of opium, it never produces thirst, or occasions the head-ache, which that drug generally does; nor does it bring on costiveness, but generally produces a loose stool or two the day following. It possesses the property of rendering the corrosive ichorous discharge from cancerous ulcers mild, and of a better consistence, and has been given with great advantage to such as are troubled with bloody ulcers, gleet, and other painful and weakening discharges: it powerfully promotes the menses, particularly when they have been suddenly restrained, by cold, or any other external accident; it moreover cures the itch, promotes perspiration in some, and a copious flow of urine in others; and though not a cure for cancerous complaints, it is one of the best palliatives in those dreadful disorders, and far superior to opium. The best way of administering Hemlock is, to give the powder, or extract in very small doses at first, which are to be increased gradually till the full dose is arrived at, which may be known by its producing giddiness in the head, a motion of the eyes as if something pushed them outwards, a slight sickness attended with a universal trembling of the body, and a loose stool or two the day after. One or more of these circumstances are the signs of a full dose, which should be continued for a considerable time, as little advantage can be expected without a perseverance in the use of it. When Hemlock is imprudently eaten, or taken in too large doses, it occasions giddiness in the head, dimness of sight, a sort of madness, coldness of the extremities, convulsions, and even death. The mode of obtaining relief in such cases, is to empty the stomach as soon as possible, by means of the most active emetics, and then to give frequent doses of sharp vinegar.—This plant may be easily propagated from seed, which will come up plentifully if permitted to scatter, and will only require to be thinned for medical use.

2. *Conium Rigens*; *Fine-leaved Hemlock*. Seeds somewhat muricated; peduncles grooved; leaflets channelled, obtuse. Root perennial; stem shrubby, short, stiff; branches longer, spreading very much, remote; leaves twice-winged, somewhat fleshy, doubled, obtuse, crenulate, hard; florets all fertile, white.—Native of the coast of the Cape of Good Hope, where it flowers in June. The seeds of this and the following species, should be sown in pots in autumn, soon after they are ripe, and placed under a common frame in winter, where they may always be exposed to the open air in mild weather, and be only covered in severe seasons; they appear early in the spring, and must then be as much in the open air as the weather will permit, otherwise they will be drawn up weak: they do not bear transplanting well, and should therefore be thinned to four or five in a pot, after which they only require to be kept clean, and to be watered in very dry weather.

3. *Conium Africanum*; *Rue-leaved Hemlock*. Seeds muricated; petioles and peduncles glossy; leaflets flatish, not channelled, smelling like Smallage or Celery; peduncles opposite to the leaves, not furrowed, as in the foregoing; many of the florets barren; the central fruit sessile; seeds longer than in the common sort.—Annual: native of the Cape.

4. *Conium Rugosum*. Seeds wrinkled. Stem somewhat shrubby.—Native of the Cape.

5. *Conium Tenuifolium*. Root and stem-leaves simple, linear. Stem herbaceous, upright, a foot high, scarcely branched, slender, round, smooth, slightly streaked; leaves very narrow, a little wider at the base, and somewhat sheathing, very smooth, the lower ones four inches long or rather more; stem-leaves remote; umbel small, five-rayed, about eight or ten flowers in the umbellule: seeds oblong, striated, small, smooth; styles permanent, divaricating.—Native of the Cape of Good Hope.

Connarus; a genus of the class Monadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, five-parted, erect, tomentose, permanent. *Corolla*: petals five, lanceolate, erect, equal. *Stamina*: filamenta ten, subulate, erect, connected at the base, alternately of the length of the flower, and alternately very short; antheræ roundish. *Pistil*: germen roundish; style cylindric; stigma obtuse. *Pericarp*: capsule oblong, gibbous, one-celled, two-valved. *Seed*: single, ovate, large. **ESSENTIAL CHARACTER.** *Style*: one. *Stigma*: simple. *Capsule*: two-valved, one-celled, one-seeded.—The species are,

1. *Connarus Monocarpus*; *Ceylon Sumach*. Leaves alternate, trifoliate, on long petioles; leaflets ovate, smooth, entire, thick, each on short petiolules, and remaining green the whole year; flowers in large upright racemes, at the ends of the branches; they are small, hairy, and of a greenish yellow colour, and rarely produce seeds in Europe. It rises with a woody stalk, about eight or ten feet high, hard, rigid, covered with a blackish bark, dividing at top into two or three branches.—Native of Ceylon. It is usually propagated in gardens, by laying down the young branches, which if tongued, in the manner practised for Carnations, and duly watered, will put out roots in twelve months, when they may be cut off from the old plants, and each planted in a separate small pot, filled with fresh light earth, plunged into a moderate hot-bed to forward their taking new root, observing to shade them from the sun every day, and to water them as they may require it. They should afterwards be treated in the same manner as other exotics, placing them in the dry-stove in winter, and for about three months in the summer in a warm sheltered situation in the open air.

2. *Connarus Africanus*. Leaves ternate; lanceolate, elliptic; veins protuberant underneath; branches round, smooth; flowers in a terminating spreading panicle.—Native of the mountains of Sierra Leone.

3. *Connarus Santaloides*. Leaves pinnate; leaflets ovate-acuminate; peduncles axillary, aggregate; flowers racemed. A tree, the branches round, smooth, with a purplish brown bark; calix ovate, the five segments lanceolate, acute, when in fruit bell-shaped; petals twice as long as the calix; filamenta unequal, the length of the corolla, scarcely united at the base. Native of the East Indies.

4. *Connarus Mimosoides*. Leaves pinnate, with about ten pairs of oval-oblong emarginate leaflets; racemes axillary. A tree, the branches round, villose towards the top; leaves towards the ends of the branches, petioled, alternate, approximating, unequally pinnate, with from nine to eleven pairs of leaflets, on very short petioles, opposite or alternate, the inner ones smaller, smooth, very finely veined on the upper surface, blunt, deeply emarginate, paler underneath; petioles slightly villose.—Native of the island of Nicobar.

Conocarpus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, superior, very small, five-parted, acute, erect, divisions subulate. *Corolla*: petals five, converging, (or none).

Stamina: filamenta either five or ten, subulate, erect; antheræ globose. *Pistil*: germen large, compressed, obtuse, inferior; style single, short; stigma obtuse. *Pericarp*: none, distinct from the seed. *Seed*: single, obovate, with a membranaceous thick margin, projecting on each side. **ESSENTIAL CHARACTER.** *Petals*: five, or none. *Calix*: bell-form. *Seeds*: naked, solitary, inferior. *Flowers*: aggregate.—The species are,

1. *Conocarpus Erecta*; *Jamaica Button Tree*. Erect: leaves lanceolate. This is an upright branching tree, frequently exceeding thirty feet in height; the younger branches are angular; leaves alternate, two to three inches long, on short petioles, and greasy to the touch; the flowers small, and of a yellowish colour.—Native of the West Indies, and all the coasts of America, between the tropics, in great plenty, near the sea and in salt water: it is esteemed the best fuel in those latitudes, and being small, it is of scarcely any other use. The English call it button-tree, and button-wood; the Spaniards *mangle saragoza*. Both this and the second species are preserved in some curious gardens for the sake of variety, but they are plants of no great beauty. They are propagated from seeds, which must be obtained from the places where they naturally grow, as the plants never produce them in Europe. If the seeds be fresh, they will come up very soon when sown upon a hot-bed; and if the plants be potted and preserved in the bark-stove, they will thrive rapidly; but they are too tender to bear the open air in this country, and will not live unless constantly kept in the stove, and treated in the same manner as other exotic plants, observing, as they are natives of swamps, to supply them often with water, but giving them only small quantities in winter. They are evergreen, casting off their old leaves when the new come out.

2. *Conocarpus Procumbens*. Procumbent: leaves obovate; cones somewhat racemed, sessile. It is a very branching shrub.—Native of Cuba, on rocks near the coast.

3. *Conocarpus Racemosa*. Leaves lanceolate-ovate, bluntish; fruits not aggregate. This is a lofty and branching tree, sometimes dividing into three or four trunks close to the ground; the younger branches are shining, red, and opposite; leaves quite entire, shining, thickish, greasy to the touch, deep green, opposite, three inches long, on a red petiole, with two glands at the top of it; the flowers are small and sessile, and have a slight and not an unpleasant smell; the petals are five, and whitish.—Native of the Caribbee islands, and the neighbouring continent, on sandy and muddy shores. The Spaniards call it *mangle bobo*, or foolish mangle; the English *white mangrove*. The Caribbees employ the bark for tanning leather; and this is the only use to which it seems possible to apply these trees.

Conopea; a genus of the class Didynamia, order Angiosperminia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, five-cornered, permanent, five-cleft; segments subovate, acuminate, erect. *Corolla*: one-petalled, ringent; tube oblong, gradually widening; border two-lipped; upper lip erect, emarginate, lower trifid, the middle segments larger, concave. *Stamina*: filamenta four, two larger, fastened at bottom to the tube of the corolla; antheræ sagittate. *Pistil*: germen roundish; style filiform, hairy; stigma two-lobed. *Pericarp*: capsule roundish, one-celled, four-valved. *Seeds*: very many, small, oblong, striated, fixed to a roundish receptacle. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Corolla*: ringent, two-lipped, lower lip trifid. *Stigma*: two-lobed. *Capsule*: one-celled, four-valved, many-seeded.—The only known species is,

1. *Conopea Aquatica*. This is a creeping plant, with

parcels of small fibrous roots at the joints ; it spreads over the neighbouring grass, and on the surface of the water, by the side of which it naturally grows ; the stems and branches are square, and each angle is bordered its whole length by a very thin sharp leaf or wing ; leaves opposite at each joint, clasping, distant three quarters of an inch from each other, kidney-form, plaited at the nerves, and waving on the edge ; flowers either solitary or in pairs, opposite from the axil of the leaves, on a slender peduncle an inch in length ; corolla blue.—Native of Guiana ; flowering in June.

Conservatory. See *Green-house.*

Contrayerva. See *Dorstenia.*

Convallaria ; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix* : none *Corolla* : monopetalous, bell-shaped, smooth ; border six-cleft, obtuse, open, reflected. *Stamina* : filamenta six, subulate, inserted into the petal, shorter than the corolla ; antheræ oblong, erect. *Pistil* : germen globose ; style filiform, longer than the stamina ; stigma obtuse, three-cornered. *Pericarp* : berry globose, three-celled, spotted before maturity. *Seeds* : solitary, or in pairs, roundish. ESSENTIAL CHARACTER. *Corolla* : six-cleft. *Berry* : spotted, three-celled.—The species are,

* *Corollas bell-shaped.*

1. *Convallaria Majalis* ; *Sweet-scented Lily of the Valley.* Flowers on a scape ; root perennial, with numerous round fibres, transversely wrinkled, creeping horizontally just below the surface to a considerable distance. The whole plant is smooth. Leaves radical, two, on long petioles, elliptical, ribbed, entire, acute, four to five inches long, of a bright green colour ; flowers six to eight in a raceme, nodding, white, fragrant ; berry scarlet when ripe. There are several varieties of the Lily of the Valley, as : One, with narrow leaves, mentioned as having been found by Mr. Lawson in Westmoreland, but upon being removed into a garden, it became in all respects like the common sort. A second, with broader leaves, from the Alps, which Mr. Miller informs us retained its difference in the garden in the same soil and situation with the common sort, and therefore he has no doubt of its being a distinct species. A third, with a double variegated flower, supposed to be only a variety of the preceding, though the flowers are much larger, and beautifully variegated with purple, but the roots do not increase so much as the common sort. A fourth, with reddish or red flowers, which Mr. Miller affirms remained the same for forty years ; the flowers are smaller, the stalks redder, and the leaves a darker green, than in the common sort : both this and the white vary with double flowers. The Lily of the Valley claims our notice both as an ornamental and a medicinal plant ; in the former point of view, few are held in greater estimation, because few can boast such delicacy with so much fragrance. When dried, they have a narcotic scent ; and if reduced to powder, excite sneezing, and relieve the head-ache : an extract prepared from the flowers or the roots, partakes of the bitterness as well as of the purgative quality of aloes ; the dose is from twenty to thirty grains : an infusion of the flowers, constantly taken instead of tea, is an excellent remedy for nervous head-aches, trembling of the limbs, and other similar complaints.—The Lily of the Valley is a native of Europe, from Lapland to Italy, in woods. Since the trees on Hampstead Heath near London have been destroyed, it has been but sparingly found there : it is found in lord Mansfield's wood, near the Spaniard ; between Shooter's Hill and Woolwich ; and in Norwood it abounds, where large patches have been observed, with very few flowers and no berries. It may also be met with on Bushy Heath, and Cashioberry in Hertfordshire ; near Chisel-

hurst, in Kent ; near Lee, in Essex ; near Woburn, in Bedfordshire, whence, according to Mr. Miller, the London markets are generally supplied with the flowers ; it has been observed in Wichwood forest in Oxfordshire ; in Beechwood, near Stokenchurch ; in Whitewood, near Gamlingay, Cambridgeshire ; in Norfolk ; in Biddon and Okely woods, Leicestershire ; King's Cliff, Northamptonshire ; Kendal, in Westmoreland ; in the county of Durham ; upon Ingleborough in Yorkshire ; and in Scotland. It flowers in May, and is therefore named May-lily. Gerarde calls it *contall lillie*, and informs us, that in some places it is called *liriconfancie*.—It is propagated by parting the roots in autumn, placing the sets a foot asunder : they require a loose sandy soil and a shady situation. They spread and multiply greatly in a rich soil, but are less productive of flowers. The only culture they require, is to keep them clean from weeds, and to transplant and separate the roots every third or fourth year ; for if this be neglected, the flowers will be small, and few in number. As the Lily of the Valley forces very well, by that means its elegant flowers may be enjoyed in a succession for two months.

2. *Convallaria Japonica* ; *Grass-leaved Lily of the Valley.* Scape ancipital ; raceme drooping ; root-leaves ten or more, linear, drawn to a point at bottom ; three-cornered, flat on one side, entire, striated, bent back, two feet long and upwards ; scape finely striated, smooth, a short span in height, flowering at the end, four-cornered ; corolla white ; divisions lanceolate, patulous, a line in length ; filamenta hardly any ; antheræ linear, acute, brown ; style the length of the corolla ; berry ovate, obtuse, smooth, blue, the size of a pea, one-celled, adorned with the permanent calix. There are two varieties, a larger and a smaller.—They are found near Nagasaki in Japan, and are there used, as well as among the Chinese, in some disorders for which the tubers of the roots preserved with sugar, are supposed to be a remedy.

3. *Convallaria Spicata* ; *Spiked Lily of the Valley.* Scape striated ; raceme spiked ; flowers aggregate. Root fibrous ; root-leaves linear, drawn to a point at bottom, bluntish, much striated ; scape from four inches to a foot in height ; raceme a finger's length, with the flowers scatteringly aggregate ; corolla six-cleft, almost globular, violet.—Native of Japan, flowering in September.

** *Corollas funnel-shaped.*

4. *Convallaria Verticillata* ; *Narrow-leaved Solomon's Seal.* Leaves in whorls. Root perennial, toothed ; stem simple, angular, striated, erect, eighteen inches high ; leaves three or four in a whorl, three or four inches long, and from half an inch to an inch in breadth, bright green, glaucous beneath ; peduncles axillary, solitary, branched, pendulous, two or three flowered ; corollas oblong, greenish-white, striated at the ends, and divided into six bluntish segments, bearded within at the tip, three or four lines in length ; berries globular, blue.—It flowers in June ; and is a native of the north of Europe, Germany, Switzerland, and Carniola. Ray observed it near Spa, and on mount Saleve, near Geneva ; and it was found by Mr. Arthur Bruce in the Den Rechip, four miles N. E. of Dunkeld in Perthshire, in July 1792. All the Solomon's Seals are very hardy plants ; they prefer a light soil and a shady situation, and are therefore very proper for plantations, where, if they be not crowded by shrubs, they will thrive and multiply exceedingly, making an agreeable variety during the summer season. They have a very singular appearance ; and multiply very fast by their creeping roots, in a proper soil and situation. The best time to transplant and part the roots is in autumn, soon after the stalks decay ; but it may be safely done at any time until they begin to shoot in the spring, when the

ground should be dug about them, and kept clean from weeds: they should also have room to spread, and must not be removed oftener than every third or fourth year.

5. *Convallaria Polygonatum*; *Single-flowered Solomon's Seal*. Leaves alternate, stem-clasping; stem angular; peduncles axillary, generally one-flowered. Root twisted, and full of knots; on a transverse section of it, characters appear that give it the resemblance of a seal, from which it derives its name of Solomon's Seal; flowers white, with a green line down the segments, sweet-scented, nodding; berry blue, with three seeds. It varies with a double flower.—Native of the north of Europe, Holland, Germany, Hungary, Switzerland, Carniola, and Piedmont. It is found in England, in the fissures of rocks near Wherf, Settle, and Skipton, and Syke's Wood, near Ingleton, in Yorkshire; and also in Virginia. The variety above mentioned, which has white leaves like Hellebore, and a purplish stalk, was found in woods on the north side of Mendip Hills. Hill says, that the root of this plant is used, and extremely recommended for an outward application against bruises; he recommends it to be taken, when dried and powdered, to assuage violent purgings with bloody stools; and when fresh, beaten up into a conserve with sugar, as a preventive against the whites. The roots of this, and of the seventh species, have been made into bread by the Turks in times of scarcity.

6. *Convallaria Latifolia*; *Broad-leaved Solomon's Seal*. Leaves alternate, stem-clasping, acuminate; stem angular; peduncles axillary, many-flowered. This has at first a sweet and afterwards an acrid taste, and is glutinous; stem from half a foot to two feet in height, round at bottom, and angular from thence the whole length, the angles being more remarkable below the middle of the back of the leaf; it has a short pile of hairs toward the top.—Native of Austria.

7. *Convallaria Hirta*. Leaves alternate, a little embracing the stem; stem hispid; peduncles with about three flowers. Root spreading; stem about a foot high, crooked, angular, sprinkled with white stiff hairs; leaves egg-shaped, broad, ending in a long obtuse point; flowers nodding, unilateral; peduncles axillary, about an inch long.—Native of North America.

8. *Convallaria Multiflora*; *Many-flowered Solomon's Seal*. Leaves alternate, stem-clasping; peduncles axillary, many-flowered. Stem round, from eighteen inches to two or three feet high, simple, leafy, nodding; leaves elliptical, nerved, usually bent upwards and to one side, underneath glaucous; flowers white, green at the base and tip, several together, (from two or three to seven or eight) axillary, on branched compressed peduncles; berries round, of a blackish blue colour, varying to purple and red, and containing three or four seeds. It varies with a double flower.—Native of the north of Europe, Germany, Switzerland, and Carniola: in England it is found at Newbury, and other places in Berkshire; at Bramdean, in Hampshire; Roehill, in Kent; High Wycomb, in Bucks; and Gorleston in Suffolk. The Dwarf Solomon's Seal is found in the woods of Wiltshire. It would be unpardonable to omit what old Culpeper says concerning the distilled water of the whole plant, which, when applied to the face, cleanseth it from morpew, freckles, spots, or marks whatsoever, leaving the place fresh, fair, and lovely, for which it is much used by the Italian dames. The roots are recommended externally as vulneraries, restringents, and discutients; internally, as incrassants and mild corroborants; they have little or no smell, and are rather sweet at first to the taste, which is soon followed by a very slight impression of bitterness and acrimony: their virtues do not appear to be very great. Haller asserts, that the berries excite vomiting, and even the

leaves a nausea. The Turks eat the young shoots in the same manner as we eat asparagus. The medical properties of this and the fifth species are nearly the same.

*** *Corollas wheel-shaped.*

9. *Convallaria Racemosa*; *Cluster-flowered Solomon's Seal*. Leaves sessile; raceme terminating, compound. Stems two feet high, unbranched, with many oblong leaves embracing them at the base, resembling the leaves of Plantain; the flowers are small and white, produced in single spikes at the top, and are succeeded by small red berries, about the same size as in the first sort, and contain two hard shining seeds. It flowers in the beginning of June, and the berries ripen in autumn.—Native of Virginia and Canada. This is a hardy perennial, easily propagated by parting the roots; but thrives most in a light soil, and shady situation. It is called *oile nowote*, child's physic, by the Cherokee Indians.

10. *Convallaria Stellata*; *Star-flowered Solomon's Seal*. Leaves stem-clasping, very many. Stem upright, about two feet high. The flowers come out from the same joints as the leaves, on short peduncles, each of which sustains five or six; they are small, with short tubes of a dirty white, tipped with green, and slightly cut into six parts at top; berries red.—Native of Canada.

11. *Convallaria Trifoliata*. Leaves stem clasping, in threes; racemes terminating, simple. Root perennial, creeping, jointed; flowers small, on long simple peduncles; corolla open, deeply divided; berries red, round.—Native of woods in Siberia.

12. *Convallaria Bifolia*; *Least Solomon's Seal, or One-Blade*. Leaves cordate; flowers four-stamined. This plant seldom exceeds four or five inches high, rising with a single stalk from the root, with one or two heart-shaped leaves, which closely embrace it; the top of the stalk is terminated by a loose raceme of white flowers, which have short tubes, and spread open at the top, where they are divided into four obtuse segments; the fruit is a soft berry, including a hard seed.—Native of the north of Europe, Holland, Germany, Switzerland, and Carniola. As it propagates very fast by its creeping roots, they will soon spread over a large space, unless confined in pots. It is remarkable, that where these and other creeping plants are allowed to spread, they seldom produce any fruit.

Convolvulus: a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, converging, ovate, obtuse, very small, permanent. *Corolla*: one-petalled, bell-shaped, spreading, large, plaited, obscurely five-lobed. *Stamina*: filamenta five, subulate, shorter by half than the corolla; antheræ ovate, compressed. *Pistil*: germen superior, roundish: style filiform, length of the stamina; stigmas two, oblong, broadish. *Pericarp*: capsule enwrapped by the calix, roundish, two-celled, one, two, or three valved. *Seeds*: in pairs, roundish. ESSENTIAL CHARACTER. *Corolla*: bell-shaped, plaited. *Stigmas*: two. *Capsule*: two-celled, with two seeds in each cell.—The general description of this genus is, that the stems are herbaceous, milky, in the greater part twining, in a very few shrubby; leaves alternate; peduncles axillary or terminating, one-flowered, with two bractes, or many-flowered.—The species are,

* *With a twining Stem.*

1. *Convolvulus Arvensis*; *Small or Field Bindweed*. Leaves sagittate, sharp on each side; peduncles generally one-flowered; bractes subulate, at a distance from the flower. Root perennial, milky, white, the thickness of a crow-quill, creeping so as scarcely to be eradicated; stalks numerous, slender, twisted, procumbent, branched, frequently suffocating

plants by twisting round them; leaves alternate, hastate, smooth, running out into two points behind; corolla elegantly variegated with red and white, sometimes wholly white; seeds angular and brown. This plant is the pest of gardens and arable land, and is more destructive than the second species, because that keeps to the hedges for the sake of climbing, whereas this wanders over whole fields, and cannot be rooted out, except by repeated ploughings in dry weather, every atom of which will grow as well as quick-grass, its rival in creeping. Mr. Miller says, it is generally a sign of gravel lying under the surface, and that the roots run very deep into the ground, whence some country people call it *devil's guts*. It is called *corn-bind* in Yorkshire, in other parts *with-bind*, *bind-weed*, *hare-bind*, and *hedge-bells*. The blossoms give a deep yellow or orange tincture to water, which is heightened by alum and alkalies. The root of this plant, says Meyrick, is a rough purgative, and, to such constitutions as can bear the operation, will prove serviceable in the jaundice, dropsies, and other disorders arising from obstructions of the viscera. The best method of administering it is to bruise the roots, and give their expressed juice in strong beer. It is remarkable, that hogs devour the roots of this and the next species in large quantities, without any visible effect. The best way to destroy this and the second species is, according to Mr. Curtis, to plough them up repeatedly in dry weather, and then pick out the roots and burn them. He declares, that the more he cut and hoed them, the more they spread and grew; although Mr. Miller observes, that in an open clear spot of ground, where the plants are carefully hoed down for three or four months, they may be effectually destroyed; for when the stalks are broken or cut, a milky juice flows out, and the roots, being thereby exhausted, soon decay.

2. *Convolvulus Sepium*; *Great or Hedge Bind-weed*. Leaves sagittate, truncate behind; peduncles four-cornered, one-flowered, with heart-shaped bractes close to the flower. Root perennial, white, the thickness of a goose-quill, creeping, and propagating itself exceedingly, so as not to be destroyed without great difficulty; corolla large, and white.—It flowers in hedges, from July to September. The inspissated juice of this plant, taken in doses of twenty and thirty grains, is a powerful drastic purge. Can it then be worth while, says Dr. Withering, to import Scammony from Aleppo, when a medicine with the very same properties, grows spontaneously in many of our hedges? The smallness of the roots, however, in our common Bindweed, would prevent its juice from being collected in the same manner with that which flows on incision from the large root of the Scammony, and which by hardening forms that purgative substance. The country people in Northamptonshire use the root of this plant, fresh gathered, and boiled in ale, as a purge. It would certainly offend a delicate stomach; but it saves the expense of an apothecary, and answers the purpose better than any other medicine, for persons of a strong constitution. See the first species.

3. *Convolvulus Scammonia*; *Syrian Bindweed*, or *Scammony*. Leaves sagittate, truncate behind; peduncles round, bearing about three flowers; corolla pale yellow. The roots are three or four feet long, and from nine to twelve inches in circumference, covered with a light-gray bark, tapering, branched at bottom, and containing a milky juice.—Scammony is a gummy resin, obtained from the milky juice of the root, by clearing away the earth from the upper part of it, and cutting off the top in an oblique direction, about two inches below where the stalks spring from it; then, under the most depending part of the slope, a shell or other convenient receptacle is fixed, to receive the juice, which gradually

becomes hard, and is the genuine Scammony. It is brought from Aleppo and Smyrna, and appears to have been well known to the Greek and Arabian physicians, who used it for various other purposes, as well as by way of purgative. It is a stimulating cathartic, but somewhat uncertain in its operation, and is frequently, and indeed generally, employed in composition with other ingredients. The dose is generally from three to twelve grains. Meyrick calls it a rough and powerful, but very useful purgative, of great service in rheumatic and other chronic disorders, for it will reach the seat of many disorders that a common purge will not affect. It should however seldom be given alone, and ought never to be administered to those of irritable habits, or in inflammatory complaints, though even then it is no more hurtful or dangerous than other strong cathartics. Hill says, that a great misfortune is, that the compositions made with Scammony are never perfectly to be depended upon, because there is so much difference in several parcels of Scammony, that they hardly seem the same medicine, some are so very strong, and some so very weak.—This plant will bear the open air of our climate, and will thrive well on a dry soil. Sow the seeds in the spring, on a border of light earth; keep the plants clean from weeds, and thin them to the distance of three feet. The stalks decay in autumn, but the roots will remain many years.

4. *Convolvulus Sibiricus*; *Siberian Bindweed*. Leaves cordate, acuminate, even; peduncles one-flowered. Root annual; stem six feet high, even, two angled from the decurrent stipules, but not ancipital; leaves scarcely repand, quite entire, ending in a point, the length of the leaf, paler underneath, and veined; corolla whitish, or having a shade of flesh-colour, with a yellowish bottom.—It flowers in July and August; and is a native of Siberia.

5. *Convolvulus Farinosus*; *Mealy-stalked Bindweed*. Leaves cordate, acuminate, repand; peduncles three-flowered; stem mealy. Corolla three times the size of the calix, somewhat flesh coloured, acute, five-cleft; stigmas oblong. Perennial: flowering in May and June.—Native of Madeira.

6. *Convolvulus Medium*; *Arrow-headed Bindweed*. Leaves linear, hastate-acuminate; ears toothed; peduncles one-flowered; calices sagittate. Stem twining, not rooting.—It is annual, flowers in July and August; and is a native of the East Indies. This, and the tenth, thirteenth, fourteenth, seventeenth, eighteenth, nineteenth, twenty-first, the twenty-sixth, twenty-eighth, thirtieth, thirty-first, thirty-fifth to the forty-first, fifty-seventh, fifty-eighth, sixtieth, sixty-second to the seventy-first, seventy-sixth, eighty-first, and from the eighty-fifth to the hundred and ninth species inclusive, being natives of warm climates, chiefly of the East and West Indies, are tender. When raised from the seed, they must be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be transplanted each into a separate pot filled with light earth, and plunged into a moderate hot-bed, observing to shade them from the sun until they have taken fresh root; then they should have a large share of air admitted to them every day, to prevent their drawing up weak, and also moderate waterings every other day. When the plants are become too tall for the hot-bed, they must be shifted into larger pots, and placed in the bark-stove, where, if they be allowed room, they will flower; but they rarely produce seeds in England. Many of them, therefore, are propagated by cuttings.

7. *Convolvulus Japonicus*. Leaves hastate-lanceolate, the side-leaves one-toothed; peduncles one-flowered. Stem filiform, simple, smooth. It flowers from May to July; and is a native of Japan, where it is also cultivated.

8. *Convolvulus Panduratus*; *Virginian Bindweed*. Leaves cordate, entire, panduriform; calices even. Root perennial, thick and long, like that of a carrot; stems very long and slender; peduncles long, slender, sustaining from one to three flowers, large and white, with the bottom of a fine purple; seeds hirsute. It flowers from June until September, and will endure the open air of Great Britain.—It is a native of Virginia and Carolina.

9. *Convolvulus Carolinus*; *Carolina Bindweed*. Leaves cordate, entire, and three-lobed; corollas undivided; fruits erect; stems slender reddish towards the root, and hairy at the joints; leaves somewhat entire and cordate, others like ivy leaves; peduncles near an inch in length, with a few narrow bractes; corollas pale purple.—The seeds were imported among rice sent from Carolina to England, where it will thrive in the open air.

10. *Convolvulus Hederaceus*; *Ivy-leaved Bindweed*. Leaves cordate, entire, and three-lobed; corollas undivided; fruits erect. This much resembles the next species; the flowers, however, are much larger, they are solitary, on very short peduncles, of a very elegant blue colour, with a whitish base. It is an annual plant, and was first raised in England from seeds brought by a slave-ship from the river Gambia in Africa.—It is a native of Asia, Africa, and America.

11. *Convolvulus Nil*; *Blue or Azure Bindweed*. Leaves cordate, three-lobed; corollas half five-cleft; peduncles shorter than the petiole. It is an annual plant, rising with a twining stalk eight or ten feet high; leaves woolly, ending in sharp points, and on long petioles. Each peduncle sustains two flowers of a very deep blue colour; whence it receives its name of Anil, or Indigo. It is one of the most beautiful plants of the whole genus: some have supposed it to be a mere variety of the twelfth sort; but the leaves have three deeply-divided lobes, whereas in the other they are entire. It flowers all the latter part of the summer; and in good seasons the seeds ripen well in the open air.—It is a native of America. It is now rarely met with in our gardens, although Gerard cultivated it before the year 1597; but it appears to have perished before it ripened its seeds. He says, that the Arabians call it *nil*; the Italians *campana azurea*, from its beautiful azure flowers; and also *fior di notte*, or *night-flower*, because its beauty appeareth most in the night. This species must be brought forward on a hot-bed, and planted out on a warm border toward the end of May.

12. *Convolvulus Purpureus*; *Purple Bindweed*. Leaves cordate, undivided; fruits drooping; pedicels thickened; peduncles erect, but the pedicels of the fruit thickened and drooping; the calix dotted, scabrous, and hairy. It is commonly known in the gardens by the name of *Convolvulus Major*. There are three or four lasting varieties of it, which are annual plants; the commonest has a purple flower; but there is one with a white, a second with a red, and a third with a whitish blue flower, and white seeds. If properly supported, these plants will rise ten or twelve feet high; they flower in June, July, and August, and will continue till the frost kills them. The seeds ripen in autumn.—Native of America and the West Indies. This is able to endure the open air in England. It is propagated by sowing the seeds in the spring, upon a warm border, where the plants are designed to remain. Some tall stakes must be placed by them for the stalks to twine about, otherwise they will spread on the ground, and make a bad appearance.

13. *Convolvulus Angularis*. Leaves cordate, five-cornered, quite entire, villose; peduncles many-flowered. Stem pubescent; leaves on short petioles, rough with reddish shining hairs; flowers orange; peduncles the length of the leaves;

calix hairy; corollas bell-shaped, thrice the length of the calix.—Native of Java.

14. *Convolvulus Obscurus*; *Hairy Bindweed*. Leaves cordate, undivided; stem somewhat pubescent; peduncles thickened, one-flowered; calices smooth. Root annual; stem round.—It flowers in August; and is a native of Batavia, China, Cochin-china, Ceylon, and Surinam.

15. *Convolvulus Batatas*; *Tuberous-rooted Bindweed*, or *Spanish Potatoes*. Leaves cordate-hastate, five-nerved; stem hispid, creeping, bearing tubers; root perennial; stem cylindrical, prostrate, sending out tubers, which are purple or pale on the outside; leaves angular, on long petioles; flowers purple, lateral, large, three or thereabouts together, on upright peduncles.—Native of both Indies, also of China, and Cochin-china. They came first into Spain from the West Indies or the Spanish Main, and the roots are annually imported into England from Spain and Portugal. They were the common Potatoes of our old English writers; the roots which are now so generally cultivated among us under that name, being then little known. They are sweet, sapid, and esteemed nourishing. They are commonly cultivated in all the tropical climates, where they eat not only the roots, but the young leaves and tender shoots boiled.—There are several varieties, if not distinct species, of Batatas. Loureiro mentions one, the roots of which are in bunches, white within, and of a tougher substance, though not so sweet as the common sort, but yet more esteemed among the natives. Forster mentions a second, which is found, not only in the South-sea islands within the tropics, but also in Easter Island, and in the northern parts of New Zealand.—They are cultivated in warm climates by their roots, in the same manner as our common Potatoe, but require much more room, for the trailing stalks extend every way four or five feet, sending out large tubers, forty or fifty of which are produced from a single root. In England, the roots must be planted on a hot bed in the spring: and if the plants be kept covered in bad weather with glasses, they will produce flowers, and many small roots from the joints; but if they be exposed to the open air, they seldom make much progress.

16. *Convolvulus Biflorus*. Leaves cordate, pubescent; peduncles in pairs; lobes of the corolla trifid. Root annual; stem round, hairy, branched at the base; petioles round, hairy, shorter than the leaf; corollas white, five-cleft, small; the lobes three-cleft, the middle cleft smallest; tube shorter than the calix; stamina the length of the tube; pistil white, the length of the stamina; stigmas two, headed, purple.—Native of China.

17. *Convolvulus Verticillatus*. Leaves cordate, oblong, naked; peduncles umbellate, bifid, many-flowered. Corolla bell-shaped; flowers bluish and small.—Native of America.

18. *Convolvulus Umbellatus*; *Umbelled Bindweed*. Leaves cordate; peduncles umbellate. Stem herbaceous, twining, filiform, stiff, subdivided, pubescent, round; flowers many, terminating, on peduncles three inches long or more; corollas yellow, the border plaited obtusely, pentangular. It flowers in June and July.—Native of the West India Islands.

19. *Convolvulus Malabaricus*. Leaves cordate, smooth; stem perennial, villose. Stem twining, round, slender; leaves acuminate, quite entire; peduncles one-flowered; corolla bell-shaped, with a long tube, white, with a dusky purple base.—Native of the East Indies and Cochin-china.

20. *Convolvulus Canariensis*; *Canary Bindweed*. Leaves cordate, pubescent; stem perennial, villose; peduncles many-flowered. Roots strong, fibrous; stems woody, branched, growing twenty feet high and more when supported; flowers axillary, several on one peduncle, for the most part of a pale

blue, but sometimes white. It flowers in June, July, and August, and sometimes ripens seeds in England.—Native of the Canaries, Cochin-china, &c. It is easily propagated by layers or cuttings; the seeds are not much regarded. Those plants, however, which are raised from layers or cuttings do not produce seed, whereas those which come from seeds seldom fail. If the young shoots be laid down in the spring, they generally put out roots in three or four months; they may be taken off an old plant at that season, and each put into a separate pot filled with light earth, and shaded until they have taken new root; after which they may be placed with other hardy green-house plants till autumn, when they must be removed into the green-house, and treated as Myrtles, &c. The tender cuttings planted during any of the summer months in pots filled with light earth, plunged into a moderate hot-bed, and shaded from the sun, will take root, and may be treated as the layers. The leaves continuing green all the year, this plant makes a pretty variety in the green-house during the winter.

21. *Convolvulus Muricatus*; *Rough-stalked Bindweed*. Leaves cordate; peduncles thickened; they and the calices even; stem muricate. Stalk very smooth, with harmless prickles scattered over it; leaves undivided; peduncles usually two-flowered; corolla purple.—Native of Surat. It is annual, and flowers in July and August.

22. *Convolvulus Anceps*. Leaves cordate; stem keeled on both sides, smooth; leaves three inches long, smooth, veined, obtuse, quite entire, on petioles nearly the length of the leaf.—Native of Ceylon and Java.

23. *Convolvulus Turpethum*; *Square-stalked Bindweed*, or *Turbith*. Leaves cordate, angular; stem membranaceous, quadrangular; peduncles many-flowered. Root perennial, having thick fleshy tubers, spreading far in the ground, and abounding with a milky juice, which flows out when the plant is wounded, and soon hardens into a resinous substance when exposed to the air. Corolla white, scarcely twice as long as the calix, bell-shaped, plaited, five-cleft.—Native of Malabar, of the Island of Ceylon, and of the Society and Friendly Isles, and also of the New Hebrides in the South Seas.

24. *Convolvulus Grandiflorus*; *Large-flowered Bindweed*. Leaves cordate, ovate, bluntish, quite entire, peduncled, bearing about two flowers; calices coriaceous; stem and petioles pubescent. Stem arboreous at first erect, then twining, pubescent; leaves large, with rounded lobes, obtuse, smooth, on pubescent petioles; flowers large.—Native of the East Indies.

25. *Convolvulus Maximus*; *Great Bindweed*. Leaves cordate, ovate, acuminate, quite entire, very smooth; stem and petioles very smooth. Stem woody at bottom, then twining and mounting to a great height. The whole plant very smooth.—Native of Ceylon.

26. *Convolvulus Speciosus*; *Broad-leaved Bindweed*. Leaves cordate, tomentose, silky on the lower surface; peduncles longer than the petiole, umbellate; calices acute. Stem arboreous, erect, then twining, round, pubescent; leaves very large, hairy on the upper surface, covered with a white down on the lower, and shining like silver in the sun-beams, the lobes rounded, and very obscure; petioles round and pubescent.—Native of the East Indies.

27. *Convolvulus Trinervius*. Leaves cordate, oblong; smooth, three-nerved; stem round; peduncles one-flowered. Stem filiform, smooth, simple; leaves opposite, petioled, acuminate, quite entire, pale underneath, an inch or somewhat more in length.—Native of Japan.

28. *Convolvulus Peltatus*. Leaves peltate; peduncles many-flowered.—Native of Amboyna and the Society Isles.

29. *Convolvulus Jalapa*; *Jalap Bindweed*. Leaves ovate, subcordate, obtuse, obscurely repand, villose underneath; peduncles one-flowered. Root large, oval, full of milky juice; stems many, herbaceous, triangular, eight or ten feet high; leaves different in shape, lower ones triangular, almost heart-shaped, upper ones more long, and acute; petioles long; flowers reddish on the outside, but dark purple within, probably varying in colour; seeds covered with a very white down like cotton.—Native of South America, as at Xalapa between La Vera Cruz and Mexico. The medicinal virtue of jalap resides in the resin. The powdered root is the part used. It is in general a safe and efficacious purge, and has been much celebrated in large doses as a hydragogue in dropsies. It is often prescribed in a compound form, as with cream of tartar, &c. The dose of the simple powder is commonly from one scruple to two. The roots of jalap, says Lewis, have scarcely any smell, and but very little taste while kept in the mouth, but after they are swallowed, the throat is affected with a slight pungency and heat, which continues for a considerable time. When reduced to powder, and taken in doses of a scruple and half a drachm, it proves in general an effectual and very safe purge, seldom occasioning any sickness or griping pains, which are the too common attendants of strong purgatives. Some of the faculty have prohibited the use of this root to children; but there appears no rational ground for such a prohibition. Young children, from the laxity of the solids, and the soft lubricating nature of their food, in general bear this kind of medicine better than adults; and adults of a weak lax habit of body better than those who are robust; and in both cases, few, if any, of the strong purgatives now made use of, are stronger than jalap. Motherby remarks, that jalap is of a diuretic, as well as a purgative nature; on which account it is peculiarly serviceable in dropsies, for which purpose it is best given in wine, wherein it has stood some hours before taking it. There is a tincture made from the root of this plant, and kept in the shops, which has all the effects of the root in substance, and may be thought by some persons to be more agreeable to take.—This plant must be preserved in the bark-stove. It may be raised from seeds on a hot-bed; the young plants being removed into pots, must be plunged into the bark-bed, and treated in the same manner as the last-mentioned set of plants, with this difference only, that as this has large, fleshy, succulent roots, it must have but little water, especially in winter. The proper soil for the Jalap is a light sandy loam, not too rich; and the plants should always remain in the bark-stove. It may also be increased from slips or cuttings.

30. *Convolvulus Sericeus*; *Silky Bindweed*. Leaves lanceolate-elliptic, tomentose, silky underneath; peduncles subumbellate; calices hairy. Stem shrubby, smooth; leaves alternate, petioled underneath, shining, marked with lines, acute.—Native of the East Indies.

31. *Convolvulus Tomentosus*; *Woolly Bindweed*. Leaves three-lobed, tomentose; stem lanuginose. The stem is round, whitish, climbing twenty feet high; leaves like the older leaves of Ivy; flowers axillary, solitary; peduncles a quarter of an inch in length; corolla of a fine purple colour, with paler streaks.—Native of Jamaica, China, and Cochin-china.

32. *Convolvulus Althæoides*; *Mallow-leaved Bindweed*. Leaves cordate, sinuate, silky; lobes repand; peduncles two-flowered. Root perennial, sending out many weak twining stalks, about three feet high when supported, and if not, lying on the ground; peduncles very long, two-flowered; corolla pale rose-colour. It flowers from June to August, but rarely ripens seed in England. There is a variety of this

species, with a pale rose-coloured corolla, with five stripes of a deeper red.—Native of the Levant, county of Nice, &c. Neither this, nor the variety of this species, often produces seeds in England, but, creeping at the roots, are propagated by offsets or shoots taken from the old plants. The best time for parting and transplanting this sort is about the beginning of May, when it may be taken out of the greenhouse, and exposed to the open air; but the young plants should be placed under a frame, and shaded from the sun till they have taken new root; they may then be gradually hardened to the open air during the summer, but in autumn they must be placed in the greenhouse, and treated in the same manner as the sixth species.

33. *Convolvulus Cairicus*; *Jagged-leaved Bindweed*. Leaves palmate, smooth, serrulate; stipules leaf-shaped, palmate; axils tomentose; calices paniced, even. The whole plant is smooth, except the axils, which are closely hairy. The corolla is bell-shaped; the stigma capitate.—It flowers in June and July; and is a native of Egypt.

34. *Convolvulus Copticus*. Leaves pedate, serrate; peduncles ensiform, two-flowered; calices mucicate. Stem herbaceous, angular, smooth, and even; corolla white, acute; stigma blood-red.—Native of the Levant.

35. *Convolvulus Vitifolius*; *Vine-leaved Bindweed*. Leaves palmate, five-lobed, smooth-toothed; stem hairy; peduncles many-flowered; racemes two-parted; calices villose.—Native of the East Indies.

36. *Convolvulus Dissectus*. Leaves palmate, seven-parted, tooth-sinuate, smooth; stem hairy; peduncles one-flowered; calix smooth.—Native of America.

37. *Convolvulus Macrocarpus*; *Long-fruited Bindweed*. Leaves palmate-pedate, five-parted; peduncles one-flowered.—Native of South America.

38. *Convolvulus Paniculatus*; *Paniced Bindweed*. Leaves palmate; lobes seven, ovate, acute, quite entire; peduncles paniced. It varies with three or five leaved lobes.—Found in the sands of Malabar.

39. *Convolvulus Macrorhizos*. Leaves digitate in sevens, quite entire; stem smooth; peduncles three-flowered.—Native of America.

40. *Convolvulus Quinquefolius*; *Smooth Five-leaved Bindweed*. Leaves digitate, smooth; toothed; peduncles even. Stem herbaceous, twining, filiform, round, hirsute; corolla bell-shaped, white; tube narrower at the base, swelling in the middle; border five-cornered, plaited, spreading.—Native of Jamaica.

41. *Convolvulus Pentaphyllus*; *Hairy Five-leaved Bindweed*. Leaves digitate in fives, hairy, quite entire; stem hairy; leaflets quite entire, pedicelled; peduncles long, branching; flower white; two large bractes include the calix; two obtuse stigmas; capsules obtuse; annual.—Native of the West Indies; flowering in August and September.

42. *Convolvulus Martinicensis*. Leaves elliptic; stem creeping, somewhat twining. Stems round, smooth, prostrate, long, rooting, twining a little; leaves elliptic, blunt with a point, quite entire, smooth, petioled, two inches long; the three outer calycine leaflets ovate, acute, very large and loose, the two inner much smaller, lanceolate, acute; corolla white.—Native of Martinico.

** *Stem not twining.*

43. *Convolvulus Spinus*; *Prickly Bindweed*. Shrubby, erect; leaves lanceolate, silky; flower-bearing branchlets thorny. Stem subflexuose, scarcely twining, the whole white, with very short shining hairs; leaves oblong or lanceolate, sessile; stems branching at top, the branches horizontal, rigid, terminated by one erect, small, whitish flower.—Ob-

served by Professor Pallas on the sandy hills near the river Irts in Siberia.

44. *Convolvulus Siculus*; *Small-flowered Bindweed*. Leaves cordate-ovate; peduncles one-flowered; bractes lanceolate; flowers sessile. This is an annual plant, rising about two feet, with slender, twining stalks. The flowers are small, of a bluish colour, and have little beauty.—It flowers in June; and is a native of the south of Europe. It will flourish in the open air of England. If it be permitted to scatter its seeds, the plants will rise in the spring, and require no other culture but to keep them clean from weeds; or if the seeds be sown in the spring where the plants are to remain, they will flower in June, and the seeds will ripen in August.

45. *Convolvulus Pentapetaloides*; *Five-petalled Bindweed*. Leaves lanceolate, obtuse, naked, marked with lines; branches declining; flowers solitary, half five-cleft, axillary, on short peduncles; corolla blue with a yellow throat, the border almost five-parted, with acuminate divisions. In a poor soil it varies with simple filiform stems, a finger's length, and somewhat hairy towards the top. A hardy annual, and a native of Majorca.

46. *Convolvulus Lineatus*; *Dwarf Bindweed*. Leaves lanceolate, silky, marked with lines, petiolate; peduncles two-flowered; calices silky, somewhat leafy. Stem four to six inches high, prostrate, flexuose; leaves remote, narrower at the base, acute; corollas very hairy on the outside. The flowers are produced on the side and at the top of the stalks, in small clusters, sitting close together; they are of a deep rose-colour. The root is perennial, and creeping.—Native of the coasts of France, Spain, Nice, and Sicily. Although it will bear the open air of our climate, it seldom produces seed in England, but the roots propagate in plenty. It prefers a slight dry soil, and requires no other care but to keep the plants clean from weeds: it may be transplanted either in spring or autumn.

47. *Convolvulus Cneorum*; *Silvery-leaved Bindweed*. Leaves lanceolate, tomentose; flowers umbelled; calices hirsute; stem erect. Stems shrubby, upright, about three feet high; leaves lanceolate, blunt, silky, placed closely on every side of the stem; they are near two inches long, and a quarter of an inch broad. The flowers are produced in clusters at the top of the stem, sitting very close; they are of a pale rose-colour, and come out in June and July, but do not perfect seeds in England.—Native of Spain, Italy, Sicily, and the Levant. If planted in a light soil and a warm situation, it will live in the open air in mild winters, but in severe winters it is destroyed: some of the plants therefore should be kept in pots, and sheltered under a common frame in winter, where they may enjoy the free air in mild weather, and yet be protected from frost: in summer they may be placed abroad with other hardy exotic plants, where the fine silky leaves will make a pretty appearance. It may also be propagated by laying down the branches and by cuttings: but they rarely put out roots the same year, and many of them will fall; so that the best way is to procure seeds from Italy, as those plants which come from seeds grow much larger than those which are propagated by other means.

48. *Convolvulus Cantabrica*; *Flax-leaved Bindweed*. Leaves linear-lanceolate, acute, hairy; lower peduncles longer than the leaves, bearing about two flowers; calices oblong-lanceolate, hirsute. Root perennial, of the thickness of a quill, and a dirty brown colour, running deep into the ground; stems several, annual, hirsute, round, half a foot high or more, slender; corolla flesh-coloured, or pale rose-coloured, with five broad red lines which are hairy on the outside. It varies much in size, but may be known by its

straight stem a little inclined, its villose white leaves and calix, and pale purple flowers rolled in a spiral form. It delights in warm rocky situations.—Native of the south of Europe. It is propagated from seeds, which must be obtained from the countries where it naturally grows. They should be sown upon a warm dry border, where they are intended to remain; for as the plants run down with long tap-roots, they will not bear transplanting, for this has often been tried without any success. When the plants come up they should be thinned where they grow too close, and afterwards constantly kept clean from weeds; which is all the culture it will require.—It flowers in July and August, and the stalks decay in autumn; but the roots will last several years, and, if they be in a dry soil and a warm situation, will endure the winter very well without covering.

49. *Convolvulus Dorycnium*. Leaves sublinear, silky; stem shrubby, paniced; calices almost naked, obtuse. Root perennial; stems a foot and a half high; leaves alternate, sessile, narrow; flowers generally solitary, sessile in the forks of the branches, or at their summit; calices very small; corollas campanulate, open, villose on the outside.—Native of the Levant.

50. *Convolvulus Scoparius*; *Broom Bindweed*. Leaves linear, somewhat hairy; peduncles bearing about three flowers; calices silky, ovate, acute; stem shrubby; branches wand-like. Root perennial, sending up several erect branching stalks about two feet high; the flowers come out singly on the side of the stalks, sessile, of a pale bluish colour, and spreading open almost to the bottom. It has the appearance of Broom: stem round, very smooth; corolla white, hairy on the outside: the wood is white and hard, with radiating streaks; when scraped it has the smell of roses, together with a slight acid taste. This, and the 52d species, produce the true *rose-wood* of the shops. Masson found it about Santa Cruz; and Mr. Miller says it grows in Candia, and several islands of the Archipelago.—Native of the Canary Islands. It may be propagated and treated in the same manner as the forty-eighth species; which see. It requires a dry soil and warm situation, to enable it to survive an English winter in the open air: if the surface of the ground about the roots be covered with some old tanner's bark, it will preserve them in the hardest frosts.

51. *Convolvulus Oenotheroides*. Shrubby, erect: leaves linear, becoming hoary; peduncles axillary, solitary, erect, one-flowered, bracted; calices lanceolate, smooth. Stems woody, round, reddish, somewhat glaucous; leaves narrow, the length of the finger, lax, flat; peduncles at the top of the stem, short, angular; bractes in pairs, recurved, subulate; corolla funnel-shaped, large, tawny-coloured. Found by Sparmann at the Cape of Good Hope.

52. *Convolvulus Floridus*; *Many-flowered Bindweed*. Leaves oblong-lanceolate, drawn to a point at the base, somewhat hairy; flowering-branches and peduncles paniced. Stems woody, procumbent; branches erect, stiff, hoary; leaves petiolate, linear, entire, waved, veined, smooth; flowers very numerous, small; leaflets of the calix ovate, concave, acute; corollas pale red, or white, hirsute on the outside.—Native of the Canary Islands; it flowers in August and September.

53. *Convolvulus Corymbosus*; *Tufted Bindweed*. Leaves cordate; peduncles umbellate; stem creeping.—Native of America, and New Caledonia.

54. *Convolvulus Spithameus*. Leaves cordate, pubescent; stem straight; peduncles one-flowered.—Native of Virginia.

55. *Convolvulus Persicus*. Leaves oval, tomentose; peduncles one-flowered; corolla white.—Native of Persia, on the shores of the Caspian Sea.

56. *Convolvulus Tricolor*; *Trailing Bindweed*. Leaves lanceolate-ovate, smooth; stem declining; flowers solitary. It is an annual plant, with several thick herbaceous stalks about two feet long, not twining, but bending towards the ground, upon which many of the lower branches lie prostrate; leaves sessile. The peduncles come out just above the leaves, at the same joint, and on the same side; they are about two inches long, each sustaining one large open bell-shaped flower, of a fine blue colour, with a white bottom, varying to pure white, and sometimes beautifully variegated with both colours; the white flowers are succeeded by white seeds, but in the blue ones they are dark-coloured.—Native of Barbary, Spain, and Sicily. It has long been considered as an ornamental plant in the borders of our flower-gardens, under the name of *Convolvulus Minor*. It is propagated by seeds, which should be sown on the borders of the flower-garden, where they are intended to remain: the usual method is to put two or three seeds in each place where they are intended to flower, covering them half an inch with earth; and when the plants come up, if the seeds all grow, there should be but two left in each place, which will be sufficient, the others should be drawn out carefully, so as not to disturb the roots of those which are left, after which they will require no care except weeding. If the seeds be sown in autumn, the plants will flower in May; but those which are sown in the spring, will not flower till the middle of June, and will continue flowering until the frosts set in. The seeds ripen in August and September. The plants which bear variegated flowers have frequently plain flowers of both colours intermixed with them, which should be pulled off as soon as they appear, in order to continue the variegated or striped flowers.

57. *Convolvulus Repens*; *Water Bindweed*. Leaves sagittate, obtuse behind, stem creeping; peduncles one or two flowered. Root perennial; stems strong, smooth, angular, compressed, extending wide, and putting out roots at the joints; flowers large, sulphur-coloured, on long peduncles from the side of the stalks, each supporting one flower, with a large swelling calix; flowers rather large, whitish.—Native of the sandy coasts of Jamaica.

58. *Convolvulus Reptans*; *Creeping Bindweed*. Leaves hastate-lanceolate; ears rounded; stem creeping; peduncles one-flowered; corolla pale purple.—Native of the East Indies, China, and Cochin-china, where it is a common pot-herb.

59. *Convolvulus Edulis*; *Eatable Bindweed*. Leaves cordate, entire, and three-lobed, smooth; stem creeping angular. This differs from the fifteenth species, in having the leaves heart-shaped, entire, three and five lobed, not narrowed in the middle, so as to become sagittate. The roots are often as big as the fist, tuberclod, fleshy like the *Batatas*, esculent, very soft and sapid: it flowers very seldom.—Brought from Japan, where it is not known far from the coast.

60. *Convolvulus Hirtus*; *Hairy Bindweed*. Leaves cordate and subhastate, villose; stem and petioles hairy; peduncles many-flowered. Annual, rising with slender, stiff, twining stalks, eight or nine feet high; flowers many together, at the end of strong peduncles; corolla purple.—Found by Osbeck in the East Indies.

61. *Convolvulus Soldanella*; *Sea Bindweed*. Leaves kidney-shaped; peduncles one-flowered. Roots small, white, stringy, sending out several weak trailing branches; leaves the size of the lesser Celandine, alternate, on long petioles. The flowers are produced on the side of the branches at each joint; they are of a reddish purple colour, appear in July, and are succeeded by round capsules, having three cells, with

one black seed in it. Every part of the leaves abounds with a milky juice. Half an ounce of the juice, or a drachm of the powder, is an acrid purge; the leaves, applied externally, are said to diminish dropsical swellings of the feet. According to Hill, the whole plant should be gathered fresh when it is about to flower, and ought to be boiled in ale, with some nutmeg and a clove or two, and this decoction should be administered in proportion to the person's strength: it is a strong purge, and sometimes also operates by urine, without any danger to the patient; it is best adapted for robust constitutions, but it will cure dropsies and rheumatism. Hill declares, that he has known a gonorrhœa cured by it; but the reader is strongly advised to place no reliance upon so precarious a remedy; his best method of proceeding is, to put himself into the hands of a regular surgeon, immediately after he discovers himself to be infected with that infamous disease, for there is no other way whereby he can so safely and easily obtain a radical cure. The juice which oozes from the stalk and roots of the Sea Bindweed may be saved; it hardens into a substance like Scammony, and is an excellent purge.—It is found on the sea-coasts of Frisia, Piedmont, Carniola; frequently upon the coasts of Norfolk, Essex, and Kent; also upon the north coast, and in Scotland, where it is called *Scottish Scurvy-grass*, and improperly *Sea Colewort*. As this plant grows naturally on the sea-beech, it cannot be long preserved in a garden.

62. *Convolvulus Pes capræ*; *Thick-leaved Bindweed*. Leaves two-lobed; peduncles one-flowered. Stem suffruticose, procumbent, creeping, somewhat villose, red, long; leaves blunt at both ends, often two-lobed, emarginate, thick, tomentose; flowers axillary, corolla purplish.—Native of the East Indies, China, Cochin-china, and the eastern coast of Africa. Annual; flowering in June and July.

63. *Convolvulus Brasiliensis*. Leaves emarginate, with two glands at the base; peduncles three-flowered; stems perennial, trailing and spreading to a great distance; flowers large, purple, produced by threes on very long peduncles.—Native of the West India islands, and of South America, near the shore. Browne says, that it is common near the sea in Jamaica; that the leaves are beautifully veined; that the whole plant is milky; and that the root is a strong purgative, sometimes used with success in hydropic cases: he calls it *Purging Sea Bindweed*.

64. *Convolvulus Sublobatus*. Upper leaves tooth-repand at the end; stem procumbent; flowers in a head; involucre six-leaved; corolla large. Annual.—Native of the East Indies.

65. *Convolvulus Littoralis*. Leaves oblong, lobe-palmate; peduncles one-flowered; stem creeping. Stems very long, much branched, the thickness of a goose-quill; leaves larger than the palm of the hand, in the likeness of a duck's foot, fleshy, and tender; flowers large, and white.—Native of America, and the West Indies.

*** *New Species*.

66. *Convolvulus Palmatus*. Leaves palmate; lobes seven, sinuate-pointed; peduncles one-flowered; calices very large, spreading; stem twining. This rises with a strong winding stalk to the height of twenty feet, dividing into several smaller; the flowers are large, purple, on long peduncles, and are succeeded by roundish seed-vessels, having three cells, in each of which is lodged a single seed.—Native of Vera Cruz in New Spain.

67. *Convolvulus Aristolochifolius*. Leaves hastate-lanceolate, with rounded ears; peduncles many-flowered; stem twining. This rises with a slender twining stalk ten feet high; the flowers are produced in small clusters on long peduncles, they are yellow, and are succeeded by three-cornered

seed-vessels. It is an annual plant.—Native of Carthageana, in New Spain.

68. *Convolvulus Glaber*. Leaves ovate-oblong, smooth; peduncles one-flowered; calices ten-parted; stem twining. An annual plant, with twining stalks seven or eight feet high; the flowers come out at every joint, on long slender peduncles, each supporting a large purple flower, with the calix cut almost to the bottom in ten parts.—It was imported from the island of Barbuda.

69. *Convolvulus Multiflorus*. Leaves cordate, smooth; peduncles many-flowered; seed villose, ferruginous; stem twining. Stalks slender, twining, eight or ten feet high; peduncles rather long, with many purple flowers in bunches growing upon each. Annual.—Native of Jamaica.

70. *Convolvulus Hederaceus*. Leaves triangular, acute; flowers many, sessile, spreading; calices acute, many-cleft; stem twining. The flowers are blue.—It is annual, and native of Jamaica.

71. *Convolvulus Roseus*. Leaves cordate, acuminate; peduncles two-flowered; stem twining, seven or eight feet high. Leaves on very long petioles, and flowers on long peduncles; seeds large, and covered with a fine down. This plant is annual, and one of the most beautiful of the genus, the flowers being very large, and of fine rose-colour.—Native of Jamaica.

72. *Convolvulus Betonicifolius*. Leaves cordate-sagittate; peduncles one-flowered; stem twining. Stalk slender, five or six feet high; corollas white, with purple bottoms.—Native of Africa.

73. *Convolvulus Tuguriorum*. Leaves cordate-sagittate, acute; stem angular, twining; peduncles four-cornered, one-flowered.—Native of New Zealand.

74. *Convolvulus Cœlestis*. Leaves cordate, extremely acuminate, pubescent; peduncles elongated, umbellate trifid; stem twining.—Native of the island of Tanna, in the South Seas.

75. *Convolvulus Mucronatus*. Leaves palmate-pedate; lobes ciliate, mucronate; peduncles one-flowered; stem twining.—Native of the island of Tanna, in the South Seas.

76. *Convolvulus Tridentatus*. Leaves wedge-shaped, three-cusped, dilated at the base, and toothed; peduncles one-flowered; stem twining. Annual; flowering in July and August.—Native of the East Indies.

77. *Convolvulus Bufalinus*. Stem shrubby, scandent; leaves cordate-sagittate, smooth; peduncles many-flowered; antheræ spiral; corolla bell-shaped.—Native of the woods of Cochin-china.

78. *Convolvulus Aggregatus*. Leaves palmate, seven-lobed, hairy; flowers aggregate. Stem twining, perennial, round, extremely hairy, branched; flowers white, large, axillary; common peduncle long, solitary; proper none; corolla tubular, five-cleft; segments acute, hairy, closed.—Native of Cochin-china.

79. *Convolvulus Hastatus*. Leaves lanceolate, hastate; peduncles axillary, in pairs, two-flowered; stem twining, hairy.—Native of Arabia.

80. *Convolvulus Lanatus*. Leaves lanceolate, linear, tomentose, older branches spiny; flowers in involucre heads. Stem shrubby, erect, branched at bottom; corolla bell-shaped, hairy on the outside, of a pale rose-colour; filamenta unequal; antheræ linear.—Native of the lower Egypt, and Mount Sinai.

81. *Convolvulus Hystrix*. Shrubby; leaves oblong; flowers sessile, subsolitary; branches spinescent. This is a rigid shrub, very much branched, diffused, and a foot high; the branchlets somewhat silky; calycine leaflets hirsute, the

two outer oblong, rigid, larger than the rest; corolla hirsute, small.—Native of Arabia.

82. *Convolvulus Imperati*. Leaves panduriform, or entire, emarginate, cordate at the base; peduncles one-flowered; stem creeping; calix smooth, with oblong leaflets.—Native of the sandy shore at Bagnoli, near Naples; flowering in August and September.

83. *Convolvulus Arenarius*. Leaves oblong, emarginate, lobed at the base, or entire; peduncles one-flowered; corollas tubular; stem twining. The whole plant is smooth; stems decumbent; corollas tubular, not bell-shaped.—Native of the Azores, or Western Islands.

84. *Convolvulus Wheleri*. Leaves sagittate, roundish, behind, and entire; peduncles round, one-flowered. This species varies with ovate leaves, having straight, shorter, rounded, lanceolate ears, or a little divaricate and lanceolate on the same plant.—Native of Spain, by the lake Albufeda, in the kingdom of Valencia.

85. *Convolvulus Lanuginosus*. Leaves cordate-oblong, subhastate, silky, tomentose; ears toothed; peduncles three-flowered. Stem hairy, herbaceous, twining, pale; corolla almost like that of Scammony, yellowish, having on the outside a lanceolate purplish line, with a pile of yellow hairs to each lobe of the border; style bifid.—Probably a native of the Levant.

86. *Convolvulus Incanus*. Silky, tomentose: leaves lanceolate, sagittate, blunt, somewhat toothed at the base; peduncles two-flowered. Stem twining, herbaceous, round; the petioles only one-fourth of the length of the leaf; peduncle the same length with the leaves; corolla villose on the outside.—Native of America.

87. *Convolvulus Emarginatus*. Leaves lanceolate, the lower ones emarginate, mucronate; peduncles one-flowered, outer calicine leaflets semiovate, large. Stem twining, rooting at the bottom, muricated upwards with little spines, and having minute hairs thinly scattered over it at top, even.—Native of the East Indies.

88. *Convolvulus Filicaulis*. Leaves linear, lanceolate, obtuse, mucronate, dilated and toothed at the base; calicine leaflets oblong. Stem herbaceous, filiform, twining, branched; stigma simple, bluish.—Found by Isert in Guinea.

89. *Convolvulus Angustifolius*. Leaves linear, hastate, obtuse, mucronate, smooth; ears almost quite entire; peduncles one-flowered. Stem filiform, twining, smooth, branched; leaves petioled, an inch or rather more in length; ears lanceolate, acute, sometimes straight; stigma bifid.—Native of the East Indies.

90. *Convolvulus Dentatus*. Leaves hastate, smooth; ears toothed; peduncles many-flowered, muricate. Stem twining, round, smooth.—Native of the East Indies.

91. *Convolvulus Bracteatus*. Leaves cordate, almost entire, and three-lobed, hastate, attenuated; peduncles one-flowered, outer calicine leaflets bracte-shaped. Stem herbaceous, twining, with short hairs thinly scattered over it; leaves two inches long, veined; corolla villose on the outer side.—Native of the East Indies.

92. *Convolvulus Bicolor*. Leaves cordate, villose, angular-sublobate at the base; peduncles one-flowered, outer calicine leaflets bracte-shaped; corolla white, with a violet purple base, hairy on the outside.—Native of the East Indies.

93. *Convolvulus Platanifolius*. Leaves cordate, three-lobed; side-lobes tooth-angular; peduncles subtriflorous, and calices almost equal, smooth; stem round; stigma capitate.—Native of America.

94. *Convolvulus Acuminatus*. Leaves cordate, and three-lobed, attenuated; peduncles elongated, many-flowered, and

calices smooth. Stem twining, with a few minute hairs scattered over it, pressed close to it, and visible only with a magnifier; flowers about five, alternate; pedicels an inch and half long, a little thicker under the leaf; corolla large, bell-shaped, purple, with a pale base, with five paler, lanceolate, attenuated rays, running to the edge; stigma capitate.—Native of the West Indies.

95. *Convolvulus Gemellus*. Leaves cordate, somewhat villose underneath; peduncles two-flowered. Stem twining, tender, pubescent at top; peduncles the length of the petiole, thickened at top, two-flowered, seldom one-flowered; pedicels a little shorter than the peduncle; one shorter, thicker, without any bracte, the other more tender, with two bractes in the middle, both turned back when ripe; corolla bell-shaped, six times as large as the calix, smooth.—Native of the island of Java.

96. *Convolvulus Striatus*. Leaves cordate, attenuated, smooth; peduncles longer than the leaf, having three or four flowers; corollas smooth, striated on the outside. Stem herbaceous, twining, pubescent, round, slender.—Grows in the East Indies.

97. *Convolvulus Guianensis*. Leaves cordate-ovate underneath, with the calices tomentose; peduncles elongated; flowers corymbed in a sort of head. Stem twining, branched, round, purplish, villose, rugged.—Native of Cayenne.

98. *Convolvulus Capitatus*. Hispid: leaves cordate-ovate; flowers in a head, five in number; peduncles axillary, solitary, a little shorter than the leaves, without any joint. Stem twining, herbaceous, rugged.—Native of the East Indies.

99. *Convolvulus Hispidus*. Extremely hirsute; leaves cordate-ovate; flowers umbelled; peduncles very short. It is easily known from the other species by its shagginess; corolla smooth; stigmas capitate.—Native of the East Indies.

100. *Convolvulus Parviflorus*. Leaves cordate, acuminate, smooth; peduncles many-flowered, and calices acuminate, villose. Stem weak, slightly villose at top; corolla blue, smooth, twice as long as the calix, five-cleft.—Native of Java.

101. *Convolvulus Violaceus*. Leaves, and the two outer leaflets of the calix, cordate-ovate, acute; peduncles elongated, bifid, many-flowered. Stem, as well as the petioles, peduncles, and calices, villose; corolla bell-shaped, violet-coloured, with five lanceolate paler rays.—Native of Santa Cruz.

102. *Convolvulus Triflorus*. Leaves cordate-lanceolate, attenuated, smooth, obtuse; peduncles three-flowered. Stem herbaceous, twining, smooth; leaves two inches long, quite entire, simply veined; the veins underneath villose when examined with a magnifier, the under surface is paler; they are rounded at the end, and mucronate; the lobes are rounded behind, and are sometimes, but seldom, obscurely angular.—Native of the East Indies.

103. *Convolvulus Bifidus*. Leaves cordate-oblong, acuminate, very soft underneath; peduncles bifid, many-flowered. Stem twining, villose; corolla almost funnel-shaped, three times as long as the calix, with five slender villose lines on the outside; lobes acute, bearded at the tip.—Native of the East Indies and the island of Java.

104. *Convolvulus Triquetus*. Leaves cordate-acute, subvillose; peduncles many-flowered. Stem three-keeled, pubescent, rendered triangular by three subfoliaceous very slender decurrent lines.—Native of the island of Santa Cruz.

105. *Convolvulus Quinqueflorus*. Leaves sagittate-ovate, attenuated, smooth, crenate, subrepand; peduncles mostly five-flowered. Stem slightly pubescent, round, branched; peduncles the length of the leaves; corolla twice as long as the calix, with the lobes bearded at the tip; stigma bifid.—Supposed to come from the isle of Bourbon.

106. *Convolvulus Crenatus*. Tomentose, silky: leaves cordate-oblong, extremely blunt, crenulate; peduncles one-flowered. Stem twining; leaves nerved, mucronate; ears straight, oblong, obtuse; stigma slightly bifid.—Native of Brazil.

107. *Convolvulus Quinquelobus*. Leaves palmate, five-lobed, serrulate, blunt, smooth; axils tomentose; peduncles one-flowered. Stem smooth, round, twining; corolla almost bell-shaped, smooth, purple.—Native of Santa Cruz.

108. *Convolvulus Venosus*. Very smooth: leaves digitate, quinque; leaflets petioled, acuminate, quite entire; peduncles many-flowered. Stem twining, round, smooth; corolla funnel-shaped.—Native country unknown.

109. *Convolvulus Tenuifolius*. Leaves digitate, in fives; leaflets linear; peduncles four or five flowered. The whole of this plant is smooth; stem angular, twining; peduncles axillary, short, upper ones sometimes one-flowered; calix smooth, with oblong leaflets; stigma acute.—Native of the West Indies.

110. *Convolvulus Saxatilis*. Extremely hirsute: leaves linear; flowers in heads; calices acuminate. This differs from the forty-seventh species, which it otherwise resembles, in being wholly covered with a lanuginous shagreen, instead of the silvery-shining, appressed, scarcely distinct hairs, as that is; and in having linear-subulate calicine leaflets, and subsessile flowers.—Native of Spain.

111. *Convolvulus Ammannii*. Leaves linear; peduncles one-flowered; bracts long; calix acute. The whole plant is covered with a short silky silvery down. Root perennial; stems four to six inches high, slender, cylindrical, branched, rather erect; leaves alternate, sessile; flowers campanulate, pale white, starred with purple lines.—Native of Siberia.

112. *Convolvulus Maritimus*. Leaves emarginate, two-lobed, wedge-shaped at the base; peduncles many-flowered; stem decumbent, throwing out roots. The whole plant is smooth. Stems cylindrical; leaves alternate, thick, fleshy; flowers purple, large, bell-shaped; peduncles three to six flowered; calix leaves egg-shaped; capsules roundish; seeds four.—Native of the isle of France, and the East Indies.

113. *Convolvulus Evolvuloides*. Leaves spatule-shaped, obtuse, hairy; upper ones embracing the stem; stem declining; flowers solitary, sessile. Root annual.—Native of Cyprus.

Conyza: a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common, imbricate, roundish, squarrose; scales acute, the outer somewhat spreading. *Corolla*: compound, tubulose; corollets hermaphrodite, numerous, tubular in the disk; females apetalous, roundish in the circuit: proper of the hermaphrodite funnel-form; border five-cleft, patulous; of the females, funnel-form; border three-cleft. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*, in the hermaphrodites: germen oblong; style filiform, length of the stamina; stigma two-cleft: in the females, germen oblong; style filiform, length of the hermaphrodite, more slender; stigmas two, very slender. *Pericarp*: none; calix converging. *Seeds*: to the hermaphrodites, solitary, oblong; down simple: to the females, solitary, oblong; down simple. *Receptacle*: naked, flat. ESSENTIAL CHARACTER. *Calix*: imbricate, roundish. *Corolla*: of the ray three-cleft. *Down*: simple. *Receptacle*: naked.—The species are,

1. *Conyza Squarrosa*; *Great Fleabane*, or *Plowman's Spikenard*. Leaves lanceolate, acute; stem herbaceous, corymbid; calices squarrose. Root biennial; stems a foot in height, upright, panicled at the end, purplish, with a white woolliness; branches straight. Numerous flowering heads terminate the stem and branches, on short downy peduncles,

with each a small lanceolate bracte; corollas yellow, yellowish, or dusky purple; florets without pistils, in the circumference with pistils; individuals, with only pistils slightly cloven into three, have at first sight the appearance of a funnel-shaped floret, but are really more of the nature of a ligulate floret; seeds small, blackish, longitudinally furrowed, crowned with a sessile feather, with simple rays as long as the calix. The smell is slightly but not ungratefully aromatic. Tragus reports it to be an emmenagogue, but it is scarcely known officinally. It is disputed, says Hill, whether this species of Fleabane, or another which is smaller and has globous flowers, have the greater virtue; but the majority contend for this. The juice of the whole plant cures the itch by external application, and the very smell of the herb is said to destroy fleas. Meyrick informs us, that it is reckoned a good wound-herb, and frequently taken in decoction for bruises, ruptures, inward wounds, pains in the side, and difficulty of breathing.—Native of Denmark, Germany, Holland, France, Switzerland, Carniola, and Piedmont, chiefly upon dry mountainous pastures, by hedge-sides, and in woods. In Great Britain it is generally found upon a calcareous soil, as at Shelford, Whittlesford, Hildersham, and Abington, in Cambridgeshire; it is common in a clayey soil in the woods of Norfolk; also in Charlton wood, and near Dartford and Greenhithe, in Kent; near Harefield in Middlesex, and Finshead in Northamptonshire also; but not commonly in Scotland. It flowers from July to October, and being a native is seldom admitted into gardens.—If the seeds be permitted to scatter, the plants will come up in the following spring, and require no other care but to keep them clean from weeds.

2. *Conyza Linifolia*; *Flax-leaved Fleabane*. Stems a foot or a foot and half in height, erect, hardish, green; leaves like those of Hyssop, only more obtuse, smooth, and stiff; branches slender, straight at the top of the stems; flowers on short peduncles, terminating; florets white, slender, reflex. It flowers in August and September, and is a hardy perennial.—Native of North America.

3. *Conyza Sordida*; *Small-flowered Fleabane*. Leaves linear, quite entire; peduncles long, three-flowered; stem undershrubby, like that of Lavender, branched and white; peduncles straight, usually three-flowered at the end; calicine scales brown at the edge.—Native of the south of Europe. It flowers from July to September. It may be kept in a green-house, dry-stove, or glass-case.

4. *Conyza Saxatilis*; *Rock Fleabane*. Leaves linear, almost entire, tomentose underneath; peduncles very long, one-flowered; calicine leaves subulate. Leaves heaped at bottom; peduncles naked; calicine scales black at the edge; stems first procumbent, then erect; calices cylindric, patulous and membranaceous at the end; very many naked female florets in the circumference.—Native of Spain, Italy, Istria, Carinthia, the Valais, Palestine, and the Cape of Good Hope. Mr. Ray found it in abundance on walls and rocks about Messina in Sicily. It requires the protection of a green-house, dry-stove, or glass-case, in our climate.

5. *Conyza Canescens*; *Hoary Fleabane*. Leaves linear; panicle fastigiate. The whole plant is hoary; stems almost simple, columnar, striated, with short lateral branches; calix subovate, shorter by half than the flower and down; flower purple, and mixed with the down.—Native of the Cape of Good Hope. It requires the same protection as the preceding species in our climate.

6. *Conyza Rupestris*; *African Fleabane*. Leaves spatulate, somewhat toothed, tomentose; stem undershrubby; peduncles elongated, one-flowered; corollas yellow, with very numerous florets.—Native of Arabia. This, and the seventh,

tenth, eleventh, twelfth, from the fourteenth to the twenty-fourth, the twenty-seventh, and from the thirty-first to the forty-third species, are too tender to thrive in the open air in England: their seed therefore must be sown upon a hot-bed in the beginning of April, and when the plants are fit to remove, they must be each transplanted into a small pot filled with light sandy earth, and plunged into a hot-bed, observing to screen them from the sun until they have taken new root: they must afterwards have free air admitted to them every day, in proportion to the warmth of the season, and should also be frequently watered in warm weather, but in small quantities at each time. As they advance in strength, their share of air should be increased, and in warm seasons they may be wholly exposed in the open air during a few weeks in the heat of summer, provided they be placed in a warm situation; but if the nights prove cold, or much wet fall, they must be immediately removed under shelter. If these plants be placed in a moderate stove in winter, they will thrive better than under great heat. With the above management they will flower well in July, but in general they do not perfect their seeds in England.

7. *Conyza Scabra*; *Rough Fleabane*. Leaves oblong, somewhat toothed, sessile, scabrous; peduncles one-flowered, elongated; leaves rugged on both surfaces, with four or five teeth on each side.—Native of the East Indies.

8. *Conyza Asteroides*; *Starwort Fleabane*. Leaves broad-lanceolate, subserrate; corollas radiate; calices squarrose.—It flowers in August and September; and is a native of North America. It is a hardy perennial.

9. *Conyza Bifrons*; *Oval-leaved Fleabane*. Leaves ovate-oblong, stem-clasping. From a thick fibrous root spring up many upright stalks; leaves rough; flowers terminating, in round bunches, yellow, appearing in July.—Native of Canada. This is a hardy perennial, and is propagated by seeds sown on a bed of light earth in the spring, taking care to thin and weed the plants when they come up: they should be removed to where they are intended to remain in the next autumn, and they also must be kept free from weeds; the second year they will flower and produce ripe seeds, and will continue two years, if it be not too good, for they often rot when planted in a rich soil.

10. *Conyza Bifoliata*; *Two-leaved Fleabane*. Leaves oval, toothed; peduncles two-leaved; bractes opposite.—Native of the East Indies.

11. *Conyza Pubigera*. Leaves oblong, somewhat toothed, subpetiolate; peduncles woolly, sustaining about two flowers; stem somewhat shrubby, eight feet high, cylindrical, climbing, branched; branches with a few scattered hairs on them; leaves alternate, wedge-shaped at the base, green on both sides, with a few scattering hairs, not scabrous; peduncles axillary towards the top, with from two to four flowers.—Native of the East Indies, and China.

12. *Conyza Tortuosa*; *Crooked Fleabane*. Stem tortuose, shrubby; leaves ovate-oblong, quite entire; racemes reflex. Branches subhirsute, striated, simple; flowers alternate, sessile, turned up, rounded; calicine scales ovate, the inner lanceolate.—Native of Madagascar and Vera Cruz.

13. *Conyza Candida*; *Woolly Fleabane*. Leaves ovate, tomentose; flowers crowded; peduncles both lateral and terminating; stem suffruticose, six inches high, upright, round, hairy, whitish, branched; leaves very white, quite entire, alternate; flowers purple, peduncled, heaped. It has a pleasant smell: it sometimes varies with a short recurved ray.—Native of Candia, Sicily, and Cochin-china.

14. *Conyza Anthelmintica*; *Purple Fleabane*. Leaves lanceolate-ovate, scabrous; peduncles one-flowered; calices

squarrose. Stem erect, roundish, branched, slightly tomentose, spotted with purple; the branches erect, scattered; leaves alternate, serrate, with acute unequal teeth, narrowed at the base into the petiole, scabrous on the upper surface, smooth, and veined on the lower; flowers in panicles at the ends of the branches, on long peduncles, thickening towards the flower, and having one leaf on each; a solitary peduncle terminates the stalk; corolla uniform, consisting of from twenty-five to forty hermaphrodite red florets; those of the ray reflex. The leaves of this plant have an exceeding bitter taste. It flowers in August and September, is biennial, and a native of the East Indies. It requires the protection of a green-house, dry-stove, or glass-case, in our climate.

15. *Conyza Balsamifera*; *Balsam Fleabane*. Leaves lanceolate, tomentose underneath, even the petioles toothed; down ferruginous.—Native of the East Indies.

16. *Conyza Cinerea*; *Ash-coloured Fleabane*. Leaves oblong; flowers panicled; corollas cylindrical, twice the length of the calix. Stem erect, panicled pubescent; corollas purple. Annual.—Native of the East Indies.

17. *Conyza Odorata*; *Sweet-scented Fleabane*. Leaves ovate, serrate, subtomentose, acute; stem arborescent, corymbed; corollas almost globular. This is an odoriferous plant, with an upright shrubby stem, four feet high, the branches rising in form of a corymb; flowers purple, lateral, and terminating, several together; the corollas so short as not to emerge from the calix.—Native of the East Indies and Cochin-china.

18. *Conyza Chinensis*; *Chinese Fleabane*. Leaves lanceolate-ovate, reflex-serrate, tomentose underneath; flowers terminating, heaped. Stem suffruticose, four feet high, upright, round, smooth, branched at top; leaves hardish, petioled, alternate; flowers yellow, peduncled, terminating.—Native of China, Cochin-china, Java, and Amboyna.

19. *Conyza Hirsuta*; *Shaggy Fleabane*. Leaves oval, quite entire, scabrous, hirsute underneath. Stem herbaceous, a foot high, upright, simple, round, hairy, having few leaves; these are oblong, sharpish, toothletted, hairy, scattered; flowers in racemes, yellow, crowded, terminating.—Native of Java, China, and Cochin-china.

20. *Conyza Arborescens*; *Tree Fleabane*. Leaves ovate, quite entire, acute, tomentose underneath; spikes recurved, one-ranked; bractes reflex. This is a shrub, with a depressed rugged stem; corolla uniform, with twelve hermaphrodite corollas in the circuit, a little higher than the others, giving the flower a radiate appearance.—It commonly rises to the height of three feet and a half or more in the low lands of Jamaica.

21. *Conyza Fruticosa*; *Shrubby Fleabane*. Leaves ovate, quite entire, obtuse; flowers sessile, alternate; branchlets flexuose.—Native of South America.

22. *Conyza Virgata*; *Winged-stalked Fleabane*. Leaves decurrent, lanceolate, serrulate; stems wand-like; flowers spiked, in scattered heaps. It is hairy, and rises generally to the height of two feet or more. The leaves are somewhat hoary; the flower-branches are very long and slender, and disposed in the form of spikes at top; the lower flowers are in threes, the upper solitary. It flowers in August and September.—Native of Jamaica and Carolina. It may be kept in a green-house, dry-stove, or glass-case.

23. *Conyza Decurrens*; *Running Fleabane*. Leaves decurrent, lanceolate, serrulate; flowers axillary, sessile, glomerate. Root annual; glomerules of flowers ash-coloured, from the axils of the leaves, globular. The stem is about a span in height, erect, villose-tomentose; as is the whole plant.—Native of India.

24. *Conyza Aurita*; *Eared Fleabane*. Leaves dentate-

sinuate; earlets subdecurent. Root-leaves larger than the rest, stiffer, smoother, obovate, with red veins, widely serrate, and waved between the serratures; stem erect, stiff, a foot high, reddish, hairy, branched; the branches erect, simple; flowers from the top of the stem, peduncled, scattered in various ways; florets minute, white, with minute linear rays; pistils very long, erect. The scent is that of *Stachys Foetida*, but more pleasant.—Native of moistish places in the East Indies.

25. *Conyza Inuloides*; *Cluster-flowered Fleabane*. Leaves cuneiform-linear, obtuse, notch-toothletted, smooth; stem shrubby; antheræ two-bristled. Stem proliferous, dichotomous, smooth; calix purplish; flowers yellow.—Native of the island of Teneriffe. This plant may be kept in a green-house, stove, or under a glass-case.

26. *Conyza Sericea*; *Snowy Fleabane*. Leaves linear-filiform; they and the stems tomentose silky; flowers panicled. This is easily known by the silky whiteness of the branches, leaves, and peduncles, and by its yellow flowers. The bark and wood have an acrid pungent taste; and the inhabitants of the Canary Islands, where it naturally grows, use it in the tooth-ache. It may be kept in a green-house, dry-stove, or glass-case.

27. *Conyza Ægyptiaca*; *Egyptian Fleabane*. Leaves oblong-spatulate, toothed, hairy; flowers subpanicled, globular; calicine leaflets subulate, soft. Stem erect, a foot and a half in height, somewhat striated, pubescent, and somewhat viscid; branches from the upper axils; flowers terminating, four or five, roundish, on purple peduncles; corollas yellow, with minute florets, naked in the ray, and very abundant; pistils yellow, quickly vanishing, surrounding the disk with a kind of broad downy ring.—It flowers in July, is annual, and a native of Egypt. This must be propagated from seeds.

28. *Conyza Rugosa*; *St. Helena Fleabane*. Shrubby: leaves wedge-shaped, serrate, villose, wrinkled, netted; peduncles villose, one-flowered; flowers radiate.—It flowers in November; and is a native of the island of St. Helena. It requires protection in our climate.

29. *Conyza Incisa*; *Ear-leaved Fleabane*. Leaves ovate, subcordate, hairy-viscid, toothed, eared at the base; disk of the receptacle honey-combed.—It flowers from June till August, and is a native of the Cape of Good Hope. It may be kept in a green-house or dry-stove.

30. *Conyza Patula*; *Spreading Fleabane*. Leaves elliptic, serrate, villose underneath; calices subglobular; leaflets lanceolate-subulate; branches spreading. Annual: stem taper, herbaceous, a foot and a half in height, covered lightly with a mealy down, and branching out almost the whole length; corollas purple. The flowers appear in July, and there is a continual succession till the cold of autumn puts a stop to them.—Native of the northern parts of China. The seeds of this species should be sown upon a moderate hot-bed in the beginning of April: when the plants are fit to remove, they should be transplanted into a fresh hot-bed, observing to shade them from the sun till they have taken fresh root. In June they may be gradually hardened to the open air, and part of them may be planted in warm borders, where they will flower, and, if the season prove warm, ripen their seeds; but it will be prudent to keep some plants in pots, placed in an airy glass-case, in order to secure good seeds.

31. *Conyza Tomentosa*; *Rough Fleabane*. Arborescent: leaves oblong-ovate, tomentose, cinerous underneath; flowers terminating, on branching peduncles. It rises with a woody stalk, ten or twelve feet high, dividing into many branches, the bark of which is covered with a brown nap; leaves alternate on short petioles; flowers in loose spikes, ranged on one side;

they are white, and are succeeded by long flat seeds.—Native of La Vera Cruz in New Spain.

32. *Conyza Salicifolia*; *Willow-leaved Fleabane*. Leaves linear, decurrent, serrate; flowers corymbed, terminating, on branching peduncles. This has a perennial root, from which spring several upright stalks, three feet high. The flowers are produced at the end of the stalks in round bunches; they are small, and of a purple colour, and are succeeded by oblong flat seeds.—Native of La Vera Cruz in New Spain.

33. *Conyza Corymbosa*; *Clustered Fleabane*. Arborescent: leaves lanceolate; flowers corymbed, terminating on branching peduncles. Stem strong, woody, fourteen or sixteen feet high, covered with an ash-coloured bark, and divided at top into many woody branches; leaves alternate, on short petioles. The branches are terminated by roundish bunches of white flowers, on long peduncles, several together.—Sent from La Vera Cruz.

34. *Conyza Viscosa*; *Clammy Fleabane*. Herbaceous: leaves ovate, serrate, villose; flowers both axillary and terminating. This is an annual plant, growing in low moist places, where the water stands in winter. It has an herbaceous branching stalk, one foot high, with one oval sessile leaf at each joint, covered with a white hairy down. The flowers are produced from the side of the branches, on slender petioles, each for the most part sustaining three flowers, which are white, and succeeded by chaffy seeds.—Native of La Vera Cruz. This plant will sometimes ripen its seeds in England, if the autumn prove favourable, but it has little beauty to recommend it. The seeds of the other natives of South America must be procured from that country; and being long upon their passage, will rarely vegetate in the first year.

35. *Conyza Symphytifolia*; *Comfrey-leaved Fleabane*. Leaves oblong-ovate, scabrous; flowers racemed, terminating; stem herbaceous. Root perennial; stem three feet high, terminated by branching peduncles, each sustaining several yellow flowers, not much unlike those of the common sort: leaves from four to five inches long, and one and a half broad in the middle, rough like those of Comfrey.—Native of La Vera Cruz.

36. *Conyza Scandens*; *Climbing Fleabane*. Leaves lanceolate, scabrous, nerved, sessile; racemes recurved; flowers ascending: peduncles lateral; stem shrubby, climbing. This has a climbing shrubby stalk, fourteen or sixteen feet high, dividing into many branches; leaves the size of those of the Bay-tree, and full as thick in their texture, having as many deep transverse nerves, running from the midrib to the sides, and of a pale green colour; flowers large and white, produced in long spikes ranged on the upper side only, from the side of the branches, and pointing upwards.—Sent from La Vera Cruz. This plant makes a fine appearance in the stove while in flower; and, retaining its leaves all the year, makes an agreeable variety among other tender plants.

37. *Conyza Trinervia*; *Three-leaved Fleabane*. Leaves ovate, smooth, three-nerved, quite entire, sessile; flowers in spikes, terminating. Stem shrubby, six or seven feet high, dividing into several woody branches; flowers white, succeeded by oblong flat seeds.—Native of Carthage in New Spain.

38. *Conyza Uniflora*; *One-flowered Fleabane*. Leaves lanceolate, acute, sessile; flowers solitary, lateral; calices coloured; stem shrubby, branching. Stalk shrubby, eight or ten feet high, dividing into many long slender branches; leaves three inches long, and three quarters of an inch broad in the middle; the smaller branches are set with very narrow, oblong, pointed leaves, which grow close to the stalks; and at

each joint is produced one pretty large white flower, with a purple calix; these flowers come out the whole length of the small branches, sitting close to the base of the leaves, so that the plants make a pretty appearance when in flower.—Native of Carthage in New Spain.

39. *Conyza Spicata*. Stem somewhat shrubby, simple; leaves ovate-lanceolate, finely serrated, downy underneath; spike terminal, dense, entire. The stem is a foot and a half high, erect, striated with green and white; leaves three to four inches long; flowers sessile; calix clothed with a thick down.—Native of South America.

40. *Conyza Pedunculata*. Leaves ovate-lanceolate, three-nerved; peduncles very long, terminating; flowers in corymbs. It rises with a shrubby stem to the height of six or seven feet, dividing into several branches, which have a dark brown bark; the flowers are purple, and form a kind of round bunch.—Native of Campeachy.

41. *Conyza Baccharis*. Leaves ovate-oblong, obtuse, serrate, half stem-clasping; flowers in terminating corymbs. Stem shrubby, ten or twelve feet high, sending out many strong woody branches, covered with a dark-coloured bark. The flowers are purple, and are succeeded by flat seeds.—Native of Campeachy.

42. *Conyza Purpurascens*. Leaves ovate-lanceolate, serrate, submentose; stem subherbaceous, simple at bottom, corymbed at top; flowers ovate. The flowers are purple, and are produced in round bunches at the end of the branches. Browne says it seldom rises above sixteen or twenty inches high, towards the top throwing out many branches: the smell of the flowers is agreeable, and they are kept by some people among their clothes, to preserve them from moths.—Native of the low marshy lands of Jamaica.

43. *Conyza Rigida*. Leaves petioled, obovate, entire, rugged, veined underneath; spikes flexuose; flowers in pairs, all directed the same way.—Native of Jamaica.

Copaifera; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals four, oblong, acute, concave, very spreading. *Stamina*: filamenta ten, filiform, incurved, a little longer than the corolla; antheræ oblong, incumbent. *Pistil*: germen round, compressed, flat, pedicelled; style filiform, incurvate, length of the stamina; stigma obtuse. *Pericarp*: legume ovate, bivalve, pointed with part of the style. *Seed*: single, ovate, involved by a berried aril. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: four. *Legume*: ovate. *Seed*: one, with a berried aril.—The only known species is,

1. *Copaifera Officinalis*; *Balsam of Copivi Tree*. This is a lofty elegant tree, with a handsome head; the extreme branches at the axils are flexuose, and have a smoothish bark, of a brownish ash-colour.—It is a native of South America, and common near Tolu, about sixty leagues from Carthage. This tree yields very considerable quantities of a fluid balsam or resin, which is obtained by perforating the trunk, and thickens by degrees. It is known in medicine by the title of *balsamum copivi*, and has an agreeable smell, with a bitterish taste; on being shaken, easily unites with water, making the liquor turbid and milky, but soon separates, and rises to the surface when suffered to stand. Dropped on sugar, or triturated with thick mucilages, or with whites of eggs, it becomes more permanently miscible with water into a uniform milky fluid, in which form it is generally taken, as well as mixed with powders in a bolus or electuary. It readily combines with distilled oils; and in rectified spirit of wine, dissolves into a transparent fragrant liquor, more agreeable than the balsam itself. It has been employed principally, and in preference to the other balsams, in fluor albus, and in ulcerations

of the urinary passages. Fuller, says, he has known dry deep coughs, expectation of blood and pus, voiding of chyle instead of urine, together with great pain and weakness, cured by it; and that, notwithstanding the warmth and bitterness of its taste, he has found it to agree in hectic cases. He observes, that it gives the urine a bitter taste, but not a violet smell, as the turpentine do, although it is, like them, of a purgative quality, if taken in doses of two or three drachms. The usual dose is from ten to thirty or forty drops. When given in too large doses, or too long continued, it has produced considerable inconveniences, exciting febrile heats, pains in the head, with other unfavourable symptoms. Hill observes, that it has the same virtues with turpentine, but is more powerful; and that it is excellent in the whites, and in all more complaints of the urinary passages.

Coppices. See *Planting*.

Coprosma; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite*. *Calix*: perianth one-leaved, inferior, very short, permanent, with five acute distant toothlets. *Corolla*: one-petalled, funnel-form, five or six cleft; segments acute, erect. *Stamina*: filamenta five, six, or seven, capillary; antheræ oblong, bifid at the base, erect, slightly incurved, acuminate. *Pistil*: germen oblong; styles two, filiform, cohering slightly at the base, longer than the corolla, divaricating; stigmas simple. *Pericarp*: berry ovate-globular, two-seeded. *Seeds*: two, ovate, flat on one side, convex on the other. *Male*, *Calix*, *Corolla*, and *Stamina*, as in the hermaphrodite. ESSENTIAL CHARACTER. *Calix*: one-leaved, five-toothed. *Corolla*: five or six cleft. *Stigma*: five, six, or seven. *Hermaphrodite Styles*: two, long. *Berry*: containing two flattish seeds.—The species are,

1. *Coprosma Fœtidissima*. Flowers solitary. A very fetid shrub.

2. *Coprosma Lucida*. Peduncles compound. A perfectly smooth shrub, resembling *Physalis* in its habit. Leaves petioled, ovate, acuminate both ways, quite entire; stipule solitary, sharp, combining the leaves; peduncles axillary, solitary, opposite, two-leaved, divided into other peduncles, terminated by capitate flowers; calix and corolla greenish.—Both these species are natives of New Zealand.

Coral Tree. See *Erythrina*.

Coral-wort. See *Dentaria*.

Corchorus; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets linear-lanceolate, acute, erect, deciduous. *Corolla*: petals five, oblong, obtuse, narrower beneath, erect, length of the calix. *Stamina*: filamenta numerous, capillary, shorter than the corolla; antheræ small. *Pistil*: germen oblong, furrowed; style thick, short; stigma two-cleft. *Pericarp*: capsule oblong, five-celled, five-valved. *Seeds*: very many, cornered, pointed. ESSENTIAL CHARACTER. *Corolla*: five-petalled. *Calix*: five-leaved, deciduous. *Capsule*: many-valved, many-celled.—All the plants of this genus are too tender to thrive in the open air in England; and therefore their seeds must be sown upon a hot-bed in spring; and when the plants are fit to remove, they should be transplanted into a fresh hot-bed to bring the plants forward, otherwise they will not ripen seeds. When they are rooted in this new hot-bed, free air must be every day admitted to them in proportion to the warmth of the season, for they must not be drawn up weakly; and when they have acquired strength, they should be transplanted each into a separate pot, and plunged into a hot-bed, always taking care to exclude the sun-beams until they have struck fresh roots; they should then have daily a large share of fresh air, and be frequently refreshed with water. In June they ought to be gradually

inured to the open air, and part of them may be shaken out of the pots, and planted in a warm border, where, if the season prove warm, they will flower and perfect their seeds; but as these will sometimes fail, it will be proper to put one or two plants of each sort into pots, which should be placed in a glass-case, where they may be screened from bad weather; and from these, good sorts may always be obtained.—The species are,

1. *Corchorus Oligotus*; *Bristly-leaved Corchorus*, or *Common Jews' Mallow*. Capsules oblong, ventricose; the lower serratures of the leaves setaceous. It is an annual plant, about two feet high, and dividing into several branches; leaves alternate, some spear-shaped, some oval, and others heart-shaped, deep green, slightly indented on their edges; flowers sessile, solitary, yellow.—Native of the East and West Indies, and of Africa. Rauwolf says, it is sown in great plenty about Aleppo, as a pot-herb, the Jews boiling the leaves to eat with their meat. It flowers in July and August, and the seeds ripen in autumn.

2. *Corchorus Trilocularis*. Capsules three-celled, three-valved, three-sided; angles bifid, scabrous; leaves oblong, the lowest serratures setaceous. Root annual; stems smooth and even, erect, a foot in height, round, green; stipules setaceous, small; leaves alternate, petiolate, marked with lines, naked, the under surface scabrous, lanceolate, wave-serrate.—Native of Arabia.

3. *Corchorus Tridens*. Capsules linear, somewhat columnar, scabrous; the lowest serratures of the leaves scabrous. Stem smooth and even, green; stipules three-parted, setaceous; capsules linear, scabrous.—Native of the East Indies.

4. *Corchorus Æstuans*. Capsules oblong, three-celled, three-valved, six-furrowed, six-cusped; leaves cordate, the lowest serratures setaceous. Stem strong, two feet high, divided at top into two or three branches; leaves on long petioles, and between them several smaller leaves nearly of the same form, sitting close to the branches. Flowers yellow, small, lateral, two together, on short petioles.—Native of the W. Indies.

5. *Corchorus Capsularis*. Capsules roundish, depressed, wrinkled; the lower serratures of the leaves setaceous. This rises with a slender stalk, about three feet high, sending out several weak branches; at each joint is one leaf of an oblong heart-shape, ending in a long acute point, serrate, and on a short petiole. The flowers come out singly on the side of the branches, to which they very closely adhere; petals emarginate. A kind of hemp is obtained from the macerated stems, which is much used in China.—Native of the East Indies and China.

6. *Corchorus Hirsutus*. Capsules roundish, woolly; leaves ovate, obtuse, tomentose, equally serrate. This shrub grows to the height of a man, with many round branches, the young ones villose; leaves alternate, petioled, crenate, thickish, veined, hoary underneath; petals yellow, roundish, spreading very much, scarcely the length of the calix; stamina the length and colour of the corolla, which is orange-coloured.—Native of Japan, and of the West Indies.

7. *Corchorus Japonicus*. Capsules round, smooth; leaves doubly serrate. Stem shrubby, two feet high or more, smooth; petiole a line in length; flowers terminating, solitary, on short peduncles; corolla dark yellow, or orange-coloured.—Native of Japan, where it is cultivated for the elegance of its flowers, which come forth in February, and the following months.

8. *Corchorus Hirtus*. Capsules oblong; they and the stem hairy; leaves oblong, equally serrate. Root annual; stem upright, round, branched, especially at top, from two to three feet high; leaves alternate, lanceolate, acute, finely serrate, on short petioles, somewhat hairy, wrinkled on both

sides; flowers without scent, axillary, peduncled, solitary or in pairs; calicine leaflets hispid, spreading very much, flat, lanceolate-linear, acuminate, yellowish-green; petals yellow, shorter than the calix, spreading much, very blunt, narrowed a little towards the base; seeds black, angular, small.—Native of the West Indies.

9. *Corchorus Siliquosus*. Capsules linear, compressed, two-valved; leaves lanceolate, equally serrate. It is an herbaceous plant, but branched like a shrub, with a round smooth stem, and alternate, upright, pubescent branches; leaves petioled, alternate, small, nerved, smooth, with smaller leaves in the axils; stipules subulate, opposite.—Native of the West Indies; where it flowers almost the whole year, though only from June till August in England. It is very common in dry places in all the sugar colonies, seldom rising above two feet and a half high, and is generally used for besoms by the negroes.

10. *Corchorus Tetragonus*. Leaves ovate-cordate, crenate; capsules four-cornered, reflected at the points. Height about two feet, dividing into small branches; flowers very small, pale yellow, succeeded by swelling, rough, four-cornered seed-vessels, about an inch long, flattened at top, where there are four reflex horns, given them some resemblance to the clove.—Native of both Indies.

11. *Corchorus Linearis*. Leaves lanceolate, serrate-toothed; capsules linear, compressed, two-valved. Height three feet, with several weak side-branches; leaves about three inches long, and one inch broad in the middle, lessening gradually to both ends, sitting close to the branches. The flowers come out singly opposite to the leaves; they are very small, of a pale yellow, and are succeeded by seed-vessels nearly two inches long, flat, two-celled, with small angular seeds.—Native of Carthage in New Spain.

12. *Corchorus Bifurcatus*. Leaves cordate, serrate; capsules linear, compressed, having two horns at the points. It rises with a strong herbaceous stalk between three and four feet high, sending out several side-branches, which grow erect. The flowers come out from the side of the branches, on short peduncles; they are very small, and of a pale yellow colour.—Native of Jamaica.

13. *Corchorus Fascicularis*. Capsules oblong, subsessile hoary, mucronate, two or three together; leaves lanceolate-oblong, smooth, serratures equal. Branches round and smooth; leaves petioled, narrow, blunt, the lower serratures not bristle-shaped; fruits ash-coloured, with hairs, three-valved.—Native of the East Indies.

14. *Corchorus Flexuosus*. Leaves doubly serrate, cuspidate; stem flexuose, round, slightly angular by the decurrent leaves, smooth, erect, two feet high; flowers at the ends of the branches, yellow.—Native of Japan.

15. *Corchorus Serratus*. Leaves oblong, serrate, cuspidate; branches smooth. Stem erect, smooth; branches round, purple, erect; leaves alternate, petioled; serratures large, setaceous at the tip.—Native of Japan.

16. *Corchorus Scandens*. Leaves ovate, setaceous-serrate, opposite; stem and branches flexuose, scandent; leaves on very short petioles, rounded at the base, acuminate, an inch long. At the ends of the branchlets are solitary yellow flowers.—Native of Japan.

Cordia; a genus of the class Pentandria, order Monandria.—GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, toothed at the top, permanent. *Corolla*: one-petalled, funnel-form; tube patulous, length of the calix; border erect, spreading, cut into five obtuse divisions. *Stamina*: filamenta five, subulate; antheræ oblong, length of the tube. *Pistil*: germen roundish, acuminate; style simple.

length of the stamina, bifid at top; divisions bifid; stigmas obtuse. *Pericarp*: drupe globose, acuminate, growing to the calix. *Seed*: nut furrowed, four-celled. **ESSENTIAL CHARACTER.** *Corolla*: funnel-form. *Style*: dichotomous. *Drupe*: with two-celled nuts.—As the plants of this genus are all natives of hot countries, they are too tender to endure an English winter, unless they are preserved in a stove. They are all propagated by seeds, which must be procured from those parts where they naturally grow, and sown in small pots, which should then be plunged into a good hot-bed of tanner's bark in the spring; and if the seeds be good, the plants will begin to appear in six or eight weeks. They must be brought forward in the hot-bed, by being treated like other tender exotics, observing frequently to water them in summer; and in July, if the plants happen to be considerably advanced, they should be gradually hardened in order to prepare them against the winter, which they will not survive, if too tenderly treated. As they acquire strength, they will become hardier; but during the two first winters, it will be proper to keep them in the tan-bed in the stove; but as soon as their stems begin to turn woody, they may be placed on shelves in a dry-stove, where, if they be kept in a moderate degree of heat, they may be preserved very well, especially the third species, which is somewhat hardier than the rest.—The species are,

1. *Cordia Mixa*; *Smooth-leaved Cordia*, *Sebesten*, or *Assyrian Plum*. Leaves ovate, smooth on the upper surface; corymbs lateral; calices ten-striated. Leaves like those of the Alder, serrate-angular, scabrous underneath, three inches long, opposite, flat, entire, obtuse, on a round petiole, half an inch in length; petals white, revolute; fruit inferior, red, nearly an inch in diameter. The timber of this tree is tough and solid, and is used for procuring fire by friction; the leaves bruised with those of the *Datura Metel*, are applied to the forehead in the head-ache; and a glue is prepared from the fruits, which are also eaten by children. Hill informs us, that the fruit is like a plum, with an oblong kernel, and that the pulpy part of it is so tough and clammy, that being beat up with water, it makes good bird-lime: he adds, the fruit is the part used. It is sent over to us dried like a prune, and used to be a constant ingredient in decoctions for coughs, and disorders of the lungs, but is now disregarded.—Native of Arabia and the East Indies.

2. *Cordia Spinescens*. Leaves ovate, acute, serrate, scabrous; petioles subsppinescent. Branches erect, tomentose, ferruginous; leaves alternate, petiolate, tomentose, the size of cherry leaves; fruits scattered, sessile, black, the size of currants; corolla bell-shaped, five-toothed, twice as large as the calix.—Native of the East Indies.

3. *Cordia Sebestena*; *Rough-leaved Cordia*. Leaves oblong-ovate, repand, scabrous. Stems several, shrubby, eight or nine feet high, having towards the top rough alternate leaves, on short petioles, of a deep green on their upper side; flowers terminating, in large clusters, upon branching peduncles, sustaining one, two, or three flowers; corolla large, with a long tube, spreading open at top, and there divided into five obtuse segments; it is of a beautiful scarlet, and makes a very fine appearance. A small piece of the wood, laid upon a pan of lighted coals, will perfume a whole house with a most agreeable smell. Browne says it is adorned with large bunches of fine scarlet flowers, which come out at the tops of the branches fifteen or twenty together, with fringed edges, and the surfaces sinuous and curled: they are at first of a high vermilion colour, which changes to a scarlet, and afterwards becomes purplish, but they have no scent. The fruit is in the form of an inverted pear. From the

juice of the leaves, with that of a species of fig, is prepared the fine red colour with which the natives of Otahcite dye their clothes; but we are informed that there are several other plants which will produce the same colour in conjunction with the fig.—It is a native of both Indies, and of the Society Isles. It being rather hardier than the other species, may be placed abroad in a warm situation in the beginning of July, where the plants may remain until the middle of September, provided the season continue warm, but if not, they must be sooner removed into the stove.

4. *Cordia Gerascanthus*. Leaves lanceolate-ovate, quite entire; panicles terminating; calices tomentose, ten-striated. Stem and branches unarmed, patulous, round, smooth; leaves petioled, scattered, acuminate, entire, veined (especially behind) smooth; panicles large, composed of patulous, alternate, trichotomous, many-flowered branchlets; the last pedicels three-flowered; flowers rather large, white, veined, permanent, shrivelling. This tree rises to a considerable height, but seldom exceeds twenty or thirty inches in diameter; it is pretty much branched towards the top, and furnished with oblong nervous leaves; the flowers have no scent, are very white, and grow in great numbers at the extremities of the branches; as the germen enlarges, they fade, and turn of a dark or dirty brown colour, continuing upon the tree until the whole fruit, which seldom grows to a perfect state, falls off. The branches are used by the coopers to make hoops; and it is esteemed one of the best timber-trees in Jamaica, where it is a native. The wood is of a dark brown colour, and slightly striped, is tough and elastic, of a fine grain, and easily worked. It is called Spanish Elm, or Princee-wood; in the other islands of the West Indies, the French call it *bois de chypre*.

5. *Cordia Macrophylla*; *Broad-leaved Cordia*. Leaves ovate, villose, a foot and a half in length. This tree attains to the height of fifty feet, but is seldom above twelve or sixteen inches in diameter, shooting generally by a straight trunk; the leaves are very large and rough; the berries white, of the size of small cherries. The heart of the tree is of a yellowish colour, and tolerably good timber.—It is called the Broad-leaved Cherry-tree in Jamaica; where it naturally grows.

6. *Cordia Collococca*; *Long-leaved Cordia*. Leaves cordate-ovate, quite entire; flowers corymbed; calices tomentose within. It seldom exceeds fourteen or sixteen feet in height; the leaves are rugged, obliquely veined, and disposed alternately. The berries are red and succulent, the size of our smallest European cherries, and disposed in umbellated groups; the pulp is sweetish and clammy: turkeys and other fowls feed much upon the berries, hence it is called Turkey-Berry Tree, and Clammy Cherry-tree, in Jamaica, where it is a native; it is also found in the other West India islands.

7. *Cordia Patagonula*; *Spear-leaved Cordia*, or *Patagonula*. Leaves oblong-lanceolate, smooth on both surfaces, upper ones serrate; branchlets hairy. A shrub, with the habit partly of Privet, and partly *Alaternus*. Stem straight; bark greenish ash-colour, spotted with white, the upper part, and particularly the ends of the branches, covered with long hairs; the flowers come forth among the leaves in small bunches, smelling like Elder-flowers. It flowers during the greatest part of the summer.—Native of Patagonia.

8. *Cordia Aspera*. Leaves ovate, acuminate, rough; flowers in cymes, wrinkled.—Native of the island of Tongataboo.

9. *Cordia Dichotoma*. Leaves oblong-ovate, scarcely crenate; corymbs dichotomous.—Native of New Caledonia.

10. *Cordia Retusa*. Leaves in bundles, wedge-form, retuse, three-toothed. Branches round, smooth, somewhat hairy at the tip; the buds are tomentose tubercles; fruit the size of pepper, the calix not growing to it, four-celled, in each cell

several seeds; there is a transverse furrow in the middle of the partition.—Native place unknown.

11. *Cordia Mieranthus*. Leaves elliptic, lanceolate, quite entire, membranaceous; veined; racemes compound, lax.—Native of Jamaica, and other West India islands.

12. *Cordia Elliptica*. Leaves elliptic, acuminate, entire, coriaceous; branches compound, diffused; drupes acuminate.—Native of Jamaica.

Coreopsis; a genus of the class Syngenesia, order Polygamia Frustranea.—GENERIC CHARACTER. *Calix*: common either simple, subimbricate, or doubled; the exterior usually with eight leaflets, which are coarse, and placed in a circle; the interior with as many large ones, membranaceous and coloured. *Corolla*: compound rayed; corollets hermaphrodite, numerous in the disk; females eight in the ray; proper of the hermaphrodite tubular, five-toothed; female ligulate, four-toothed, spreading, large. *Stamina*: in the hermaphrodites, filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: in the hermaphrodites, germen compressed; style filiform, length of the stamina; stigma bifid, acute, slender: in the females, germen like the hermaphrodites; style and stigma none. *Pericarp*: none; calix scarcely altered. *Seed*: in the hermaphrodite, solitary, orbiculate, convex on one side, concave on the other with a transverse protuberance at top and bottom, surrounded by a membranaceous edge, with a two-horned tip; in the females, none. *Receptacle*: chaffy. ESSENTIAL CHARACTER. *Calix*: erect, many-leaved, surrounded at the base with spreading rays. *Down*: two-horned. *Receptacle*: chaffy.—The species are,

1. *Coreopsis Verticillata*; *Whorl-leaved Coreopsis*, or *Tickseed Sun-flower*. Leaves decapound-linear. Root perennial; stems many, stiff, angular, upwards of three feet high; ray yellow; disk dark purple. Being a showy plant, growing very tall, and continuing long in flower, it is a great ornament to the shrubbery; the yellow florets, which appear from July till September, are used in North America to dye cloth red.—Native of North America. This species, and also the second, fifth, ninth, twelfth, and thirteenth to the sixteenth, are hardy plants, and may be plentifully propagated by parting the roots, the best time for which is in autumn, when the stalks begin to decay. The first species requires a light loamy earth, and sunny exposure.

2. *Coreopsis Coronata*. Leaves pinnate, serrate, marked with lines, smooth. Annual.—Native of Virginia.

3. *Coreopsis Leucantha*. Leaves pinnate, serrate; ray of the flowers of a different colour from the disk. Stem three or four feet high, four-cornered, smoothish, the opposite sides channelled; flowers terminating, alternate, two or three on longish peduncles; ray of the corolla usually with five white florets, which are ovate, three-toothed at the end, the middle one longest, three-nerved underneath.—Annual: and a native of America.

4. *Coreopsis Chrysantha*. Leaves ternate, ovate-oblong, serrate; ray of the flowers concolor. Stem quadrangular, simple, jointed; leaves on the branch opposite, smooth; on the flowering branches alternate, smaller; flowers terminating, on long peduncles, solitary, with six three-toothed florets in the ray, which are nevertheless often wanting. Root and stem sweet-scented.—Native of South America.

5. *Coreopsis Tripteris*; *Three-leaved Coreopsis*. Leaves subternate, quite entire; root perennial; stems strong, round, smooth, six or seven feet high; flowers in bunches, on the top of the stem, in long peduncles; ray of the corolla pale yellow; disk dark purple. Native of North America. It requires a light loamy earth, and sunny exposure.

6. *Coreopsis Alba*; *Climbing Coreopsis*. Leaves subternate, cuneate, serrate. This is a climbing plant; the florets of the margin of which are all neuter, and rise immediately from the bottom of the inward scales; the seeds are bidentate.—Native of the hills of Jamaica, and of the island of Santa Cruz.

7. *Coreopsis Reptans*; *Trailing Coreopsis*. Leaves serrate, ovate, upper ones ternate; stem creeping. Root small, fibrous, annual with us; stem climbing, weak, five feet high, branching, leafy, striated, smooth, square at the base, roundish above; florets all gold-coloured, those of the ray with about four teeth and veined, those of the disk five-cleft.—Native of the woody inland parts of Jamaica.

8. *Coreopsis Baccata*; *Berried Coreopsis*. Leaves serrate, ovate; seeds berry-form. Stem eight feet in height, herbaceous, erect; leaves opposite, petioled, three-nerved; flowers terminal, often three, peduncled, very small; ray of the corolla neuter, yellow, three-toothed, longer than the disk; fruit the exact form of a blackberry.—Native of Surinam.

9. *Coreopsis Auriculata*; *Ear-leaved Coreopsis*. Leaves quite entire, ovate, the lower ones ternate. Stem from nine inches to a foot in height, upright, covered with a soft down; flowers golden-coloured, with about eight florets in the ray.—Native of Virginia.

10. *Coreopsis Lanceolata*; *Spear-leaved Coreopsis*. Leaves lanceolate, quite entire, ciliate. Stems several, decumbent at bottom, and thence rising obliquely a foot and a half or two feet in length; florets in the ray eight or nine, broad, with four deep large teeth at the end; calix double, each consisting of eight or nine leaflets, the outer thick and spreading, the inner larger, upright, and pressed close to the flower, transparent, and of a pale ochre-colour. The seeds, which resemble a small hemispheric beetle or bug, must be sown upon a gentle hot-bed in the spring, and when the plants are fit to remove, they should be set each in a separate small pot, and plunged into a fresh hot-bed to bring them forward. They must be gradually inured to the open air in June, and some of them may be afterwards taken out of the pots, and planted in a warm border, where, if the season be good, they will flower in the middle of July, and ripen their seeds in the beginning of September.

11. *Coreopsis Bidens*. Leaves lanceolate, serrate, opposite, stem-clasping.—A more variety of *Bidens Cernua*, to which the reader is referred.

12. *Coreopsis Alternifolia*; *Alternate-leaved Coreopsis*. Leaves lanceolate, serrate, alternate, petiolate, decurrent. Root woody, perennial; stems several, annual, erect, angular, filled with white pith, winged, from five to ten feet high, simple, having only very short subdivisions at the top, into roundish villose peduncles; florets in the ray from four to eight, yellow; border slightly toothed, very concave, with the sides rolled in; the flowers have but little scent, and coming forth late in October or November, seldom perfect their seeds in England.—Native of Virginia, and Canada. It will thrive in almost every soil and situation.

13. *Coreopsis Aurea*; *Hemp-leaved Coreopsis*. Leaves serrate; root-leaves three-parted; stem-leaves trifid and entire, lanceolate, linear. Perennial; flowering in August and September.—Native of North America.

14. *Coreopsis Crassifolia*; *Thick-leaved Coreopsis*. Leaves obovate-oblong, obtuse, quite entire, pubescent. Perennial; flowering from August till October.—Native of Carolina.

15. *Coreopsis Angustifolia*; *Narrow-leaved Coreopsis*. Leaves alternate, linear-lanceolate, quite entire, even; petals of the ray oblong, trifid, the middle segment largest. A perennial plant; flowering in June.—Native of Carolina and Florida.

16. *Coreopsis Procera*; *Tall Coreopsis*. Leaves elliptic, acuminate, serrate, petiolate, veined, decurrent, the lower in whorls, the upper alternate. It is perennial; flowering in September and October.—Native of North America.

17. *Coreopsis Radiata*. Leaves linear-lanceolate, sharply serrate, opposite; ray of the flower large, entire. Root annual; stems upright, four feet high; leaves acuminate, from three to four inches long, three quarters of an inch broad in the middle, deep green on their upper surface, and pale on their lower, on short petioles. It flowers in August, and, if the autumn prove favourable, ripens its seeds in October.—Native of Carolina.—It is propagated by seeds, which should be sown on a warm border in autumn, and the plants will appear in the following spring; but if the seeds be sown in the spring, the plants seldom rise till the year after. When fit to remove, they should be taken up carefully, and either replanted where they are intended to remain, or placed in a nursery-bed, at four inches' distance, to get strength, observing to exclude the beams of the sun until they have taken fresh root, after which, those which are planted out to remain, will only require to be kept clean from weeds, and as they advance in height, should be supported by sticks, otherwise the strong winds of autumn often break them. Those which are placed in the nursery-bed, should be taken up when they have acquired proper strength, and transplanted, with balls of earth adhering to their roots, wherever they are designed to stand for flowering.

18. *Coreopsis Leucorhiza*. Leaves pinnate, with five leaflets, serrate-gashed; ray six-flowered; down three-horned. Stem herbaceous, a foot and a half high, erect, four-cornered, grooved, arising from a simple, perpendicular, fusiform, white, fleshy root; flowers entire, saffron-coloured, few together, on terminating peduncles; calix erect, many-leaved.—Native of Canton in China.

19. *Coreopsis Bitermata*. Leaves bitermate, ovate-lanceolate, serrate; panicle diffused; ray six-flowered. Stem herbaceous, two feet high, erect, four-cornered, four-grooved; flowers entirely yellow.—Native of China near Canton.

20. *Coreopsis Fœtida*. Leaves three-lobed; lobes acuminate, serrate, middle one longer. Root annual; stem round; upright, a fathom in height, branched, covered with a short glutinous nap; flowers corymb; corolla yellow; florets of the ray eight; border ovate-oblong, three-nerved, shortly emarginate.—Native of Mexico.—As these plants continue to produce flowers till arrested by the frost, they merit a place in every curious garden, especially those of them which do not ramble and spread too much.

Coriandrum; a genus of the class Pentandria, order Digenia.—GENERIC CHARACTER. *Calix*: umbel universal with few rays; partial with very many; involucre, universal scarce one-leaved; partial three-leaved, halved, linear; perianth proper, five-toothed, standing out. *Corolla*: universal difform, rayed; floscules of the disk abortive. Proper of the disk hermaphrodite; petals five, inflex, emarginate, equal. Proper of the ray hermaphrodite; petals five, inflex, hearted, unequal, of which the exterior is very large, two-parted; but the nearest lateral ones have a very large division. *Stamina*: filamenta, five, simple; antheræ roundish. *Pistil*: germen inferior; styles two, distant; stigmas of the ray headed. *Pericarp*: none; fruit spherical, bipartite. *Seeds*: two, hemispheric, concave. ESSENTIAL CHARACTER. *Corolla*: rayed. *Petals*: inflex, emarginate. *Involucre*: universal, one-leaved; partial halved. *Fruit*: spherical.—These plants are propagated by sowing their seeds in the autumn, in an open situation, on a bed of good fresh earth, hoeing out the plants to about four inches apart every way as soon as they appear,

and also clearing them from weeds, which will enable the plants to acquire more strength, and produce a greater quantity of good seeds.—The species are,

1. *Coriandrum Sativum*; *Common or Great Coriander*. Fruits globular. Root annual, strong-scented; stem a foot or a foot and half in height, smooth, branched; leaves compound; root-leaves larger, doubly pinnate; pinnules broad, gashed on every side, serrate, and even half two-lobed; petals white or reddish; fruits obsoletely ribbed, aromatic.—It flowers in June and July, in corn-fields, by road-sides, and on dung-hills; the seeds ripen in August. The leaves have a strong disagreeable scent; the seeds are grateful to the taste, and are sold by the confectioners encrusted with sugar. The Edinburgh College use them as correctors; in the bitter infusion and the preparations of senna, nothing so effectually covering the disagreeable taste of that medicine. When taken in large quantities they have been considered deleterious; but Withering informs us, that he has known six drachms of them to be taken at once, without any remarkable effect. Meyrick states, that the seeds are the only part used in medicine. While green, they have a strong unpleasant smell, which they lose in drying, and become sweet and aromatic: they are of great service in warming and strengthening the stomach, dispersing wind, and assisting the digestive faculties, and also relieve pains of the head, and operate as a check in violent purges.—This plant is found wild in Essex, yet, though it has also been long cultivated about Ipswich, and in a few other places, it is not a native of this country, but the south of Europe, China, and Cochinchina. It was formerly cultivated in the gardens as a salad herb, and is still used in the East Indies for the same purpose, being a principal ingredient in most of the compound dishes of the inhabitants of those regions, and much esteemed as a culinary herb, the seed is also employed in the same way; but in Europe neither of them are now much used. For the field culture of Coriander, see *Carum Carui*. The produce of Coriander is from ten to fourteen hundred-weight on an acre, and the price varies from 16s. to 42s. per hundred-weight, but is commonly at 24s. Unless great care be taken, the largest and best part of the seed will be lost; to prevent this, women and children are employed to cut it plant by plant, and to put it immediately into cloths, in which it is carried to some convenient part of the field, and there threshed upon a sail-cloth: a few strokes of the flail bring the seeds clean out, and the threshers are ready for a fresh bundle in a few minutes. There is a ready sale for Coriander seed among the distillers, druggists, and confectioners; the former, especially, purchase very large quantities.

2. *Coriandrum Testiculatum*; *Small or Twin-fruited Coriander*. Fruits twin. This has a much stronger scent than that of the common sort. Root annual; stem angular, branched, about sixteen inches high; leaves once or twice pinnate; umbels small, often simple; seeds a little wrinkled, but not striated.—Native of the south of Europe. Both species are raised from seeds sown in autumn, in an open situation, on a bed of good fresh earth. They require no other care than to be hoed to about four inches asunder every way, and kept clear from weeds.

Coriaria: a genus of the class Diœcia, order Decandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth five-leaved, very short; leaflets subovate, concave. *Corolla*: petals five, very like the calix, connected. *Stamina*: filamenta ten, length of the corolla; antheræ oblong, two-parted. *Female*. *Calix*: perianth five-leaved, very short; leaflets subovate, concave. *Corolla*: petals five, cuspidate, caliciform, converging. *Stamina*: filamenta ten, very short;

antheræ barren. *Pistil*: germea five, compressed, inwardly conjoined; styles as many, bristle-form, long; stigmas simple. *Pericarp*: none; five, fleshy, ovate, lanceolate, three-sided petals, with one of the angles looking inwards, covering the seeds. *Seeds*: five, kidney-form. **ESSENTIAL CHARACTER.** *Calix*: six-leaved. *Corolla*: five-petalled, very like the calix. *Male. Antheræ*: two-parted. *Female. Styles*: five. *Seeds*: five, covered with succulent-berried petals.—The species are,

1. *Coriaria Myrtifolia*; *Myrtle-leaved Sumach*. Leaves ovate-oblong; flowers in racemes. It seldom exceeds three or four feet high, creeping at the root, and sending forth many stems. The plant with male flowers only was common in England, until that which bears hermaphrodite flowers was raised in the Chelsea garden, from seeds sent from Italy. This plant possesses considerable astringency, and is used not only in tanning leather, but in dyeing black. It sends up so many stems as to form a thicket; it is useful to fill up vacancies in plantations of shrubs, but is only proper for large gardens.—Native of the south of France, and Africa, about Mount Atlas. It may be propagated in abundance from the suckers which are plentifully produced from the creeping roots. They should be taken off in March, and planted into a nursery to form good roots, where they may continue one or two years, and must then be removed to the places where they are to remain. This plant delights in a loamy soil, which is not too stiff, and should be sheltered from the north and east winds, where it will endure the cold of our ordinary winters, and flower better than if preserved in pots under cover during the winter.

2. *Coriaria Ruscifolia*. Leaves cordate-ovate, sessile; flowers hermaphrodite. A tree, 20 to 25 feet high, with a trunk the thickness of a man.—Native of Chili.

3. *Coriaria Sarmentosa*. Procumbent, diffused: leaves cordate-ovate, acuminate, quite entire, five-nerved, subpetiolate; racemes axillary, nodding.—Native of New Zealand.

Coris; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, bellied, converging, five-toothed, externally crowned with spines, of which the five superior ones are simple, the inferior ones toothed. *Corolla*: one-petalled, irregular; tube the length of the calix, cylindrical; border flat, five-parted; divisions oblong, emarginate, obtuse, the two inferior ones shorter and more distant. *Stamina*: filamenta five, bristle-form, length of the corolla, declining; antheræ simple. *Pistil*: germen roundish, superior; style filiform, length of the stamina, declining; stigma thickish. *Pericarp*: capsule globose, placed in the bottom of the calix, one-celled, five-valved. *Seed*: very many, nearly ovate, small. **ESSENTIAL CHARACTER.** *Calix*: spinous. *Corolla*: one-petalled, irregular. *Capsule*: five-valved, superior.—The only known species is,

1. *Coris Monspeliciensis*; *Montpellier Coris*. This plant seldom grows above six inches high, and spreads near the surface of the ground like Heath; the stem is red; the leaves are alternate, linear, thickish, spreading; the flowers in spikes, red or white, coming out in June, and making a beautiful appearance.—It is a native of sandy shores in the south of France. It may be propagated by sowing the seeds upon a bed of fresh earth in the spring. When the plants are about an inch high, they should be transplanted, some of them into pots filled with fresh light earth, that they may be sheltered in winter; and the others into a warm border, where they will bear the common cold of winter very well. These plants will sometimes produce ripe seeds in England; but as that is seldom the case, it will be proper to increase them from slips and cuttings, which will strike root if planted about the end of August on a very gentle hot-bed, shaded from the sun, and duly watered.

Corispermum; a genus of the class Monandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals two, compressed, incurved, acuminate, opposite, equal. *Stamina*: filamenta one, but in the lowest flowers often from two to five, filiform, shorter than the petals; antheræ simple. *Pistil*: germen acute, compressed; styles two, capillary; stigmas acute. *Pericarp*: none. *Seed*: single, oval, compressed, gibbous on one side, with the margin acute. **ESSENTIAL CHARACTER.** *Calix*: none. *Pistils*: two. *Seed*: one, oval, naked.—The species are,

1. *Corispermum Hyssopifolium*; *Hyssop-leaved Tickseed*. Spikes terminating; leaves linear, nerveless, awnless. Root annual; stem scarcely a foot high, pubescent towards the top, reddish beneath, striated, branched.—It is common all over the Russian empire, in sandy soils, especially on the banks of lakes and rivers, and in low moist places; where it affords pasture for the camels. It is also found in the south of France. It will stock the ground plentifully, if it be only permitted to scatter its seeds.

2. *Corispermum Squarrosum*; *Rough-spiked Tickseed*. Spikes axillary, squarrose; leaves lanceolate, acuminate, pungent, nerved. Root annual.—Native of Russia. It will only grow in marshy places, and will soon cover the surface of standing water, when once established.

Cork Tree. See *Quercus*.

Cornel; *Cornelian Cherry.* See *Cornus*.

Corn Flag. See *Gladiolus*.

Corn Salad. See *Valeriana*.

Cornucopiæ: a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth common one-leafed, funnel-form, very large; mouth crenated, obtuse, from spreading upright, many-flowered; glume one-flowered, two-valved; valves oblong, obtusely acuminate, equal. *Corolla*: one-valved, in figure, size, and situation, very much resembling the valves of the glume of the calix. *Stamina*: filamenta three, capillary; antheræ oblong. *Pistil*: germen turbinate; styles two, capillary; stigmas cirrhose. *Pericarp*: none. *Corolla*: including the seed. *Seed*: simple, turbinate, on one side convex, on the other flat. **ESSENTIAL CHARACTER.** *Involucre*: one-leafed, funnel-form, crenate, many-flowered. *Calix*: two-valved. *Corolla*: one-valved.—The species are,

1. *Cornucopiæ Cucullatum*; *Hooded Cornucopiæ*. Spike beardless, with a crenate hood, or involucre. Root annual, fibrous, branched; culms numerous, ascending, jointed, round, smooth, striated, branched, leafy, dark purple at the joints; leaves narrow, striated, smooth; sheaths inflated, spreading, pointed; flowers in a little head or spike, projecting somewhat beyond the involucre, green, often tipped with purple; seed small. Of all grasses, this is perhaps the most singular, as well as the most uncommon.—Native of the vales about Smyrna.

2. *Cornucopiæ Alopecuroides*. Spike bearded, within a hemispheric hood, or involucre. It very much resembles *Alopecurus Pratensis*. Culms ascending, even; leaves even. The singular mark of this species is, a hood in the form of a pitcher, quite entire, of the same consistence with the leaf, surrounding the base of the spike like a common calix.—Grows in Italy.

Cornus; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: involucre generally four-leaved, many-flowered; leaflets ovate, the opposite ones smaller, coloured, deciduous; perianth very small, four-toothed, superior, deciduous. *Corolla*: petals four, oblong, acute, flat, smaller than the involucre. *Stamina*: filamenta four, subulate, erect, longer than the corolla; antheræ

roundish, incumbent. *Pistil*: germen roundish, inferior; style filiform, length of the corolla; stigma obtuse. *Percarp*: drupe roundish, umbilicated. *Seed*: nut heart-shaped, or oblong, two-celled. **ESSENTIAL CHARACTER.** *Involucre* generally four-leaved. *Petals*: four, superior. *Drupe*: with a two-celled nut.—The species are,

1. *Cornus Florida*; *Great flowered Dogwood*. Arboreous: involucre very large; leaflets obovate. It seldom rises above seven or eight feet high, but is generally well furnished with large leaves. Although it be very hardy, it neither flowers freely, nor produces berries in England. There is a variety of this species, with a rose-coloured involucre, which was found wild in Virginia. They are great ornaments to the woods of America, by their early flowering in the spring, before the leaves appear, and by their berries hanging all the winter on the trees. The wood is white, has a close grain, and is very hard, like that of Box.—It flowers in April and May, and is common in our nurseries, where it is known by the name of Virginian Dogwood. All the sorts of Dogwood may be propagated by their seeds, which, if sown soon after they ripen in autumn, will generally appear in the following spring; but if not sown in autumn, they will lie a year in the ground before the plants will come up, and in dry seasons have been known to be two years in making their appearance; for which reason, the ground where they have been planted ought not to be disturbed. When they spring up, let them be watered in dry weather, and weeded, and in the following autumn removed into beds in the nursery, where they may stay two years, and at the end of that time will be fit to transplant where they are designed to remain: the best season for transplanting them is in autumn. They are also propagated by suckers, and laying down the branches. Most of the Dogwoods produce plenty of suckers, especially when planted on a moist light soil. These suckers may be taken off from the old plants in autumn, and planted into a nursery for a year or two, and may then be finally transplanted into those places where they are destined to remain. But the gardener ought to be informed, that the plants produced from suckers seldom have so good roots as those which are propagated by layers, and are not so valuable as the latter plants, because they are also so very liable to put out suckers themselves. Some of the scarcer species, from America, are often engrafted into the fourth or fifth species.

2. *Cornus Mascula*; *Cornelian Cherry*. Arboreous: umbels equalling the involucre; leaves serrate; shoots ash-coloured, and pubescent; leaves in pairs, ovate-lanceolate, subhirsute. The flowers come out very early in the spring before the leaves; corolla yellow, spreading, and at length reflected, longer than the stamina; fruit oblong, the size of an olive, bright scarlet, sometimes yellow. It is a shrub in its wild state, and about four or five feet high, but advances, when cultivated, into a tree twenty feet in height and is very common in our plantations of shrubs. If the season be mild, the flowers will come out in the beginning of February; and though there be no great beauty in them, yet they come forth in great numbers at a time when few other flowers appear. It was formerly cultivated for the fruit, which was used to make tarts, and a *rob de cornis* was kept in the shops. Meyrick says, that the dried fruit, or the juice of it, boiled up with sugar, is an excellent cooling astringent medicine, and of great utility in fevers attended with purging. Cornel, says Evelyn, grows with us of good bulk and stature, and is exceedingly recommended for its durability in wheel-work, pias, and wedges, in which it wears like the hardest iron.—Native of Russia, Germany, Switzerland, Austria, Carniola, France, Piedmont, and the Milanese.

3. *Cornus Japonica*. Arboreous: umbels exceeding the involucre; leaves serrate; stem erect, six feet in height; branches opposite, striated, ash-coloured, smooth; flowers terminating, umbelled, white.—Native of Japan.

4. *Cornus Sanguinea*; *Common Dogwood*. Arboreous: cymes depressed; branches straight; leaves ovate, concolor. Height from four or five to eight or ten feet; leaves opposite, quite entire, but sometimes with the edge waving. The fruit is globular, dark purple, very bitter, oily, and styptic.—Native of Europe, found in hedges, especially in a calcareous soil. It flowers in June, and the berries ripen in August. It has a variety of names in different parts of England, as *female cornel*, *dog-berry tree*, *hound's-tree*, *hound's-berry tree*, *prickwood*, from its use in making skewers, *gaten* or *gatten-tree*, *gater* or *gatter-tree*. Mr. Miller informs us, that the fruit of this tree is often brought into our markets, and sold for Buckthorn berries; from which, however, it may be easily distinguished, there being only one stone in this, whereas the Buckthorn has four stones; the latter also stains paper green, but the juice of the former is purple. Dogwood is called *virga sanguinea*, or bloody-rod, by old authors, from the fine red colour of its young shoots. The wood, according to Evelyn's account, is like the Cornel for compactness, and is used for cart-timber and rustic instruments, for mill-cogs, spokes, bobbins for bone-lace, for the best tooth-picks, and for butcher's skewers. Being hard and even, it is also fit for the turner. In foreign countries, a lamp-oil is extracted from the berries, by boiling them in water, and afterwards pressing them. Baron Haller observes, that these berries are very bitter and styptic, but not employed in medicine.

5. *Cornus Alba*; *White-berried Dogwood*. Arboreous: cymes depressed; branches recurved; leaves broad-ovate, hoary underneath. Stem woody, putting out many lateral branches near the ground, so that unless it be trained while young, it generally spreads low. During summer the branches are brownish, but change in winter to a fine red. The flowers are produced in large cymes, at the extremity of every shoot, towards the end of May, and are white.—Native of Siberia, and of North America.

6. *Cornus Sericea*; *Blue-berried Dogwood*. Arboreous: cymes naked, depressed; branches patulous; leaves ovate, ferruginous, silky underneath. This shrub grows two fathoms in height, with an upright, round, branched, gray stem; branches round, opposite, spreading, dusky purple; flowers pedicelled, horizontal, white, with the disk at first white, but afterwards brown or dark purple. The leaves are narrower and deeper veined than in the fifth species; the flowers grow in smaller cymes, and the fruit is smaller, and of a deep blue colour when ripe. The shoots are of a beautiful red colour in winter; and in summer, the leaves being large, of a whitish colour on their underside, and the bunches of white flowers growing at the extremity of every branch, render this a valuable shrub; and in autumn, when the large bunches of blue berries are ripe, it makes a very beautiful appearance.—Native of North America.

7. *Cornus Alternifolia*; *Alternate-leaved Dogwood*. Arboreous: leaves alternate; branches subdeterminate, round, glossy, dark purple, with whitish vague dots or lines; leaves petioled, ovate, acute, quite entire, glossy, marked with lines, pale underneath. The branches are sometimes red, and sometimes green.—Native of North America.

8. *Cornus Suecica*; *Herbaceous Dogwood*. Herbaceous, with branches in pairs. This elegant plant is about six inches high; stem four cornered, thinly branched, forked at top; leaves oval, opposite, smooth, sessile, ribbed, with five nerves, the lower ones rounder. The involucre consists of

four or five white leaves resembling petals, in the centre of which are twenty or more small blackish flowers, on short peduncles; the flowers are very small, in a simple umbel; they are succeeded by a cluster of berries, which are red when ripe, and each contain a heart-shaped stone. The berries have a sweetish watery taste, and are acceptable to children. The Highlanders suppose, that they create an appetite, and hence the plant is called by the Erse language, *lus a chrais*, or plant of gluttony. It flowers in June, and in England is commonly known under the name of *Dwarf Honeysuckle*. It is found on the Cheviot Hills, and other parts of the northern counties; and in moorish places near rivulets, on the sides of the Highland mountains in Scotland.—Native also of the north of Europe, and of the whole northern tract of the Russian empire, from the Baltic to the Eastern Ocean. It is very difficult to preserve this plant in gardens: the only method is, to remove it from its natural place of growth with good balls of earth adhering to the roots, and replant it in a moist shady situation, where it will not be annoyed by the roots of other plants. It may be preserved two or three years in such a situation, but will seldom continue longer.

9. *Cornus Canadensis*; *Canadian Dogwood*. Herbaceous, with no branches. It is only a hand in height; stems several, herbaceous, upright, four-cornered, purplish, having some opposite slightly clasping leaves at bottom, which wither and fall off; flowers pedicelled, upright, white, with a violet-coloured bottom.—It flowers in August, and is a native of Canada, Labrador, and Newfoundland.

10. *Cornus Circinata*. Branches warty; leaves orbiculate, tomentose, and hoary underneath; cymes depressed. Stem upright, branched, gray, about six feet high; flowers pedicelled, upright, white, five lines wide. It is distinguished by its orbicular, wrinkled, very green leaves, the cymes bracted at bottom, and its very thick tubercled branches.—It is a native of Pennsylvania, where it has long been cultivated; and may be met with, but not commonly, in France.

11. *Cornus Stricta*; *Upright Dogwood*. Branches strict; leaves ovate, concolor, almost naked; cymes panicled. Stem several, upright, brownish, six feet high; branches opposite, round, in younger plants strict, in older patulous. The twigs, and especially the suckers, stiffish, having rings at the joints, purple, warted closely at the base; flowers pedicelled, white, with the disk only red, four lines in diameter. The fruit appears too late to ripen in our climate, and the leaves continue green till the frost comes on.—Native of North America.

12. *Cornus Paniculata*; *New Holland Dogwood*. Branches erect; leaves ovate, hoary underneath; cymes panicled. Stems very many, upright, much branched, round, gray; leaves acuminate, almost entire; flowers pedicelled, upright, white, three lines in diameter; fruits white, retaining the style. It is distinct from every other species, in having the cymes elongated into a thyrse, or panicle. It is handsome, and very full of flowers, which come out in the spring, or early in the summer, and is loaded with fruit during several months in autumn.—Native of North America.

Cornutia: a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, roundish, very small, tubular, five-toothed, permanent. *Corolla*: one-petalled, ringent; tube cylindric, much longer than the calix; border four-cleft, upper division erect, roundish, lateral ones distant, lower roundish, entire. *Stamina*: filamenta four, of which two project beyond the tube of the corolla; antheræ simple, inclining. *Pistil*: germen roundish; style very long, two-parted; stigmas thickish. *Pericarp*: berry globose, at the base comprehended by the

calix. *Seed*: single, kidney-form. ESSENTIAL CHARACTER. *Calix*: five-toothed. *Stamina*: two of them longer than the corolla. *Style*: very long. *Berry*: globular, one-seeded.—The species are,

1. *Cornutia Pyramidata*; *Hoary-leaved Cornutia*. Leaves opposite, ovate; flowers in terminating corymbs. It grows to the height of ten or twelve feet. The branches are four-cornered, and grow straggling; flowers in corymbs at the ends of the branches, of a fine blue colour; they appear usually in autumn, and sometimes remain in beauty for two months or more.—It abounds in several of the West India islands, and also at Campeachy and La Vera Cruz. *Cornutia* is propagated by seeds, which should be sown early in the spring, on a hot-bed. The plants should be each transplanted into a small pot of light fresh earth, as soon as they appear, and immediately plunged into a hot-bed of tanner's bark, observing to shade them from the sun until they have taken root; after which, fresh air must be admitted in proportion to the warmth of the season; and it should be frequently watered, as it naturally grows on swampy soils. When the plants have filled the pots with their roots, they ought to be removed into others of a larger size, and again plunged into a hot-bed, where they should remain till October, and should then be plunged into the tan or the bark-stove; for unless this be done, it will be very difficult to preserve them through the winter. In the third year they will flower in the stove, and make a fine appearance: but they never perfect their seeds in England. They may also be propagated by cuttings, which if planted into pots filled with earth, and plunged into a bark-bed, observing to shade and water them, will take root, and must be afterwards treated as the seedling plants.

2. *Cornutus Quinata*. Leaves quinate, lanceolate-ovate; flowers in racemes. This is a middle-sized tree, with spreading round branches; leaves acuminate, quite entire, smooth, on a long common petiole; flowers greenish yellow; corolla somewhat funnel-shaped, the upper lip trifid, the lower bifid, and shorter.—Native of China, in the woods near Canton.

Coronilla; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: umbellule simple; perianth one-leafed, very short, compressed, bifid, erect, the three inferior teeth smaller; the two superior conjoined, permanent. *Corolla*: papilionaceous; standard heart-shaped, reflected on all sides, scarce longer than the wings; wings ovate, converging at top, gaping at bottom, obtuse; keel compressed, acuminate, ascending, usually shorter than the wings. *Stamina*: filamenta diadelphous, single, and nine-cleft, ascending at almost a right angle, the tips widish; antheræ simple, small. *Pistil*: germen columnar, oblong; style bristled, ascending; stigma small, obtuse. *Pericarp*: legume very long, columnar, straight, contracted, with an isthmus between each seed, two-valved, one-celled, parting by joints. *Seeds*: many. ESSENTIAL CHARACTER. *Calix*: two-thirds two-lipped, the upper teeth connate. *Standard*: scarcely longer than the wings. *Legume*: contracted between the seeds.—The species are,

1. *Coronilla Emerus*; *Scorpion Senna*. Shrubby; peduncles with about three flowers, claw of the corolla three times the length of the calix; stem angular, not very straight, branched, and brachiate; leaves alternate; leaflets seven or nine, inclining to inversely heart-shaped. Height, when wild, from two to six feet, and in gardens, from eight to nine; corolla yellow; standard very remote from the other petals.—Native of Germany, Austria, Carniola, Switzerland, France, and Savoy. It is easily propagated by sowing the seed, which it commonly

CRATÆGUS — Maple-leaved Hawthorn.

produces in great abundance in March, upon a bed of light sandy earth. It should be kept clean from weeds, and refreshed with water in dry weather, which, especially after it comes up, will promote its growth. At Michaelmas, if the plants have thrived well, let the largest be drawn out, and transplanted into a nursery, where they should continue two years, and will then be fit to plant out where they are to remain. This species may also be propagated by laying down the tender branches, which will take root in about a year's time, and may then be transplanted into a nursery, and managed like the seedling plants.

2. *Coronilla Juncea*; *Linear-leaved Coronilla*. Shrubby: leaflets quinate and ternate, linear-lanceolate, somewhat fleshy, obtuse. This rises from two to four feet high, with many slender woody branches, which resemble broom; flowers yellow, six or seven together in small peduncled terminal umbels.—Native of the south of France. This, together with the fourth and seventh species, are propagated by sowing the seeds in the spring, either upon a gentle hot-bed, or on a warm border of light fresh earth; and when the plants are come up about two inches high, they should be transplanted either into pots, or a bed of good rich earth, at about four or five inches' distance every way, where they are to remain until they have acquired strength enough to be wholly planted out: if the winter be not very severe, they will abide very well, provided they are in a dry soil. Some of the plants of the second species should be sheltered under a common frame in winter, because they are often destroyed in hard frosts; but in mild weather, they ought to be freely exposed to the air, to prevent their drawing up weak.

3. *Coronilla Valentina*; *Small Shrubby Coronilla*. Shrubby: leaflets about nine; stipules suborbiculate. It attains to three or four feet high. The flowers appear in close bunches, on long axillary peduncles; they are small and of a deep yellow colour, at all times diffusing a very powerful odour. The stipules are large, almost round, and strikingly conspicuous in the young plant. Linneus remarks, that early in the spring the leaves have the colour of Rue: hence Mr. Curtis gives it the name of Rue-leaved *Coronilla*. Native of Spain and Italy.—This, with the fifth and sixth species, are propagated by seeds sown in April, upon a bed of light earth. When they are fit to remove, some of them should be transplanted into a border close to a warm wall or pale, to which the branches ought to be trained, observing carefully to shade them from the sun till they have taken fresh root, and also to supply them with water when they require it; after they are well rooted, they will require no further culture, but weeding, and keeping their branches trained to the pale or wall. They flower in the second year, and will continue many years upon a dry soil, and a warm situation.

4. *Coronilla Glauca*; *Great Shrubby Coronilla*. Shrubby: leaflets seven, very obtuse; stipules lanceolate. This seldom exceeds three or four feet high, with a woody branching stem; flowers bright yellow, in a roundish bunch; wings gaping widely at bottom, so as to discover the whole keel. This, according to Linneus, has little or no smell in the night, but is remarkably fragrant during the day. It flowers from September till May; indeed, almost the whole year.—Native of the south of France. See the second species.

5. *Coronilla Coronata*; *Crowned Coronilla*. Shrubby: leaflets nine, obovate, the inmost approximating to the stem; stipule opposite to the leaf, two-parted. Stems erect, little branched, round, smooth, about eighteen inches in height, woody at bottom only; calix a line long, yellowish; corolla yellow. The end of the keel is apt to be green, and this, with

the glaucous hue of the leaves, indicates that a blue colour may be produced from these flowers by putrescence.—It flowers in July, and is a native of the southern countries of Europe. See the third species.

6. *Coronilla Minima*; *Least Coronilla*. Undershrubby, procumbent: leaflets nine, ovate; stipule opposite to the leaf, emarginate; legumes angular, knotty. Root perennial; stems slender, woody, branched, two or three inches long, and prostrate; hence spring annual herbaceous, round branches, pale green, also prostrate; leaflets at the top, and ending in a little bunch of flowers; flowers about six, yellow, sweet-smelling; calix small, green; seeds oblong, brown. The whole plant very smooth.—Native of the southern countries of Europe. See the third species.

7. *Coronilla Argentea*; *Silvery-leaved Coronilla*. Shrubby: leaflets eleven, silky, the outmost larger than the rest. A very humble shrub, rarely exceeding two feet in height in a good soil. The stem is hard and woody; from which the branches are produced on every side near the ground. The flowers are on long, slender, axillary peduncles, they are yellowish, and have a strong sweet scent; and as the plants always produce an abundance of them, they make a fine appearance during the month of May, in which they flower. The seeds ripen in August and September. The silvery colour of this plant is occasioned by its growing on a poor dry soil, which it will change for a glaucous colour if removed into better ground.—Native of Crete. See the second species.

8. *Coronilla Securidaca*; *Hatchet Vetch*. Herbaceous: legumes sickle-sword-shaped; leaflets very many. Root annual, composed of a few slender fibres; which run pretty deep in the ground; stems herbaceous, trailing, a foot and a half long, dividing into several branches. It sleeps with the leaflets converging above the petiole, and bent towards the base of it. It flowers in July.—Native of Spain. The seeds should be sown where the plants are destined to remain, on borders of light fresh earth in the spring, allowing them at least to be two feet distance every way apart.

9. *Coronilla Varia*; *Purple Coronilla*. Herbaceous: legumes erect, cylindric, swelling, numerous; leaflets very many, smooth. Root perennial, creeping widely; stems from four to six feet in height when supported; otherwise trailing. The flowers come out many together in roundish bunches, on peduncles which are about the same length with the leaves; the corolla varies from a deep to a light purple, to whitish, and even wholly white, and sometimes there is a mixture of all. This plant was formerly proposed to be cultivated as a proper food for cattle; and being found to grow very readily, promised to be very beneficial to the farmer. Mr. Miller informs us, that he remembers to have seen a large spot of ground at Deepden, near Dorking, in Surry, at the seat of the Honourable Mr. Howard, planted with it; where, although it had been neglected for many years, it was grown so rank, as to get the better of all the weeds, brambles, &c. He found some of the branches upwards of five feet long, and very tender in every part of that length, so that a small spot of ground will supply a considerable quantity of fodder, especially in dry seasons. Horses and cows, he adds, seemed to eat it greedily; though Mr. Curtis thinks that its bitterness will be an objection to its being cultivated for cattle. But notwithstanding this, a gentleman, who had sown it upon Professor Martyn's recommendation, assured him, that cows eat it very readily.—The roots creep very far under ground, by which it increases greatly, and when permitted to remain unremoved two or three years, it will overbear the plants growing near it; on which account the roots should be confined, and it should be planted at a distance from any other

plants. It will grow in almost any soil and situation, but thrives best in a warm sunny exposure, in which the flowers appear in great quantities, and are also more beautiful.

10. *Coronilla Cretica*; *Cretan Coronilla*. Herbaceous: legumes five together, erect, columnar, jointed; leaflets even. Stems ascending, angular, even, two or three feet long; corollas blood-red; the standard marked with purple veins; the wings confluent on the outside; the keels dark purple at the end.—Native of Candia. Sow the seeds on a bed of light earth in the spring, where the plants are intended to remain, and take care to thin them when too close, and keep them clear from weeds.

11. *Coronilla Scandens*; *Climbing Coronilla*. Stem climbing, flaccid. This has a slender, hairy, twining stalk, of a brown colour, twisting round any of the shrubs that stand near it, whereby it rises eight or ten feet high; for the most part composed of five oval leaflets, one inch long, and half an inch broad, of a deep green. Flowers pale yellow.—Native of South America. The seeds should be sown early in the spring, on a moderate hot bed; and when the plants are come up, they should be each transplanted into a halfpenny pot filled with fresh rich earth, and plunged into a hot bed of tanner's bark, observing to shade them until they have taken root, after which time they should have air and water in proportion to the warmth of the season; and when they have filled these pots with their roots, they should be shifted into pots of a larger size, and plunged into the hot-bed again, where they must remain until autumn, when they should be removed into the stove, and plunged into the tan. These plants must be kept constantly in the bark stove, and placed among such as require a moderate heat, where they will thrive and flower. They require to be supported by tall sticks, round which they will twine as Hops do; for if they have not this support, they will twist round other plants, and spoil them. They are very proper plants to place against an espalier, on the back part of the stove, amongst other climbing plants, where they will make an agreeable variety, and if carefully managed in the winter, may be preserved two or three years, and will flower annually in July, and sometimes produce ripe seeds in England.

12. *Coronilla Cochinchinensis*. Suffruticose: leaflets about fifteen pairs; peduncles subtriflorous; legumes erect, torulose; stems four feet high, upright, branched; leaflets oblong, blunt, with a slender point; flowers yellow, axillary.—Native of Cochin-china.

13. *Coronilla Hispanica*; *Spanish Coronilla*. Shrubby: leaflets nine, emarginate; stipules large, roundish. Supposed to be the same as the third species.

14. *Coronilla Orientalis*. Herbaceous: legumes numerous, radiate, thick, jointed; leaflets glaucous underneath. Root perennial; stem annual, erect, upwards of two feet high; leaflets five or six pairs, oblong; peduncles strong, upwards of six inches in length, supporting large bunches of yellow flowers, succeeded by short thick pods, about an inch long. It flowers in June and July, and in warm seasons will ripen its seeds in autumn. There is a variety with large white flowers.—Native of Cappadocia. It is propagated by seeds sown on a warm border of light earth in the spring, carefully weeding the plants when they appear, and transplanting them, as soon as they are fit to remove, into a warm border, where they are to remain, and will only require to be shaded from the sun, and kept free from weeds. In autumn, when the stalks are decayed, if the surface of the ground be covered with some old tan to keep out the frost, it will be the surest method of preserving the roots, which will continue some years with proper care. The plants will flower in the second year.

Corrigiola; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, concave, spreading, size of the corolla, membranaceous on the margin, permanent. *Corolla*: petals five, ovate, spreading, scarcely larger than the calix. *Stamina*: filamenta five, subulate, small; antheræ simple. *Pistil*: germen ovate, three-cornered; style none; stigmas three, obtuse. *Pericarp*: none. *Calix*: converging. *Seed*: single, ovate, three-sided. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five. *Seed*: one, three-sided.—The species are,

1. *Corrigiola Littoralis*; *Bastard Knot Grass*. Stems many, slender, round, with a few branches at the end, two or three inches long, covered with leaves; flowers in glomerate racemes, sessile, terminating; calix of a whitish bay-colour, converging; corolla white. It flowers in June and July, and is annual.—Native of France, Germany, Denmark, Switzerland, and Piedmont, in sandy soils, generally on the banks of rivers, or near the sea. It has been found on Slapham sands near Dartmouth, and near the Start point.

2. *Corrigiola Capensis*. Flowers sessile; calices green.—Native of the Cape.

Cortusa; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-cleft spreading, very small, permanent; divisions lanceolate, three-toothed. *Corolla*: one-petalled, wheel shaped; tube scarcely any; border flat, five-parted, ample; divisions ovate, acute; throat with an elevated ring. *Stamina*: filamenta five, obtuse; antheræ two plaited, oblong, erect, affixed to the outward part. *Pistil*: germen ovate; style filiform, longer than the corolla; stigma almost headed. *Pericarp*: capsule oval, acuminate, half five-valved. *Seeds*: numerous, compressed, cornered. *Receptacle*: columnar, free. ESSENTIAL CHARACTER. *Corolla*: wheel-shaped, the throat having an elevated ring. *Capsule*: one-celled, oval, five-valved at the end. These plants are difficult to keep in a garden: the only method by which they have been preserved, was by planting them in pots, and placing them in a shady situation, where they were regularly watered in dry weather: cold will not destroy them, but rich soils or dung is very injurious, and they should therefore be planted in a very light soil. The only method by which we can propagate them, as they never produce any seeds in England, is by parting the roots in the same manner as is practised for Auriculas; the best time for this is about Michaelmas, soon after which the leaves decay.—The species are,

1. *Cortusa Matthioli*. Calices shorter than the corolla. This plant sends out many oblong smooth leaves, a little indented on the edges. The peduncles come out in the centre of the leaves, rise about four inches high, and support an umbel of flowers, each on a slender short pedicel. The flowers are of a flesh colour, and spread open like those of the Auricula; they appear in April and May.—Native of the Alps, Austria, Silesia, and Siberia.

2. *Cortusa Gmelina*. Calices longer than the corolla. Very like the first, but the flowers much smaller, and the calices larger. The umbel has about three flowers; the corolla is white; and the leaflets of the involucre ovate.—Native of Siberia.

Corylus: a genus of the class Monœcia, order Polyandria.—GENERIC CHARACTER. *Male Flowers*, disposed in a long ament. *Calix*: ament common, imbricated on every side, cylindric, permanent; scales one-flowered, narrower at the base, wider at the top, and more obtuse, inflex, three-cleft; middle division equal in length to the others, but as wide again, and covering the others. *Corolla*: none. *Stamina*:

filamenta eight, very short, growing to the interior side of the calcine scale; antheræ ovate-oblong, shorter than the calix, erect. *Female Flowers*, remote from the males, on a very small subglobular ament, in the same plant, sessile, included within the bud. *Calix*: perianth two-leaved, leathery, lacerated on the margin, erect, length of the fruit, scarcely visible during the time of inflorescence, on account of its smallness. *Corolla*: none. *Pistil*: germen roundish, very small; styles two, setaceous, much longer than the calix, coloured; stigmas simple. *Pericarp*: none. *Seed*: nut ovate, scalped as it were at the base, but little compressed at the tip, slightly pointed. **ESSENTIAL CHARACTER.** *Male. Calix*: one-leaved, three-cleft, scale-form, one-flowered. *Corolla*: none. *Stamina*: eight. *Female. Calix*: two-leaved, lacerated. *Styles*: two. *Nut*: ovate.—All the species of this well-known genus, may be propagated by sowing their nuts in February; which, in order to preserve them good, should be kept in sand in a moist cellar, where the vermin cannot come at them to destroy them; nor should the external air be excluded from them, which would make them grow mouldy. The method of sowing their seeds is well known; but not one in four of the plants so produced prove so good as those raised from the nuts. Mr. Miller, however, recommends the method of propagating them by layers, as being not only the surest, but also the most expeditious plan, for those especially who cultivate the trees for the sake of their fruits. To sow the nuts, let the ground be well ploughed and harrowed; and let drills be drawn one yard asunder, into which drop the nuts, at about ten inches' distance, and let them be covered with two inches of earth. They must be carefully weeded and thinned, as soon as they appear, until the plants be left half a yard asunder each way. Or they may be thus raised in a nursery, and removed thence when they are from a foot to two feet high, and planted finally at the distance before-mentioned. In twelve years they may be cut down for poles, but may afterwards be cut every seventh or eighth year.—The species are,

1. *Corylus Avellana*: *Hazel-nut Tree*. Stipules egg-shaped, obtuse; leaves roundish, heart-shaped, acuminate; branchlets hairy. The varieties are *Corylus Sylvestris*, Common Hazel-nut Tree; *Corylus Alba*, White Filbert-nut Tree; *Corylus Rubra*, Red Filbert-nut Tree; *Corylus Grandis*, Cob-nut Tree; and *Corylus Glomerata*, Cluster-nut Tree. The common Hazel-nut tree is properly a shrub: the trunk is covered with a whitish cloven bark, which is smooth on the branches, frequently of a bay colour, and spotted with white; leaves alternately gash-serrate, wrinkled. The male catkins appear in Autumn, and wait for the expansion of the female germina in the spring; the styles are of a bright red colour, long and setaceous; the flowering branches, especially those which bear the fertile flowers, are set with short fine hairs, terminating in globules. The varieties grow more erect than the common Hazel: the Cob-nut has a very large round fruit; and the Cluster-nut is so called from the fruit growing in great clusters at the ends of the branches. The Hazel, says Swinburn, has the name *Avellana*, from Avellino, a city in the kingdom of Naples, near which it is cultivated; it covers the whole face of the neighbouring valleys, and in fruitful years produces an enormous profit. The nuts are mostly of the large round filbert kind, which we call Spanish, and were originally imported into Italy from Pontus, and therefore known to the Romans by the appellation of *nux Pontica*, which in process of time was changed into that of *nux Avellana*, from the place where they had been cultivated with the greatest success.—The common Hazel-nut is found wild in many woods and coppices in Eng-

land, where the country people gather the fruit, and send it in abundance to the London markets. As a shrub it is well adapted for thickening woods; and when allowed to grow, will make poles of twenty feet; but it is generally cut down sooner for walking-sticks, fishing rods, withes for fagoting, and other purposes for which it may be profitably employed. Where yeast is scarce, they twist the twigs, and steep them in ale during its fermentation, then hang them up to dry, and, when they brew, put them into the wort.—The Filbert can only be kept from changing by propagating it from suckers or layers, the last of which make the best trees. Plantations of Filbert-trees are much attended to in some parts of Kent; they are never suffered to rise above six feet in height, and are regularly pruned like Gooseberry bushes. They are planted twelve feet asunder, and when full spread, the cup formed by the branches is six feet in diameter; the intermediate space is generally filled up with hoeing crops, the vigour of the trees greatly depending on the stirring of the ground: it is therefore the usual mode to raise them in hop-grounds, where Cherry and sometimes Apple-trees are also planted. The Kentish men seem to know nothing of raising them from layers, but propagate them by suckers, which ought to be previously trained in a nursery. The best soil for them is what is called coomey in Kent, consisting of a strong loam, with a clayey or marley bottom. In this kind of ground they bear fruit in such great abundance, that an acre has been sometimes sold for fifty pounds.

2. *Corylus Rostrata*; *American Cuckold-nut Tree*. Stipules lanceolate; leaves oblong-cordate, acute; branchlets smooth; calices of the fruit beaked. This is remarkable for the length of the calix, which continues to cover the nut entirely even after it is ripe.—Native of North America.

3. *Corylus Colurna*; *Constantinople, or Byzantine Hazel-nut Tree*. Stipules linear, acute. The leaves in this are a little lacinated at top; the raceme of nuts very large; the nuts themselves roundish, and in shape like those of the common Hazel, but more than twice their size.—Native of the country about Constantinople.

Corymbium; a genus of the class Syngenesia, order Monogamia. **GENERIC CHARACTER.** *Calix*: perianth two-leaved, one-flowered, inferior, long, prismatic, six-cornered; leaflets erect, converging longitudinally, triangular on the back, truncated, obscurely three-toothed, permanent, having two very small leaflets at the base. *Corolla*: one-petalled, equal; tube very short; border five-parted, spreading; divisions lanceolate. *Stamina*: filaments five, simple, erect, seated on the tube; antheræ oblong, erect, shorter than the corolla, growing together into a cylinder. *Pistil*: germen within the calix, inferior to the corolla, hirsute; style simple, erect, length of the corolla; stigma oblong, two-parted, spreading. *Pericarp*: none. *Calix*: unchanged. *Seed*: single, oblong, almost the length of the calix, covered with a wool resembling down, in the manner of a pappus. **Receptacle**: naked. **ESSENTIAL CHARACTER.** *Calix*: two-leaved, one-flowered, prismatic. *Corolla*: one-petalled, regular. *Seed*: one, below the corolla, woolly.—The species are,

1. *Corymbium Scabrum*. Leaves lanceolate, channelled, nerved, recurved, smooth, shorter than the stem. It rises with an erect rough stalk about a foot high, with a single leaf at each joint, which half embraces the stalk; the upper part of which divides into several peduncles, which are terminated by purple flowers.—Native of the Cape. *Corymbium* should be propagated by seeds, sown in a small pot filled with light earth as soon as ever they arrive from abroad; the pots should be plunged into a bed of tanner's bark, where the heat is nearly spent, and covered with a common frame in winter.

In the spring, the plants will soon appear if the pots be removed into a moderate hot-bed. They should be transplanted when about an inch high, each into a separate small pot, shading them until they acquire new roots, and gradually inuring them soon after to the open air. In June they should be placed abroad in a sheltered situation, where they may remain till October, and should then be placed in a common frame to protect them from the frost.

2. *Corymbium Glabrum*. Very smooth: leaves ensiform, plane-nerved; panicle lax, diffuse; flowers distinct.—Native of the Cape.

3. *Corymbium Filiforme*. Leaves filiform, very smooth, erect, shorter than the stem.—Native of the Cape.

4. *Corymbium Villosum*. Villose, woolly: stem-leaves clasping, subulate, straight, plain.—Native of the Cape.

Corynocarpus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth inferior, five-leaved; leaflets oblong, concave. *Corolla*: petals five, roundish, narrowed at the base, erect. *Nectary*: leaflets five, erect, shaped like the petals, but narrower, scarcely shorter, having a globular gland at the base, alternate with the petals. *Stamina*: filamenta five, subulate, from the base of the petals; antheræ oblong. *Pistil*: germen superior, globular; style short, filiform; stigma obtuse. *Pericarp*: nut turbinate-club-shaped, one-seeded. *Seed*: an oblong kernel. **ESSENTIAL CHARACTER.** *Nectaries*: five, petal-shaped, alternate with the petals, glandulous at the base.—The only known species is,

1. *Corynocarpus Lævigata*. Leaves alternate, petioled, obovate or wedge-shaped, subemarginate, entire, veined, very smooth; panicle terminating, sessile, large, wrinkled; flowers white.—Native of New Zealand.

Corypha; a genus of the class Palmæ, order Flabellifoliæ.—**GENERIC CHARACTER.** *Calix*: spathe universal none; spathes partial numerous, alternate, on a common peduncle or spadix, one-leaved, embracing the peduncle, producing panicles of hermaphrodite flowers; perianth proper, short, with three divisions. *Corolla*: petals three, egg-shaped, concave, half open, longer than the calix. *Stamina*: filamenta six, about the length of the petals; antheræ almost arrow-shaped, short, versatile. *Pistil*: germen superior, conical; style short; stigma obtuse, pubescent. *Pericarp*: berry (or drupe) spherical, smooth. *Seeds*: solitary, bony, with a white, rather firm kernel. **ESSENTIAL CHARACTER.** *Flowers*, hermaphrodite. *Spathe universal*, none. *Spathes partial*, numerous. *Berry*, or *Drupe*, globular. *Seed*, bony.—The species are,

1. *Corypha Umbraculifera*; *Great Fan Palm*. Fronds pinnate-palmate, plaited, and having a thread between them; stipes ciliate-spiny. Linneus says, that this tree seldom flowers before it is thirty or forty years old. Knox gives us the following description of it, under the name of *tallipot*. "It is as big and tall as a ship's mast, and very straight; the leaves, which all grow on the top of the tree, are of great use, one being so broad and large that it will cover twenty men. Being dried, it is very strong and limber, and, though it be very broad when open, will fold close like a fan, and is then no bigger than a man's arm; the whole leaf when spread out is round, but is cut into triangular pieces for use, which the Malays and Ceylonese lay upon their heads as they travel, with the narrow end foremost, to make their way through thickets. Soldiers always carry them, not only to shade them from the sun, and to screen them from rain, on their march, but also to make their tents to lie under. The tree bears no fruit until the year before it dies, and then the most beautiful strong-smelling yellow blossoms come out on the top, and

spread out in great branches, terminating in a very hard round fruit, about the size of our largest cherries, which are produced in such plenty, that one tree will yield seed enough for a whole country, but unfortunately they are not fit to eat; and the flowers smell so strong that the tree is generally cut down when it grows near to any houses. The trunk consists of nothing but pith, which the natives beat in a mortar to flour, and bake into cakes, which have the taste of white bread; the leaves, besides the uses above-named, also serve for thatching houses, and for writing on with an iron style; and most of the books shown in Europe for the Egyptian papyrus are made from the leaves of this palm." Native of Malabar, the island of Ceylon, and other parts of the East Indies, and of the Marquesas and Friendly Islands.

2. *Corypha Minor*. Fronds palmate, fan-shaped, plaited, subfidid, having a few threads interposed; stipes unarmed. Leaves springing from the crown of the root, smooth, rigid, striated, plaited below, and spreading upwards into sword-shaped, acute segments; spadix erect, two or three feet high, rising among the leaves from the crown of the root, clothed with membranaceous sheathing spathes; flowers in panicked racemes, white, sessile, small, without scent, all hermaphrodite, numerous; fruit the size of a pea, and of a sweet taste, smooth, black, not very succulent.

Costmary. See *Tanacetum*.

Costus; a genus of the class Monandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth three-toothed, very small, superior. *Corolla*: petals three, lanceolate, somewhat erect, concave, equal; nectary one-leaved, large, oblong, tubular, inflated, two-lipped, lower lip broader, longer than the corolla; border spreading, three-cleft, middle division three parted: upper lip lanceolate, shorter, doing the office of a filamentum. *Stamina*: the office of a filamentum is performed by the upper lip of the nectary: to which grows a two-parted anthera. *Pistil*: germen inferior, roundish; style filiform, length of the filamentum, stigma headed, compressed, emarginate. *Pericarp*: capsule roundish, crowned, three-celled, three valved. *Seeds*: many, three-cornered. **ESSENTIAL CHARACTER.** *Corolla*: inner inflated, ringent; the lower lip trifid.—These plants are propagated by parting their roots in the spring, before the roots put out new stalks: they should be planted in pots filled with light kitchen garden earth, and plunged into a tan bed in the stove, where they ought constantly to remain, and may be treated in the same manner as Ginger; see *Amomum*.—The species are,

1. *Costus Arabicus*; *Arabian Costus*. Leaves silky underneath. Root perennial, irregular, two inches thick, knotty; stems annual, simple, round, three or four feet high, near an inch in diameter at bottom, fleshy, with a strong bark, sheathed all over; spike very handsome, terminating, subsessile, solitary, erect, close, as big as the hand closed.—Native of the East Indies; whence the roots were formerly imported, being much used in medicine, but of late years they have not been regarded, the roots of Ginger being used in their stead.

2. *Costus Glabratus*. Leaves smooth on both sides; spike few-flowered; scales leafy at the tip, the upper ones fastigate. Spike or head of flowers imbricate, with ovate, blunt, concave scales, each one flowered, permanent, green, not coloured.—Native of the West Indies.

3. *Costus Spicatus*. Leaves smooth on both sides; spike many-flowered, subovate, closely imbricate; scales ovate, simple. Root perennial, fleshy, irregular, white; stems somewhat jointed, almost upright, round, smooth, one or two feet high; flowers yellow, scentless, and quickly withering.—Native of the Caribbee islands, where it is found by the side of torrents. It is called *canna de riviere*, in Martinique, where

a decoction of the roots and stalks is often given in the gonorrhœa, &c. as a cooling drink.

4. *Costus Malacensis*. Leaves very finely tomentose underneath; raceme terminating; bunches six flowered. Stems several, approximating, upright, simple, a little compressed, smooth, clothed with the sheaths of the leaves, half as high as a man; all the flowers are on very short club-shaped pedicels, somewhat compressed.—Native of thick woods near Tsing, in the neighbourhood of Malacca.

Cotton. See *Gossypium*.

Cotton Grass. See *Eriophorum*.

Cotton Silk. See *Bombax*.

Cotton Thistle. See *Onopordum*.

Cotton Weed. See *Athanasia* and *Filago*.

Cotula; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common, convex, divided into about sixteen ovate parts, of which eight are exterior, of these the inferior ones are rather bigger than the interior ones. *Corolla*: compound the length of the calix, a little convex; corollules hermaphrodite, numerous in the disk; females in the circumference more than twenty: proper of the hermaphrodites tubular, four-cleft, unequal, the outer division larger; of the females, scarcely any. *Stamina*: in the hermaphrodites, filamenta four, very small, antheræ tubular, the length of the corollule. *Pistil*: in the hermaphrodites, germen obovate; style filiform; stigmas two, obtuse: in the females; germen obovate, compressed, two-edged, larger; style filiform, length of the hermaphrodite; stigmas two, simple. *Pericarp*: none. *Calix*: unchanged, permanent. *Seeds*: of the hermaphrodites, solitary, smaller, ovate, three-sided, the interior angle obscure; down margined: of the females, solitary, larger, cordate on one side, flat on the other, gibbous, surrounded by an obtuse border; down bordered. *Receptacle*: almost naked. flat. ESSENTIAL CHARACTER. *Receptacle*; almost naked. *Down*: margined. *Corollules*: of the disk, four-cleft, in the ray, scarcely any.—The species are,

1. *Cotula Anthemoides*; *Dwarf Cotula*. Leaves pinnate, multifid, dilated; flowers floscular. Root annual; stem about six feet high, at first erect, then procumbent; flowers drooping, much compressed before they open, the size of a lentil; florets yellow.—Native of Spain, and the island of St. Helena. If the seeds of this and of the second species be permitted to scatter, the plants will come up in the spring and require no other care but to keep them clean from weeds and thin them.

2. *Cotula Aurea*; *Golden Cotula*. Leaves pinnate-setaceous, multifid; flowers floscular, drooping. The flowers have no chaffs, and the florets are four-cleft.—Annual: and a native of Spain

3. *Cotula Stricta*; *Silvery Cotula*. Leaves pinnatifid, plane, naked, dotted; stem erect, strict; flowers radiate. Stem herbaceous, five feet high, erect, somewhat angular, even, covered with a bluish dew; corollets of the disk four-cleft.—Native of the Cape. This, as well as all the other natives of the Cape, must be raised on a moderate hot-bed in the spring, and when the plants have obtained strength, they may be transplanted into a warm border, where they will ripen their seeds very well. All the *Cotulas* flourish best, however, under the protection of the dry-stove, and several of them may be increased, not only from seeds, but freely from cuttings.

4. *Cotula Coronopifolia*; *Buck's-horn Cotula*. Leaves lanceolate-linear, stem-elapsing, toothed; flowers floscular. It is an annual, and sends out trailing stalks about six inches long, with succulent leaves, shaped like those of Buck's-horn

Plantain: the flowers grow from the divisions of the stalks, upon short weak footstalks, being destitute of rays; they are of a sulphur-colour, appearing in July, and, like those of the eighth species, stand erect when they first appear, but as soon as the florets become impregnated, their colour changes, the footstalks become very flaccid towards the top, and the flowers hang downwards; but when the seeds are ripe, the footstalks become stiff, and their heads stand erect for the winds to disperse the seeds.—Native of the Cape.

5. *Cotula Umbellata*. Leaves lanceolate, hirsute; flowers umbelled; stem erect, round, hirsute, a foot and a half in length; receptacle naked.—Native of the Cape.

6. *Cotula Quinqueloba*. Leaves five-lobed, subtomentose; stems erect, simple, pubescent; leaves petioled.—Native of the Cape.

7. *Cotula Viscosa*. Leaves alternate, lyrate, pinnate; flowers radiate; stem a span high; receptacle conical, naked.—Found in the island of La Vera Cruz.

8. *Cotula Turbinata*. Receptacles underneath, inflated, turbinate; flowers radiate. It sends out many branching stalks, which spread on the ground: leaves very finely divided, covered with a cottony substance. Flowers solitary, on long peduncles, from the side of the branches they have a narrow border of white rays, with a pale yellow disk. Annual: flowering in July and August.—Native of the Cape.

9. *Cotula Tanacetifolia*. Leaves tripinnate, the small segments acute; stem erect; flowers floscular, corymbed. Stem scarcely suffruticose, but rather entirely herbaceous, firm, slightly angular, pubescent, much branched; leaves glaucous, petioled; corymb of flowers compound, fastigate, large, terminating, consisting of several corymbiferous branches; scarcely any female florets; those of the disk four-cleft.—Annual: Native of the Cape.

10. *Cotula Capensis*; *Cape May-weed*. Leaves pinnate, somewhat fleshy and columnar, the lowest subbipinnate; flowers radiate. Stems many, very much branched, diffused a span in height, round, somewhat glossy.—Annual: native of the Cape. This plant has the appearance of Chamomile.

11. *Cotula Filnifera*; *Rounded May-weed*. Leaves bipinnate; heads globular; stems erect, subfastigate, with a panicle.—Native of the Cape.

12. *Cotula Sericea*. Leaves superdecompound, tomentose; linear. Root perennial; corolla floscular, shorter than the calix, yellow; stems herbaceous, short, tomentose, simple, procumbent, white.—Native of the Cape.

13. *Cotula Pyrethriaria*. Leaves opposite, ovate, crenate, petioled; peduncles one-flowered. Stem herbaceous, dichotomous; flower ovate, white, with four-cleft corollets.—Native country unknown.

14. *Cotula Minuta*. Leaves alternate, almost stem-clasping, oblong, toothed; flowers solitary, sessile, opposite to the leaf.—Native of New Caledonia.

15. *Cotula Bicolor*. (Specific character not given.)—Native of the isle of Tanna in the South Seas.

Cotyledon; a genus of the class Decandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, acute, very small. *Corolla*: petal bell-shaped, five-cleft; nectary consisting of a concave scale, seated at the exterior base of each germen. *Stamina*: filamenta ten, subulate, straight, the length of the corolla; antheræ erect, four-furrowed. *Pistil*: germina five, oblong, thickish, ending in subulate styles, which are longer than the stamina; stigmas simple. *Pericarp*: capsules five, oblong, bellied, acuminate, one-valved, gaping longitudinally inwards. *Seeds*: very many, small. ESSENTIAL CHARACTER.

Calix: five-cleft. *Corolla*: one-petalled, with five nectarous scales at the base of the germens. *Capsule*: five.—The species are,

1. *Cotyledon Orbiculata*; *Round-leaved Navelwort*. Leaves ovate-spatulate, obtuse, with a point, even; flowers paniced. This species varies much in the form of the leaves, &c. Mr. Miller describes several of the varieties as distinct species; one of these, the *Branching Navelwort*, has a short thick succulent stalk, which rarely rises more than a foot high, branching out on every side, so as to spread over the pots in which it is planted. Another variety, called also the *Round-leaved Navelwort*, has likewise a thick succulent stalk, which becomes woody by age, and rises three or four feet high, sending out crooked branches which grow irregular, with thick fleshy succulent leaves about two inches long, and near as wide toward the top; flowers on thick succulent peduncles, from the ends of the branches, near a foot long, supporting eight or ten flowers hanging down; tube long, brims turning back; stamina and styles longer than the tube, and hanging down. They flower from July till September. There are two other varieties, viz. *Oval-leaved Navelwort*, with the stem erect, and leaves ovate-spatulate; and *Oblong-leaved Navelwort* with an erect stem, and oblong-spatulate leaves.—Native of the Cape. This species, together with the second, fourth, eighth, ninth, tenth, eleventh, twelfth, thirteenth, and sixteenth, are all propagated by planting cuttings in any of the summer months, which ought to be laid in a dry place a fortnight or three weeks after they are taken from the plant before they are planted, that the wounded part may heal over, and the great redundancy of sap evaporate. They thrive best in a soil which is formed of one-third fresh light earth from a pasture, one-third sand, and the other third part lime rubbish and rotten tan, in equal quantities, which should be well mixed, and laid in a heap six or eight months before it be used, turning it over five or six times, that the parts may be the better incorporated. It will also be proper to pass it through a screen, to separate the large stones, clods, &c. from it, before it be used. Having prepared this earth, and the cuttings being also in fit order for planting, you must fill as many halfpenny pots with earth as you have cuttings to plant, then put one cutting in the middle of each pot about two or three inches deep, or more, according to their strength, then give them a little water to settle the earth close about them, and set them in a warm shady place for about a week, to prepare the cuttings for putting forth roots, after which they should be plunged into a moderate hot-bed of tanner's bark, which will greatly facilitate their rooting, but observe to give them air by raising the glasses at all times when the weather will permit, as also to shade the glasses in the heat of the day. In about six weeks they will be rooted, when they must be exposed to the air by degrees. The best method to treat most of these plants, is to place them in an open airy dry glass-case, where they may enjoy as much of the sunshine as possible, and have a free open air; for if they be placed in a common greenhouse among shrubby plants which perspire freely, these succulent plants imbibe too much of the damp air, and thereby becoming too replete with moisture, often cast their leaves, and sometimes even their branches decay, and then the whole plant perishes.

2. *Cotyledon Spuria*; *Narrow-leaved Navelwort*. Leaves spatulate, obtuse with a point, naked. This has a short, greenish, succulent stalk, seldom more than a span high; flowers on short pedicels, yellow; tubes long; brims reflex, tipped with purple; stamina longer than the tube.

3. *Cotyledon Spinosa*; *Prickly Navelwort*. Leaves ob-

long, spiny-mucronate; stem spiked. A perennial plant, a long span in height.—Native of Siberia. This sort requires a very shady situation, for if it be exposed to the sun in summer, the plants will soon decay. It is propagated by offsets, like Houseleek, and requires a strong soil.

4. *Cotyledon Hemispharica*; *Thick-leaved Navelwort*. Leaves suborbiculate, dotted with scurf, convex underneath; flowers subsessile. It has a thick succulent stalk, rarely more than a span high, dividing into many branches; leaves short, thick, succulent, greyish, with green spots; flowers greenish, with purple tips, in a terminal spike.

5. *Cotyledon Serrata*; *Notch-leaved Navelwort*. Leaves oval, crenate; stem spiked. Stalk upright, succulent; flowers purplish, in a loose spike. Biennial.—Native of Candia and Siberia. If this, and the sixth and seventh species, be sown upon a wall, they will thrive better than in the ground, and be less liable to suffer by frost; so that where the seeds scatter themselves on walls or rock-work, the plants thrive better than when they are cultivated.

6. *Cotyledon Umbilicus*; *Common Navelwort*, *Kidney-wort*, or *Wall Pennywort*. Leaves peltate, crenate; stem almost simple; flowers erect; bractes entire. Of this there are two varieties: *Cotyledon Repens*, leaves peltate-crenate; stem almost simple; flowers erect; bractes toothed: and *Cotyleaon Tuberosa*, root tuberous, roundish; the whole plant succulent, having a shining frosted appearance. The first variety is called *Yellow Navelwort*, and the second, *Common Navelwort*. Mr. Hudson has distinguished the *Yellow* from the *Common Navelwort*, by the circumstances of the flowers being upright, and the bractes toothed in the first; whereas in the second the flowers hang down, and the bractes are entire. Morison remarks, also, that the root of the *Yellow Navelwort* is not round like a turnip, but oblong and creeping. The *Yellow* is found in Somersetshire, and the *West-Riding* of Yorkshire.—Meyrick informs us, that a decoction of the leaves of *Navelwort* is cooling and diuretic; and that the bruised leaves are a good application for slight burns or scalds. Hill says, that the leaves are cooling, and good against pains, when externally applied: that they are used by outward application in the piles with great success; and that the juice of them taken inwardly operates by urine, and is excellent for stranguries, the gravel, and in inflammations of the liver and spleen.—This plant is a native of Judea, Spain, Portugal, Italy, and Britain, on moist rocks and walls; it is found in an old gravel-pit close to Highberry Barn, near London; at Peterborough, Northampton; and Thorpe, between Peterborough and Wandesford; in the slate-pit rocks at Smithland, in Leicestershire; Church Brampton in Northamptonshire; about Troutbeck, in Westmoreland; at Godstow Bridge, in Oxfordshire; about Malvern, in Worcester-shire; Shepton Mallet, in Somersetshire; Carnarvonshire, and Merionethshire, in Wales; in Cornwall, and other western counties; and in some of the Scotch islands. It flowers from June till August.

7. *Cotyledon Hispanica*; *Spanish Navelwort*. Leaves, oblong, almost columnar; flowers fascicled. Root fibrose; stem simple, columnar, almost erect, a finger's length in height; flowers in a terminating corymb; corollas funnel-shaped, dusky red on the outside, somewhat hairy.—Biennial: native of Africa, the Levant, and Spain.

8. *Cotyledon Papillaris*. Leaves opposite, columnar, ovate; flowers corymbed.—Native of the Cape.

8. *Cotyledon Mamillaris*. Leaves alternate, columnar, ovate; flowers alternate, subsessile.—Native of the Cape.

10. *Cotyledon Triflora*. Leaves ovate, entire; flowers subpeduncled, in threes.—Native of the Cape.

11. *Cotyledon Cacalioides*. Leaves columnar; flowers corymbed; stem shrubby.—Native of the Cape.

12. *Cotyledon Reticulata*. Leaves columnar; flowers corymbed; stem shrubby.—Native of the Cape.

13. *Cotyledon Paniculata*. Leaves oblong-ovate; sessile; panicle divaricated, racemed; stem shrubby.—Native of the Cape.

14. *Cotyledon Laciniata*; *Cut-leaved Navelwort*. Leaves pinnatifid; flowers four-cleft in a panicle. Stem leafy to the very top; the inflorescence paniced; stamina eight short, two long; peduncles terminating, about six inches long, sustaining seven or eight small flowers of a deep yellow colour. It flowers in July and August.—Native of Egypt, and the East Indies. This, and the next species, require a warm stove to preserve them through the winter in England; nor should they be exposed abroad in summer; for if they receive much wet, the stalks are very subject to rot, so that they should constantly remain either in the stove, or in summer should be placed in an airy glass case. They are propagated by cuttings, which should be taken off in summer and planted into small pots, and plunged into a moderate hot-bed, and when they have taken root they should be removed into the stove, and must have but little water, especially in winter.

15. *Cotyledon Nudicaulis*. Leaves spatulate, ovate; flowers four-cleft, in a cyme; stem almost naked at the end.

16. *Cotyledon Fascicularis*; *Cluster-leaved Navelwort*. Leaves wedge-shaped, fasciated, terminating; trunk thickened branches fleshy, subconic. It flowers from July till September. Root perennial; leaves green; flowers drooping, reflexed.—Native of the Cape.

17. *Cotyledon Viscosa*. Leaves columnar; racemes terminating, villose, viscid; stem branched. Root annual; corolla bell-shaped, pale yellow, with purple streaks.—Native of the mountains of Spain, near Toledo, and elsewhere.

18. *Cotyledon Lanceolata*. Leaves lanceolate, serrated towards the tip; panicle villose; flowers quadrifid.—Native of Arabia.

19. *Cotyledon Alternans*. Leaves orbiculate-spatulate, quite entire; flowers paniced, smooth, quadrifid. The whole plant smooth.—Native of Arabia.

Cow Itch. See *Dolichos*.

Cow Parsley; *Cow Weed*. See *Charophyllum*.

Cow Quakes. See *Briza*.

Cowslip. See *Primula*.

Cowslip, Virginian. See *Dodecatheon*.

Crab Tree. See *Malus*.

Crake Berry. See *Empetrum*.

Crambe; a genus of the class Tetradynamia, order Siliquosa.

—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets ovate, channelled, somewhat spreading, deciduous. *Corolla*: four-petalled, cruciform; petals large, obtuse, broad, spreading; claws erect-spreading, length of the calix. *Stamina*: filamenta six, two the length of the calix, four longer, with a two-cleft tip; antheræ simple, on the exterior branch of the filamenta; a melliferous gland between the corolla and the longer stamina on each side. *Pistil*: germen oblong; style none; stigma thickish. *Pericarp*: berry dry, globose, one-celled, deciduous. *Seed*: single, roundish. ESSENTIAL CHARACTER. *Filamenta*: the four longer two-cleft at the end, one only of the tips bearing an anthera. *Berry*: dry, globose, deciduous.—The species are,

1. *Crambe Maritima*; *Sea Colewort*. Leaves and stem smooth. The roots are perennial, creep under ground, and propagate it very fast; stems several, proceeding from the crown of the roots, spreading, a foot and half or two feet

high; leaves alternate, petioled, elliptic-oblong, or roundish, variously lobed and toothed. The whole plant is smooth; the flowers white, and on long peduncles. There are two varieties, one with jagged leaves, and another with yellowish blossoms. The young leaves, covered up with sand, and blanched, are boiled and eaten as a great delicacy; but when full grown they are said to produce giddiness, although all sorts of cattle eat them.—It is found on the sandy shores and beaches of Denmark, Sweden, and Britain; as, at Rosebeck in Low Furness, Lancashire; near Megavissey, in Cornwall; between Whitstable and the isle of Thanet, near Colchester; about Lyde in Kent, and elsewhere on the Essex and Kentish shores; and in great plenty on the coast of Sussex and Dorsetshire. It flowers in May and June.—In order to cultivate the Sea Colewort, or Sea-cole, prepare the bed intended to receive the seeds as for Asparagus. Sow them in March. Before putting them in the ground, bruise the outer coat without wounding the seeds, which will accelerate their growth. Set three seeds in a triangular form, six inches apart, leaving a space of two feet between the triangles, and bury the seeds about three inches deep. They will make their appearance in four or five months, but should not be cut until the third spring. About the end of November, when the leaves are become rotten, let them be cleared away, and the bed covered with a coat of half-rotten dung. In the second year, about March, when the plants are beginning to perforate the surface, take or rake off lightly the coat of dung, and give the plants full liberty to grow. And in November, or sooner if the leaves be rotten, clear them off, and cover with rotten dung, as in the preceding year. In the third year, immediately after removing the dung in the spring, cover the plants with a thick coat of sand, or coal ashes, or small pebbles. As they grow, continue to keep them from the air until they be cut for use, and in cutting them remove the sand, ashes, or pebbles, and then cover the roots again. Some of them will bear cutting twice or thrice in a season. After the last cutting is finished, remove the cover, and let the plants grow until the leaves are decayed; afterwards clear and cover them for the winter. Some prefer to cover their plants with earthen pans, or large garden pots, putting a tilesherd over the hole, for all air must be excluded in order to have them white.

2. *Crambe Orientalis*; *Eastern Colewort*. Leaves scabrous; stem smooth; root biennial.—Native of the Levant. This and the next species may be propagated in the same manner as the preceding.

3. *Crambe Hispanica*; *Spanish Colewort*. Leaves and stem scabrous; root whitish, annual, fusiform; flowers in corymbs; calices yellowish; petals white. It flowers in June, and the seeds ripen in autumn.—Native of Spain and Italy.

4. *Crambe Tatarica*; *Black Colewort*. Leaves compound-multifid. Root perennial, fusiform, as thick as the human arm, from two to four feet long, round, brown or blackish on the outside when fresh, within fleshy, white, with a tinge of dirty yellow, of a sweet taste; flowers very numerous, in terminating branched corymbs, smelling strong of honey. It flowers about the middle of April, and the fruits ripen in June, but few of them come to maturity. The roots are eaten, in a scarcity of bread, by the Tartars and Hungarians, and the hares also are very fond of them.—Native of Hungary, Tartary, Moravia, and Bohemia.

5. *Crambe Fruticosa*; *Shrubby Colewort*. Shrubby: leaves ovate, pinnatifid, serrate, hoary; racemes in a dishevelled dichotomous panicle. It is a stiff shrub, with leafy branches and flowers during most part of the year. Found by Masson in the highest rocks of the island of Madeira.

This and the sixth species are inhabitants of the green-house, and grow freely from cuttings.

6. *Crambe Strigosa*; *Rough-leaved Shrubby Colewort*. Frutescent: leaves at the base unequal, two-eared, strigose. It is a rugged shrub; stem erect, round, loosely branched, ash-coloured, the height of a man; flowers pedicelled, erect, white.—It flowers in May and June, and was found in the Canary Islands by Masson.

Cranberry. See *Vaccinium*.

Crane's-bill. See *Erodium*, *Geranium*, and *Pelargonium*.

Cranichis; a genus of the class Gynandria, order Dianthia.—GENERIC CHARACTER. *Calix*: spathes wandering; perianth none. *Corolla*: petals five, oblong, subhorizontal; the three outer, (or two upper lateral, and one anterior,) ovate, lanceolate, equal, spreading, the two inner anterior scarcely smaller, more slender, ovate-lanceolate, erect; nectary or upper petal (between the outer superior petals) galeate or vaulted erect, ovate, gibbous, slightly keeled, entire at the tip, often bifid at the base, dotted within, covering and embracing the genitals behind. *Stamina*: antheræ two or four, pedicelled, placed on the apex of the style, turned towards the helmet, with an upright two-celled lid, fastened to the column of the style in front, they are covered at the back. *Pistil*: germen ovate, oblique, inferior; style an erect column, shorter than the helmet, dilated at the tip, obtuse, bearing the stamina at the back; stigma funnel-form between the column of the style and the lid of the stamina. *Pericarp*: capsule oblong or obovate, attenuated at the base, three-cornered, three-keeled, one-celled, opening under the ribs, cohering at the tip and base. *Seeds*: numerous, very small, like sand or saw dust, affixed to a columnar receptacle. ESSENTIAL CHARACTER. *Nectary*: galeated.

—The species, which are all natives of Jamaica, are,

1. *Cranichis Aphylla*. Bulbs in bundles, columnar, acute; scape almost naked; petals converging.

2. *Cranichis Oligantha*. Bulbs in bundles, club-shaped; leaves petioled, oblong, acuminate, shining: scape almost naked; spike filiform; petals converging.

3. *Cranichis Diphylla*. Bulbs in bundles, filiform, naked; leaves petioled, cordate, acuminate, twin; scape almost naked.

4. *Cranichis Stachyodes*. Bulbs in bundles, columnar, obtuse; leaves petioled, ovate, acuminate; scape sheathed; spike columnar; petals revolute.

5. *Cranichis Muscosa*. Bulbs filiform, in bundles, tomentose; root-leaves petioled, ovate; stem-leaves sheathed; nectary dotted within.

Craniolaria; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth inferior, four-leaved; leaflets linear, short, spreading, permanent; perianth superior, ovate, inflated, large, cut lengthways on one side. *Corolla*: one-petalled, unequal; tube very long, very narrow, border flat, two-lipped, upper lip entire, roundish, like the other divisions, but larger; lower lip three-cleft, divisions roundish, the middle one wider. *Stamina*: filamenta four, length of the tube of the corolla, of which two are somewhat shorter; antheræ simple. *Pistil*: germen ovate; style thread-form, length of the tube of the corolla; stigma thickish, obtuse. *Pericarp*: coriaceous, ovate, sharp on both sides, two-valved, *Seed*: nut woody, depressed, sharpened on both sides, with a bent two parted point, marked on each side with three-toothed furrows, (of the figure of a quadruped's skull,) two-cleft on the sides. ESSENTIAL CHARACTER. *Calix*: double of the flower. *Perianth*: four-leaved. *Spathe*: one-leaved. *Corolla*: tube very long. *Capsule*: the same as in *Martynia*.—The only known species is,

1. *Craniolaria Annuæ*. Leaves cordate angled; outer calix two-leaved. This is an annual plant, two feet high; the whole of it villose, and extremely viscid. Branches dichotomous, round, thick; flowers handsome, but without scent, hirsute; calix green; corolla white, with three large dark purple spots at the bottom of the throat; nut black, abiding some days after the pericarp has fallen, not opening, or even separable with considerable force, though it appears to be four-valved. The throat of the corolla, which is clammy than any part of the plant, generally contains great numbers of small flies, which are attracted by the honey juice, and killed by being entangled in it. The root, which is brown without but white within, round, fleshy, thick, has a sweet taste, and is eaten fresh with milk, or preserved with sugar. It is used in the Spanish West Indies for the same purpose as that of *Scorzonera* is in Europe, and is called by the same name.—Native of New Spain, near Carthage.

Cranzia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, small, permanent; parts ovate, acute, concave, spreading. *Corolla*: petals five, oblong, sessile, erect, bluntish, channelled, vaulted at top, keeled behind the tip, shrivelling. *Stamina*: filamenta five, broader at the base, three-sided, subulate at the tip, erect, opposite to, and longer than the petals; antheræ roundish, incumbent. *Pistil*: germen subglobular five-lobed, each lobe scored with a longitudinal groove; style cylindric, thicker in the middle, grooved longitudinally, scarcely longer than the germen; stigma three-lobed, obtuse, truncate, capitate. *Pericarp*: berry angular-globose, acuminate, dotted on the outside, one-celled. *Seeds*: three to nine, kidney-form, oblong, full of pits. ESSENTIAL CHARACTER. *Calix*: five parted. *Petals*: five. *Nectary*: none. *Berry*: a berried capsule.—The only species known is,

1. *Cranzia Aculeata*. A prickly shrub; leaves ternate, with pellucid dots; flowers panicled, axillary; fruit dotted like the Orange.—Native of the East Indies. See *Scopolia*.

Craspedia: a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: common imbricate; florets in a few depressed bundles; perianth partial none. *Corolla*: compound tubular; corollets hermaphrodite. *Stamina*: filamenta five; antheræ cylindric. *Pericarp*: none. *Seeds*: with a feathered down. *Receptacle*: chaffy. ESSENTIAL CHARACTER. *Calicle*: none. *Calix*: imbricate. *Florets*: in depressed bundles, all hermaphrodite, tubular. *Down*: feathered. *Receptacle*: chaffy.—The only known species is,

1. *Craspedia Uniflora*.—Native of New Zealand.

Crassula; a genus of the class Pentandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft; divisions lanceolate, channelled, concave, erect, acute, converging into a tube, permanent. *Corolla*: petals five; claws long, linear, straight, converging, connected at the base with the ovate bractes at the border, reflex-expanding; nectaries five, each with a very small emarginate scale, annexed outwardly to the base of the germen. *Stamina*: filamenta five, subulate, length of the tube, inserted into the claws of the corolla; antheræ simple. *Pistil*: germen five, oblong, acuminate, ending in subulate styles the length of the stamina, stigmas obtuse. *Pericarp*: capsules five, oblong, acuminate, straight, compressed, gaping inwards lengthwise. *Seeds*: many, small. ESSENTIAL CHARACTER. *Calix*: one-leaved, five-cleft. *Petals*: five; nectareous scales, five at the base of the germen. *Capsule*: five, many-seeded.—The species are,

**Shrubby.*

1. *Crassula Coccinea*; *Scarlet-flowered Crassula*. Leaves ovate, plane, cartilaginous-ciliate, connate-sheathing at the base. Stem reddish, jointed, about three feet high, dividing at top into many irregular branches; flowers at the ends of the branches in close umbels; corolla funnel-shaped, erect, with a pretty long tube cut at the top into five parts, of a fine scarlet colour; leaves so closely opposite as to appear to be in two rows. It flowers in July or August.—Native country unknown.—All the hardy species of this genus, are propagated by cuttings, during any of the summer months. These cuttings should be taken off about a fortnight before planting, and laid in a dry place, that the wounded part may heal over; they should then be each planted in a small pot of light sandy earth, and plunged in a moderate hot-bed, allowing them but little water. In about six weeks they will put out roots, and begin to grow, and should have a large share of air admitted to them, that they may be gradually inured to bear the open air, into which they should be taken, and placed in a sheltered situation until autumn, when they must be removed into a dry airy glass case, where they may enjoy as much sun as possible, and be defended from the wet and cold. While they are abroad in dry warm weather, during the summer months, they should be gently watered twice or thrice a week, but should have very little water in winter, lest it rot their stems. They require no artificial heat, but merely to be secured from the frost and wet.

2. *Crassula Cymosa*; *Cyme-bearing Crassula*. Leaves linear, cartilaginous-ciliate, connate-sheathing; stem shrubby, cyme terminating. Stems a span high, erect, smooth, annual; roots perennial; leaves opposite, smooth, cartilaginous-scaly about the edge.

3. *Crassula Flava*; *Yellow-flowered Crassula*. Leaves plane, connate-perfoliate, even; flower corymb-panicled, fasciated, but each pedicelled; petals yellow, erect.

4. *Crassula Pruinosa*; *Frosted-leaved Crassula*. Leaves subulate, frosted scabrous; flowers corymbed; stem shrubby, a foot high, dichotomous; the small branches round, blood-red, covered, as is the whole plant, with the resemblance of a crystalline hoar-frost.

5. *Crassula Scabra*; *Rugged Crassula*. Leaves opposite, spreading, connate, scabrous, ciliate; stem scabrous backward. Stem weak, succulent, about a foot and a half high, divided at top into small branches; flowers in small clusters at the end of the branches, small and herbaceous: the corolla is so deeply divided, as to make it doubtful whether it be monopetalous or pentapetalous; leaves green, thick, succulent. It flowers in June and July. The stem and leaves are every where rough with whitish bubbles.

6. *Crassula Perfoliata*; *Perfoliate Crassula*. Leaves lanceolate, sessile, connate, channelled. The stem is upright, rising ten or twelve feet high, if not broken or injured; but it requires support, being slender, and the leaves very weighty: the flowers terminate in large clusters, of a white herbaceous colour, with short tubes, and the brim is cut into five parts; they appear in July. The flower-stalk is thick and succulent, generally turning first downwards, then upwards again, almost in form of a syphon.

7. *Crassula Fruticulosa*. Leaves opposite, subulate, acute, spreading, somewhat recurved; stem shrubby.

8. *Crassula Tetragona*; *Square-leaved Crassula*. Leaves subulate, somewhat incurved, obscurely four-cornered, spreading; stem erect, arborescent, rooting. Stem arborescent, two or three feet high, erect, even-surfaced, reddish, branched; leaves longer than the internodes, about the thickness of a goose-quill, acute, green, smooth, opposite in cross pairs so

as to form two regular rows; flowers very small, white; in a terminal trifid much-branched cyme; antheræ purplish.

9. *Crassula Ramosa*; *Branching Crassula*. Leaves subulate, plane above, connate-perfoliate, even-surfaced, spreading very much; peduncles elongated; flowers cymbed. Stem a foot high, filiform, smooth, leafy, branched at bottom; branches alternate, smooth, rufescent; leaves longer than the internodes, entire.

10. *Crassula Obvalla*. Leaves opposite, sublanceolate, sharp-edged, approximating. Stem three or four inches high, closely branched from the base.

11. *Crassula Cultrata*; *Sharp-leaved Crassula*. Leaves opposite, obovate, subcultrate, oblique, connate, quite entire. It rises about two feet high, with a weak succulent stalk, which sends out many irregular branches. The stalk which supports the flowers rises from the top of the branches, and is from four to six inches long, putting out several side-branches, which grow erect, and are terminated by large clusters of small greenish flowers, which never expand, but appear in June and July.—If the cuttings of this species be planted in a border of light earth, they will put out roots, and may afterwards be taken up and potted, to be sheltered in the winter.

12. *Crassula Cotyledon*; *Tree Crassula*. Leaves roundish, fleshy, dotted on the upper surface; stem arboreous. The whole plant is smooth. Stem two feet high, very thick, erect, branched near the top; branches grayish or reddish, cylindrical, fleshy, leafy; flowers numerous, inodorous, at first white, but afterwards rose-coloured.

13. *Crassula Pinnata*; *Wing-leaved Crassula*. Leaves pinnate; stem arboreous; panicle axillary, shorter than the leaves; flowers red.—Native of China.

***Herbaceous.*

14. *Crassula Centauroides*; *Centaury-flowered Crassula*. Stem dichotomous; leaves sessile, oblong-ovate, cordate, plane; peduncles axillary, one-flowered. Root annual or biennial; stem roundish, brachiate, somewhat pubescent, three or four inches high; flowers yellowish-red. It flowers in May and June.

15. *Crassula Dichotoma*; *Forked Crassula*. Stem dichotomous; leaves sessile, ovate-oblong, channelled, recurved; peduncles axillary, one-flowered; flowers purple on the outside, golden-coloured within, with a blood-red heart-shaped spot at the bottom of each petal; stem simple, round, pale green, dichotomous at top, scarcely a palm in height, flowering in June and July.

16. *Crassula Glomerata*; *Clustered Crassula*. Stem dichotomous: leaves lanceolate; the last flowers fasciated. Annual. Stem a palm in height, very slender, round, purplish; leaves opposite, fleshy, sessile, spreading very much, sharpish; flowers sessile; some almost sessile in the forks of the stem; others clustered, two or three together at the ends of the branches; petals white. It flowers in June and July.

17. *Crassula Strigosa*. Stem dichotomous, erect; leaves obovate, strigose; peduncles one-flowered. Root annual; stem six inches high; leaves opposite, obtuse, marked with lines, quite entire, the lower often on petioles; flowers several together, terminal.

18. *Crassula Muscosa*. Stem prostrate; leaves opposite, ovate, gibbose, imbricate; flowers sessile, solitary. Root annual; stems filiform, seldom branched, covered with leaves; flowers very small, axillary.

19. *Crassula Ciliata*. Leaves opposite, oval, flattish, distinct, ciliate; corymbs terminating. Stems short, ending in a few leafy branches, which are elongated into round shoots; a long span in length; leaves obtuse, green, and smooth on

both sides thickly fringed with white hairs; flowers small, yellow, collected into small terminal corymbs. Perennial.

20. *Crassula Punctata*; *Dotted Crassula*. Leaves opposite, ovate, dotted, ciliate, the lower oblong. Stems divided, eight or nine inches long, terminated by clusters of small white flowers, sitting very close to the top: these appear in spring, and again at the end of summer.

21. *Crassula Subulata*; *Awl-leaved Crassula*. Leaves subulate, columnar, spreading. Stem annual, covered with truncate ciliate sheaths of leaves; spikes headed, terminating, subsessile, with an imbricate involucre.

22. *Crassula Alternifolia*; *Alternate-leaved Crassula*. Leaves serrate-toothed, plane, alternate; stem very simple; flowers pendulous, on short peduncles, yellow, solitary; branches two feet long, lax, purple, hairy.

23. *Crassula Rubens*; *Hardy Annual Crassula*. Leaves scattered, semicylindric, smooth; flowers lateral, solitary, subsessile; branches villose. Stem round, pubescent, decumbent; branches ascending, a finger's length; flowers in the branches among the leaves, scattered, remote, on very short peduncles; nectaries white, very small.—Native of Switzerland and Italy.

24. *Crassula Verticillaris*; *Whorl-flowered Crassula*. Leaves spreading; flowers verticilled, awned. Root annual; stem the length of a finger, much branched, diffuse; branches opposite; leaves oblong-egg-shaped, sprinkled with minute pimples; flowers axillary, sessile, very minute.—Native of the south of Europe.

25. *Crassula Nudicaulis*; *Naked-stalked Crassula*. Leaves subulate, radical; stem naked. This species never rises with a stalk, but the leaves come out close to the ground, forming a sort of head; they are succulent, taper, ending in points, and frequently put out roots, out of the centre of which arises the flower-stalk, which is round, and from four inches to a foot in height. The flowers do not open. This species has been long known in the gardens of the curious. It flowers in May, and sometimes again in the latter part of the summer.—Both this and the twenty-sixth species are propagated by the heads or offsets, laid to dry three or four days before they are planted, during any of the summer months.

26. *Crassula Orbicularis*; *Starry Crassula*. Runners prolific, determinately leafy; leaves very much spreading; imbricate. This is a very low perennial plant, with open spreading heads, very like those of some sorts of Houseleek, growing on the ends of very slender trailing stalks, produced in plenty on every side of the parent plant, in the same manner as the Childing Marigold. Scape four or five inches long, rising from the centre of the tufts of leaves; flowers small, whitish-red, in several small clusters, disposed in a short branched spike, sweet-scented.

27. *Crassula Pellucida*. Stem flaccid, creeping; leaves opposite. Stems trailing, slender, succulent, of a reddish colour, and putting out roots at the joints. The flowers appear in small clusters at the end of the branches, and are white, with a blush of purple at the brim: they appear at different times in summer, and are often followed by seeds.

28. *Crassula Columnaris*. Stem erect; leaves connate, orbiculate, ciliate, hemispherically imbricate; flowers terminating, very copious, white; head hemispherical.—All the foregoing are natives of the Cape, except the 13th, 23d, and 24th species.

*** *Additional Species.*

29. *Crassula Barbata*; *Bearded-leaved Crassula*. Leaves connate, orbiculate, bearded, hemispherically imbricate; stem almost naked; flowers in whorls; root biennial.

30. *Crassula Argentea*; *Silver-leaved Crassula*. Leaves connate, ovate, entire, silvery; stem covered; corymb superdecompound, Root perennial; stem shrubby, branched, a foot or more in height; branches round, smooth; flowers terminating in an ovate corymb.

31. *Crassula Vestita*. Leaves connate, deltoid, obtuse; stem covered; flowers terminating in a head; root fusiform, creeping, perennial; flowers sessile, yellow.

32. *Crassula Corallina*. Leaves connate, deltoid, obtuse; stem covered; flowers in an umbel; root fusiform, perennial; flowers from the ends of the branchlets, very many, terminating, upright, peduncled. This and the foregoing resemble Sea Corallines in the structure of the leaves, but are larger.

33. *Crassula Retroflexa*; *Orange-flowered Crassula*. Leaves connate, oblong, remote; stem simple; cyme compound; pedicels bent back at an angle. Root annual; stem filiform, flexuose-erect, a finger's length, smooth, purple; stem-leaves two or four, ovate-lanceolate, blunt, spreading, entire; flowers erect, in a decompound subdichotomous cyme. There are three varieties: 1. with orange-coloured flowers: 2. with middle-sized yellow flowers: 3. with smaller and more tender white flowers.

34. *Crassula Deltoidea*; *Deltoid-leaved Crassula*. Leaves connate, deltoid; stem covered; flowers corymbed. Stem herbaceous, fleshy, round, upright, naked at bottom; leafy above, branched.

35. *Crassula Cordata*. Leaves petioled, cordate; flowers solitary. Root annual; stems herbaceous, weak, gradually more slender, leafy at bottom, branched at top, fleshy, round, flesh-coloured, almost upright, a palm in height; branches opposite, capillary, from spreading upright, smooth; flowers terminating, on capillary peduncles, appearing from May till August.

36. *Crassula Montana*. Leaves connate, ovate, acute, ciliate; stem almost naked; flowers headed, aggregate. Root-leaves concave, very frequent, patulous, smooth, green, tinged with purple; stem-leaves about three pairs, similar, but smaller and remote; stem filiform, upright, a finger's length, purple.

37. *Crassula Mollis*; *Fig-marigold-leaved Crassula*. Leaves connate, cylindrical-triquetrous, smooth, soft, remote; stem erect, simple; corymb trichotomous, superdecompound. Root perennial; stem frutescent; leaves acute, smooth on every line, subtomentose, patulous; flowers in a subfastigiate corymb. It flowers with us in August, and at the Cape in January.

38. *Crassula Crenulata*; *Notch-leaved Crassula*. Leaves connate, lanceolate, dotted, and crenulate, remote; corymb decompound. Stem herbaceous, upright, cylindric, leafy, jointed, smooth, green, variegated with white lines, the thickness of a quill, a foot high; flowers white, in a trichotomous fastigiate corymb.

39. *Crassula Alpestris*; *Large Mountain Crassula*. Leaves connate, ovate, acute, entire, imbricate in four rows; heads peduncled. Stem round, smooth, upright, branched at bottom, before flowering time wholly covered with leaves, a palm high, purple; flowers in several terminating heads, which are larger than peas; peduncles purple.

40. *Crassula Pyramidalis*. Leaves connate, ovate, obtuse, entire, imbricate in four rows; heads sessile; root perennial; flowers at the ends of the branches, in solitary globular heads, larger than a pea.

41. *Crassula Spicata*. Leaves connate, linear-subulate; scape almost naked; flowers in whorls. Root-leaves fastigiate opposite, erect, concave above, convex below, smooth,

a finger's length, very much crowded; stem leaves opposite, smaller; stem round, herbaceous, erect, smooth, a span high.

42. *Crassula Turrata*. Leaves connate, imbricate in four rows, ovate-oblong, acute, ciliate. Root annual; stem herbaceous, weak, erect, round, jointed, covered with leaves; smooth, a palm high; branches, if any, axillary, very short; leaves alternately opposite, thick, smooth, red; lower ones oblong, concave above, convex underneath, upper ones egg-shaped, flat above.

43. *Crassula Rupestris*; *Rock Crassula*. Leaves connate, ovate, entire, smooth; stem covered; corymb superdecompound. Root perennial, branched; stem round, branched, a palm high; leaves green, with a rufescent margin.

44. *Crassula Thyriflora*. Leaves perfoliate, ovate, ciliate, patulous; corymb compound, spiked. Stem round, herbaceous, upright, a span high, smooth; flowers white, in a thyrse, gradually attenuated, decompound, a palm in length.

45. *Crassula Capitella*; *Square-spiked Crassula*. Leaves oblong, connate, cartilaginous-ciliate, patulous; flowers in headed whorls; stem round, smooth, erect, a span high, the thickness of a quill, sometimes branched at top; flowers white, in sessile, many-flowered, approximating whorls.

46. *Crassula Pubescens*. Leaves connate, ovate-subulate, villose; stem branching; flowers corymbed; root perennial; stem filiform, frutescent, erect, red, smooth, a span high; corymb compound, trichotomous.

47. *Crassula Cephalophora*. Leaves connate, linear, oblong, obtuse, entire; heads lateral, peduncled. Stem round, erect, subtomentose, a span high; heads of flowers opposite, the size of a pea.

48. *Crassula Tomentosa*. Leaves connate, lanceolate, villose, ciliate; stem almost naked; flowers in whorls: root-leaves bluntish, hirsute, imbricate; stem-leaves three pairs, smaller; stem angular, erect, villose, a foot high.

49. *Crassula Cotyledonis*; *White-flowered Crassula*. Leaves connate, oblong, tomentose, ciliate; stem almost naked; flowers corymbed, aggregate. Stem herbaceous, slightly four-cornered, leafless, tomentose, the thickness of a quill, a foot high; flowers white, pedicelled; peduncles dichotomous; corymb decompound.

50. *Crassula Tecta*. Leaves connate-ovate, obtuse, ash-coloured, lamellose; scape naked; flowers sessile. Stem scarcely any; flowers several, minute, collected into a head; leaves subradical, very abundant, imbricate, convex beneath, concave above, thick, covered with an ash-coloured meal, like the scales of a butterfly's wing.

51. *Crassula Perforata*. Leaves connate-perfoliate, ovate, ciliate, remote; stem erect, thyrse-bearing, round, jointed, gradually attenuated, leafy, smooth, a foot high; peduncles and pedicels filiform.

52. *Crassula Expansa*; *Awl-leaved Crassula*. Leaves semi-cylindric, subulate, channelled above, spreading; peduncles axillary, solitary, one-flowered; stems dichotomous. Annual: flowering in June and July.

53. *Crassula Lineolata*; *Channelled Crassula*. Stem herbaceous; leaves cordate, sessile; peduncles almost terminating, axillary, approximating, umbel-shaped. Biennial: flowering from June to August.

54. *Crassula Pulchella*; *Reflex-leaved Crassula*. Stem herbaceous, dichotomous; leaves ovate-oblong, fleshy, reflex; flowers in the forks peduncled; peduncles turbinatè.—Annual; flowering in July.

55. *Crassula Imbricata*; *Imbricate Crassula*. Leaves ovate, acute, imbricate in four rows, glossy; flowers axillary, sessile. Shrubby. It flowers in June.

56. *Crassula Obliqua*; *Oblique-leaved Crassula*. Leaves

opposite, ovate, oblique, quite entire, acute, distinct, somewhat cartilaginous at the edge. Stem near three feet high, erect, dividing into many branches; leaves of a lively green, half stem-clasping. Shrubby; flowering in April and May.

57. *Crassula Alboides*; *Spike-flowered Crassula*. Leaves ovate, distinct, acute, ciliate; stem simple, somewhat hairy; raceme compound; branches panicle-shaped. Biennial; stem scarcely a span in height; leaves fleshy, smooth, with minute red impressed dots scattered over them, and an inch in length; nectaries yellow; filaments white. It flowers from June till August.

58. *Crassula Sparsa*; *Alternate-leaved Crassula*. Leaves alternate, subspatulate, acute, quite entire; raceme compound.—Biennial; flowering in July.

59. *Crassula Diffusa*. Leaves oblong, attenuated at the base, remotely crenate; peduncles opposite to the leaves, and axillary, solitary.—Annual; flowering in July.

60. *Crassula Spathulata*; *Crenated Crassula*. Leaves petioled cordate-ovate, acutish, crenate; corymbs panicle-shaped. Shrubby: it flowers in July and August.

61. *Crassula Marginalis*. Stem shrubby; leaves cordate, perfoliate, acuminate, plane, spreading, dotted within the margin. Shrubby: flowering in July and August.

62. *Crassula Lactea*; *Snowy Crassula*. Stem shrubby: leaves ovate, attenuated at the base, connate, quite entire, dotted within the margin; cymes panicle-shaped. Shrubby: flowering in September and October.

63. *Crassula Cespitosa*; *Turfy Crassula*. Leaves globose-ovate, imbricate four ways; cyme three-flowered; flowers sessile. This is a thick annual plant, scarcely three lines in height; stem red; leaves sessile, green with a red dot at the end, becoming red by age. Stamina four or five.—Common near Madrid; flowering in March.

64. *Crassula Umbella*. Leaves roundish, perfoliate; racemes axillary and terminating; upper peduncles in whorls. Root perennial; the whole plant smooth; stem one or two, annual, round, fleshy, the size of a quill, a span high, upright, subpellucid.—This, and all the foregoing species from 29 inclusive, except the 63d, are natives of the Cape.

Cratægus; a genus of the class Icosandria, order Digenia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, concave, spreading, five-cleft, permanent. *Corolla*: petals five, roundish, concave, sessile, inserted into the calix. *Stamina*: filaments twenty, subulate, inserted into the calix; anthers roundish. *Pistil*: germen inferior; styles two, filiform, erect; stigmas headed. *Pericarp*: berry fleshy, roundish, umbilicated. *Seeds*: two, somewhat oblong, distinct, cartilaginous. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: five. *Berry*: inferior, two-seeded.—The species are,

1. *Cratægus Aria*; *White Beam Tree*. Unarmed: leaves ovate, gashed, serrate, tomentose underneath. It rises to the height of thirty or forty feet, with a large trunk, dividing into many branches: the young shoots have a brown bark covered with a mealy down; the leaves are two or three inches long, and an inch and a half broad in the middle, of a light green on their upper side, but very white underneath; the flowers are produced at the ends of the branches, in bunches or corymbs, two inches or more in diameter, and very much branched. There is a Swedish variety, which has the leaves deeply sinuated, pinnatifid, and even pinnate; which is never the case with the British species. The wood being very white, hard, tough, and smooth, is used for axle-trees, walking sticks, and the handles of tools; the fruit is eatable when mellowed by the autumnal frosts, and yields an ardent spirit when distilled.—It flowers in May, and is a native of most parts of Europe, being chiefly found on dry hills and open

exposures, in gravel, clay, or chalk, and from the fissures of limestone rock; it is found in all parts of Great Britain, but principally in Derbyshire, where it is called the *wild pear tree*; and at Norwood, near London: it was formerly found upon Hampstead Heath, and, according to Mr. Ray, in Worcestershire and Staffordshire; it is called *red chess-apples*, and *sea-owlers*, in Lancashire and Westmoreland; and *mehlbeerbaum* or *mehlbaum*, by the Germans; *axelbaer*, by the Danes; *oxel*, *oxeltraed*, or *oxelbaer*, by the Swedes; *alizier*, by the French; *aria* or *sorbo peloso*, by the Italians; and *mostaco*, by the Spaniards.—The White Beam Tree may be propagated by seeds, which should be sown soon after they are ripe, for if they be kept out of the ground till spring, they must remain at least one year in the earth before they can appear. On this account the fruit should be buried in the ground, in the same way as the Haws, Holly-berries, and those other hard seeds which do not come forth in the same year that they are sown; they should also be treated in the same manner as the Haws when they appear, but ought by no means to be headed or cut down. It may also be propagated by layers in the same manner as the Lime and Elm, but these should be laid in the young wood; two years will elapse before they produce sufficient roots to transplant. It may also be raised from cuttings planted in a shady border in autumn, although scarcely an eighth part will ever succeed; so that the trees raised from seeds are greatly to be preferred, because they are more productive, and grow much larger and straighter, than those raised from layers or cuttings. It will take very well by grafting or budding upon Pear-stocks, as the Pear-tree will also take, when engrafted upon it; and though both will sometimes succeed upon the Mespilus, yet in that case they never thrive so well, nor last so long as when they are grafted or budded upon each other. The straight and handsome growth of the tree, the smoothness of the bark, the extreme whiteness on the under surface of the leaves, the handsome bunches of white flowers on thin mealy peduncles, which are succeeded by red berries, all conspire to render this desirable for mixing among other ornamental plants, especially as it bears lopping, and permits the grass to grow under it.

2. *Cratægus Torminalis*; *Wild Service* or *Sorb*; or *Maple-leaved Service*. Unarmed: leaves smooth, seven-angled, the lowest lobes divaricate; calices villose. It rises to the height of forty or fifty feet, with a large trunk, spreading at the top into many branches, so as to form a large head: the young branches are covered with a purplish bark, marked with white spots; leaves alternate, on longish footstalks, cut into many acute angles, like those of the Maple-tree, near four inches long, bright green above, woolly underneath; the flowers are produced in large bunches towards the end of the branches; they are white, and shaped like those of the Pear-tree, but smaller and on longer peduncles; they appear in May, and are succeeded by roundish compressed fruit, shaped like common Haws, but larger, ripening in autumn, when they are of a brown colour, and when kept till soft, in the same manner as Medlars, have a very agreeable acid flavour in their taste. The fruit is sold in the London markets in autumn; and the wood being very hard and white, is very serviceable in mill-work.—It is a native of Denmark, Germany, Austria, Switzerland, Burgundy, and Piedmont. It is found in many parts of England, and principally upon strong soils, especially in Caen Wood, and Bishop's Wood, near Hampstead; in Hertfordshire, &c. There is an Alpine variety, about twenty feet high, with ovate-oblong leaves, slightly serrated; the flowers in small bunches; and the fruit dark-brown, about the size of the common

Haw; it is a native of Monte Baldo, and other mountains of Italy. The Wild Service tree may be propagated in the same way as the first species, (which see) but requires a strong soil.

3. *Cratægus Coccinea*; *Great American Hawthorn*. Thorny: leaves cordate-ovate, gash-angled, smooth; petioles and calices glandular; flowers five-styled. It rises to the height of twenty feet in England, with a large upright trunk, dividing many strong, irregular, smooth branches; with large leaves, bending backwards; the flowers come out from the sides of the branches in large clusters, and as they are large, make a noble show in the month of May: they are also succeeded by large pear-shaped fruit of a bright scarlet colour, which ripens in September.—Native of Virginia and Canada. All the sorts of American Hawthorn may be raised from seeds sown in autumn, in the same manner as the first sort, or as the common Hawthorn; but as these seeds can only be procured from America, and frequently do not arrive here till spring, the fruit may be buried in the ground till the autumn following, when they may be taken up and sown in drills, taking care to cover them, so that birds cannot destroy them. The plants will come up in the following spring, and should be moderately watered twice or thrice a week in dry weather; and if not often weeded, will soon be destroyed. In the second spring they should be planted out, before they begin to shoot, into a nursery-bed, where they may grow two years to get strength, and afterwards be transplanted wherever they are to remain. In a light moist soil their roots will extend to a considerable distance, and put up many shoots, which may be taken off in the spring, and thereby may be increased; these will also take, if grafted on the Pear; and the young branches also will take root if laid down.—The several kinds of Hawthorn are generally planted among flowering shrubs of the same growth, where they add to the variety. Although the largest and most beautiful plants can only be raised from seed, the varieties of the Hawthorn are continued by budding upon stocks of the common sort; which is also the method that is commonly adopted for several of the species. See *Inoculating*.

4. *Cratægus Viridis*; *Green-leaved Virginian Hawthorn*. Unarmed: leaves lanceolate-ovate, subtrilobate, serrate, smooth.—Native of North America. Probably a variety of the foregoing.

5. *Cratægus Punctata*; *Great-fruited Hawthorn*. Thorny, or unarmed: leaves obovate, wedge-form, smooth, serrate; calices subvillose; leaflets subulate, entire; fruit orange-red dotted with brown, whitish within; stones very hard.—Native of America. There is a variety with red fruit, and another with yellow.

6. *Cratægus Cris Galli*; *Cockspur Hawthorn*. Thorny: leaves subsessile, glittering, coriaceous; calicine leaflets lanceolate, subserrate; flowers two-styled. Stem strong, ten or twelve feet high; bark of the stem rough, and of the branches smooth and reddish; flowers axillary, in roundish clusters, generally two together; petals white, with a blush of red, they appear in June; the fruit is globular, and of a fine red colour.—Native of North America. There are three varieties of this species, differing in the shape of their leaves.

7. *Cratægus Tomentosa*; *Woolly-leaved Hawthorn*. Branches thorny; leaves wedge-form, ovate, serrate, somewhat angular, villose underneath. It has a slender shrubby stem, about six or seven feet high, sending out many irregular branches armed with long slender thorns. It flowers at the beginning of June, and ripens fruit very late in the autumn.—Native of North America. There is a variety of this species, which has longer and whiter leaves, larger flowers and fruit, but no thorns; which is called *Carolina Hawthorn*.

8. *Cratægus Indica*; *Indian Hawthorn*. Unarmed: leaves lanceolate, serrate; corymbs scaly. This is a large thornless tree; the wood is heavy, reddish, and so tough that it is well adapted for oars, and other purposes where elasticity is required.—Native of the East Indies and Cochin-china,

9. *Cratægus Oxycantha*; *Common Hawthorn*, or *White Thorn*. Leaves obtuse, trifid, serrate; styles two, sometimes three or four; seeds usually two, but sometimes one, three, or four. The varieties are, *Cratægus Vulgaris*, or Common; *Cratægus Major*, or Great-fruited; *Cratægus Præcox*, or Glastonbury; *Cratægus Plena*, or Double-flowered; *Cratægus Flava*, or Yellow-berried; *Cratægus Alba*, or white berried; and *Cratægus Incisa*, or Fine-leaved. The common Hawthorn and its varieties usually flower in May; but the Glastonbury variety usually flowers in January or February, so that it may happen to be in flower on *Christmos-day*. The great-fruited variety has an exceedingly large, oblong, smooth, and bright scarlet-coloured fruit. The buds of the yellow variety, are of a fine yellow colour, and are succeeded by a golden-coloured fruit, which it continues to bear throughout the winter, and was originally imported from Virginia. The white variety, is but a paltry tree. The double-flowered is one of the greatest ornaments of which our shrubberies can boast, and may be kept down to any size; its beautiful flowers come out in large bunches in May, they are of a pure white, and often appear entirely to cover the shrub; they change at length to a faint red, and are frequently succeeded by a small imperfect fruit. Few trees can surpass the Hawthorn in beauty, during the season when it is in bloom; it is therefore well adapted for ornamental plantations, and particularly proper for standing single in lawns or parks, where it will grow to the height of twenty or even thirty feet, and sometimes measure from five to nine feet in the circumference of its trunk. The wood is tough, and may be employed for axle-trees, and the handles of tools. The root of an old thorn, says Evelyn, is excellent both for boxes and combs; when planted singly, it rises with a stem big enough for the use of the turner, and the wood is scarcely inferior to Box. The common Hawthorn flowers and dried fruit are said, by Hill, to be used in medicine as diuretics, and serviceable in all gravelly complaints; but are not much esteemed. A decoction of the bark affords a yellow dye, which, with the addition of copperas, is used for dying black. The berries are the winter food of the thrush, and of many other birds; and hogs and deer are also very partial to them. The peasants of many countries are known to eat them, and the Kamtschadales even make a wine from them. In addition to the name of *white thorn*, the English call it *May-bush*, and *quick*, when used for hedges, for which purpose it surpasses all other live fences; (see *Hedge* and *Quick*.) The Germans call it *hagedorn*; the Danes *hagetorn*; and the Swedes *hagtorn*; whence the English also derive the name *hawthorn*, and apply the contraction *haws* to the fruit; in France it is known by the appellation of *aubepine*, or *epine blanche*; in Italy by the term *bianco spino*; and in Spain, *espino blanco*: all of which signify *white thorn*.—In order to raise the White Thorn, the most usual practice is, to sow the berries either in October or November, or else very early in the spring, either broadcast or in drills, in beds of about four feet wide, with alleys of eighteen inches in width between them, and covering the berries an inch deep with fresh light mould. Thus, though most of them should not come up until the second spring, yet they will have the continual benefit of the sun, air, and rain, all of which, it may be presumed, will make them come up better, and shoot stronger, than when they lie buried in a heap during more than a year. The following plan of Mr.

Boutcher's is subjoined, as containing some useful directions on this subject. The haws should remain on the bushes till the end of October, when they become blackish; if you do not sow them immediately as soon as they are gathered, spread them on an airy floor for five or six weeks, till the seeds are dry and firm, then plunge them into water, and rub off all the pulp between your hands with the assistance of a little sand: spread them again on the loft for three or four days till quite dry, mix them with a fine loose sandy mould, in quantity not less than the bulk of the seeds, and lay them in a heap against a south wall, covering them over three or four inches deep with soil, of the same quality as that with which they are mixed. If you do not sow them in the first, let them remain in this situation till the second spring, as the seeds, when sown, will not appear in the first year. That the berries may be as equally mixed with the soil as possible, turn over the heaps once in two months, blending the covering with the seeds, and at every turning give them a fresh covering in the winter months. They must be sown in the first dry weather in February or the beginning of March: let them be separated from the loose soil in which they were mixed with a wire sieve: choose good fresh dry well-prepared laud; divide it into beds of three feet and a half broad, with alleys of eighteen inches; push over a little of the surface of the beds into the alleys; sow them with great care, so that they may not rise in clusters, and that the plants may in general be at least an inch asunder; clap them into the earth with the back of a spade, draw the soil back from the alleys, and cover the seeds only half an inch deep. In the succeeding spring, draw out all the largest plants, wherever they rise too close together; shorten their roots, and lay them in lines a foot asunder, and four inches distant in the rows, having cut off so much of their tops as to leave them about two inches above ground; and there let them remain for two years. Those who are not straitened for ground may drop the seeds in drills that are eight inches asunder, and double that distance between each pair of drills; they also may be drawn off, wherever too thickly set, in the following spring, and the rest cut with a spade five or six inches below ground, to remain another year.—Thorns also may be propagated to much advantage, and two years' time be saved, by cuttings from their roots; for this purpose, at removing a nursery of these plants, cut off all unnecessary roots that are straight and clean, and only of one or two years' growth; let them not exceed four or five inches, and either early in October or February lay them in drills cut out by the spade, with their tops a quarter of an inch below the surface; let these drills be a foot asunder, and lay the roots three or four inches separate: in the next spring cut them within three or four inches of the surface, for they will be in general about eighteen inches high, and well rooted, at two years old. In whatever way thorns are propagated, in October they should be planted out in rows, at least eight inches asunder, and six inches in the row, their roots having been shortened, and their tops cut off so as to stand four or five inches above ground: in this nursery they should remain no more than two years, the ground being dug in spring and autumn, and the plants cut in the first season, an inch or two above the former cutting: when again removed, they should be placed in rows four feet asunder, and two feet distant in the row; they should also be cut to the height of a foot or fourteen inches; and about the end of June clipped straight in the sides, and then in the tops. Having stood a year longer, they should be again cut to the height of thirty inches, and clipped as before. At Midsummer in the third season they may be cut at about three feet and a half high, and may be planted in the

succeeding autumn for handsome hedges at four feet high. If plants of a larger size be desired, they must be removed once more, and will be six feet high in three years. Quick thus removed, and planted out at large, will make an almost immediate fence, and be a great saving, wherever fencing is expensive.

10. *Cratægus Monogynia*; *Single-styled Cratægus*. Leaves subtrifid, acute; lobes spreading, quite entire below; flowers one-styled. Trunk ascending, round, very much branched; bark smooth. This is supposed by some to be our English White-thorn described above: but as Linneus thought otherwise, and Mr. Lyons observes, that the style, though simple at first, is afterwards divided into two; and Dr. Withering also observed two styles in one plant; their opinion has been preferred before that of their opponents.

11. *Cratægus Azarolus*; *Parsley-leaved Hawthorn*, or *Azarole*. Leaves obtuse, subtrifid, somewhat toothed. It has a strong stem twenty feet high, having many strong irregular branches, covered with a light coloured bark. The flowers come out in small clusters from the side of the branches, and are like those of the common Hawthorn, but much larger; as is also the fruit, which, when fully ripe, has an agreeable acid taste, and is much esteemed.—Native of the south of Europe, and of the Levant.

12. *Cratægus Maura*. Leaves oblong, toothed at the end; bark ash-coloured, no spines; flowers in branched corymbs, resembling those of the common Hawthorn.—Native of Barbary.

13. *Cratægus Villosa*. Leaves oblong, acuminate, smooth, serrate; flowers in a compound umbel; styles two; fruit villose.—Native of Japan.

14. *Cratægus Lævis*. Leaves ovate, acuminate, smooth, serrate; flowers in an almost simple umbel. Stem smooth; flowers terminating, spreading very much; peduncles capillary, callous, an inch long; perianth only half the length of corolla.—Native of Japan.

15. *Cratægus Glabra*. Leaves oblong, acute, smooth, serrate; flowers in a compound panicle; branches and branchlets subverticilled, striated, smooth, spreading.—Native of Japan.

16. *Cratægus Cordata*; *Maple-leaved Hawthorn*. Thorny: leaves cordate-ovate, gash-angled, smooth; petioles and calices without glands; flowers five-styled. It rises with a strong woody stem about four feet high, sending out many spreading branches, which incline to a horizontal position; flowers smaller than those of the Common Hawthorn; fruit an oblate spheroid, scarlet, the size of a red currant. It flowers the latest of the genus.—Native of North America.

17. *Cratægus Pyrifolia*. Thorny, or unarmed: leaves ovate, elliptic, gash-serrate, somewhat plaited and hirt; calices a little villose; leaflets linear-lanceolate, serrate; flowers three-styled.—Native of North America.

18. *Cratægus Elliptica*. Thorny: leaves elliptic, unequally serrate, smooth; petioles and calices glandular; berries globular, five-seeded.—Native of North America.

19. *Cratægus Glandulosa*; *Hollow-leaved Hawthorn*. Thorny: leaves obovate-wedge-form, angular, smooth, glittering; petioles, stipules, and calices glandular; berries oval, five-seeded. It has very stout thorns: it flowers in May and June.—Native of North America.

20. *Cratægus Flava*; *Yellow Pear-berried Hawthorn*. Thorny: leaves obovate-wedge-form, angular, smooth, glittering; petioles, stipules, and calices glandular; berries turbinate, four-seeded. There are often small leaves on the thorns, which are slender, and a little bent in at the end.—It flowers in May; and is a native of North America.

21. *Cratægus Parviflora*; *Gooseberry-leaved Hawthorn*. Thorny: leaves, wedge-form-ovate, gashed serrate; calicine leaflets gashed, the length of the fruit; flowers five-styled. It is a humble shrub, seldom rising more than six or seven feet high, sending out a great number of slender branches, interwoven and armed with very long, slender, sharp thorns; the flowers are produced at the end of the branches; the fruit is smaller than that of the common Hawthorn, and is of an herbaceous yellow colour when ripe. It flowers in May and June; and is generally known by the name of Lord Islay's Hawthorn.—Native of America.

22. *Cratægus Sanguinea*. Thorny: leaves seven-angled, serrate, produced at the base; petioles submarginate. Height often extending to two or three fathoms; trunk the thickness of the human arm or thigh, very much branched from the bottom, and spreading; flowers in corymbs at the ends of all the branchlets, and so abundant that the tree is very handsome when in flower and fruit. It flowers at the end of May. The fruit is large, very red, subglobular, two-celled, two or four-seeded, and ripens at the end of August, and after the first frosts becomes very eatable.—Native of Siberia, probably the same as that of Kamtschatka.

23. *Cratægus Bibas*. Unarmed: leaves lanceolate, serrate, tomentose; racemes terminating, hispid. It is a middle-sized tree, with spreading branches; leaves unequally serrate, scattered, on short petioles; flowers white, in large bunches; styles two; fruit middle-sized, pear-shaped, yellow, lanuginose, of a sweet acid flavour, juicy, eatable; the skin thin; the pulp white, one celled, containing two or three seeds.—Cultivated in abundance about Macao and Canton, in China.

Crateva; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, four-cleft, deciduous, flat at the base; divisions spreading, ovate unequal. *Corolla*: petals four, oblong, bent down to the same side; claws slender, length of the calix, inserted into the divisions. *Stamina*: filamenta sixteen, or more, bristle-form, declining to the side opposite the petals, shorter than the corolla; anthera erect, oblong. *Pistil*: germen on a very long filiform pedicel, ovate; style none; stigma sessile, headed. *Pericarp*: fleshy, globose, very large, pedicelled, one-celled, two-valved. *Seeds*: many, roundish, emarginate, nestling. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Corolla*: three-petalled. *Berry*: one-celled, many-seeded.—All the plants of this genus are propagated by seeds, which must be procured from the places where they naturally grow, and must be sown upon a good hot-bed in the spring. When the plants are fit to remove, let them be transplanted each into a small pot of light kitchen-garden earth, and plunged into a hot-bed of tanner's bark, shading them every day from the sun, until they have taken fresh root, and watering them sparingly in winter. For further particulars, see the directions under the genus *Annona*, which equally relate to these plants.—The species are,

1. *Crateva Gynaudra*; *Thin-leaved Crateva*. Unarmed: leaflets ovate, quite entire; flowers gynandrous; trunk more than twelve feet high; branches spreading, round, unequal; leaves alternate; flowers rather large, purple. It has a burning taste, and nauseous smell.—It flowers in May and June; and is a native of Jamaica, in dry coppices near the sea.

2. *Crateva Tapia*; *Smooth Crateva*, or *Garlic Pear*. Unarmed: leaflets ovate, acuminate; petals ovate-roundish, blunt germina globular. Trunk very large, rising to more than thirty feet high; leaves all smooth, of a light green on the upper side, but pale underneath, and their edges entire. The fruit is about the size of an orange, having a hard brown shell or

cover, inclosing a mealy pulp, filled with kidney-shaped seeds : it has a strong smell of garlic, which is communicated to the animals that feed upon it, and to which the tree owes its name.—Native of the West Indies.

3. *Cratēva Marmelos*; *Prickly Cratēva*. Thorny: leaves serrate. This species grow to a great height, with a large trunk, sending out many long branches, garnished with trifoliate leaves; the leaflets are oblong, entire, and end in acute points, between which the branches are armed with long sharp thorns, which come out by pairs, and spread asunder; the flowers are produced in small clusters from the side of the branches, five or seven standing upon a common branching peduncle; they have each five acute petals, which are reflex, and are sweet-scented, green on the outside, and whitish within; after the flower is past, the germen swells to a large fruit the size of an orange, having a hard shell, which incloses a fleshy viscous pulp, of a yellowish colour, having many oblong flat seeds situated within it. The pulp of this fruit has an agreeable flavour when ripe, and is frequently eaten in India; where the fruit is served up, mixed with sugar and orange, and accounted one of their greatest delicacies.—Native of the East Indies.

4. *Cratēga Religiosa*. leaflets and petals lanceolate-elliptic, acute at both ends. Trunk of a middling height, upright; branches spreading, round, ascending, covered with an olive bark dotted with white; common petioles spreading, semi-cylindric, smooth and even, a hand in length; partial petioles very short; cyme terminating, subcorymbed, and sometimes solitary flowers from the axils of the upper leaves; flowers an inch and half in diameter, greenish-white, with red stamina; fruit globular, the size of a small plum.—Native of the East Indies, and the Society Isles. In the latter it is planted at the burial places of the natives, and supposed to be sacred to their idols. In Otaheite it is called *pura-au*, or *puratururu*; and the fruit of it is eaten by the natives.

5. *Cratēva Obovata*. Leaflets and petals obovate; germen oblong; leaves and leaflets petioled; peduncle heaped at the top; style longer than the filamenta. In other respects it has the habits of the rest.—Native of Madagascar.

Crepis, a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common double; exterior very short, spreading, deciduous; interior ovate, simple, furrowed, permanent; scales linear, converging. *Corolla*: compound, imbricate, uniform; corollets hermaphrodite, very many, equal; proper, one-petalled, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta, five capillary, very short; antheræ cylindric, tubular. *Pistil*: germen somewhat ovate; style filiform, length of the stamina: stigmata two, reflex. *Pericarp*: none; calix roundish. *Seed*: solitary, oblong, fusiform, sometimes columnar; down hairy, generally stipitate. *Receptacle*: naked, with cells or pits. ESSENTIAL CHARACTER. *Calix*: calicled with deciduous scales. *Down*: hairy, stipitate. *Receptacle*: naked.—Some of these plants are weeds in gardens and pastures, and but few of them are cultivated. They may all easily be propagated by sowing their seeds in the spring, where they are designed to remain, so that if six or eight seeds be sown in each patch, and when the plants come up they may be reduced to three or four, and if these be kept clean from weeds, they will require no other culture, except putting down small sticks, to which the stalks are to be fastened in order to prevent their being broken by winds or rains. If the seeds be sown in autumn, or permitted to scatter, the plants will come up, and live through the winter without any shelter, and will flower early in the spring.—The species are,

1. *Crepis Pygmæa*. Leaves ovate, entire, villose, petioled;

stem procumbent. Height not more than six inches; flowers yellow.—Native of the mountains of Italy.

2. *Crepis Bursifolia*. Leaves pinnatifid, crenate; scape naked, few-flowered. Stems a span in height, having on them a few short lacinate leaves.—Perennial: found in the county of Nice; and near Palermo; and in other parts of Sicily.

3. *Crepis Barbata*; *Spanish or Bearded Crepis*, or *Purple-eyed Succory Hawk-weed*. Involucres longer than the calix; scales setaceous, scattered. This is an annual, putting out leaves next the root, nine inches in length, and almost two broad in the middle, of a light green colour; stems a foot and a half high, dividing into many branches, and having leaves with the same form as the others, but smaller and sessile. The flowers are produced at the ends of the branches; they are yellow, and purplish at the base, but the florets in the disk are almost entirely of a dark purple. There are two varieties of this species, one in which the flowers are of a deep yellow, and the other in which they are of a sulphur colour, inclining to white, but both have a very dark purple bottom or middle, and make a pretty appearance in the flower garden, where they come forth in June and July, and ripen seeds in autumn.—Native of the South of Europe.

4. *Crepis Vesicaria*. Involucres scariosæ, the length of the calix; flowers corymbed; bractes ovate. Root thick; stem short; flowers yellow.—Native of Apulia.

5. *Crepis Alpina*. Involucres scariosæ, the length of the calix; flowers solitary. Annual: stems strong, upright, two feet high, dividing into three or four erect branches, terminated by pale-coloured flowers, inclosed in a strong hairy calix, which contracts close towards the top.—It flowers in June, ripens seed in autumn; and is a native of the Alps.

6. *Crepis Rubra*; *Purple Crepis*. Leaves stem-clasping, lyrate-runcinate. Root annual; root-leaves many, lanceolate deeply jagged; from these arise the stalks, which are a foot and a half high, dividing into many slender branches, each terminated by one large red-coloured flower. The calix nods before the flower opens.—Native of Italy.

7. *Crepis Fœtida*; *Stinking Crepis*, or *Succory-Hawk-weed*. Leaves runcinate-pinnate, rough with hairs; petioles toothed. Stems a foot or eighteen inches in height, the central one erect, the others diffuse, branched, leafy; flowers yellow, purple on the outside, and nodding before they open. Villars remarks, that this plant varies in size, form, colour, and smell; but that in all the varieties the root is fusiform; the stem rough, channelled, and branched; the leaves ash-coloured, and more or less indented at the base; that it has generally the smell of bitter almonds, especially the bruised calix; in which Linneus and Tournefort coincide: while Haller more justly attributes a bituminous scent to it; and Ray informs us, that both it and the preceding species smell strongly of castor; and Martyn, to complete this discord of opinion, declares, that to him the flowers always seemed to have the smell of opium. It is biennial, (although Linneus calls it annual,) and flowers from June to August. Petiver distinguishes it by the name of *Castor Hawkweed*.—Native of Germany, Switzerland, Austria, France, Piedmont; and of England, near Cambridge, on Banstead Downs in Surry, near Charlton, Northfleet, and Greenhithe, in Kent, and near Swaffham in Norfolk.

8. *Crepis Aspera*. Leaves toothed, lower ovate-earred, upper sagittate; stiff bristles scattered over the stem.—Native of Sicily, the Levant, and Palestine.

9. *Crepis Rhagadioloides*. Leaves entire, stem clasping, oblong; interior calices torulose-jointed, hispid; leaflets boat-form. Annual: stem half a foot high, erect, striated, scabrous, branched; corolla yellow, purplish on the outside.

10. *Crepis Sibirica*. Leaves stem-clasping, oblong, wrinkled, toothed at bottom; stem rough with hairs; calices ciliate on the keel. Perennial; stem stiff, two feet high, straited hispid. It flowers in July and August.—Native of Siberia and Switzerland.

11. *Crepis Tectorum*; *Smooth Crepis*. Leaves lanceolate-runcinate, sessile, even, the lower toothed. This is a very common plant, of an ash-coloured green; stem angular, furrowed, with branches as long as the stem; root annual; leaves very variable, smooth, or slightly hirsute; flowers yellow, in a kind of loose corymb. The flowers, heads, and seeds of this plant, are smaller than most English Hawkweeds. The flowers expand about four in the morning, and close about noon. Our old writers call it *Yellow Succory*, *Succory-dandelion*, and *Succory-hawkweed*. Petiver calls it *Hawk-beard*; and Dr. Withering applies that name to the whole genus.—It flowers from June till September; and is a native of Europe, in pastures, by way-sides, on banks, and on walls.

12. *Crepis Biennis*; *Rough Succory-Hawkweed*. Leaves runcinate-pinnatifid, scabrous, toothed at the base above; calices muricate. Stem angular, scabrous, from four to six feet high, brittle; flowering branches divaricate, bearing several flowers on separate peduncles. The flowers close between three and four in the afternoon.—Native of Scania, Switzerland, Italy, Germany, and of England, where it is found in calcareous soils, near Northfleet, and between Sittingbourne and Rochester, in Kent, and about Linton in Cambridgeshire. It is biennial; flowering in July and August.

13. *Crepis Virens*. Leaves runcinate, smooth, stem-clasping; calices subtomentose; root-leaves lanceolate, obtuse, smooth, somewhat toothed; flowers small; and yellow.—Native of France, Switzerland, Silesia, and Italy.

14. *Crepis Dioscorides*. Root-leaves runcinate; stem-leaves hastate; calices subtomentose. Annual; stem a foot high, somewhat angular, smooth, and even; branches but few, round, and spreading; corolla yellow, purple beneath before it expands.—It flowers in June; and is a native of France, the Palatinate, Silesia, Italy, and Siberia.

15. *Crepis Pulchra*; *Small-flowered Crepis*. Leaves sagittate, toothletted; stem panicled; flowers pyramidal, smooth. It is an annual; flowering from July till August.—Native of France and Italy.

16. *Crepis Neglecta*. Leaves stem-clasping, runcinate, toothed, somewhat hairy; stem panicled; calices with one or two spines on each leaflet. Stem a foot high, branched, somewhat hairy, erect; flowers small, yellow.—Native of Italy.

17. *Crepis Albida*; *Pale-flowered Crepis*. Leaves runcinate-toothed, somewhat hoary; peduncles naked, one flowered; calicine scales whitish at the edge. Perennial; stems, several, twice or thrice dichotomous, with a sessile leaf at each division of the branches; root-leaves elliptic, gradually lessening into a leafy petiole, thickish, toothed, seldom quite entire; stem-leaves half embracing, rougher, sharper, with a more evident prickle; flowers large, pale yellow, or whitish, composed of a great number of florets.—Native of the south of France and Italy.

18. *Crepis Rigens*; *Bristly-leaved Crepis*. Leaves oblong, doubly serrate, bristly; stem naked, branched; flowers panicled; calices cylindrical, smooth; down sessile.—It flowers in July and August; is perennial; and a native of the Azores, or Western Isles. This, and the two following, require the shelter of a green-house.

19. *Crepis Filiformis*; *Fine-leaved Crepis*. Leaves linear, filiform, very entire, smooth; down sessile; biennial, flowering in June, and Native of Madeira.

20. *Crepis Succulenta*; *Fleshy-leaved Crepis*. Leaves

pinnatifid, or toothed, somewhat fleshy, even, calices somewhat tomentose; down sessile.—It is annual, flowering in August and September; and native of Madeira.

Crescentia; a genus of the class Dikynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, two-parted, short, deciduous; divisions unequal, concave, obtuse, equal. *Corolla*: one-petalled, unequal; tube gibbous, crooked, torulose; border erect, five-cleft; divisions unequal, tooth-sinuated. *Stamina*: filamenta four, subulate, length of the corolla, spreading, of which two are a little shorter; antheræ incumbent, obtuse, twin. *Pistil*: germen pedicelled, ovate; style filiform, length of the corolla; stigma headed. *Pericarp*: berry oval, hard, one-celled. *Seeds*: very many, subcordate, nestling, two-celled. ESSENTIAL CHARACTER. *Calix*: two-parted, equal. *Corolla*: gibbous. *Berry*: pedicelled, one-celled, many-seeded. *Seeds*, two-celled.—These trees require a warm stove, to preserve them in England. They are easily propagated by seed, which must be procured from the countries where they naturally grow; the best way of doing which, is to import the entire fruit when fully ripe. They must be sown on a good hot-bed in the spring, and when fit to remove should be each transplanted into a small pot filled with light sandy earth, and plunged into a hot bed of tanner's bark, where they must be shaded from the sun until they have taken fresh root, and be afterwards treated in the same manner as other plants which are natives of the same countries. They should be gently watered two or three times a week in summer, according to the warmth of the season, and must have a large share of air in hot weather. In winter they should be placed in the tan-bed of the bark-stove, and should have but little water during that season. With this management the plants will make great progress; and, their leaves being of a fine green, they make a pretty variety in the stove. The two first species have been long cultivated in England, but have not yet flowered.—The species are,

1. *Crescentia Cujete*; *Narrow-leaved Calabash Tree*. Leaves wedge-lanceolate, crowded. This tree grows to the height of about twenty feet, and is easily distinguished from all others by its peculiar appearance. It divides at top into very long, thick, scarcely subdivided branches, stretching out almost horizontally, adorned with leaves disposed in bundles or tufts, scatteringly, at irregular distances. The wood is light and pliant; the bark unequal, ash-coloured, or whitish; the leaves are four or five inches long, bright green, and veined; flower large, sometimes entirely green, but often differently variegated, with purple, red, and yellow; it does not wither, but becomes putrid, and in that state exhales a cadaverous, very nauseous, and intolerable stench. The form of the fruit varies on different trees, being spherical, spheroidal, or shaped like a bottle; and differing in size, from two inches to a foot in diameter: but it must be confessed, that if these be only varieties, they are very constant. The fruit is covered with a thin skin, of a greenish yellow colour when ripe; and under this is a hard, thin, woody shell, inclosing a pale yellowish soft pulp, of a tart unsavoury flavour, surrounding a great number of flat seeds. The shells, when cleansed of their pulp, deprived of the outer skin, and dried, are used in the West Indies for drinking-cups, tipped with silver, and with handles fastened to the neck. The long small fruit is formed into spoons and ladles; that which is round is cut through the middle, and used as chocolate cups, and other domestic utensils. They are frequently large enough to hold a gallon, and are so thin and close, that they serve to boil water as well as an earthen pot, and will bear the fire equally well. The thicker parts are manufactured

CROCUS OFFICINALIS — Saffron.

P. 381.

CROCUS — Small American Crocus.

into button-moulds throughout the colonies. The Caribs engrave the outside of these shells with a variety of grotesque figures, which they sometimes colour black or red. They also eat the pulp occasionally, but it is not esteemed to be either agreeable or wholesome, although much used as a poultice, and yielding a syrup, which is greatly esteemed by the natives in inward bruises, contusions, and disorders of the breast. The wood being very tough and flexile, is well adapted for the coach-maker, and is frequently used for making saddles, stools, and other furniture. In times of scarcity, the leaves and branches are eaten by cattle, as well as the pulp of the fruit.—Native of the low lands of Jamaica, the Leeward Islands, and the neighbouring continent.

2. *Crescentia Cucurbitina*; *Broad leaved Calabash Tree*. Leaves egg-shaped, petioled, alternate; fruit egg-shaped, acuminate; seeds orbicular, compressed. A middle-sized tree, with a large umbrageous head, nearly upright branches, and a trunk thicker than the human body. Leaves six inches long and three broad, shining, ending in a sharp point, on short petioles; flowers whiter than those of the preceding; fruit nearly the shape of a citron, but larger, with a thin brittle shell and whitish pulp.—Native of St. Domingo.

3. *Crescentia Jasminoides*. Leaves wedge-shaped, obtuse, emarginate; flowers funnel-shaped; border equal, five-cleft. A shrub, six or seven feet high, with stem the thickness of a finger; flowers resembling the common Jasmine, white, with a mixture of red; fruit yellowish-green, oval, obtuse, about the consistence of a soft pear, and containing a pulp not unlike Cassia in taste and colour.—Native of the Bahamas.

Cress. See *Cardamine*.

Cress, Bastard. See *Thlaspi*.

Cress, Garden. See *Lepidium*.

Cress, Indian. See *Tropaeolum*.

Cress, Rock. See *Iberis*.

Cress, Rocket. See *Vella*.

Cress, Swine's. See *Cochlearia*.

Cress, Water: *Cress Winter*. See *Sisymbrium*.

Cressa; a genus of the class Pentandria, order Digynia.

—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, obtuse, incumbent, permanent. *Corolla*: one-petalled, salver-form; tube length of the calix, bellied below; border five-parted; divisions ovate, acute, spreading. *Stamina*: filamenta five, capillary, long, sitting on the tube of the corolla; antheræ roundish. *Pistil*: germen ovate, styles two, filiform, length of the stamina; stigmas simple. *Pericarp*: capsule ovate, one-celled, two-valved, a little longer than the calix. *Seeds*: single, ovate-oblong. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: salver-form. *Filamenta*: sitting on the tube. *Capsule*: two-valved, one-seeded.—The species are,

1. *Cressa Cretica*. Corollas beardless; capsules one-seeded. This is a small and very shrubby plant; root long, slender, jointed, white; stems several, long, slender, round, whitish; leaves the size and form of a lentil; flowers small at the ends of the twigs; fruit resembling a grain of wheat. The whole plant is white, and has a salt taste.—Native of the sea-shores of Crete, and of Ostia near Rome.

2. *Cressa Indica*. Corollas bearded at the tip; capsules four-seeded; corolla snowy white, hairy on the outside.—Native of salt marshes in the East Indies.

Crimson-grass Vetch. See *Lathyrus Nissolia*.

Crinodendrum; a genus of the class Monadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: none. *Corolla*: bell-shaped; petals six, oblong, erect, spreading at the tip. *Stamina*: filamenta ten, erect, united at the bottom; antheræ ovate, erect. *Pistil*: germen superior, ovate; style subulate,

a little longer than the stamina. *Pericarp*: capsule coriaceous, obtusely three-cornered, one-celled, gaping elastically at top. *Seeds*: three, roundish. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: bell-shaped, six-petalled. *Capsule*: one-celled, gaping elastically at top.—The only known species is,

1. *Crinodendrum Patagua*; *Lily-tree*. This is a superb evergreen branchy tree, with a body of seven feet in diameter. The leaves are opposite, much longer than the petioles, of a bright green, lanceolate, and serrated. There are no stipules: the flowers are scattered and axillary; the peduncles one-flowered, the flowers having the odour of lilies. The seeds are the size of a lentil.—It is a native of Chili.

Crinum; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre spathe-form, two-leaved, oblong, umbelluliferous, after gaping, reflected. *Corolla*: one-petalled, funnel-form; tube oblong, cylindrical, inflexed; border six parted; divisions lanceolate-linear, obtuse, concave, reflected, of which the three alternate ones are distinguished by a hooked appendicle. *Stamina*: filamenta six, subulate, from the base of the border, of the length of the border, converging; antheræ oblong, linear, rising upwards, incumbent. *Pistil*: germen inferior. *Style*: filiform, length of the flower; stigma three-cleft, very small. *Pericarp*: capsule subovate, three-celled. *Seeds*: several. ESSENTIAL CHARACTER. *Corolla*: funnel-form, half six-cleft; tube filiform; border patulous, recurved; segments subulate, channelled; filamenta inserted into the throat of the tube, distinct.—These bulbs are very ornamental plants for the stove, and are easily propagated by offsets, which the roots put out in plenty; or by the bulbs which succeed the flowers, and ripen perfectly in England. They must both be planted in pots of rich earth, and if plunged into the tan-bed in the stove, will make greater progress, and flower oftner, than when placed on shelves, even when kept in a good temperature of heat. The roots should be transplanted in the spring, and all the offsets taken off, otherwise they will fill the pots, and starve the old plants: they must be frequently refreshed with water, but it must not be given them too plentifully, especially in winter. They flower at every season of the year, which increases their value; for where there are many plants, there will be almost a perpetual succession of flowers, which emit a very agreeable odour.—The species are,

1. *Crinum Asiaticum*. Leaves keeled. Root solid, turbinate, surrounded with long branching fibres; stem short, thick, coated, white, single; leaves three feet long, three inches wide, subulate-linear, erect, striated, thick, imbricate; flowers white, large, in a simple flat umbel. Rumphius extols the efficacy of the roots in expelling the poison of both serpents and arrows, and also in oedematous swellings, &c.—Native of Malabar, Ceylon, Tranquebar, and Cochin-china.

2. *Crinum Americanum*; *Great American Crinum*. Leaves oblong-lanceolate, very smooth at the edge, with the end contracted and hooked; flowers pedicelled, with the tube shorter than the border; flowering-stem a foot and a half in height, the thickness of a finger, slightly compressed, coming out, not from the centre of the leaves, but on one side; leaves two feet or more in length, and a hand broad; flowers pale yellow before they open, each opening successively, and lasting a day or two; when open of a milky whiteness, not disagreeable in scent.—They appear in July and August; and the plant is a native of South America.

3. *Crinum Erubescens*; *Small American Crinum*. Leaves lanceolate, cartilaginous-crenulate, the end produced and unfolded; flowers sessile; tube longer than the border. The flower-stem arises immediately from the root, on the outside

of the leaves, and is about two feet high; on the top are eight or ten flowers, in the form of an umbel, closely joined at their base, but spreading above: they are of a beautiful white colour, and smell very sweet. The stamina are stretched out to a considerable length beyond the petals. After the flowers are past, the germen swells, and becomes an oblong bulb. The plants generally flower three or four times in a year, but at no regular season; and as the petals are of a very tender texture, they do not continue in beauty above four or five days.—Native of the Spanish West Indies.

4. *Crinum Tenellum*. Spathe many-flowered; corollas equal; leaves filiform.—Found by Sparrmann at the Cape.

5. *Crinum Lineare*. Leaves linear; corollas bell-form, with two segments narrower than the rest; flowers large and white.—Found by Thunberg at the Cape.

6. *Crinum Nervosum*. Leaves roundish, nerved; filamenta widened at the base; scape many-flowered, many-leaved; flowers on long peduncles.—Native of the Philippine Islands.

Crithmum; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal, manifold, hemispheric; partial similar; involucre universal, many-leaved; leaflets lanceolate, obtuse, reflex; partial lanceolate-linear, length of the umbellule; perianth proper scarcely observable. *Corolla*: universal, uniform; florets all fertile; proper petals five, ovate, inflex, equal. *Stamina*: filamenta five, simple, longer than the corolla; antheræ roundish. *Pistil*: germen inferior; styles two, reflex; stigmas obtuse. *Pericarp*: none. *Fruit*: oval, compressed, bipartite. *Seeds*: two, elliptic, compressed-flat, striated on one side. ESSENTIAL CHARACTER. *Fruit*: oval, compressed. *Florets*: equal.—The species are,

1. *Crithmum Maritimum*; *Sea or Rock Sampire*. Leaflets lanceolate, fleshy. Perennial: stems smooth and even entirely simple; roots triternate, the middle one often five-leaved. It has a root composed of many strong fibres, which penetrate deep into the crevices of the rocks, sending up several fleshy succulent stalks, which rise about two feet high, with winged leaves, composed of three or four divisions, each of which has three or five succulent leaflets near half an inch long. The flowers are produced in circular umbels at the top of the stalks; these are of a yellow colour, and are succeeded by seeds resembling those of fennel, but larger. This herb when pickled is very agreeable to the palate, and is esteemed as a stomachic. It operates also as a gentle diuretic, removes the obstructions of the viscera, and creates an appetite; on which account it is commonly used for sauce. Meyrick and Hill agree in saying, that the leaves make an excellent and very agreeable pickle; that their juice operates very powerfully by urine, and is good for the gravel, stone, suppressions of the menses, and the jaundice. It is not only used as a pickle, but fresh as a potherb, by the inhabitants of the sea-coast. It is gathered upon rocks, where it naturally grows; but those persons who supply the market with it, seldom bring the right herb, but gather the *Inula Crithmoides* instead of it, which they call *Golden Sampire*, but which has a very different flavour from the true, and is wholly destitute of its virtues. This Golden Sampire, as it is called, grows more abundantly, especially upon flat ground, overflowed by salt water; whereas the true Sampire grows only out of the crevices of perpendicular rocks, where it is very difficult to come at.—Native of the rocky shores of the European ocean. Allioni informs us, that it grows on old walls in the Alps. It is found on Dover Cliff; near Winchelsea, Rye, Southampton, the Isle of Wight, and on all the cliffs of the Cornish coast. Not only the *Inula Crithmoides*, above-mentioned, is used for Sampire, but

the *Salicornia* is the only herb known by that name on the east coast, where it is called *Marsh Sampire*; it is tasteless, and has a tough string running through the middle; whereas the true Sampire has a warm aromatic flavour, and presents no impediment to the teeth in eating. Mr. Pennant asserts, that cows and sheep eagerly eat it, and soon grow fat upon it. It has the name *Sampire* or *Sampier*, sometimes incorrectly spelt *Samphire*, from the French *St. Pierre*. Gerarde says, some call it *crest marine*, which is also from the French *criste marine*; in which language it is also named *bacille maritime*, *fenouil marin*, *passe-pierre*, and *herbe de St. Pierre*, evidently from the roots striking deep into the crevices of the rocks. In Italian it is *critmo fnoecchio marino*, and *herba di Santo Pietro*; in Spanish, *hinojo marino*; in Portuguese, *funcho marino*; in German, *meerfenchel*, *seefenchel*, *bacillen*; in Danish, *søfenkel*; in Swedish, *sjöfenkal*.—It may be propagated either by seeds or by parting the roots, and, if planted on a moist gravelly soil, will thrive tolerably well, and may be preserved some years, but will grow best when rooted in a wall, or on an artificial rock-work.

2. *Crithmum Pyrenaicum*; *Pyreanean Sampire*. The side leaflets twice trifid.—This is a biennial plant, and a native of the Pyrenees.

3. *Crithmum Latifolium*; *Wedge leaved Sampire*. Leaflets wedge-form, cleft. A very smooth plant; root biennial; stem erect-cylindrical, furrowed; leaves petioled; pinnated, leaflets in two or three pairs, sessile; flowers yellow.—Native of Teneriffe.

Crocus; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*. spathe one-leaved. *Corolla*: tube simple, long; border six-parted, erect; divisions ovate, oblong, equal. *Stamina*: filamenta three, subulate, shorter than the corolla; antheræ sagittate. *Pistil*: germen inferior, roundish; style filiform, length of the stamina; stigmas three, convolute, serrate. *Pericarp*: capsule roundish, three-lobed, three-celled, three-valved. *Seeds*: several, round. ESSENTIAL CHARACTER. *Corolla*: six-parted, equal. *Stigmas*: convolute.—The species are,

1. *Crocus Officinalis*; *Officinal or Autumnal Crocus*, or *Saffron*. Leaves narrower, rolled in at the edges; stigma trifid to a considerable length. This plant has a roundish bulbous root, as large as a small nutmeg, which is a little compressed at bottom, and covered with a coarse brown, netted skin; from the bottom of this bulb are sent out many long fibres, which strike pretty deep into the ground. The flowers come out from the upper part of the root, and, like the young leaves, the tops of which just appear, are closely wrapped about a thin spathe or sheath, which parts within the ground, and opens on one side. The tube of the flower is very long, arising immediately from the bulb without any footstalk, and at the top divides into six ovate obtuse segments, equal, and of a purple blue colour. In the bottom of the tube is situated a roundish germ, supporting a slender style, crowned with three golden stigmas, which is the Saffron.—It flowers in October, and the leaves keep growing all the winter, but it never produces any seeds in England. Haller remarks, that the Autumnal Saffron differs from the Spring Crocus, in having the stigma divided into three long segments, the ends of which are also trifid. These three horns of the stigma are also odorous and aromatic, which is not the case with the Vernal Crocus, and the flowers are much larger. Add to this, that the corolla does not vary much from its high native purple; that they differ also in the root and leaves, the time of flowering, and the place of growth. The native country of Saffron is not well ascertained; the

most probable opinion seems to be, that it came originally from the East, where it had acquired that high reputation in medicine, which it has now almost lost in Europe, although it is still cultivated in Italy, Sicily, Germany, Hungary, France, Spain, and also sparingly in England, where it is commonly said to have been introduced in the reign of Edward the Third, by Sir Thomas Smith, who brought it into the neighbourhood of Walden in Essex, which place has, on that account, since received the name of Saffron Walden. Although Essex was not the only county into which Saffron was introduced, it was cultivated there in great abundance, at the end of the sixteenth and beginning of the seventeenth century. About the middle of the eighteenth century, it had migrated into the parishes of Huxton, Ickleton, and Triplow, bordering on the Roman way, called the Ikenild-street; and westward of these to Gogmagog Hills, in the parishes of Duxford, Newton, Hareton, Hauxton, Great and Little Shelford, Sawston, Stapleford, and even as far as Fulborn, which is to the north of the hills; all in the county of Cambridge. The quantity of land occupied in cultivating Saffron has been gradually decreasing during the last twenty or twenty-five years, which is supposed to arise from the importation of foreign Saffron. It is now confined to two or three parishes only, of which Stapleford is one; and if some means be not employed to encourage it, the cultivation of Saffron will probably soon be entirely lost in this country. Whether, says Mr. Miller, Saffron be of any national consequence, I am not a competent judge; I only know, that when the culture is entirely dropped, it will be no easy matter to revive it. Our modern European term of *Saffron* is derived from the Arabic *sahafaran*; hence the Moorish and Spanish *azafran*, *azafron*, *safrá*; the Italian *zaffarano*; and the German, Danish, Swedish, and French *safran* or *safran*. Lewes assures us, that Saffron is a very elegant and useful aromatic, of a strong penetrating smell, and warm, pungent, bitterish taste; it is said to be more cordial and exhilarating than any of the other aromatics, and is particularly serviceable in disorders of the breast, in female obstructions, and hysteric depressions. Hill also says, that the whole class of medicinal subjects cannot afford a greater cordial than Saffron; which also promotes perspiration, and removes obstructions of the viscera. Mr. Miller enumerates four varieties of the Autumnal Crocus; 1. the sweet-smelling, with deep blue flowers, varying to a sky-blue; growing naturally on the Alps and Swiss mountains; 2. Autumnal Mountain, which has a flower of a paler blue colour; 3. Many-flowering Bluish, with many sky-blue flowers; 4. Small-flowering, with a deep blue flower.—With respect to propagation and culture, the Autumnal Crocuses are not so productive as the Vernal; and as they do not bring forth seed in our climate, they are less common in gardens. These plants must be taken up every third year, or the roots will run long and produce no flowers; they should not, however, be kept out of the ground longer than the beginning of August, for they commonly produce their flowers at the beginning of October, otherwise they will not produce so many nor such strong flowers as when planted early. The following is the method of cultivating Saffron, as it was presented to the Royal Society by Sir James Douglas. 1. *The Choice and Preparation of the Ground.* The greatest part of the tract between Saffron Walden and Cambridge, is an open level country with few enclosures, and the custom there is, to crop two years, and let the land lie fallow the third. Saffron is generally planted on fallow ground, and if all other advantages be equal, that will be preferred which has borne Barley the year before. The Saffron grounds are

seldom above three acres, or less than one; and the principal rule in choosing is, that they be well exposed, the soil not poor, nor a very stiff clay, but a temperate dry mould, such as commonly lies upon chalk, and is of an hazel colour. The ground being made choice of about Lady-day, or the beginning of April, it must be carefully ploughed, the furrows being drawn much closer together, and deeper if the soil will allow it, than is required for any grain; and hence the charge is greater. Five weeks afterwards, or any time in the month of May, between twenty and thirty loads of dung are laid upon each acre, spread with great care, and ploughed in as before: the shortest rotten dung is the best; and the farmers who possess the conveniency of making it, spare no pains to make it good, being sure of a proportionable price for it. About Midsummer they plough a third time, and between every sixteen feet and a half, or pole in breadth, they leave a broad furrow or trench, which serves both as a boundary to the several parcels, when there are several proprietors to one enclosure, and to throw the weeds in at the proper season. To this head likewise belongs the fencing of the grounds, because that is generally, though not always, done before planting. The fences consist of what they call dead hedges or hurdles, to keep out not only cattle of all sorts, but especially hares, which would otherwise feed during the winter on the Saffron leaves. Concerning the weather, it is only necessary to observe, that the hottest summers are certainly the best, and therefore if there be gentle showers from time to time, they can hardly miss of a plentiful crop, unless the extreme cold, snow, or rain, of the preceding winter, have injured their heads. 2. *Planting or Setting the Roots.* The only instrument used for this is a narrow spade, commonly termed a spit-shovel. The time of planting is commonly in the month of July, a little sooner or later, as the weather answers. The method is: One man with his spit-shovel raises between three and four inches of earth, and throws it before him about six or more inches; two persons generally women, following with heads, place them in the farthest edge of the trench he makes, at about three inches' distance from each other: as soon as the digger or spitter has gone once the breadth of the ridge, he begins again at the other side, and digging as before, covers the roots last set, and makes the same room for the setters to place a new row, at the same distance from the first that they are from one another. Thus they proceed, until a whole ridge, commonly containing one rod, is planted; and the only nicety in digging, is to leave some part of the first stratum of earth untouched to lie under the root, and in setting to place their roots directly upon their bottom. Formerly, when roots were very dear, they did not plant them so thick as they do now, and that some notice is always taken of the size of the roots, so as to leave the largest farther apart. The quantity of roots planted in an acre, is generally about sixteen quarters, or an hundred and twenty-eight bushels, which, according to the distances before assigned to be left between them, and averaging the diameter of the plants at one inch, ought to amount to three hundred and ninety-two thousand and forty in number. From the time that the roots are planted, till about the beginning of September, or sometimes later, there is no farther labour required, but as they begin to spire, and are ready to shew themselves above ground, (which is ascertained by digging a few out of the earth,) the ground must be carefully pared with a sharp hoe, and the weeds be raked into the furrows, otherwise they would hinder the growth of the plants. 3. *Gathering and Drying the Flowers.* The flowers are gathered as well before as after they are fully blown, and the most proper time for gathering is early in the

morning. The owners of the Saffron get together a sufficient number of hands, who place themselves in different parts of the field, pull off the whole flowers, and throw them handful by handful into a basket, till they are all gathered. As soon as they have carried them home, they immediately spread them out upon a large table, and fall to picking out the stigmas, together with a considerable part of the style itself; the rest of the flower they throw away as useless. The stigmas being all picked out of the flowers, the next labour is to dry them on the kiln, which is built upon a thick plank, supported by four short legs, that it may be moved from place to place; the outside consists of eight pieces of wood about eight inches thick, in the form of a quadrangular frame, about twelve inches square at the bottom on the inside, and twenty-two inches at top, which is likewise equal to the perpendicular height of it: a hole about eight inches square is left in the front, about four inches above the plank, through which the fire is put in; over all the rest are laid laths close to each other, nailed to the frame already described, and then plastered over very thickly on both sides, as are also the planks at the bottom, which serve for a hearth: over the mouth or widest part is placed a hair-cloth, fixed to the sides of the kiln, and also to two rollers, or moveable pieces of wood, which are turned by screws, in order to stretch the cloth: instead of which many persons now use a net-work or iron-wire, with which, it is observed, that the Saffron dries sooner and with less fuel; but the difficulty of preserving the Saffron from burning, occasions the hair-cloth to be preferred by the nicest judges in drying. The kiln is placed in a light part of the house, and they begin by laying five or six sheets of white paper on the hair-cloth, upon which they spread the wet Saffron two or three inches thick; this they cover with other sheets of paper, and over this lay a coarse blanket five or six times double, or instead thereof, a canvass pillow filled with straw; and after the fire has been lighted for some time, the whole is covered with a board having a large weight on it: at first they apply a pretty strong heat to make the chives sweat, as they term it: and in this, unless very careful, they are in danger of scorching, and thereby of spoiling all that is on the kiln. When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the Saffron off from that which lies next it, raising at the same time the edges of the cake with a knife, then laying on the paper again, they slide in another board between the hair-cloth and upper papers, and turn both papers and Saffron upside down, afterwards covering them as before: the same heat is continued for an hour longer; they then look on the cake again, free it from the papers, and turn it; then they cover it, and lay on the weight as before. If nothing detrimental occur during these first two hours, they reckon the danger to be over, for they have afterwards only to keep a gentle fire, and to turn their cakes every half hour till thoroughly dry, for the doing of which as it ought, twenty-four hours' attention is required. In drying the larger plump threads, they use nothing more; but towards the latter end of the crop, when these begin to be smaller, they sprinkle the cake with a little small beer, to make it sweat as it ought, and have latterly begun to think that using two linen cloths next the cake, instead of the two innermost papers, may be of some advantage in drying, although that practice is followed by few: the fire may be made with any kind of fuel, but that which smokes the least is best, and therefore charcoal is preferred.—What quantity of Saffron a first crop will produce, is very uncertain; sometimes five or six pounds of wet threads are got from one root, sometimes not above one or two, and sometimes not

enough to make it worth while to gather and dry it; but this is always to be observed, that about five pounds of wet Saffron make one pound of dry, for the first three weeks of the crop, and six pounds during the last week; and when the heads are planted very thick, two pounds of dried Saffron may at a medium be allowed to an acre for the first crop, and twenty-four pounds for the two remaining, the third being considerably larger than the second: in order to obtain these crops, the labour of hoeing, gathering, picking, and drying, must be repeated every year, without any addition, except that they let cattle into the fields after the leaves are decayed, to feed upon the weeds; or perhaps mow them for the same use. 4. *Management of the Roots.* About the Midsummer after the third crop is gathered, the roots must all be taken up and transplanted. To take up the Saffron heads, or break up the ground, they sometimes plough it, and sometimes use a forked kind of hoe called a pattock, and then the ground is harrowed once or twice over, during all which time of ploughing, or digging, and harrowing, fifteen or more persons will be sufficiently employed in following and gathering the heads as they are turned up; they are next to be carried to the house in sacks, and there cleansed and dressed, which consists in clearing the roots thoroughly from the earth, and from the remains of old roots, old skins, and excrescences, and thus they become fit to be planted in new ground immediately, and to be kept for a considerable time without danger of spoiling. The quantity of roots which will be taken up, in proportion to those which were planted, is uncertain; but it may be calculated at a medium, allowing for all the accidents which happened to them in the ground, and in breaking up from each acre, to be twenty-four quarters of clean roots, all fit to be planted. The owners are sure to choose the largest, plumpest, and fattest roots, for their own use, but most dislike the longest pointed ones, which they call spickets or spiekards, for very small, round, or flat roots are sometimes observed to flower well. Mr. Miller calculates that the charge of cultivating Saffron for three years, will be upwards of £.23 per acre, which he supposes to average twenty-six pounds of Saffron during each year, which, at thirty shillings per pound, will leave five pounds four shillings annual profit per acre.—In the annexed Plate, a shows the filaments of the flower, from which the Saffron is prepared.

2. *Crocus Vernus; Spring Crocus.* Leaves broader, with flat edges; stigma very shortly trifid. This species has a largish compressed bulb, covered with a light-brown netted skin, from which arise four or five leaves of a purplish colour on their lower parts; from among which one or two flowers come out, sitting close between the young leaves, never rising above two inches high, and having an agreeable colour; out of the centre of the tube arises a slender style, crowned by a broad flat stigma of a golden colour: after the flowers are past, the germen pushes out of the ground. Haller says that it is white, with a purple base, in Switzerland, in a wild state; and purple and white in Austria, according to Jacquin. Gesner gathered it with a yellow flower on the mountains of Glarus. Scopoli does not mention its colour, but says that it is not uncommon in Carniola. It is also a native of Italy and Spain; but not indigenous in Britain, though Mr. Miller states that he remembered to have seen it apparently wild, in a considerable quantity, in Battersea meadow, near the mill; and it has also been found by Dr. Deering in the meadows near Nottingham. Though the varieties of Spring Crocus are very numerous, Mr. Miller only enumerates the following twelve: 1. the Broad-leaved Purple, variegated; which has a flower of a deep blue, and striped;

2. Broad-leaved plain Purple; 3. Broad-leaved Violet-coloured, or large Deep Blue; 4. White with a purple bottom; 5. Broad-leaved White variegated; 6. Broad-leaved with many violet-purple flowers striped with white; 7. Broad-leaved Ash-coloured; 8. Broad-leaved large yellow; 9. Broad-leaved small pale yellow; 10. Broad-leaved small yellow striped with black; 11. Narrow-leaved small brimstone; 12. Narrow-leaved small white. Modern catalogues set down many varieties of the several colours, which are blue and purple, yellow and white, or striped: new ones are also constantly imported from Holland, each of which has a French or Dutch title. The most common varieties now in our gardens are, the Scotch, beautifully striped; the Blue; the Blue-striped; White; Yellow of several shades, larger and smaller; Yellow striped with black; Cloth of gold.—All these several varieties of Crocuses are very hardy, and will increase exceedingly by their roots, especially if they be suffered to remain two or three years unremoved: they will grow in almost any soil or situation, and are very great ornaments to a garden, early in the spring of the year before many other flowers appear; they are commonly planted near the edges of borders on the sides of walks, in doing which, care should be taken to plant such sorts in the same line as flower at the same time, and are of an equal growth, otherwise the lines will seem imperfect. These roots loose their fibres with their leaves, and therefore may then be taken up, and kept dry until the beginning of September, observing to keep them from vermin, for the mice are very fond of them. When you replant these roots, after having drawn a line upon the border, make holes with a dibble about two inches deep or more, according to the lightness of the soil, and about two inches apart, in which you must place the roots with the bud uppermost; then with a rake fill up the holes in such a manner as that the upper part of the root may be covered an inch or more, taking care not to leave any of the holes open, for this will entice the mice to them, and when once they have found them out, they will destroy all your roots, if not prevented. The best way, however, to dispose of these flowers in gardens, is to plant them six or eight near each other in bunches, between small shrubs, or on the borders of the flower-garden, where, if the varieties of these flowers be planted in different patches, and properly intermixed, they will make a much better appearance than when they are disposed in the old method of straight edgings. In January, if the weather be mild, the Crocus will often appear above ground, and their flowers will come out in February, before the green leaves are grown to any length, so that the flowers seem at first to be naked, but soon after the flowers decay, the green leaves grow to be six or eight inches long, and should not be cut off until they decay, notwithstanding they appear a little unsightly, for, by cutting off the leaves the roots will be so weakened as not to arrive at half their usual size, nor will the flowers of the succeeding year be half so large. Their seeds are commonly ripe about the latter end of April, or the beginning of May, when the green leaves will begin to decay.

Crossostylis; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth terribinate, quadrangular, fastened to the germen; four-parted; segments ovate, spreading, permanent. *Corolla*: petals four, elliptic; claw narrow, inserted into the calix; nectary corpuscles twenty, filiform, ciliate, between the stamina. *Stamina*: filamenta twenty, filiform, shorter than the calix, connected at the base into a little pitcher; antheræ small, roundish. *Pistil*: germen convex, superior; style cylindric, the length of the stamina, permanent; stigmas four, spread-

ing very much, trifid. *Pericarp*: berry hemispherical, grooved, one-celled. *Seeds*: very many, on a columnar receptacle in the centre of the fruit. ESSENTIAL CHARACTER. *Calix*: simple, four-parted. *Corolla*: four-petalled. *Nectary*: twenty corpuscles between the filamenta. *Stigmas*: four, jagged.—The only known species is,

1. *Crossostylis Biflora*.—Native of the Society Isles.

Crotalaria; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth three-parted, large, rather shorter than the corolla; the two superior divisions lanceolate, leaning on the standard; the third lanceolate, concave, supporting the keel, three-cleft. *Corolla*: papilionaceous; standard cordate, acute, large, depressed on the sides; wings ovate, shorter by half than the standard; keel acuminate, length of the wings. *Stamina*: filamenta ten, connate, rising, with a split line on the back, and gaping base; antheræ simple. *Pistil*: germen oblong, reflex, hirsute; style simple, bent inwards at an angle, rising; stigma obtuse. *Pericarp*: legume short, turgid, one-celled, two-valved, pedicelled; seeds one or two, globose, kidney-form. ESSENTIAL CHARACTER. *Legume*: turgid, inflated, pedicelled. *Filamenta*: connate, with a fissure on the back.—Most of these plants are propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are come up an inch high, they should be transplanted to another hot-bed to bring them forward, observing to shade them from the sun till they have taken new root; after which they should have free air admitted to them in proportion to the warmth of the season, to prevent their being drawn up weak. When the plants have acquired strength in this bed, they should be carefully taken up, with balls of earth to their roots, and each planted in a separate pot, filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanner's bark, carefully shading them till they are rooted again. They must afterwards be treated in the same manner as other tender exotics, giving them a due proportion of air and water in warm weather, and when they are grown so tall as nearly to reach the glasses of the hot-bed, the pots may be removed into an airy glass-case or stove, where they will be screened from inclement seasons, and have sufficient air in hot weather. With this treatment the plants will flower in July, and continue to produce fresh spikes of flowers till the end of August: those spikes which appear early in the season, will be succeeded by ripe seeds in September; soon after which the plants will decay.—The species are,

* *Leaves simple.*

1. *Crotalaria Perforata*; *Perforated Crotalaria*. Leaves perfoliate, cordate, toothletted. Eight feet high; stem smooth and even, with alternate branches; leaves smooth, veined, scarcely an inch long; flowers smooth, yellow, in a kind of umbel, two together, terminating the branches.—Native of the Cape; where a decoction of the leaves is esteemed a powerful diuretic.

2. *Crotalaria Perfoliata*; *Perfoliate Crotalaria*. Leaves perfoliate, cordate-ovate; stem shrubby, four or five feet high, round, covered with a light-brown bark; leaves smooth, about four inches long, and nearly three broad, much resembling those of our common *Thoroughwax*, or *Bupleurum*, both in shape and size, only stiffer and more veined; the flowers are almost the size of those of the Pea, all the petals being large; they are of a pale yellow colour, and come out singly from the upper part of the branches, sitting close on the axils of the leaves, and appearing in August: it has the appearance of being shrubby, but the branches perish every year.—It is a native of open woods in the back settlements of Carolina.

3. *Crotalaria Amplexicaulis*; *Stem-clasping Crotalaria*.

native marshes has broad flat stalks, and leaves three inches long, a quarter of an inch broad, rough, and but little indented on the edge; but that on dry ground the leaves are ovate, two inches broad, and serrate.—Discovered near La Vera Cruz; where it flowers in July, and the seeds ripen in autumn.

5. *Croton Glabellum*; *Laurel-leaved Croton*. Leaves ovate, bluish, very entire, smooth, and even; fruits peduncled. This grows in a shrubby form, and is seldom under seven or eight feet in height. All the parts of the plant are of an active warm nature, and have a pretty agreeable smell.—Common in all the low lands about Spanish Town and Kingston, in Jamaica.

6. *Croton Tinctorium*; *Official Croton*. Leaves rhomboid, repand; capsules pendulous; stem herbaceous. Root annual; stem branching, about nine inches high; leaves near two inches long, on slender petioles near four inches in length; flowers in short spikes, from the sides of the stalks at the ends of the branches. The women about Albudebar dye their stockings with it. Nissole dyed both silk and wool of an elegant blue colour; but the French attempt to extract a material from it for dyeing, similar to indigo, did not succeed. This is the plant from which the *tournsol*, used for colouring wines and jellies, is made. It is made from the juice that is lodged between the calix and the seeds: this, if rubbed on cloths, at first appears of a lively green, but soon changes to a bluish purple. If these cloths be put into water, and afterwards wrung, they will dye the water of a claret colour. The rags thus dyed are brought to England, and sold in the druggists' shops under the name of *tournsol*.—Native of the South of France, Spain, Italy, and the kingdom of Tunis. The seeds of this plant should be sown in the autumn, soon after they are ripe; in a small pot filled with light earth, and plunged into an old tan-bed in a frame, where they may be screened from the cold in the winter; and in the spring following, the pot should be removed into a fresh hot-bed, which will bring up the plants in a month's time; and when grown large enough to remove, they should be each planted into a small pot, and plunged into a fresh hot-bed, being careful to shade the glasses daily, until the plants have taken new root: they should then have air daily admitted to them, in proportion to the warmth of the season, but must be sparingly watered.

7. *Croton Glandulosum*. Leaves oblong, serrate, biglandular at the base; fruits sessile. It seldom exceeds seventeen or eighteen inches high. The seeds are small, and picked up every where in the fields, both by the wild and tame fowls, in the island of Jamaica, of which it is a native, in the savannas of Liguanea.

8. *Croton Argenteum*; *Silvery-leaved Croton*. Leaves cordate-ovate, tomentose beneath, entire, serrate. Root annual; stem a foot high, angular; flowers in short close terminating spikes, the upper ones male, the lower female, all white, the former soon falling.—Found in La Vera Cruz.

9. *Croton Sebiferum*; *Poplar-leaved Croton*, or *Tallow Tree*. Leaves rhomb-ovate, acuminate, flat, smooth; glands subpetiolar; leaflets broader than they are long, and involute. The leaves dye a very fine black; they wither in October, turn to a dirty crimson colour, and fall off before the capsules. The young leaves shoot out again in March. Each capsule contains three hard black shells, the size of pepper-corns or common peas, covered entirely with a delicately snow-white substance. This does not produce the tallow, as it is commonly supposed; it is made from the oil expressed from the kernel; and the white substance above mentioned must be well cleaned from the shells before they are broken, for that will absorb a considerable quantity of oil. For this purpose, the shells should remain ten or fifteen days in water to

soak, and then they may be cleared of the white substance by rubbing, although it will not easily separate from the shell. The oil drops from the press like thick glutinous lamp-oil, and soon hardens by cold to the consistence of common tallow, and by boiling becomes as hard as bees' wax. Native of China; where it is called *sheu*, or *u-kieu*.

10. *Croton Japonicum*. Leaves undivided and three-lobed, ovate, acuminate, entire, smooth; stem subangular, naked at bottom, tomentose at top, simple, a foot high and more.—Native of Japan, flowering in July and August.

11. *Croton Acutum*. Leaves ovate, serrate, acuminate, two-glanded; stem herbaceous, angular, simple, smooth; petals white, woolly, the length of the calix.—It flowers in September, and is cultivated in Japan, where it was introduced by the Portuguese.

12. *Croton Tigilium*; *Purging Croton*. Leaves ovate, smooth, acuminate, serrate; stem arboreous. This is a middle-sized tree, with few spreading branches; flowers in erect simple terminating racemes.—Native of the East Indies, China, and Cochinchina.

13. *Croton Lucidum*; *Smooth Croton*. Leaves ovate, smooth; flowers in spikes; styles many-cleft, depressed, pubescent, becoming shrubby.—Grows in Jamaica.

14. *Croton Lacciferum*; *Lac Croton*. Leaves ovate, tomentose, serrulate, petioled; calices tomentose. A middle-sized tree, with a few long spreading branches; flowers white, with five-leaved calices; leaves tomentose, subacuminate, unequally toothed, scattered over the branches. The leaves infused in warm water or milk, purge and vomit. It exudes a very fine lac spontaneously, but sparingly, which appears like a bud at the origin of the branches; and is employed by the Ceylonese to varnish their lances, the handles of their tools, &c. It is said to be much finer and superior to that formed by the ants in Siam and Pegu. Lac is said also to exude in small quantities from other species of this genus; but all that substance which we commonly call gum-lac in Europe, is the work of the red ants, who are supposed to collect or suck the resinous juice from this, and perhaps other trees, to digest it with the animal acids in their stomachs, and then to encrust the branches with it, to serve as a nest or comb for their young. It is not properly a gum-resin or oil, not being soluble either in water or fat oils. The use of this substance is well known in dyeing silks, woollens, and morocco leather, of a scarlet colour, which it also communicates to sealing-wax and varnish. The wood of this tree is white, light, and brittle. The bark and resin are reputed to be serviceable in ulcers of the mouth, in the gonorrhœa, fluor albus, dysentery, &c.—Native of the East Indies, the southern provinces of Cochinchina, and Cambodia. It is called *bihar* on the borders of Thibet.

15. *Croton Balsamiferum*; *Balsam Croton*. Leaves ovate-lanceolate, scabrous, very entire, tomentose beneath. This is an upright, branched, diffused, sweet-smelling, shrub, abounding with a balsamic, thickish, odorous, brownish sap. In Martinico this juice is distilled with spirits of wine, and a cordial liquor obtained, called *Eau de Mante*. Flowers white, with small petals.—Native of Martinico, Curaçao, and Jamaica.

16. *Croton Aromaticum*; *Aromatic Croton*. Leaves cordate-ovate, scabrous, serrate at the base beneath and on the edge, having petioled glands; racemes terminating. This is a middle-sized tree, with spreading branches; leaves large, spreading, unequally serrate; flowers numerous, scattered, villose.—Native of the island of Ceylon, and near Canton in China.

17. *Croton Humile*; *Humble Croton*. Leaves cordate

very entire, scabrous, subciliate, tomentose beneath. A shrub, two feet high, with a smooth branching stem; the branches hoary at the end. The smell of the whole herb is strong and balsamic; it is very hot and pungent upon the palate; and is frequently used in baths and fomentations for nervous weaknesses.—Native of Jamaica.

18. *Croton Ricinocarpus*; *Surinam Croton*. Leaves subcordate, crenate; peduncles racemed, opposite to the leaves; stem herbaceous. Branches and leaves alternate, the latter petioled, naked; flowers heaped together in racemes.—It is an annual plant, and a native of Surinam.

19. *Croton Moluccanum*; *Molucca Croton*. Leaves cordate, angular, scabrous, tomentose beneath. This is a tree, eight feet high, with long reclining branches; flowers white, in short racemes; capsules smooth and even, bigger than a walnut: a great quantity of oil is extracted from it.—Native of Ceylon, and the Molucca Islands.

20. *Croton Flavens*; *Yellow Croton*, or *Balsam*. Leaves cordate, oblong, very entire, tomentose on both sides; branchlets more closely tomentose. It frequently rises to the height of two or three feet; it much resembles the 17th sort, but is easily distinguished by the thickness of its extreme branches, which are pretty soft and luxuriant. All parts of the plant are equally sharp, and sometimes used in resolute baths.—Native of Jamaica, in savannas about Kingston.

21. *Croton Capense*; *Cape Croton*. Leaves hastate, and undivided, lanceolate, very entire, and very smooth.—Found at the Cape, by Thunberg.

22. *Croton Lobatum*; *Various-leaved Croton*. Leaves unarmed, serrate, the lower five-lobed, the upper three-lobed. Stems round, furrowed, herbaceous, slightly hairy, erect, branched, a foot and a half in height; flowers of a purple colour, in spikes five or six inches long. Annual: flowering in July.—Found by Houston, near Vera Cruz.

23. *Croton Spinosus*; *Thorny-leaved Croton*. Leaves palmate, five and three lobed, thorny-serrate; flowers scattered over the stem; and sessile.—Native of the East Indies.

24. *Croton Astroites*; *Woolly Croton*. Leaves oval, subcordate, very entire, starry-tomentose on both sides; branchlets more closely tomentose, shrubby; flowering in July and August.—Native of the East Indies.

25. *Croton Punctatum*; *Dotted-leaved Croton*. Leaves ovate, acute, entire, tomentose, and dotted underneath; stem shrubby.—Native of Ceylon.

26. *Croton Nutans*. Leaves rhomb-ovate, acuminate, wavy, smooth; glands marginal.—Native of the Society and Friendly Islands, and of the New Hebrides.

27. *Croton Inophyllum*. Leaves obovate, very entire; stem arboreous.—Native of New Caledonia.

28. *Croton Hirtum*. Leaves ovate, serrate, with glanduliferous hairs at the base; spikes sessile; stem hispid. It is an annual, and a foot in height; stem herbaceous, erect, round, glandular. It is singular in having glands of three different sorts.—Native of Guiana.

29. *Croton Althææfolium*. Leaves oblong-cordate, tomentose; stem shrubby, branched; flowers in terminating spikes, it rises with a shrubby stalk, six or seven feet high, dividing upwards into several branches, which are covered with a yellowish down, garnished with long heart-shaped leaves, ending in acute points; flowers white.—Native of Jamaica.

30. *Croton Salviæfolium*.—Leaves cordate, acute, tomentose beneath; stem shrubby; flowers in spikes, terminating, and axillary. It rises nearly four feet high, with a shrubby stalk. The flowers are produced in short spikes at the ends of the branches; they are small, white, and have woolly calices.—Native of the West Indies.

31. *Croton Sessiliflorum*. Leaves ovate, acuminate, quite entire, smooth; flowers sessile, axillary, diœcous, five-stamined.—Native of Hispaniola.

32. *Croton Globosum*. Leaves ovate, obtuse, entire; peduncles in pairs; flowers diœcous; fruits globular, echinate-hispid.—Native of Jamaica.

33. *Croton Divaricatum*. Leaves oblong, obtuse, serrate, rough with hairs, biglandular at the base; racemes terminating, solitary; stem shrubby; branches dichotomous, divaricate.—Native of the West Indies.

34. *Croton Nitens*. Leaves cordate-elliptic, acuminate, almost entire, smooth, shining above, dotted and silvery underneath; racemes axillary; leaves shorter, erect.—Native of Jamaica.

35. *Croton Laurinum*. Leaves oblong, acute, quite entire, of some consistence, smooth; petioles rugged, they and the leaves dotted underneath; racemes axillary, very long, patulous; stem arborescent.—Native of Jamaica.

36. *Croton Pallens*. Leaves ovate, acuminate, quite entire, smooth on both sides; racemes solitary, erect, terminating; calices larger than the fruit. It rises with a shrubby stem to the height of seven or eight feet, is covered with an ash-coloured bark, and divides at top into many slender branches; flowers of an herbaceous colour, inclosed in green calices.—Native of Jamaica.

37. *Croton Macrophyllum*. Leaves cordate-roundish, acuminate, entire, thick, tomentose, nerved underneath.—Native of the West Indies.

38. *Croton Populifolium*. Leaves broad-ovate, acuminate, serrate-toothed, somewhat rough with hairs, with one gland at the base above; petioles the length of the leaves; racemes terminating, erect, solitary; stem shrubby; branches smooth, scarred.—Native of Jamaica, and other parts of the W. Indies.

39. *Croton Cochinchinense*. Leaves lanceolate, quite entire, hoary underneath, shining, dotted; capsules scurfy. This is a middle-sized tree, with spreading branches. The flowers are white, in simple, oblong, terminating racemes.—Native of the woods of Cochinchina.

40. *Croton Lanatum*. Leaves ovate-lanceolate, quite entire, smooth, opposite; corollas ovate; capsules six-valved. This is a large tree with spreading branches, and white flowers in simple terminating racemes. The wood is white, heavy, and very durable; it is used in building, and for piles of bridges.—Native of mountain-woods in Cochinchina.

41. *Croton Congestum*. Leaves ovate, gash-serrate, smooth veined; flowers heaped, naked, axillary. Stem suffruticose, five feet high, with many reclining branches; leaves alternate, unequal.—Native of China, about Canton.

42. *Croton Dioicum*. Leaves oblong, obtuse, hoary; flowers terminating, on the male in spikes, on the female by threes. Stem suffruticose, round, with divaricating branches; the whole plant covered with a soft nap.—Native of Mexico.

43. *Croton Plicatum*. Leaves ovate, plaited, crenate, hirsute; stem herbaceous; branches round, somewhat rugged, hoary, hirsute above, as are also the leaves, with close, stellate hairs; capsules pendulous, of a violet purple colour.—Native of Arabia.

44. *Croton Obliquum*. Leaves ovate-lanceolate, quite entire; stem herbaceous, tomentose.—Native of Egypt.

45. *Croton Coccineum*. Leaves ovate, acuminate, quite entire, smooth, biglandular at the base, dotted with scarlet underneath; racemes terminating; branches round, with a brown bark, mealy, villose at top; flowers subsessile.—Found by Kœnig in Ceylon.

46. *Croton Lavigatum*. Leaves elliptic, very smooth and even, without glands, entire and serrate, obtuse; racemes

terminating, elongated. Branches round, proliferous, scaly with meal, and ash-coloured at top.—Observed by Dahl in Hainam.

47. *Croton Betulinum*. Leaves ovate-obtuse, crenate, toothed, rugged, with dots on the upper surface, somewhat rough with hairs underneath; racemes axillary. This has the appearance of *Betula* or *Birch*: branches round, with a purplish bark, tomentose-hoary at the end; flowers small, rough with hairs.—Native of the island of St. Thomas in the West Indies.

48. *Croton Gossypifolium*. Leaves cordate, three-lobed; tomentose, biglandular at the base underneath; stem arborescens. This is a tall tree, with round branches, tomentose and hoary at top; leaves alternate, heaped, towards the end of the branches; flowers copious, scattered males intermixed with females.—Native of the island of Trinidad.

49. *Croton Procumbens*. Leaves wedge-shaped, acute, quite entire. This plant is shrubby, inodorous, smooth, three feet high; the stems partly procumbent, partly erect; leaves petioled, alternate, two inches long; flowers small and green.—Common at Carthage.

50. *Croton Niveun*. Leaves cordate, acuminate, serrulate, tomentose, shining beneath; stem shrubby. It is ten feet high, erect, having a pleasant aromatic smell through all parts of it; corolla white.—Native of Carthage.

51. *Croton Polygamum*. Leaves lanceolate, serrate, thinly set with decumbent hairs. This is an upright shrub, four feet high, but little subdivided; branches round, smooth, ash-coloured; flowers whitish, inodorous, hermaphrodite, male and female on the same or different plants. It flowers in June and July.—Native of Carthage.

52. *Croton Cyanospermum*. Calix five-leaved, small, turned back below the capsule, which is globular, smooth, very obscurely three-grooved, three-celled, tricocous. The Ceylonese call it *lyan-gheddie*. This and the next species are very doubtful.—Native of Ceylon.

53. *Croton Cardiospermum*. Capsule globular, terminated by a three-sided three-tubercled point, smooth, without any groove, tricocous; rind corky, thick, opening into six parts from the base; shells the substance of paper, elastic, white, ovate. This the Ceylonese call *kebella* and *kebbele*.—Native of Ceylon.

Crow Berry. See *Empetrum*.

Crowfoot. See *Ranunculus*.

Crow Garlic. See *Allium*.

Crown Imperial. See *Fritillaria*.

Crucianella; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved, inferior; leaflets lanceolate, slightly keeled, acuminate, stiff, converging, compressed. *Corolla*: one-petalled, funnel-form; tube cylindric, filiform, longer than the calix; border four-cleft; divisions tailed, with the points inflex. *Stamina*: filamenta four, placed in the mouth of the tube; antheræ simple. *Pistil*: germen compressed, between the calix and corolla; style two-cleft, filiform, length of the tube; stigmas two, obtuse, oblong. *Pericarp*: capsules two, connate. *Seeds*: solitary, oblong. ESSENTIAL CHARACTER. *Calix*: two-leaved; involucre two or three leaved, chaffy. *Corolla*: one-petalled, funnel-form, with a filiform tube, and tailed border. *Seeds*: two, linear, inferior, naked, bald.—

The species are,

1. *Crucianella Angustifolia*; *Narrow-leaved Crucianella*. Erect: leaves in sixes, linear; flowers in spikes. It has several upright stalks, which rise a foot high, having six or seven very narrow leaves in whorls at each joint. The flowers grow in close spikes at the top and from the sides of the

branches; they are small, white, not longer than the calix, and not remarkable for beauty. They appear in June and July, and ripen seeds in autumn.—Native of the south of France, and Italy. This species, as well as the second, fifth, and sixth, are preserved in some gardens for the sake of variety. If the seeds be sown on a bed of light earth early in the spring, where they are designed to remain, they will require no other culture, but to thin them where they are too close, and keep them clean from weeds; or, if the seeds be permitted to scatter, the plants will come up in the spring, and require no other treatment.

2. *Crucianella Latifolia*; *Broad-leaved Crucianella*. Procumbent: leaves in fours, lanceolate; flowers in spikes. This is an annual plant, sending out several branching stalks from the roots, which lie prostrate. The flowers are produced in long spikes, at the extremities of the branches; they are very small, and make no great appearance.—It flowers in June and July; and is a native of the south of France, and the islands of the Archipelago.

3. *Crucianella Ægyptiaca*; *Ægyptian Crucianella*. Leaves in fours, sublinear; flowers in spikes, five-cleft. Annual: stems not at all woody, a palm in height, at first erect, then spreading at the root, diffused or prostrate; flowers hirsute, longer than the bractes, yellowish white, five-cleft, and awned.—Native of Egypt.

4. *Crucianella Patula*; *Spreading Crucianella*. Diffused: leaves in sixes; flowers scattered.—It is an annual plant; and a native of Spain.

5. *Crucianella Maritima*; *Sea Crucianella*. A procumbent undershrub: leaves in fours, mucronate; flowers opposite, five-cleft. Root perennial; stems woody, about a foot long, branched, leafy their whole length; flowers trist, yellowish colour, closed in the day, opening in the night, and of a strong smell.—Native of the south of France, Italy, and Sicily. It flowers in June and July; but will not ripen its seeds in England when the autumn is unfavourable.

6. *Crucianella Monspelica*; *Montpellier Crucianella*. Procumbent: leaves acute, those on the stem in fours, and ovate, on the branches about five, and linear; flowers in spikes. Root annual, creeping; plant small, glaucous all over; stems thickish, diffused; spikes five or six inches long, slender and variegated.—Native of the south of France, about Montpellier and Vienne, and also found in Palestine.

7. *Crucianella Hispida*. Stem hispid; leaves lanceolate, hirsute, opposite; flowers umbelled, terminating. This plant has four-cornered, rough, prickly stalks, which bend downwards. The flowers are produced in small clusters at the ends of the branches; the corolla is blue, and cut into four parts at the top.—Native of La Vera Cruz.

8. *Crucianella Americana*. Leaves linear-lanceolate, hirsute, opposite; stem erect, villose; flowers solitary, axillary. This rises with a shrubby branching stalk, nearly three feet high, with narrow lanceolate leaves, covered with stinging hairs; flowers pale blue. Native of La Vera Cruz.

9. *Crucianella Pubescens*. Erect: leaves generally in sixes, linear pubescent; heads of flowers peduncled, axillary and terminal. Whole plant hoary-pubescent; flowers purple.—Native of Canada.

10. *Crucianella Capitata*. Procumbent, suffruticose: leaves in sixes, sublinear; flowers in heads, five-cleft. Root perennial, horizontal, strong, woody; stem suffruticose, weak, naked at bottom; branches filiform; leaves usually six together, ovate-lanceolate, acute, rugged, rolled back on the sides, on the fruit-bearing branches remote, on the others approximating; flowers dark-coloured; border of the corolla five-cleft, the segments bent in, and having a claw at the tip;

filamenta five, very short; antheræ oblong, two-grooved, dark-coloured.—Native of Mount Lebanon, near the summit.

Crus Galli. See *Cratægus*, and *Panicum*.

Cruzita; a genus of the class Tetrandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth three-leaved, the anterior leaf linear, acute, the lateral ones ovate, concave, permanent. *Corolla*: petals four, of the appearance of the calix, ovate, concave, the two outer ones perfectly entire, the inner ones with a very thin lacinated border. *Stamina*: filamenta four, capillary, a little shorter than the calix; antheræ small. *Pistil*: germen ovate, obtuse, compressed; style very short, two-parted, with spreading divisions; stigmas simple. *Pericarp*: none. *Corolla*: diverging, deciduous with the seed. *Seed*: single, naked. **ESSENTIAL CHARACTER.** *Inner Calix*: four-leaved; *outer* three-leaved. *Corolla*: none. *Seed*: one.—The only known species is,

1. *Cruzita Hispanica*. Stem high; leaves opposite, lanceolate, quite entire; flowers spiked, collected into a panicle.—Native of South America.

Crypsis; a genus of the class Diandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: glume one-flowered, two-valved; valves oblong-lanceolate, keeled, awnless, outer smaller. *Corolla*: glume two-valved; valves lanceolate-oblong, awnless, inner longer, and outer shorter than the calix. *Stamina*: filamenta two, capillary, longer than the corolla; antheræ oblong, cordate, incumbent. *Pistil*: germen superior, oblong; styles two, capillary, shorter than the stamina; stigmas hairy. *Pericarp*: none. *Corolla*: enclosing the seed. *Seed*: single, subcolumnar. **ESSENTIAL CHARACTER.** *Calix*: glume two-valved, one-flowered. *Corolla*: glume two-valved, awnless.—The only known species is,

1. *Crypsis Aculeata*; *Prickly Crypsis*. Root annual; culms many, diffused, four inches high, branching, covered with the sheaths of the leaves, which are smooth, except at the edge, the upper ones gradually broader; spike subglobular, almost fastigate, with the flowers almost sessile in the bosom of the involucre, which is three-leaved, and a little longer than the spike. This Grass is a native of Europe, of Siberia, and is common in Barbary.—There are two varieties.

Cryptostomum; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, funnel-form, ventricose at the base, coloured, with a five-cleft border; segments lanceolate, unequal. *Corolla*: one-petalled, funnel-form; tube very short, inserted into the throat of the calix; border five-cleft; segments lanceolate, acute, unequal, converging; nectary fastened to the base of the corolla, broad, arched, closing the mouth of the corolla, five-toothed. *Stamina*: filamenta none; antheræ five, each inserted below each toothlet of the nectary. *Pistil*: germen roundish, in the bottom of the calix; style cylindrical, the length of the calix; stigma capitate. *Pericarp*: berry globular, three-celled. *Seeds*: solitary, ovate, acute, marked with a large hilum or scar. **ESSENTIAL CHARACTER.** *Calix*: ventricose, five-cleft; tube of the corolla inserted into the throat of the calix; border five-cleft. *Nectary*: five-toothed, closing the mouth of the corolla. *Berry*: dry, three-celled, with one seed in each cell.—The only known species is,

1. *Cryptostomum Gujanense*; *Guiana Cryptostomum*. It is a kind of spreading shrub, which grows in the isle of Cayenne, and in Guiana, where it is called *aimoutabu*. The root puts forth several twiggy and branching stems, five or six feet long, and sometimes longer. By means of these twigs and branches, it forms bushes more or less thick. These branches are garnished with alternate, nearly sessile, smooth, green, entire, oval leaves, terminating in a point.

The flowers are produced in little clusters from the bosoms of the leaves, and exhale an odour much like that of the Syringa. The ovary becomes a three-celled yellow berry, each cell containing a kind of almond, of an agreeable substance, and gelatinous nature, of which the Creoles are very fond.

Cubæa; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, turbinate, spreading, permanent, five-parted; parts roundish, concave, four erect, the fifth and lowest larger, declined. *Corolla*: petals five, oblong, almost equal, furnished with claws, inserted into the neck of the calix, the three upper ones erect, the two lower declined. *Stamina*: filamenta ten, villose at the base, inserted into the calix below the petals, the three upper ones shorter, filiform, erect, pressed close to the upper petals, the seven lower ones longer, capillary, incumbent on and longer than the lower petals; antheræ oblong. *Pistil*: germen oblong, pedicelled; style capillary; stigma acute. *Pericarp*: legume long, coriaceous, villose, ventricose, obliquely acuminate, one-celled. *Seeds*: several, somewhat kidney-form. **ESSENTIAL CHARACTER.** *Calix*: turbinate, five-parted, unequal, permanent. *Petals*: five, unequal. *Filamenta*: villose, three shorter. *Germen*: pedicelled. *Legume*: villose, six or seven seeded.—The species are,

1. *Cubæa Paniculata*; *Panicled Cubæa*. This is a tree sixty feet high, extremely branching at top; the branches are thick, the smaller ones, or ramulets, trigonal, growing in a scattered manner; the leaves are large, alternately pinnate; the leaflets in six pairs, opposite, subovate, acute, quite entire, green, and smooth above, somewhat downy beneath, and of an ash-coloured green; there are two opposite stipules at the base of the leaf-rib; the flowers are spicated, terminal, and disposed into a very ample panicle, the ramulets of which are long, trigonal, and many-flowered.

2. *Cubæa Trigona*; *Trigonal Cubæa*. Leaves pinnated; leaflets alternate. This is probably a mere variety of the former.—Both these species are natives of Guiana in woods on the banks of rivers.

Cuckold Tree. See *Mimosa*.

Cuckoo Flower. See *Cardamine*.

Cuckoo Pint, or *Pintle*. See *Arum Maculatum*.

Cucubalus; a genus of the class Decandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, five-toothed, permanent. *Corolla*: petals five; claw the length of the calix; border flat; divisions often bifid; nectary none, crowning the corolla. *Stamina*: filamenta ten, subulate, the alternate ones later, alternately inserted into the claws of the petal; antheræ oblong. *Pistil*: germen somewhat oblong; styles three, longer than the stamina, subulate; stigmas pubescent, oblong, bent in an opposite direction to the sun. *Pericarp*: capsule covered, acuminate, three-celled, gaping five ways at the tip. *Seeds*: very many, roundish. **ESSENTIAL CHARACTER.** *Calix*: inflated. *Petals*: five, having claws, but no crown. *Capsule*: three-celled. This genus is distinguished from *Silene*, by the corolla having no nectarial crown.—The species are,

1. *Cucubalus Bacciferus*; *Berry-bearing Campion*. Calices bell-shaped; petals distant; pericarps coloured; branches divaricate; root perennial, creeping, and spreading far in the ground. The whole plant somewhat hairy; stems mounting four or five, and even eight or ten feet, among bushes, but trailing if not supported, herbaceous, and dying to the root every year; the leaves grow opposite at every joint, and resemble those of Chickweed, both in shape and colour; flowers axillary, standing single on slender pedun-

cles, and nodding; fruit an oval capsule resembling a berry, almost as large as a small black cherry, very black when ripe, smooth, shining, soft, and full of pulp. Mr. Miller asserts, that the berries of this plant are as poisonous as those of the *Atropa*, or Deadly Nightshade, itself.—It is a native of Germany, Flanders, France, Switzerland, Carniola, Italy, and Spain, and is found in woods and hedges; it has only been noticed in one place in Great Britain, being found in the isle of Anglesea, by Mr. Foulkes of Llandeber, near Ruthin; other botanists, however, have sought for it in vain. It delights in shade, and will thrive in almost any soil, but multiplies too fast by its creeping roots.

2. *Cucubalus Behen*; *Bladder Campion*, or *Spattling Poppy*. Calices subglobular, smooth, netted-veined; capsules three-celled; corollas almost naked; root perennial, woody, yellow on the outside, white within. Plant generally free from hairs; stem decumbent at the base, branched, and dichotomous near the summit, round, green or red, a foot or eighteen inches in height, the joints large; leaves below the forkings of the stem connate, frequently tinged with purple; flowers some solitary at the divisions of the stem, others crowded at the ends of the branches, some on long peduncles, nodding; calix inflated, longer than the claws of the petals, veined with green or brownish purple, but sometimes without veins; petals white, cleft beyond the middle, distant, the segments frequently slightly serrulate. This species varies with broader and narrower leaves, smooth and hairy; also with a double flower. It is a native of almost every part of Europe, in corn-fields and dry pastures, flowering in June, July, and August. Schreber says, that cattle reject it; but Linneus informs us, that horses, cows, sheep, and goats eat it; and that in Gothland they apply the herb externally in erysipetalous eruptions. The boiled leaves have something of the flavour of peas, and proved of great use to the inhabitants of Minorca, in the year 1685, when a swarm of locusts had destroyed the harvest: it is frequently called *white corn campion*, and *white bottle*. It is a rambling weed, and seldom cultivated; the root strikes so deep into the ground as not to be easily destroyed by the plough, and hence it is frequently growing in bunches among the corn.

3. *Cucubalus Fabarius*; *Bean Campion*. Leaves obovate, fleshy; root biennial, putting out many succulent leaves near the ground, out of the middle of which arises an upright stalk, about fifteen inches high, the lower part of which has leaves of the same form and consistence as those at the bottom, but smaller; these are placed opposite: the upper part of the stalk divides into two smaller, on which stand a few small herbaceous flowers at each joint: it flowers in June, and sometimes ripens seeds in Autumn.—It was discovered in the Levant by Tournefort; and is a native of Sicily. This is a biennial plant, generally perishing when it has produced seeds; and unless it be sown upon very dry rubbish, and in a warm situation, it will not survive an English winter.

4. *Cucubalus Viscosus*; *Clammy Campion*. Flowers lateral, every way decumbent; stem undivided; leaves reflex at the base; root biennial; root-leaves narrow, lanceolate, almost smooth, acuminate; stem-leaves broader, clasping, viscid, villose, somewhat waved, reflex at the base, not on the sides; peduncles opposite, short, three-flowered. The flowers are decumbent; not all turning one way, as in most of the species, but nodding every way, and smelling sweet at night.—Native of the Levant, Italy, Carniola, and Sweden. Linneus observes, that this is one of the many plants common to Sweden and Mount Ararat, as we find from Tournefort's collections.

5. *Cucubalus Stellatus*; *Four-leaved Campion*. Leaves

in fours. This plant has a perennial root, from which arise two or three slender upright stalks, about a foot high, their lower part having four leaves at each joint, placed in the form of a cross. The flowers appear in June, and in warm seasons the seeds will ripen in England.—Native of Virginia and Canada.

6. *Cucubalus Ægyptiacus*; *Egyptian Campion*. Flowers erect; petals emarginate, retroflex, with a toothlet on each side. Stem weak, branching, spread upon the ground; leaves linear, not smooth, the younger ones ciliate at the base; flowers axillary, solitary, sessile; calix cylindrical, in the fruit obovate, ten-cornered, with the interstices membranaceous, and the teeth small; petals minute, hardy, longer than the calix; styles often four.—Found by Hasselquist in Egypt.

7. *Cucubalus Italicus*; *Italian Campion*. Petals semibifid; calices club-shaped; panicle dichotomous, erect; stamina and pistils declined. Stem erect, about two feet high, viscid, hoary, especially at bottom, with a scarcely visible cotton; flowers on peduncles, erect; calices club-shaped, marked with ten grooves; petals broadish, white, beneath lead-colour. Retzius considers our Dover Campion as a variety of this, not being able to distinguish the one from the other. This is indeed more tender and delicate; that of Dover stiffer, larger, and hardier, the petals somewhat deeper cloven, and not stained underneath as the Italian is; although he does not regard these differences as sufficient to constitute a distinct species, and therefore regards them as varieties. Mr. Miller says that the root is perennial; the corolla pale red; and that it flowers in May and June, and ripens seeds in autumn.—Native of Italy. This, with the eighth, ninth, tenth, and twelfth species, is propagated by seeds which should be sown where the plants are intended to remain; for as they send out long tap-roots, they do not bear transplanting, unless it be performed while the plants are young.

8. *Cucubalus Tataricus*; *Hyssop-leaved Campion*. Petals two-parted; flowers in one row, decumbent; peduncles opposite, solitary, erect; stem entirely simple. Perennial, flowering from June to August.—Native of Siberia.

9. *Cucubalus Sibiricus*; *Siberian Campion*. Petals emarginate; flowers subverticilled; whorls umbellate, leafless. It is perennial; and flowers in August.—Native of Italy and Silesia.

10. *Cucubalus Catholicus*; *Panicled Campion*. Petals two-parted; flowers panicled; stamina long; leaves lanceolate-ovate. It is a perennial plant, sending out many long leaves near the ground; between these arise round viscid stalks, three feet high, having at each joint two long narrow leaves, ending in acute points; flowers in a nodding panicle; calix ventricose, inflated, not sinuated or angular; petals white, anthers reddish; styles white; capsule subglobular.—It flowers in July and August, and is a native of Italy, Sicily, and Silesia. Dillenius's *Lychnis nocturna non viscosa*, is a variety of this. It is a perennial; stem two feet high, round smooth, purplish towards the top, glaucous; towards the middle and upper part come out branches in pairs, of a purplish green colour, dividing into others that are similar, which put forth flowers in June and July. The root-leaves are many, oblong, narrow, smooth, and without veins.

11. *Cucubalus Mollissimus*; *Velvet Campion*. Petals half two-parted; panicle dichotomous; stem and leaves soft like velvet; root-leaves spatulate. Stems many, rather stiff, erect, a foot high, somewhat tomentose, very soft; branches at bottom alternate, shorter; lower leaves spatulate, the rest lanceolate; flowers white, erect; stamina the length of the calix; perennial and shrubby.—Native of the sea-coasts of Italy.

12. *Cucubalus Otites*; *Spanish Campion* or *Catchfly*. Flowers dioecious; petals linear, undivided. Root long, fusiform, slender; the root-leaves form a thick tuft, and are wedge-shaped, or rather spatulate, entire, and acuminate, diminishing into a long channelled footstalk; from these rise one or several stems, from one to two feet high, upright, and the lower part clothed with a few opposite leaves, shaped like the root-leaves, the upper part of which is naked and clammy; at the bottom of the panicle are two membranaceous connate bractes, and the same under each set of flower-stalks; the lower part of the panicle, both of the male and female flowers, consist of opposite branches, each topped with a kind of umbel. The male plant, says Haller, has a larger flower, and a redder calix; the female a smaller, and a green calix: the male flowers often produce abortive pistils, and the females abortive stamina. According to Scopoli, the male flowers are apetalous, and have the rudiment of a three-styled germen. In England, both sexes have the same narrow entire yellowish petals; and in Tartary it is found with an hermaphrodite flower. Neither Gerard nor Parkinson seem to have been aware that this plant is a native of England. Ray seems to have been the first who noticed this, and says it was known in Suffolk by the name of *Star of the Earth*, being in great repute as a remedy for the hydrophobia; but although Mr. Ray entertained no doubt of its efficacy, we should be sorry now to depend on such a remedy in such a disorder.—This plant flowers in July and August, and is a native of Germany, Denmark, Switzerland, the Valais, France, Italy, Carniola, Spain, Siberia, and of England, in gravelly and sandy soils; as in gravel pits, on the north side of Newmarket, about Chippenham; beyond Barton mills in the way to Brandon; beyond Brandon, in the road to Hillborough; and near Swaffham and Narborough, in Norfolk.

13. *Cucubalus Reflexus*. Flowers spiked alternate in one row, subsessile; petals subpartite, obscure. According to Magnol, root white, fibrous; stem (sometimes there are two) a palm and half in height; root-leaves hairy, forming a tuft on the ground, like those of the Daisy; stem-leaves two, opposite at each joint, narrow and oblong; at the top of the stem a spike of flowers, bent down at first like a scorpion's tail, but becoming gradually erect after the fall of the flowers; petals whitish, deeply cloven, bending inwards when they begin to wither.—Annual: and a native of Montpellier.

14. *Cucubalus Saxifragus*. Petals bifid; calices striated, the terminating ones subsessile, the side ones peduncled; root perennial; stem a palm in height, with linear leaflets.—Native of the Levant.

15. *Cucubalus Pumilio*; *Dwarf Campion*. Stems one-flowered, shorter than the flower; root-leaves forming a tuft, linear, obtuse, smooth and even; stem very simple and short, bearing one flower, but having often three joints; corolla red, the borders elliptic; germen sessile; styles short.—Found near Geneva; in Stiria, and the mountains bordering on Carinthia; and also in the mountains of Italy and Moravia: perennial.

16. *Cucubalus Glutinosus*. Petals two-parted; calices club-shaped; panicle dichotomous, spreading very much; stamina and pistils straight. Root flowering the second year; stems erect, dichotomous, somewhat villose, here and there covered with a tenacious viscid juice; leaves lanceolate, acute, very entire, hispid, especially the midrib, the upper ones linear; corolla greenish white; claws the length of the calix; border cloven almost to the base; stamina straight, the length of the corolla, or rather longer; antheræ incumbent.—Native country unknown.

17. *Cucubalus Paniculatus*. Root-leaves ovate, acute; stem-leaves lanceolate, opposite; flowers, panicled, erect.

Root-leaves many, on long petioles; from among which rises an upright stalk, sending out two opposite side-branches at each joint, under each of which is one lanceolate acute leaf: the side-branches, and also the upright stems, are terminated by whitish flowers, formed into a panicle, and standing erect. They appear in June.—The plant itself is biennial; and a native of Spain and Italy.

Cucumis; a genus of the class Monœcia, order Syngenesia.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth one-leaved, bell-shaped, the margin terminated by five subulate teeth. *Corolla*: five-parted, growing to the calix, bell-shaped; divisions ovate, veiny-wrinkled. *Stamina*: filamenta three, very short, inserted into the calix, converging, of which two are bifid at the tip. The antheræ are lines creeping upwards and downwards, outwardly adnate. *Receptacle*: three-cornered, truncated, in the centre of the flower. *Female Flowers*, on the same plant with the males. *Calix*: perianth as in the males, superior, deciduous. *Corolla*: as in the males. *Stamina*: none; filamenta three, acuminate, very small, without antheræ. *Pistil*: germen inferior, large; style cylindrical, very short; stigmas three, thick, gibbous, two-parted, turned outwards. *Pericarp*: pome (berry, according to Gærtner) three-celled, or four-celled; cells membranaceous, soft, separated into two secondary ones. *Seeds*: numerous, ovate-acute, compressed, placed in a double order. ESSENTIAL CHARACTER. *Calix*: five-toothed. *Corolla*: five-parted. *Male*. *Filamenta*: three. *Female*. *Pistil*: three-cleft. *Pome*: with acute seeds.—The species are,

1. *Cucumis Colocynthis*; *Bitter Cucumber* or *Gourd*, or *Coloquintida*. Leaves multifid; fruits globular, smooth. The leaves are dark green, rough, and deeply lacinated: the stems rough and trailing, like those of Bryony; the flowers are small, and of a dull yellowish colour; the fruit round, and the size of an orange; it is green at first, but grows yellow when quite ripe; the pulp or internal part, is light, spongy, and white, it is most intensely and intolerably bitter, and, when dried, constitutes the coloquintida of the shops, which is an extremely strong and irritating cathartic, and has been sometimes commended, not only as an efficacious purgative, but also as an alterative in obstinate chronic disorders; others, however, have considered it as a dangerous drug. It has been principally used as a stimulus to other purgative medicines, as, for instance, an extract has been ordered in conjunction with aloe, and for mixing with various purgative pills, &c. It flowers from May to August.—Native place unknown.—This species, together with the second, third, fourth, fifth, tenth, eleventh, twelfth, and thirteenth, are raised from seeds; and, coming from hot or warm climates, require the protection of the dry or bark stove, especially the third.

2. *Cucumis Prophetarum*; *Globe Cucumber*: Leaves cordate, five-lobed, toothletted, obtuse; fruits globular, spiny-muricate. This plant is every way smaller than the common melon, and has a nauseous odour: the fruits are smooth, but armed with soft prickles; they are variegated with uncertain streaks, alternately greenish and yellowish; and are as bitter as coloquintida itself.—Native of Arabia and the Levant, flowering from June to September. Its specific name is an allusion to Jonah's gourd.

3. *Cucumis Anguria*; *Round Prickly-fruited Cucumber*. Leaves palmate-sinuate; fruits globular, echinate. Root annual; stems angular, hispid, four or five feet long; flowers small, like those of Bryony. The fruit seldom grows so large as a pigeon's egg, which it resembles in shape; but the rind is closely beset with blunt prickles, somewhat like the skin of a hedgehog: where it is exposed to the full air, it is of a dark green colour, but when closely

covered, either by the leaves or weeds, it becomes white. It is as indigenous as the Cucumber in the West Indies, but far inferior to it, although the inhabitants of the West India islands often eat it, and in the sugar islands frequently use it, with other herbs, in soups, and reckon it an agreeable and wholesome ingredient in them.

4. *Cucumis Africanus*; *African Cucumber*. Leaves palmate-sinuate; fruits oval, echinate; stems numerous, somewhat angular, prostrate; leaves five-cleft; flowers small.—Native of the Cape.

5. *Cucumis Acutangulus*; *Acute angled Cucumber*. Leaves rounded-angular; fruits with ten acute angles; five inches long, brownish yellow, smooth; flowers yellow. The fruit is very insipid, but it is eaten boiled and pickled.—Native of India; flowering from June till September.

6. *Cucumis Melo*; *Common or Musk-Melon*. Angles of the leaves rounded; fruits torulose. It has the stems procumbent, or trailing to a great length, and very much branched, furnished with tendrils for climbing; leaves palmate-sinuate, or entire, waving about the edge, and slightly toothed, with rounded corners; rough with bristles; flowers pale yellow, lateral, solitary; calix covered with white hairs; corolla wrinkled, ribbed, and having bristles along the ribs on the outside; fruit roundish or oval, blunt, commonly furrowed longitudinally, sometimes netted, sometimes warted or carbuncled, four to ten inches in length and diameter, yellowish green, or white; pulp firm, musky, reddish, seldom green; seeds many, oblong, pale, in a watery pulp.—Some say it is a native of Calmuc Tartary; but as it has been cultivated from time immemorial, it is difficult to determine its native country; however, it was first introduced into Europe from Persia.—

There are many varieties of the Melon cultivated in different parts of the world; and in England there are too many of them propagated which are of no value, especially by those who supply the markets, where the size is principally regarded, so that by endeavouring to augment their bulk, the fruit is rendered of no value; on this account, we shall only mention a few of the varieties which are the most deserving of care, excluding the common Melons, as being unworthy of the trouble and expense of cultivation. 1. The Melon most esteemed is the Cantaleupe, so named from a place near Rome, where it has been long cultivated: it was brought thither from that part of Armenia which borders on Persia, where it is so plentiful that a horse-load is sold for a French crown. This Melon is delicious when in perfection, may be safely eaten, and will not offend the tenderest stomach: the Dutch are so partial to it, that they scarcely cultivate any other, but call it Cantaleupe by way of preeminence, never adding the surname *Melon*, as in all the rest: its outer coat is rough, and full of knobs and protuberances like warts; it is of a middling size, rather round than long; and the flesh is for the most part of an orange colour, though there are some in which it has a greenish hue, which are not so good. 2. The Romana is a good Melon, when perfectly healthy, in dry seasons; and as it may be brought more forward than the Cantaleupe, those who desire to have early Melons should cultivate this sort. 3. The Succado may also be cultivated for early fruit, but is not so good as the Cantaleupe. 4. The Zatte is good, but very small, being seldom bigger than a large orange, and a little flattened at each end, but contains so little flesh, that it is hardly worth the trouble of propagating. 5. The small Portugal, or Dormer Melon, is a pretty good fruit, and may be cultivated for an early crop; they are produced in plenty, and are preferred by those who are not nice respecting the quality, if the quantity be but sufficient. 6. The black Galloway, which will ripen in a shorter time,

from its first setting, than any other sort here named, and is not a despicable fruit when suffered to ripen naturally.—*Of the Seeds*. Place no dependence upon seeds brought from abroad; they are not only generally unproductive, but when they do produce, the fruit is hardly ever tolerable. Different sorts of Melons or Gourds should not be planted near each other, as the farina from each, by impregnating other plants, makes it impossible to preserve the different sorts distinct; and as this mixture always occasions a great deterioration in point of quality, it ought the more carefully to be avoided. As it is very difficult to clean the seeds properly, Mr. Miller advises every one to do it for himself; as every person will then know from what sort it has been taken, and will not be deceived by the duplicity or ignorance of others. The seeds should not be sown before they are three years old, nor after they are six: seeds that will swim upon the water are to be avoided; the heavy seeds should be preferred.—*Methods of Cultivation*. It is common, says Mr. Miller, to hear many persons valuing themselves upon having two or three early Melons, which, when brought to the table, are not better than a pumpkin, though raised at great trouble and expense; for in order to have them ripe a little earlier than they would naturally come, if suffered to grow to their full size, the stem of the fruit is commonly twisted, to prevent the nourishment from entering it, by which the growth is checked; then the fruit is closely covered with the mowings of grass plats, laid of a sufficient depth to cause a fermentation, by which the fruit becomes coloured: but where this unnatural method is practised, the fruit has but little flesh, without either moisture, firmness, or flavour; so that after three or four months' attendance, with a great expense of dung, &c. there may perhaps be three or four brace of Melons produced, which are fitter for the dunghill than the table. He therefore advises never to attempt to have these fruits ripe earlier than the middle or latter end of June, or from that time till the end of September, during which period, if skillfully managed, they may be plentifully obtained.—*Sowing the Seeds*. But in order to continue the fruit so long, the seeds must be sown at two or three different times; first at the middle of February in forward seasons, but in backward springs at the end of that month. As the success greatly depends on raising the plants with strength, which cannot be so well effected if the severity of the weather should preclude the admission of fresh air, on this account it is advisable not to be too early in sowing the seeds. When the weather favours, they should be sown on the upper side of a Cucumber-bed, where there are any; and otherwise, a quantity of new horse-dung must be provided, thrown in a heap to ferment, and turned over that it may acquire an equal heat, in the same manner as is directed for Cucumbers: the plants also must be raised in the same manner as prescribed for the Cucumber; to which article, to prevent repetition, the reader is referred. The second season for sowing is about the middle of March. Both these sowings must be planted under frames, for those which are designed for bell or hand glasses, or to be covered with oil-papers, should not be sown till about a week in April, otherwise they will extend their roots to the sides of the glasses, before it will be safe to let them run out, that is, during the sharp frosty mornings which often happen in the month of May; and if when they fill the glasses they are not allowed to run out, they will suffer as much from the heat of the sun during their confinement in the day, as from the frost of the morning and the cold of the night: the seeds of those plants intended for the glasses, should be put a little later into the hot-bed than those which are to be covered with the oil-papers.—*Preparing the Beds*

or *Ridges*. The ridges into which the plants are to be put out to remain, should always be in a warm situation; the best position is where they are open to the south, or a little inclined to the east, and sheltered at a distance by trees from the other points: the ridges should be enclosed with a good reed fence, but at such a distance every way from the bed, as not to obstruct the rays of the sun during any part of the day, with a door wide enough to admit the wheelbarrows, dung, &c. and kept locked up, to prevent children or ignorant persons from taking up the glasses, and letting in the cold air to the young plants.—*Preparation of the Earth and Dung*. The next thing is the preparation of the earth, in which the Dutch and German gardeners are very exact: the mixture which they generally prepare, is one-third of hazel loam, one third of the scouring of ditches or ponds, and one-third of very rotten dung; these are mixed up at least one, and often two years before they are used, and are often turned, to incorporate and sweeten their parts: but the compost in which they succeed best in England, is two-thirds of fresh gentle loam, and one-third of rotten cow-dung, which if mixed together one year before it is wanted, so as to have the benefit of a winter's frost and summer's heat, observing to turn it over often, and never suffering weeds to grow upon it, will be found equal to any other compost whatever. As these plants succeed best when they are planted young, so before the plants appear, there should be a quantity of new dung thrown in a heap, in proportion to the number of lights intended, allowing about fifteen good wheelbarrows full to each light; this must be two or three times turned over, in the same manner as directed for Cucumbers, and will be fit for use in a fortnight: the trench must then be made to receive the dung, and the bed must be made wider than the frames, but in length proportioned to the number of frames intended: the trench should be a foot or more deep in dry ground. When the bed is made, the frame should be placed over it to keep out wet, but there should be no earth laid upon it till after it has been three or four days made, and is found to be of a proper temperature of heat.—*Planting and Management of the Beds*. As soon as the bed is found to be of a proper warmth, the earth should be laid upon it, not more than two inches thick at first, except in the middle of each light where the plants are to be placed, where a hill terminating in a flat cone, fifteen inches high or more, must be raised; and in two or three days after the earth is put on the bed, it will be of a proper temper to receive the plants, which must be transplanted in the evening when there is little wind stirring: the roots must be raised with a trowel, carefully preserving all their fibres, for if they be broken off, the plants do not soon recover, nor ever after flourish so well as those which have been carefully removed; for these plants are more tender than those of the Cucumber, especially the Cantaleupe Melon, which if planted out soon after the third, or what the gardeners call the rough leaf, is put out, is long in recovering its vigour: so that when the beds cannot be ready for them in time, it will be a good method to put each plant into a small pot while they are young; they may also be plunged into the hot-bed where they were raised, or into the Cucumber-bed where there is room, so that they may be brought forward; and when the bed is ready, they may be turned out of the pots, with the whole ball of earth to their roots, whereby they will receive no check in removing; which is the best method that can be pursued with the Cantaleupe. When the plants are placed on the top of the hills, they should be gently watered, which should be repeated once or twice till after the plants have taken good root; after which they seldom require more, for too much wet canker their roots, and then they never produce

good fruit. When they have taken root, there should be a greater quantity of earth laid on the bed, beginning round the hills where the plants grow, that their roots may have room to strike out, and as the earth is put in from time to time, it must be trodden or pressed down as closely as possible; and it should be raised at least a foot and a half upon the dung all over the bed, observing also to raise the frames, that the glasses may not be too near the plants, lest the sun should scorch them. When the plants have got four leaves, the tops should be pinched off with the finger and thumb, but not bruised or cut with a knife, because in either of these cases the wound will not so soon heal over; this pinching is intended to compel the plants to put out lateral branches, for these are what will produce the fruit; therefore, when there are two or more of these lateral shoots produced, they must also be pinched, to force out more; and this must be practised often, that there may be a supply of what the gardeners call runners, to cover the bed. The management of these beds must be nearly the same as is directed for Cucumbers; it needs only be observed, that the Melons require a greater share of air, and very little water, which should be given at a distance from their stems. If the plants succeed well, they will spread over the bed, and reach to the frames in about five or six weeks, at which time the alleys between the beds should be dug out; or, where there is but one bed, there should be a trench made on each side, of about four feet wide, about as low as the bottom of the bed, and hot dung wheeled in to raise a lining to the same height as the dung of the bed, which should be trodden down close, and afterwards covered with the same earth, a foot and a half thick or more, as was laid upon the bed, treading it down as closely as possible. This will add to the width of the bed, so as to make it in the whole twelve feet broad, which is absolutely necessary, for the roots of the plants will extend themselves quite through it; and it is for want of this precaution, that it is common to see the vines of Melons decay before the fruit is well grown; for where there is no addition made to the width of the beds, the roots will have reached the sides by the time that the fruit appears, and having no room to extend themselves, their extremities are dried by the sun and the air, which is soon discovered by the plants hanging their leaves in the heat of the day, many of which decay near the stem; and the plants from that time gradually languish, so that the fruit cannot be supplied with nourishment; and when ripe, will be found to have little flesh, and even that mealy and ill-flavoured; whereas those plants which have sufficient breadth for their roots to run, and the earth laid of a proper depth, and closely trodden down, will remain in vigour until the frost destroys them, so that a second crop of fruit has sometimes ripened very well upon them, even after the first had been produced, of an unusually large size and excellent quality; whereas in most places where the Cantaleupe Melons have been raised in England, the beds have been no wider than they were first made, and had not generally more than three inches thickness of earth upon them, so that the plants have decayed many times without producing a single fruit; and from thence people have imagined, that this sort of Melon was too tender for this climate, while their ill success was entirely owing to their not understanding the culture. There is also another advantage attending this widening the beds, as above directed, which is that of communicating fresh warmth to them, by the hot dung, which is buried on each side, which will cause the dung in the bed to renew its heat; and as the plants will by this time show their fruit, this additional heat will be of great service in setting the fruit, especially if the season should prove cold, which frequently

happens even in May. When the beds are made up in the manner here directed, and the vines have extended so far as to fill the frames, and want more room, the frames should be raised about three inches upon bricks, to admit the shoots of the vines to run from under them; for if the plants be strong, they will run six or seven feet each way from the stems, and ought therefore to have room allowed them. On this account only one plant should be put in each light; for when the vines are crowded, the fruit will seldom set well, but will often drop off when they are about the size of an egg; neither should the frames be small, but about six feet wide, for the wider they are, the better the plants will thrive, and the more fruit they will produce.—*Pruning and Management of the Plants.* Mr. Miller observes, that there is no part of gardening in which practitioners differ more than in this: indeed, he says, rules laid down in books, and the different methods pursued by different individuals, have appeared so absurd to him, that no one that follows them ought to expect to succeed. Having before advised the pinching off the ends of the plants to produce lateral shoots, and their tops to force out more runners,—after a sufficient number are put out, the fruit should be waited for, which will soon come out in abundance; at which time the vines should be carefully looked over two or three times a week, to observe the fruit, and make choice of one upon each runner, which is situated nearest the stem, having the largest footstalk, and appearing to be the strongest fruit: then immediately pinch off all the other fruit which may appear upon the same runner, and also the end of the runner at the third joint above the fruit; and if the runner be gently pinched at the next joint above it, that will stop the sap, and set the fruit. Those who are so covetous of having a number of fruit, as not to suffer any to be taken off, generally fail in their expectation, for one fruit is as much as a single plant can properly nourish. As the pinching the three joints of the runners above the fruit will cause fresh runners to come out a little below the places where the others were pinched, the vines should be carefully looked over, to stop these new runners soon after they come out, as well as to pull the superfluous young fruit which will appear; and this must be repeated as often as necessary, which will be until those intended to stand are grown so large as to draw off all the nourishment which the plants can supply, for then the plants will begin to abate of their vigour. These few directions, if properly made use of, is all the pruning that will be necessary; they will only want to be watered at a distance from their stems, which will assist in setting the fruit, and cause it to swell; but this must be done with great caution. They should have as much air as possible in warm seasons, and in alterations of heat to cold should have their extremities covered every night with mats.—*Culture under Hand or Bell Glasses.* The plants must be raised in the same manner as the preceding: and at the latter end of April, in forward seasons, the beds should be made of a quantity of hot dung in proportion to their intended number. They must not be placed nearer than four feet apart, or the vines will not have room to run without entangling, which will fill the bed so closely as to prevent the fruit from setting. The bed should be made as above directed. If the plants intended for them be in pots, one only should be put under each glass; if not in pots, two, one of which may be afterwards removed, if both should happen to grow. They must be watered at first planting, to settle the earth to their roots, and shaded every day until they have taken new root; but if the nights be cold, it will be proper to cover the glasses with mats, to preserve the warmth of the bed. After they have taken root, they must be treated as directed for plants

under frames. It must however be remarked, that as the Cantaleupe is very impatient of wet, the beds where it is raised must be arched over with hoops, to support the mats, and defend them at all times from the rain, which is the only means of ensuring their success in our variable climate; for Melons under these glasses, in as fine order as possible, have been destroyed totally by one day's heavy rain in June. Water must be given them with great caution, and never applied to their stems.—*Raising under Paper Covers.* Many persons, of late years, have raised Melons under oiled paper, and have often succeeded very well; but care must be taken not to keep the covering too close over them, in which case the vines draw up weak, and rarely set their fruit in any plenty. Mr. Miller, therefore, advises the bringing up of the plants under hand or bell glasses, in the manner before directed, until they are grown far enough to let them out from under the glasses, and then, instead of the covering with mats, to cover them with oiled paper, which, if prudently managed, will be the best that can be used. The best sort of paper for this purpose is that which is strong, and not of too dark a colour, and it should be done over with linseed-oil, which will dry soon. A proportionable number of these sheets of paper should be pasted together, such as will spread to the dimensions of the frame for which it is intended; and if it be fixed before the oil be rubbed over, it will be an improvement, only observing that the paper should be oiled so long before they are used, that the oil may be thoroughly dry, and the stench gone off, otherwise it will destroy the plants. Some persons make these frames of broad hoops, in imitation of waggon-covers; but as they are too cumbersome to move, and have no convenience for admitting air to the plants, (except by raising the whole frame on one side) frames made of pantile laths, shaped like the ridge of a house, and each slope having hinges by which each side may be raised at pleasure to admit the air to the plants, should be preferred.—*Management after the Fruit is set.* Continue to pinch off all superfluous fruit, and weak runners; turn the fruit gently twice a week, that each side may have equal benefit of the sun and air. The plants will only require a little water in dry weather, once in a week or ten days will be sufficient, and will encourage the growth of the fruit, and cause the flesh to be thick; but the great caution to be observed is, not to over-water them, and to give them as much free air as possible whenever the weather will permit, for this is absolutely necessary to render the fruit good.—*Time of Cutting.* When the fruit is fully grown, they must be daily watched, to cut them at the proper time; for if left too long upon the vines, they will lose much of their delicacy. They should be looked over at least twice every day; and if the fruit intended for the table be cut early in the morning, before the sun has warmed them, they will be much better flavoured; but should any of them be wanted in the course of the day, they should be put into cold spring water, or ice, before they are brought to the table: those cut in the morning should also be kept in the coolest place possible until served up to table. The sign of this fruit's maturity is, that of its beginning to crack near the footstalk, and its beginning to smell, which never fail; for as the Cantaleupes seldom change their colour until too ripe, that should never be waited for. The directions here given for the raising of the Cantaleupe, will answer equally well for all the other sorts; and are greatly superior to the common method of raising this delicious fruit.—The seeds only are used in medicine, and not often, though they are not destitute of virtues. They are very cooling, and have a tendency to promote the urinary discharge, when beaten into an emulsion with barley-water; they make an ex-

cellent drink to be given in fevers, and other disorders, where a cooling regimen is necessary. It must, however, be confessed, that these are very old prescriptions, which are now little esteemed. The Melon is generally esteemed one of the most delicious summer fruits, and when taken in moderate quantities, is of easy digestion; but to excess, is apt to produce violent and sometimes dangerous disorders in the stomach and bowels. It is peculiarly refreshing in hot climates, abounds more in saccharine matter, and is said rarely to disagree.

8. *Cucumis Chate*; *Hairy Cucumber*. Hirsute: angles of the leaves entire, rounded; fruits fusiform, drawn to a point at each end, rough with hairs: Stems decumbent, cirrhose, obscurely five-cornered. The whole plant covered close and thick with soft, white, pellucid hairs, like the germen in the common Melon, which differs in this, in being rough, with stiffish, conical, distant hairs. The fruit swells in the middle, is rough, with erect white hairs, and has a beak at each end. It is found in the fertile earth round Cairo, after the inundation of the Nile, but no where else in Egypt; (Linneus adds,) and in Arabia.—It is a native of the Levant. The fruit is rather watery; the flesh almost of the same substance as the Melon; the taste somewhat sweet and cool, but not equally so with the Water-Melon. The grandees and Europeans in Egypt, eat it as the most pleasant fruit, and that from which they have least to apprehend; but in England it is very indifferent, and is rarely cultivated.

9. *Cucumis Sativus*; *Common Cucumber*. Leaves straight between the angles; fruit oblong, scabrous. The Cucumber is so well known, it is only necessary to remark, that the leaves differ very much in their form from those of the Melon, running out into sharp angles, especially at the end, with the line between the angles straight, having the nerves prominent on the upper surface, and very rough with bristles; they are also of a firmer texture. In the flowers, the segments of the calix are much longer; the corolla of a deeper yellow, each petal or part much wrinkled, commonly rolled in at the edges; the ribs at the back bristly as in the Melon, and the principal rib ending in a long green point. The principal varieties are, 1. Common rough green prickly; six or seven inches long, with a dark green skin, closely set with small prickles: it is hardy, and a plentiful bearer, but does not fruit early: 2. short green prickly; three or four inches long, skin rather smooth, but having small black prickles: one of the hardest and early sorts: 3. long green prickly; from six to eight or nine inches long, thinly set with prickles: this is a good bearer, and the best for main crops: there is also a variety of it with white fruit: 4. early green cluster, shortish, early, and remarkable for the flowers appearing in clusters: 5. long smooth green Turkey; the stalks and leaves much larger than those of the former sorts; the fruit generally twice as long, from ten to fifteen inches, and has a smooth rind without prickles: 6. long smooth white Turkey; differs little from the foregoing, except in colour; it is however less watery, and is therefore generally better esteemed: 7. large smooth green Roman; the plants are very strong; and the fruit large, long, and quite smooth: 8. long white prickly Dutch; fruit eight or ten inches long, white, with small black prickles. It is a bad bearer in England, and not so hardy as the common sorts; but the fruit is less watery, and has fewer seeds. Ray observes, in his *Travels*, that the Italians call our Cucumbers *citrulli*; and Water Melons, and Pompions, *cucumeri*: in Spanish it is called *cohombro*; in French, *concombre*; in Swedish, *gurka*; in Danish, *angurke*, *agurke*; in Dutch, *komkommer*; in German, *gurke*, *kukummer*.—*Culture of the Cucumber*. Those persons who wish to be early with

their Cucumbers, generally put them in before Christmas; but the generality of gardeners commonly put their seeds into the hot-bed about Christmas. A stove will raise these plants of a better quality, and with less danger of failure, than a common hot-bed. The seeds should be sown in small pots filled with light dry earth, and plunged into the tan-bed, in the warmest part of the stove. The pots with earth should be plunged three or four days before the seeds are sown, that the earth may be properly warmed to receive them: the seed should be at least three or four years old, or more the better, provided it will grow. The plants will appear in a week or nine days; then as many small pots filled with dry light earth, as there are plants intended for planting, should be prepared by plunging them into the bark-bed, that the earth may be warmed to receive the plants; two of which should be pricked into these pots, as soon as the two first leaves are raised above the ground; but when they have taken root, and are safe, the worst should be drawn out, taking care not to disturb the roots of those which are left. The water given to these plants should be lukewarm, and they must be guarded from the moisture which frequently drops from the glasses of the stove. They should not be kept long in the stove, but a hot-bed must be prepared to receive them, the size of which must be in proportion to the quantity of plants. A cart load of dung will make a bed large enough for a middling family. The dung should be new, not too full of straw, with some sea-coal ashes well mixed together, and thrown in a heap, until it has fermented a few days, when it should be turned over and mixed, laying it up again in a heap. The bed should be well sheltered by reed hedges, and the ground should be dry. The trench ought at least to be a foot deep, into which the dung should be wheeled, and carefully stirred up and mixed, so that no part of it should be left unseparated; for where there is not this care taken, the bed will settle unequally; there should also be great care taken to beat the dung down close alike in every part of the bed. The frame and glasses should then be put upon it to keep out the rain, but no earth ought to be laid upon the surface until two or three days after, that the steam of the dung may have time to evaporate. If there should be any danger of the bed burning, it will be proper to lay some short old dung, two inches thick, over the top of the other, which will prevent it by keeping down the heat. After this, there should be a sufficient number of three-farthing pots placed upon the bed, filled with light dry earth, and all the interstices between them filled up with any common earth. In two or three days the earth in these pots will be of a proper temperature to receive the plants, which should then be turned out of the first small pot, and planted into these, with the ball of earth adhering to their roots, taking care not to give them too much wet; and as they will have such large balls of earth, as not to feel their removal, they will not require shading from the sun; but the glasses should be raised up a little on the contrary side to the wind, to let the steam of the bed pass off; and the glasses should be frequently turned in the day-time, that the wet occasioned by the steam of the dung may be dried, otherwise the moisture will fall on the plants, which will be very injurious to them. If the bed should heat too violently, so as to endanger scalding the roots of the plants, the pots may be raised so as to allow of a little hollow at their bottoms, which will effectually prevent it; and when the heat declines, the pots may be settled down again. The glasses of the hot-bed should be well covered with mats every night, to keep the bed in a proper temperature of heat; and great care must be taken to admit fresh air every day to the plants, which must

be cautiously done, so as to guard against the cold winds, which usually blow at that season. A mat or canvass ought to be hung over the opening made by the raising of the glasses, to prevent the cold from rushing in too violently. If the weather prove inclement, and the heat of the bed decline, there should be some hot dung laid round the sides to renew the heat, which must not be suffered to fail; for as the plants have been tenderly brought up, the cold would soon destroy them. In this bed the plants may remain three weeks or a month, in which time, if they have been properly managed, they will have acquired sufficient strength to be put out altogether; therefore a proper quantity of dung should be mixed, and turned before-hand, for making the beds into which they are now to be removed. The quantity usually allowed is one good cart-load to each light, which should be well mixed and turned over in the manner before directed, and then wheeled into a trench of the length and breadth of the intended bed, and worked and covered with old cow-dung as before. The frames and glasses should then be put on the bed, and raised every day to let the steam pass off, and in about three days the bed will be in a proper temperature of heat to receive the plants. The dung should then be covered over with dry earth, four inches thick, or eight inches in the middle of the bed, which should be done at least twenty-four hours before the plants are removed into it, in order that the earth may be properly warmed. The plants should then be carefully shaken out of the pots, preserving all the earth to their roots, and placed on the top of the earth in the middle of the bed. Two, or at most three, of these plants will be sufficient for each light; they should be placed seven or eight inches asunder, but never close together. There should always be a magazine of good earth laid under cover to keep it dry, for the earthing of these beds; for if it be taken up wet it will chill the beds, and occasion great damps therein; it is therefore quite necessary to have a sufficient quantity of earth prepared long before it is used. When the plants are settled, they must have proper air and water, but not too much of either. The glasses should be kept well covered with mats every night, to keep up the warmth of the bed, and some fresh earth should be introduced at different times, which should be laid at some distance from the roots of the plants until it be warmed, and should then be drawn up round the heap of earth in which they grow, to increase its depth. By this method of supplying the earth, the whole bed will be covered nine or ten inches deep with it, which will cherish the roots of the plants, and prevent them from hanging their leaves in the heat of the day. It will however be necessary to raise the frames, after the earth has been laid to the full thickness on the bed, otherwise the glasses will be too close to the plants; but when this is done, there must be care taken to stop the earth again very close round the side of the frame, to prevent the cold air from entering under them. When the fruit appears, many male flowers will also come out on different parts of the plant; but as the female flowers have the young fruit situated under them, and the male have none, they are thus easily distinguished, especially as the male have three stamina in their centre, with their antheræ, which are loaded with a golden powder. This is designed to impregnate the female flowers, and when the plants are fully exposed to the open air, the soft breezes of wind convey this male powder or farina from the male to the female flowers; but if the air be too much excluded at this season, the plants will drop off for want of it. Bees have been observed to creep into the frames when the glasses were raised to admit the air, and being accidentally shut in, have supplied the want of those gentle breezes

of wind, by carrying the farina of the male flowers on their hind legs into the female flowers, where they have left a sufficient quantity to impregnate them. These insects therefore have taught the gardener a method to supply the want of free air, which is so indispensable in the natural way of accomplishing that purpose. This is done by carefully gathering the male flowers at the time when the farina is fully formed, and carrying them to the female flowers, turning them down over them, and with the nail of one finger gently striking the outside of the male, so as to cause the powder on the summits to scatter into the female flowers, by which means the crop is much more certain to be produced. After the Cucumbers are thus fairly set, if the bed be of a proper temperature of warmth, they will soon swell, and become fit for use; it is therefore only necessary to water the plants properly, which is done by sprinkling the water all over the bed, for the roots will extend to the sides of the bed; therefore, those who wish to continue these plants as long as possible in vigour, should add a sufficient thickness of dung and of earth all round the sides of the beds, so as to enlarge them to nearly double their first width; this will supply nourishment to the roots of the plants, whereby they may be continued fruitful during great part of the summer; whereas, when this is not practised, the roots of the plants, when they have reached the side of the beds, are dried by the wind and sun, so that they languish and decay long before their time.—In gardens where there are no stoves, the seeds should be sown upon a well-prepared hot-bed. It should be sown in halfpenny pots, that they may be easily removed from one bed to another, if the heat should decline; or raised up, if the heat should prove too great. When they are come up, a fresh hot-bed must be prepared, as was before directed, and the after-management of the plants must be nearly the same; but as the steam of the hot-beds frequently occasions great damps, the glasses must be frequently turned, and have the condensed moisture wiped off them, which is very destructive to the plants on which it falls. Care also must be had to let in fresh air at all proper times, and also to keep the bed in a proper temperature of heat; for as there is no fire to warm the air, that must be supplied by the heat of the dung; and finally, the plants may be ridged out as before directed. In about a month after they are ridged out, you may expect to see the beginnings of fruit, which is often preceded by male flowers, which ignorant persons sometimes pull off, calling them false blossoms; which is very absurd, as these flowers are of absolute service to promote the welfare of the fruit, which very often falls away and comes to nothing, in consequence of the removal of these false blossoms, as they are ridiculously termed. Neither ought the vines to be pruned, as is the custom of unskilful people, especially when they are too luxuriant, which often occurs when the seeds were fresh, or of the last year's saving, and the plants in good heart. When this is the case, it is very proper to pull up one of the plants before it has run so far as to entangle with the other; for it often happens that one or two plants, when they are vigorous, are better than four or five; for when the frame is too much crowded with vines, the fruit is seldom either so good or so plentiful as when there is a moderate quantity of shoots, for the air being thereby excluded from the young fruit, they are consequently liable to decay and fall off. The glasses must be covered every night, and during the extreme heat of the day; and when the vines are spread so as to cover the hot-bed, it will be very serviceable, when you water them, to sprinkle them all over gently, so as not to hurt the leaves, but never to do this when the sun is very hot; or the exhalations, which his beams might draw up from this watering, would

destroy the plants. *Culture of Cucumbers under Hand or Bell Glasses.* In the middle of March or a little later, according to the earliness of the season, you must put in your seeds either under a bell-glass, or in the upper side of your early hot-bed; and when the plants are come up, they should be pricked upon another moderate hot-bed, which should be covered with bell or hand glasses, placed as closely as possible to each other: the plants should be pricked in two inches apart, observing to shade and water them until they have taken new root, which will be in a very short time. This is to be understood of such places where a great quantity of plants are required, which is constantly the case in the kitchen-gardens near London; but where a family only is to be supplied, there may be plants enough raised on the upper side of the beds, where the first crop is growing; or if the vines should have extended themselves so far as to cover the whole bed, whereby there will not be sufficient room to prick the plants, a single light will contain such a number of young plants for planting out in ridges, as will supply the largest family with Cucumbers during the latter part of the season. In severe weather, and at night, the glasses should be covered with mats, but raised during the day in hot weather, on the opposite side from the wind, to give air to the plants, which will greatly strengthen them; but they must be very sparingly watered while young. By the middle of April these plants will be strong enough to ridge out; you must therefore be provided with a heap of new dung, in proportion to the quantity of holes you design to plant, allowing one load to six holes. When the dung is fit for use, dig a trench about two feet four inches wide, and in length just as you please, or the place will allow; if the soil be dry, it should be ten inches deep; but if wet, very little in the ground, levelling the earth in the bottom, then putting in the dung, mixing and stirring up every part of it, as was directed for the first hot-beds, laying it close and even. When this is done, you must make holes about eight inches over, and six deep, just in the middle of the ridge, and three feet and a half distance from each other; but if there be more than one ridge, eight feet and a half from each other; fill the holes with good light earth, put a stick into the middle of each for a mark, and afterwards cover the ridge over with earth about four inches thick, laying the same thickness of it round the sides. When the earth is thus levelled smooth, set the glasses upon the holes, leaving them close down about twenty-four hours, in which time the earth in the holes will be sufficiently warmed to receive the plants; then stir up the earth of these holes with your hand, hollowing it out in the form of a basin, in each of which set three or four plants, taking care to shade and water them until they have again taken root; they must afterwards have air admitted to them, in proportion to the heat of the weather, by raising the glasses on the side opposite to the wind, which must only be done in the middle of the day; the glasses should then be raised by a forked stick on the south side, in height proportioned to the growth of the plants, that they may not be scorched by the sun, which will also harden and prepare them to endure the open air, to which, notwithstanding, they ought not to be prematurely exposed, as they are often killed by the morning frosts in May. Towards the latter end of that month, when the weather appears settled and warm, turn your plants down gently out of the glasses, not in hot sunny weather, but when the sky is cloudy, with an appearance of rain. In doing this, raise the glasses either upon bricks or forked sticks, upon which they may stand securely at four or five inches from the ground, that the plants may lie under them without bruising. The glasses should not be wholly removed till the latter end

of June or the beginning of July, for they will preserve the moisture much longer at the roots than when the plants are exposed to the open air. About three weeks after you have turned the plants out of the glasses, they will have made a considerable progress, especially in favourable weather: the spaces of ground between the ridges should then be dug up, making it very even, and laying out the runners of the vines in exact order, taking care not to disturb them too much, nor to break or bruise the leaves: this digging of the ground will loosen it, and make it more penetrable for the roots of the plants to strike into, and at the same time make the surface of the earth more suitable to the vines that run upon it. After this there will be no farther care needful, except to keep them clear from weeds, and to water them as often as they shall require, which is when they hang their greater leaves. The ridges thus managed, will continue to produce large quantities of fruit, from June until the latter end of August, after which time the coldness of the season renders them unwholesome, especially if the autumn prove wet. From these ridges it is common to select Cucumbers for seed, reserving two or three of the fairest fruit upon each hole, never leaving above one upon a plant, and that situated near the root, for if more be left, they will weaken the plant so much as greatly to diminish the size and quantity of the other fruit. Those persons who value themselves upon producing Cucumbers very early in the season, generally leave three or four of the first produce of the earliest crop when the fruit is promising, and the seeds of these early fruit are generally preferred to any other for the first crop; these should be situated near the main stem of the plant near the root: they should remain upon the vines till the middle or end of August, that the seeds may be perfectly ripe; and when you gather them from the vines it will be proper to set the fruit in a row upright against a hedge or wall, where they may remain until the outer covers begin to decay, at which time you should cut them open, and scrape out the seeds, together with the pulp, into a tub, which ought to be afterwards covered with a board, to exclude dirt of every kind; let it remain eight or ten days in the tub, observing to stir it well to the bottom every day with a long stick, in order to rot the pulp, that it may be easily separated from the seeds; then pour some water into the tub, stirring it well about, which will raise the scum to the top, but the seeds will settle to the bottom, so that by two or three times pouring in water, and afterwards straining it off, they will be perfectly cleared from the pulp: the seeds ought then to be spread upon a mat, and exposed three or four days to the open air till perfectly dry, when they may be put up in bags, and hung up in a dry place out of the reach of vermin, where they will keep good for several years, but are generally preferred when three or four years old, as being apt to produce less vigorous but more fruitful plants.—*Culture of Cucumbers in the open Ground.* The season for sowing these is towards the latter end of May, when the weather is settled; the ground where they are commonly sown is between Cauliflowers, in the wide rows between which, four feet and a half space is allowed at planting: in these rows square holes should be dug three feet and a half distance from each other, breaking the earth well with a spade, and afterwards smoothing and hollowing it into the form of a basin with your hand, then put eight or nine seeds into the middle of each hole, covering them over with earth half an inch thick; and if it should be very dry weather, it will be proper to water the holes gently in a day or two after the seeds are sown, in order to facilitate their vegetation. In five or six days, if the weather be good, the plants will begin to thrust their heads above ground, at which time it will be very

necessary to keep off the sparrows, which are extremely fond of the young tender seed-leaves of these plants, and will soon destroy the whole crop, if not prevented. But as the plants do not remain above a week in danger, it will be no great trouble to look after them during that time; for when the plants have appeared, and expanded their seed-leaves, the sparrows will no longer molest them. You must not fail to water them gently, according to the season; and when the third or rough leaf of the plants begin to appear, pull out all the weakest plants, leaving only three or four of the most promising and best-situated in each hole, stirring the earth round about them with a small hoe, to destroy the weeds, and raise the earth about the shanks of the plants, introducing a little earth between them, and pressing it down gently with your hand, to separate the plants more distinctly from each other to a greater distance: they must be carefully watered in dry weather, and kept entirely free from weeds. When the Cauliflowers are drawn off the ground from between the Cucumbers, you must hoe and clean the ground, drawing the earth up round each hole in the form of a basin, the better to retain the water that is given them. The plants must also be laid out in the exact order in which they are to run, and to extend so that they may not interfere with each other. A little earth must then be laid between them, and pressed down gently with the hand, giving them at the same time a little water to settle the earth about them, repeating it as often as is necessary, and taking care to remove the weeds. The plants thus managed will begin to produce fruit towards the end of July, when you may either gather them young for pickling, or suffer them to grow for large fruit. The quantity of holes necessary for a family is about fifty or sixty, for if you have fewer, they will not produce enough at one gathering to make it worth the trouble and expense of pickling, without keeping them too long in the house: for from fifty holes, more than two hundred cannot be gathered at each time, but this may be done twice a week throughout the season, so that about two thousand may be gathered if they be taken small, which will not be too many even for a private family; but should so many not be wanted, they may be left to grow to a proper size for eating.

10. *Cucumis Anguinus*; *Serpent Cucumber*, or *Melon*. Leaves lobate; fruit cylindrical, very long, smooth, and even writhed. Flowers smaller than others of the genus, with a long tube, they scarcely exceed the size of Jessamine flowers; the fruit or cucumber is three feet and a half long, never straight, but strangely twisted, so as to resemble a snake; it is externally of a grayish-green, and grows very red in time; the odour is rank, and the taste bitter.—Native of the East Indies. This, says La Marche, is only a variety of *Trichosanthes Anguina*.

11. *Cucumis Flexuosus*; *Flexuose Cucumber*, or *Melon*. Leaves angular-sublobate; fruits cylindrical, furrowed, curved. Fruit the size of a large pear, of an oblong cylindrical form, smooth, even, eatable, and delicious.—It ripens in June; is called *banket-melon* by the Dutch, and is cultivated about Nagasaki, and in other parts of Japan.

12. *Cucumis Conomon*. Leaves angular-sublobate, toothed; fruits fusiform, ten-furrowed, smooth. Stem decumbent, striated, hispid, with scattered hairs, as are the petioles; leaves cordate, nerved, pale underneath; flowers axillary, peduncled, aggregate, yellow; peduncles very short, hispid; fruit the size of a man's head or larger, oblong.—It is cultivated every where in Japan; the fruit preserved is sold under the name of *connemon*, and is a common food among the Japanese; it is also frequently eaten by the Dutch at Batavia, and is sometimes brought to Holland.

13. *Cucumis Maderaspatanus*. Leaves cordate, entire, toothletted; fruits globular, smooth. Loureiro informs us, that it is very nearly allied to *Melothria*; according to him the stem is round, slender, branched, climbing; leaves roundish, petioled, alternate, small; flowers white, axillary, on many-flowered peduncles; fruit yellow, half an inch in diameter.—Native of Ceylon, and other parts of the East Indies, of Cochinchina, and also of the Cape.

Cucurbita; a genus of the class *Monœcia*, order *Syngenesia*.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: perianth one-leaved, bell-shaped, the margin terminated by five subulate teeth. *Corolla*: five-parted, growing to the calix, bell-shaped; divisions veiny-rugose; nectary a gland in the centre of the flower, concave, triangular. *Stamina*: filaments three, converging, connected above, distinct below, growing to the calix; antheræ creeping upwards and downwards, linear. *Female Flowers.* *Calix*: perianth as in the male, superior, deciduous. *Corolla*: as in the male; nectariferous glandule concave, spreading. *Stamina*: margin surrounding, ending in three very short cusps. *Pistil*: germen large, inferior; style conic, three-cleft at the tip; stigma single, with a thick convex margin creeping upwards and downwards, three-cleft. *Pericarp*: pome generally three-celled; cells membranaceous, soft, distinct. *Seeds*: very many, compressed, swollen on the margin, obtuse placed in double order. **ESSENTIAL CHARACTER.** *Calix*: five-toothed. *Corolla*: five-cleft. *Male. Filamenta*: three. *Female. Pistil*: five-cleft. *Seeds* of the pome with a swelling margin.—The plants of this genus are very nearly allied to those of *Cucumis*, and are distinguished from it chiefly by the swelling rim of the seed: like them, they are annual, with trailing herbaceous stems, furnished with tendrils for climbing.—The species are,

1. *Cucurbita Lageneria*; *Bottle Gourd*, or *Long Gourd*. Leaves somewhat angular, tomentose, biglandular at the base underneath; fruit woody. Stems thick, long, climbing, with tendrils, branched, extending nearly twenty feet in length, covered with a fine soft hairy down; flowers large, white, on long peduncles, solitary, lateral; fruit shaped like a bottle, with a large roundish belly and a neck very smooth, when ripe of a pale yellow colour, some nearly six feet long, and eighteen inches round; the rind hardens on being dried, and will contain water: the Arabians call it *charrah*. The poor people eat it boiled with vinegar, or fill the shell with rice and meat, thus making a kind of pudding of it. In Jamaica the shells are generally used for water-cups, and frequently serve for bottles among the negroes, and poorer sort of white people in that country. A decoction of the leaves is strongly recommended in purging clysters; and the pulp of the fruit is often employed in resolute poultices; it is bitter and purgative, and may be used instead of coloquintida.—The large gourd, (the *Cucurbita Lignosa* of Miller) a variety of this species, is cultivated on account of the woody shell of the fruit, which will frequently contain between twenty and thirty quarts: where aloe is manufactured in any quantity, it is commonly preserved in these shells; but in Jamaica they are only employed to hold water and small grain. The shells are of different forms, some shaped like a pear, others like a bottle, others again like an orange.—They grow in all parts of Egypt and in Arabia, wherever the mountains are covered with rich soil; and is also a native of both Indies. This, as well as the second, third, fourth, fifth, and sixth species, may be propagated by sowing their seeds on a hot-bed in April, and transplanted when the plants come up, to another moderate hot-bed, where they should be brought up hardily, and have a great deal of air to strengthen them; and when they have

got four or five leaves, they should be transplanted into holes made upon an old dunghill, or some such place, allowing them ample room, as some of them will run to a great distance. The first species requires to be more tenderly treated than the others, in order to procure ripe fruit; the seeds therefore should be sown upon a moderate hot-bed in April, and the plants afterwards planted each into a penny pot, and plunged into a very moderate hot-bed to bring them forward, but must not nevertheless be tenderly treated, for if they have not a large share of free air admitted to them every day, they will draw up weak. When the plants are grown too large to remain in the pots, holes must be dug wherever they are designed to grow, and three or four barrows-full of hot dung be put into each; these must be covered with earth, in which the plants must be set, and covered with hand-glasses till they run out. There are some persons who place these plants by the sides of arbour, over which they train the vines, so that in a short time they will cover the whole arbour, and afford a strong shade: others plant them near walls, pales, or hedges, to which they fasten the vines, and train them to a considerable height: the orange-shaped gourd is the sort that is commonly so planted, for the ornament of its fruit, which has a pretty effect when seen at some distance. All these plants require a large supply of water in dry weather.

2. *Cucurbita Hispida*; *Rough Gourd*. Leaves angular; stem and petioles hispid. Stem furrowed, climbing, covered with ash-coloured hairs; leaves petioled, having five angles, or sublobed with straight angles, nerved, villose on both sides; petioles round, hispid, a finger's length; flowers axillary, very closely set with ferruginous hairs, the lower a finger's length, the upper shorter; tendrils simple, bifid or trifid; calix and peduncle very closely hirsute, with ferruginous hairs.—Native of Japan, where it flowers in September.

3. *Cucurbita Ovifera*; *Egg Gourd*. Leaves lobed; fruits obovate; tendrils in sevens, digitated. The herb and flowers are very like the Pompion, but not so rough; the leaves are not many-cleft, neither is the fruit bitter; the tendrils are straight, and end in small spiral tendrils, usually seven in number; fruit smooth and even, the size and form of a hen's egg, with the rind so hard as to be scarcely cut with a knife, painted with ten milk-white longitudinal lines.—Native of Persia, in the neighborhood of Astracan.

4. *Cucurbita Pepo*; *Pompion*, or *Pumpkin Gourd*. Leaves lobed; fruits glossy. Stems thick, angular, extremely hispid, branched, climbing by means of bifid tendrils, or spreading to the distance of forty feet, so that a single plant, if properly encouraged, and all the side-branches be permitted to remain, will overspread twenty rods of ground: leaves cordate, large, roundish, angular, toothed, wrinkled, hairy on both sides, on alternate, thick, flexuose, hirsute petioles; flowers yellow, lateral, solitary, on peduncles resembling the petioles, but shorter; teeth of the calix large, gashed, waved, reflex; fruit roundish, ovate-globular or oblong-ovate, pale green on the outside, and commonly hispid with bristly hairs; within having a spongy insipid white pulp or flesh, divided in the middle into three primary cells, each of which is double, and again subdivided into the proper cells of the seeds, which are very numerous, horizontal, elliptic, of a compressed lens-shape. The fruit varies in form and size; two hundred and sixty of them, on an average the size of half a peck, have been produced from a single plant in New England. In Europe, the Pompion, which we have corrupted to *Pumpkin*, is frequently planted by the country people on their dunghills, and suffered to trail at length over the grass of an orchard, When the fruit is ripe, they cut a hole in the side, take out the seeds, fill the void with sliced apples, adding a little

sugar and spice, and bake it; but it is esteemed hard of digestion. The Eastern nations reckon it to be the most wholesome of its genus, and give it to the sick as a cooling diuretic. In England, Pompions were formerly called English Melons, or, corruptly, *Millions*; and the true Melons, *Musk Melons*. The Pompion flowers from June to August; but its native place is not known.

5. *Cucurbita Verrucosa*; *Warted Gourd*. Leaves lobed; fruits knobby-warted. The plant, flower, and seeds of this, are the same as in the Pompion; but the fruit is smaller, with a harder and almost woody rind.—It is very common in most parts of America, where it is cultivated as a culinary fruit: the form and size are various, being round, flat, shaped like a bottle, or oblong: the rind becomes white when the fruit is ripe, and is covered with large protuberances or warts. It is commonly gathered when half grown, and boiled by the inhabitants of America, to eat as sauce with their meat. In England it is cultivated merely as a curiosity.

6. *Cucurbita Melopepo*; *Squash Gourd*. Leaves lobed; stem erect; fruits flattened, knobby. Stem roundish, hairy; procumbent or climbing, with trifid tendrils; branches many, long; leaves lobed, angular serrate, hairy, alternate on long petioles; flowers yellow, on lateral one-flowered peduncles; segments of the calix linear, spatulate, spreading; antheræ linear, distinct, erect; fruit large, reddish, yellow or yellowish white within and without, commonly roundish, often flattened at top and bottom, always torulose, sometimes ovate, seldom warted. Linnæus seems to be mistaken in describing the tendrils on the stem as neither climbing nor procumbent; for Loureiro informs us, that in India it is always scandent when a support is at hand, but when there is none, always procumbent. Mr. Miller also remarks, that it often grows with a strong bushy erect stalk, without putting out runners from the sides like the other sorts, but that after it has been cultivated a few years in a garden, it will become trailing, and that seeds out of the same fruit have produced erect plants, bearing the same fruit with the parent in one garden; and trailing plants, with larger fruit of a different shape, in another.—It is common in North America, where it is cultivated like the preceding species as a sauce; and also in the East Indies and China. The fruit is of great use in long voyages, for it may be kept several months fresh and sweet.

7. *Cucurbita Citrullus*; *Water Melon*. Leaves many-parted. Stem round, striated, long, branched, hairy, procumbent, diffused, with lateral bifid tendrils; flowers yellow, on short, solitary, lateral peduncles; fruit large, smooth, round, oblong, a foot and a half in length, within watery, sweet, very red or pale; seeds black or rufous. The fruit varies much in form and colour: it serves the Egyptians for meat, drink, and physic, and is eaten by them in abundance during the season, which is from the beginning of May until the overflowing of the Nile, that is, to the end of July or the beginning of August. It is the only medicine the common people use in ardent fevers, for which purpose they have a variety, which is softer and more juicy than the common sort; when this is very ripe, or almost putrid, they collect the juice, and mix it with rose-water and a little sugar. Europeans should be cautious in eating this fruit; for when taken in the heat of the day whilst the body is warm, colics and other bad consequences often ensue; and it is well known that worms are a very prevalent complaint while this fruit is in season. Gerarde calls the Water Melon *citruls*, *cucumber citruls*, and *pome citruls*; Parkinson the *citrull*, or *Turkey Million*. The Water Melon is cultivated in the warm countries of Europe and also in Asia, Africa, and America, where it is greatly esteemed for its wholesome cooling quality.—*Culture*. The best sorts

to cultivate in England, are those with small sound fruit which come from Astracaa; those which have large fruit seldom ripen in this climate. First procure the seeds three or four years old; prepare a heap of new dung in the beginning of February, which should be thrown in a heap for about twelve days to heat, turning it over twice, mixing it well; then make a hot-bed, in which those seeds and also Cucumber and Musk-Melon seeds may be sown: the dung should be well wrought in making the bed, and should be beaten down pretty close with a dung-fork, that the heat may not be too violent, but of longer continuance: when the dung is thus laid, cover it about four inches thick with a good light earth; and, having spread it very even, put the frame and glass over it, leaving it to warm four or five days before the seed be sown, and observing, if much steam arise, to raise the glass that it may pass off. When the bed is in proper temper, sow the seeds in drills, covering them over with about half an inch of earth; after this, if you find the bed very warm, air must be admitted by raising the glasses in the day-time; but if the bed be cool, cover it well with mats in cold or wet weather, and every night. In four or five days' time another hot-bed must be prepared to receive these plants, which will be fit to transplant in ten days, or at farthest in a fortnight, after the seeds are sown. This second bed need not be very large, for a few of these plants, when planted out, will fill a large quantity of frames; and while they are young, the same quantity may be kept in one light, so that those persons who raise early Cucumbers and Musk-Melons, may also raise these plants in the same bed, for two or three lights will be sufficient to raise plants of all the three kinds to supply the largest families, until they are planted out to remain. In the management of these plants while young, there is little difference from the directions given for raising Musk-Melons, which need not be repeated here. (See p. 398, &c.) The chief thing to be observed is, to let them have a large share of air whenever the weather will permit, otherwise the plants will draw up weak, and be good for little. As they will require two or three hot-beds to bring the fruit to perfection, it will be the better way to put the plants into baskets, when they have put forth four leaves, two in each basket will be sufficient, for when both plants succeed, the weakest must be drawn out, which must be done before they put out their side-shoots, otherwise they will entangle, and then one can hardly be removed without seriously injuring the other. The baskets need only be twelve inches in diameter, so that one light will contain twenty-four of them, which will be sufficient to stock twenty-four others when they are planted out to remain; for where they are vigorous, a single plant will spread so far as to cover three lights, which they must be allowed to do, as they seldom set their fruit well when restrained from spreading: the baskets may remain in the nursery-bed until the plants have spread and put out many runners; for when the heat of the bed declines, it is soon revived by adding a proper lining of warm dung quite round the sides of the bed; so that when the plants are taken out and planted in the ridges where they are to remain, the heat of the beds will last so long as to set their fruit; which is of great consequence, for when the plants are ridged out very young, the beds are generally made of great thickness in dung in order to continue their heat, so that for some time after they are made, they are so extremely hot as to endanger the scalding of the plants; and by the time the fruit begins to appear, there is little heat left in the beds, which often causes the fruit to drop off, and come to nothing. After these plants are placed in the beds where they are to remain, carefully lead the shoots as they are produced, so as

to fill each part of the frame, but not to crowd each other; and be careful to keep them clear from weeds, and also to admit fresh air whenever the weather will permit, and to water them, but only in small quantities. In short, there is little difference to be observed in the management of these from that of Musk-Melons, except that they require more room.

Cudweed. See *Athanasia*, *Filago*, and *Gnaphalium*.

Cuminum; a genus of the class Pentandria, order Digynia. —GENERIC CHARACTER. *Calix*: umbel universal and partial, often four-parted; involucre universal of as many leaves, which are very long, perfectly entire, but in some three-cleft; partial similar; perianth proper scarcely manifest; florets all fertile. *Corolla*: universal uniform; proper of five petals, inflex-emarginate, somewhat unequal. *Stamina*: filamenta five, simple; antheræ simple. *Pistil*: germen ovate, larger than the flower, inferior; styles two, very small; stigmas simple. *Pericarp*: none; fruit ovate, striated. *Seeds*: two, ovate, striated on one side and convex, on the other flat. ESSENTIAL CHARACTER. *Involucres*: four-cleft. *Umbellules*: four. *Fruits*: ovate, striated. — The only known species is,

1. *Cuminum Cyminum*; *Cumin*. Root annual, round, scarcely branched. Stem a palm in height; leaves divided into long narrow segments like those of Fennel, but much smaller, of a deep green, and generally turned back at the end; peduncles opposite to the leaves, spreading the length of the internodes; rays of the umbel from four to six, nearly equal, spreading the third of an inch in length; corollas purplish, or pale blush-colour, rayed; fruit oblong, thicker in the middle, the same size as those of Fennel, and aromatic; seeds convex on one side, on which are nine streaks, with minute bristles scattered over it, the other side is flat. The seeds are kept in the shops, and have a very disagreeable flavour, but possess considerable virtues, being excellent against the colic, and wind in the stomach: bruised, and externally applied in the form of a plaster, they will frequently remove stitches, and other pains in the sides and breast; a large quantity of them must be laid on, when used in the latter case.—This plant flowers in June and July; and is a native of Egypt; cultivated in the south of Europe, and all over Lesser Asia. It is also commonly sold in Malta, where they call it *cumino aigro*, hot cumin, to distinguish it from anise, which they term *cumino dolce*, or sweet cumin. If the seeds of this plant be sown in small pots, filled with light kitchen-garden earth, and plunged into a very moderate hot-bed to bring up the plants, and these, after having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preserving the balls of earth which adhered to their roots in the pots, and afterwards taking care to keep them clean from weeds, the plants will flower pretty well, and by thus being brought forward in the spring, will probably perfect their seeds when the season happens to be very warm.

Cunila; a genus of the class Diandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth one-leaved, cylindrical, permanent, ten-streaked; mouth somewhat lipped, five-toothed, permanent. *Corolla*: one-petalled, ringent; upper lip erect, flat, emarginate; lower lip three-parted; divisions rounded, middle one emarginate. *Stamina*: filamenta two, filiform, and two rudiments of filamenta; antheræ roundish, twin. *Pistil*: germen four-parted; style filiform, length of the stamina; stigma two-cleft, sharp. *Pericarp*: none; calix with its throat closed with shaggy hairs. *Seeds*: four, oval, minute. ESSENTIAL CHARACTER. *Corolla*: ringent; upper lip erect, flat. *Filamenta*: two, barrea

Seeds: four.—These plants are all hardy, and may be propagated by seeds which they sometimes produce here.—The species are,

1. *Cunila Mariana*; *Mint-leaved Cunila*. Leaves ovate, serrate; corymbs terminating, dichotomous. There are two varieties of this species; one has narrower leaves and larger heads, and the leaves have very little scent; whereas those of the common sort smell so like Pennyroyal as scarcely to be distinguished from it.—It is perennial, flowering from July to September; and a native of North America. This may be increased by planting cuttings in the spring in the same manner as is practised for Mint; they will take root freely, and flourish exceedingly, if planted in a moist soil.

2. *Cunila Pulegioides*; *Pennyroyal-leaved Cunila*. Leaves oblong, two-toothed; flowers in whorls. Annual; a span high, and brachiate; whorls of flowers the whole length of the plant; corolla white, with a violet-coloured throat; the upper lip scarcely emarginate. It has a strong scent, and an infusion of it is used in North America, by persons who have taken cold, or have pains in their limbs.—Native of dry places in North America. It flowers with us in August.

3. *Cunila Thymoides*; *Thyme-leaved Cunila*. Leaves oval, very entire; flowers in whorls; stem four-cornered, erect, a span in height, with a few simple short branches. Whorls of flowers the whole length of the stem.—Annual: and a native of the country about Montpellier.

1. *Cunila Capitata*. Leaves ovate; flowers terminating; umbel roundish; stem a palm in height; leaves somewhat oblong, naked; calices smooth and even, streaked; corollas purple; antheræ black.—Native of Siberia.

Cunninghamia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, four-toothed, very small, permanent. *Corolla*: one-petalled; tube short; border four-cleft, acute; nectary a rim surrounding the base of the style. *Stamina*: filamenta four, the same length with the border of the corolla, inserted in the throat; antheræ roundish. *Pistil*: germen roundish, inferior; style filiform, bifid; stigmas obtuse. *Pericarp*: berry ovate, crowned, one-celled. *Seed*: single, ovate, two-celled, with oblong kernels. **ESSENTIAL CHARACTER.** *Calix*: very small four-toothed. *Corolla*: four-cleft, with a short tube. *Berry*: crowned with a two-celled two-seeded nut.—The species are,

1. *Cunninghamia Sarmetosa*. A sort of ramping shrub, with the stem about six feet high, and four or five inches in diameter. The bark is reddish, wrinkled, and cloven; the wood whitish. As the shrub grows, it pushes out towards right and left long twiggy branches, which apply themselves to the trunks of large trees, and insensibly climb to their tops, where they also spread, but in the same kind of long twiggy branches, many of which hang pendent to within six or eight feet of the ground. The leaves are six inches long, and four broad, two on each knot, opposite. The flowers, which are small, grow in spikes, proceeding from the bosoms of the leaves towards the extremities of the twigs; their colour is bluish; the calix reddish.—This shrub is found on trees which grow near the Crique de Galibis.

2. *Cunninghamia Bifurcata*. Leaves egg-shaped, acute at both ends, nearly smooth; peduncles forked at their upper part; flowers unilateral.

3. *Cunninghamia Nitida*. Leaves egg-shaped, quite smooth, shining; peduncles dichotomous.—This, and the foregoing, natives of the Caribbee islands.

4. *Cunninghamia Verticillata*. Leaves inversely egg-shaped, acuminate, whorled, generally in threes; peduncles axillary, forked.—Native of the isle of France and Bourbon.

Cunonia; a genus of the class Decandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved, very small; leaflets ovate, concave, acute. *Corolla*: petals five, obovate, spreading, sessile. *Stamina*: filamenta ten, subulate, the length of the corolla; antheræ roundish, twin. *Pistil*: germen conic; styles two, subulate, longer than the corolla; stigmas obtuse. *Pericarp*: capsule oblong, acuminate, two-celled. *Seeds*: very many, roundish. **ESSENTIAL CHARACTER.** *Corolla*: five-petalled. *Calix*: five-leaved. *Capsule*: two-celled, acuminate, many-seeded. *Styles*: longer than the flower.—The only known species is,

1. *Cunonia Capensis*. A shrub: leaves opposite, pinnate, with an odd leaflet, sessile, and not larger than the rest; leaflets often seven, lanceolate, smooth, serrate; racemes terminating, in pairs, simple, with many one-flowered scattered pedicels springing from one point.—Native of the Cape of Good Hope.

Cupania; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved, inferior; leaflets oblong, erect. *Corolla*: petals five, cowlled at top, upright. *Stamina*: filamenta eight, capillary, longer than the calix, erect; antheræ incumbent. *Pistil*: germen ovate; style short, trifid; stigmas blunt. *Pericarp*: capsule coriaceous, turbinate-ovate, three-lobed, three-celled, three-valved. *Seed*: solitary, roundish, with a bell-shaped crenate aril embracing the seed like a calix. Observe, many of the flowers are abortive. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: five, cowlled at the top. *Style*: trifid. *Capsule*: three-celled. *Seeds*: solitary, arilled.—The species are,

1. *Cupania Tomentosa*. Leaves pinnate, obovate, retuse, ferruginous-tomentose underneath. Jacquin describes this tree as twelve feet high, the younger branches and ribs of the leaves slightly tomentose; leaves alternate, half a foot long; leaflets usually three pairs, alternate; flowers small, numerous, with yellowish petals, in the shape of an isosceles triangle inverted, whence the name *trigonis*.—Native of the woods of Hispaniola.

2. *Cupania Glabra*. Leaves pinnate, ovate, obtuse crenate, smooth. It rises to the height of twelve or fourteen feet. The leaves are large, and the wood soft and useless.—This shrubby tree is common in the lower hills of Jamaica, where it is called *loblolly-tree*.

3. *Cupania Saponarioides*. Leaves pinnate, oblong, entire, rugged underneath.—Native of the West Indies.

Cupressus: a genus of the class Monœcia, order Monadelphia.—**GENERIC CHARACTER.** *Male Flowers*, about twenty, disposed in an egg-shaped catkin. *Calix*: scale roundish, acuminate, concave, pedicelled, peltate. *Corolla*: none. *Stamina*: filamenta none; antheræ two or four, oval-roundish, one-celled, adnate to the base of the inner side of the scale. *Female Flowers*, from eight to ten, clustered into a small short cone. *Calix*: scale egg-shaped, thickish, spreading. *Corolla*: none. *Pistil*; scarcely discernible; but at the base of each scale there are several points which appear to be germina, with simple or double sessile stigmas. *Pericarp*: a strobile; scales thickened, at first shut, afterwards expanding, orbicular, angular, generally peltate, convex and almost pointed on the outside, a little concave within, appearing like the heads of nails. *Seeds*: several, small, oblong, angular. **ESSENTIAL CHARACTER.** *Males. Catkin*: imbricated. *Calix*: a scale. *Corolla*: none. *Antheræ*: two or four, sessile, without filaments. *Females. Catkin*: strobilaceous. *Calix*: a scale. *Corolla*: none. *Stigma*: one or two concave points. *Nut*: angular.—These trees are all propagated by seeds, sown early in the spring, on a bed of warm dry

sandy earth, which must be levelled very smooth. The seeds should be sown rather thick, sifting the same light earth over them, half an inch deep. If the weather should prove very warm and dry, it will be proper to shade the bed from the sun in the day, and water it carefully, observing not to wash the seeds out of the ground. If the seed sown be good, the young plants will appear in about two months' time. They must be kept clean from weeds, and often refreshed with water in dry weather. If the seeds be sown upon a moderate hot-bed, covered with mats, they will come up much sooner, and with greater certainty, than when they are sown in the cold ground. When the young plants have remained two years in this bed, they will be strong enough to bear transplanting into the nursery; but as they are very tender while young, they should be covered with mats in severe frosts. The best season for removing them is the beginning of April, when the drying easterly winds of March are over, selecting if possible a cloudy day, when the weather inclines to rain. In taking them out of the seed-bed, preserve the roots as entire as possible, and, if you can, a ball of earth to each plant. The soil for the two first sorts should be a warm sand or gravel, which should be levelled, after it has been dug and cleansed from all noxious weeds. Then draw the lines where the trees are to be planted, at three feet asunder, planting them at eighteen inches' distance in the rows, observing to close the earth well to their roots, as well as to lay a little mulch upon the surface of ground about their stems, and water them well, so as to settle the earth to their roots, which should be repeated twice a week until the plants have taken fresh root. They may remain in the nursery three or four years, according to the progress they make, or till the ground where they are to be planted is ready. If, however, you desire to let them remain longer, you should take up every other tree in the row, to transplant them out, for otherwise their roots will be matted together, so as to make it difficult to transplant them, as well as to endanger their future growth. They ought on no account to be left too long in the nursery before they are transplanted out to remain, because they do not mat together so closely as many other sorts of evergreen-trees, whereby they may be taken up with a good ball of earth to their roots, but the roots of the Cypress being apt to extend out in length, it is one of the most difficult trees to remove when grown large; therefore most curious persons prefer putting the young plants into small pots, when they first take them up out of the seed-bed, and so train them up in pots two or three years, until they are fit to plant out where they are to stand for good, and by this management they are secure of all the plants. When they are planted out to remain, if they be intended for timber, they should be placed twelve or fourteen feet every way apart. Those in the full ground should be carefully removed, observing not to shake the earth from their roots; to prevent which, you should open the ground about each tree, cutting off all long roots, then working under the ball of earth, cut the downright roots off, and after paring off all the earth from the upper part of the ball, to reduce the bulk of it, (so that its weight may not be too great for its fibres to support,) they may be carried upon a hand-barrow by two persons, to the place where they are to be planted, which if very distant, will make it necessary to put them into baskets, or have their roots closely matted up. When they are planted, you must settle the earth close to their roots as before, laying a little mulch upon the surface of the ground about their stems, to prevent the sun and wind from entering the earth and drying their fibres. They must also be well watered, to settle the ground to their roots, which must also be repeated, if the weather prove dry, until

they have taken root; after which time they will require little more care than to keep them clean from weeds.— The species are,

1. *Cupressus Sempervirens*; *Evergreen Cypress*. Leaves imbricate; fronds quadrangular. Stem upright, with many round branches, either growing upright or spreading abroad, strigose and toothed with the rudiments of leaves; fronds dichotomous, subquadrangular; leaflets alternately opposite, decurrent, subcarinate; fruits globular, or somewhat ovate, on the sides or at the ends of the branches when unripe dark green; seed linear, oblong, subcolumnar, bay-coloured. Mr. Miller specifically distinguishes the *upright* from the *spreading Cypress*, (*Cupressus Horizontalis*;) the former, he says, is very common in most of the old gardens in England, but are not at present so much in request as formerly; though it is not destitute of advantages, for it serves to add to the beauty of wildernesses, or clumps of evergreens, and has considerable effect where properly disposed. It was formerly planted in the borders of pleasure-gardens, and kept shorn to a pyramidal or conic form, while others, who thought that cutting would destroy them, tied them up with cords, in order to form the same figure in which they are naturally disposed to grow; but this winding them about prevented the air from entering the inward parts of the branches, so that the leaves decayed, and became unsightly, and the growth of the whole plant was greatly retarded: even those which are sheared, if the operation be not performed in the spring or early in the summer, are very subject to be injured by sharp winds and cutting frosts in winter. Upon the whole, therefore, it is much better to suffer them to assume their natural form, planting them among other evergreen trees, where, by the darkness of their green leaves, together with their waving heads, they will greatly add to the variety. The spreading Cypress is by far the largest-growing tree, and is the most common timber in some parts of the Levant: this, if planted upon a warm, sandy, gravelly soil, will prosper exceedingly; and though the plants of this sort are not so finely shaped as the first, yet they greatly compensate that defect by their vigorous growth and strength, in resisting all weathers. This tree is very well adapted for intermixing with evergreens of a second size, next to Pines and Firs, to form clumps, in which class it will keep pace with trees of the same line, and be very handsome. The wood of this tree is very valuable, when grown to a size fit for planks, which it will reach as soon as Oaks; why, therefore, should not this tree be cultivated for that purpose, since there are many places in England where the soil is of a sandy or gravelly nature, and seldom produces any thing worth cultivating? Now in such places these trees will thrive wonderfully, and greatly add to the pleasure of the owner while growing, and produce afterwards as much profit to his successors probably as the finest plantation of Oaks; especially if the timber prove as good in England as in the islands of the Archipelago, where we find it was so gainful a commodity to the island of Candia, that the plantations were called *dos filie*, the felling of one of them being reckoned a daughter's portion. The timber of this tree is said to resist the worm, moth, and all putrefaction, and to last many hundred years. The doors of St. Peter's church at Rome were made of this material, which lasted from the time of the Emperor Constantine to that of Pope Eugenius II. and were then sound and entire, when the Pope exchanged them for gates of brass. Thucydides informs us, that the coffins in which the Athenians used to bury their heroes, and the mummy-chests brought with those condited bodies out of Egypt, were made of this wood; which is of a dusky brown red colour, has a sweet

smell, and is fitted by its hardness for a variety of purposes. It is fit, says Evelyn, for chests, and other domestic furniture; harps and other musical instruments, being a sonorous wood; for stakes to vines, pales, rails, and planks, of which there were some of this wood at Venice above four feet in breadth. It is used for building by the Maltese and Cretans. It is recommended for the improvement of the air, and as a specific for the lungs, by sending forth great quantities of aromatic and balsamic scents; hence, many of the ancient physicians of the Eastern countries, used to send their patients, who were afflicted with disorders of the lungs, to the island of Candia, which at that time abounded with these trees. The Cypress, among the ancients, was sacred to Pluto and Proserpine, and was used at funerals, especially of persons of fashion. It was placed in front of the house, or in the vestibule, that no person who was to perform any sacred rites might enter a place polluted by a dead body; and the reason assigned for its use on this melancholy occasion was, that the Cypress, when once cut down, never springs up again: hence it would be an improper emblem in a Christian country. The use of evergreens is yet not uncommon among us; but they are supposed to be significant of immortality, at the same time that their balsamic scent guards the attendants against the effluvia and infection that may be apprehended from a putrid body. On account of its extreme durability, Plato would have the laws and sacred rites inscribed on Cypress tablets; and Pliny informs us, that the statue of Jupiter in the capitol, made of this wood in the year of Rome 661, was sound in his time. Notwithstanding all the excellent qualities it possesses; it is not much cultivated in England, principally because it cannot endure the frost of our winters, and the severe blasts which follow in the spring. The upright Cypress above described is the most common sort in England, although it seldom produces good seeds; it is therefore the best way to have the cones brought over entire from the south of France and Italy, where they ripen perfectly well, and take them out just before you sow them. When you wish to extract the seeds, expose the cones to a gentle heat, which will cause them to open, and easily emit their seeds. Dr. Hunter recommends the ground, in which the seeds are to be sown, to be well worked, turned over, and mellowed by frost; and, if the soil be not naturally sandy, to work in some drift-sand all over the bed, six inches deep; to sow the seeds moderately thin, because when they are sown too thick the roots become matted together, so that the plants cannot be removed out of the seed-bed into the nursery without great danger. Mr. Boutcher informs us, that if in the beginning of winter some saw-dust be sifted over them, it will much contribute to their preservation, in case of severe weather. In the spring after sowing, the plants, if well managed, will be six or seven inches high, and should be removed and planted in rows eighteen inches asunder, and eight or nine inches from each other; they should remain here only one year, when they ought to be upwards of a foot high. In the second spring, they ought to be planted in the common nursery, in rows three feet asunder, and eighteen inches from each other; and after having stood two years in this nursery, they may be removed to the place where they are to remain. As it is no uncommon thing for a hard winter to destroy whole beds of these plants, it becomes necessary to provide against such a misfortune, by sowing some seed in pots, which must be placed in a sheltered situation, so as to receive the morning sun till eleven o'clock, kept moderately watered, and removed in October under a frame. In the succeeding spring, let them be shaken out of these pots, and planted in others of fourteen or sixteen

inches diameter, each of which will admit from sixteen to twenty plants, which must be placed in the shade till in a free growing state, and removed in winter under a frame. Mr. Miller declares, that the spreading Cypress is rare in England, and that the tree which has passed under that title is only a variety of the common sort, the branches of which grow much looser; but that the true spreading Cypress extends its branches horizontally from the first year, and continues to extend them to a great length, as the tree advances. He affirms, that it is certainly a distinct species, growing to a much larger size, and that there are some of a considerable stature in Italy.—The fruit of the Cypress, gathered before it is quite ripe, and dried, is an excellent balsamic and styptic medicine. It stops bleeding at the nose, the bloody flux, spitting of blood, and is beneficial in excessive discharges of the menses. Hill observes, that the fruit, which is the only part employed in medicine, ought to be gathered before it bursts, and carefully dried; and given in powder; five and twenty grains is the dose. Few are aware how powerful this remedy is, or it would certainly be held in greater estimation.

2. *Cupressus Disticha*; *Deciduous Cypress Tree*. Leaves distich, spreading.—It is a native of America, where it grows in watery places, and rises to a prodigious height and wonderful bulk, some reaching seventy feet high, and being several fathoms in circumference. They grow constantly in water; and may therefore be of singular advantage to plant in such swampy or wet soils where few other trees will grow, especially of the resinous kind. That they are very hardy with respect to cold, is evident from some few trees of this kind, which were formerly planted in England; particularly one in the gardens of John Tradescant, at South Lambeth, near Vauxhall, “which (says Miller) is upwards of thirty feet high, and of a considerable bulk though in a common yard, where no care is taken of it, but, on the contrary, many hooks are driven into the trunk to fasten cords thereto for drying clothes, yet the tree is in great health and vigour, but it has not produced any fruit, which may be occasioned for want of moisture; for we often see many aquatic plants growing upon a drier soil, but seldom so productive of either flowers or fruit as those which grow in the water.” The tree above described has however been long destroyed, and is only introduced here, to shew how well this species will resist the cold of our climate. The cones may be easily procured from Virginia or Carolina, of which it is a native; and the seeds will rise as easily as those of the first species, for it is at least equally hardy. It was formerly kept in pots, and housed in winter; but did not succeed so well with this management, as since it has been planted in the full ground; and it has always been observed to thrive best in a moist soil. By casting its leaves in winter, it does not suit with plantations of evergreens at that season, but in summer it has much the appearance of an evergreen. It may also be propagated by cuttings, which should be planted in a bed of moist earth in the spring, before they begin to shoot.

3. *Cupressus Thyoides*; *White Cedar*, or *Arbor-Vitae-leaved Cypress*. Leaves imbricate; fronds ancipital.—This tree grows to a considerable size in North America, where it is a native. It seldom exceeds fifteen feet high in England; and when raised from cuttings, has rather the appearance of a shrub, not being above nine or ten feet high. Loureiro informs us, that in China, and Cochin-china, where it also grows naturally, it is only eight feet high. The branches are numerous, and stand two ways; the tree naturally forms itself into a regular head; the leaves are evergreen, flat, sharp, very short, imbricated, and resemble those of the *Arbor-Vitae*;

they are small, and of a browner green than the common Cypress. The fruit is blue, and not larger than the berry of the Juniper, from which it is not easily distinguished at a little distance ; but it is a perfect cone or strobile, having several nuts, like that of the common sort. It abounds in the swamps of New Jersey, and in some parts of Pennsylvania and New York, but not further northward than lat. 41. 25. The number, however, has been greatly reduced ; and as this tree requires to be of eighty years' growth from the seed before it can be used for timber, posterity will probably feel the want of this useful tree in America. It is used for fencing, and even for posts, but does not last in the ground so well as the red cedar, or *Juniperus Virginiana*, but makes good canoes, hoops, and other coopers' ware. Many houses are built of it ; but it is in the highest esteem for shingles, and great quantities of it are sent for that purpose to New York ; and it is also exported to the West Indies, both for shingles and pipe staves. This tree, if planted in a strong moist soil, may become profitable for timber, and growing in a climate much colder than England, would undoubtedly succeed in the open air of our climate ; and as it is an evergreen of regular growth, thrives in cold situations, and a moist soil, which is unfavourable to other species of the same genus, besides being a great ornament to large plantations, it certainly deserves to be much encouraged.—It is propagated by seeds sown in the spring, in boxes or tubs filled with light fresh earth, and placed where they are to enjoy the morning sun till eleven or twelve o'clock. They must be watered in dry weather, and kept clear from weeds. At Michaelmas they should be removed to a warmer place, for the plants seldom appear till the following spring, so that it will be proper to place the boxes or tubs near a south fence during the winter season, lest by being too much shaded, the wet should rot the seeds. In the second spring, if the tubs or boxes be placed on a moderate hot-bed, it will bring up the plants very soon, and greatly forward their growth ; but as the spring advances, they should be introduced into the open air by degrees, and placed in a sheltered situation, where they may enjoy the morning sun, taking care to remove all weeds, and supply them with water in dry weather. In the following winter, it will be proper to remove the tubs near a south wall or pale ; for while the plants are young, they are sometimes tenderer than they afterwards become. At the end of March, or the beginning of April, just before the plants begin to shoot, they should be carefully taken up out of the boxes, and having prepared a bed or two of fresh earth (according to the quantity of plants raised) in a sheltered situation, place the plants in it in rows about eighteen inches asunder, and about a foot from each other. This should be done in cloudy weather, when there is rain ; for in dry weather, when easterly winds commonly blow at this season, it will be very dangerous to transplant these plants ; so that in dry weather, it had better be deferred a fortnight longer, until a change in the weather. When first planted, they should be watered, to settle the earth to their roots ; and then the surface of the ground should be covered with mulch, to prevent the sun and wind from penetrating to the roots of these plants, for nothing is more injurious to them than to have their fibres dried when they are transplanted. They ought not, therefore, to be taken out of the tubs, until the ground be ready to receive them, for they cannot lie any time out of it, without great danger of perishing.

4. *Cupressus Juniperoides* ; *African or Cape Cypress*. Leaves opposite, decussated, subulate, patulous. The young plants of this species, raised from seeds in England, have loose spreading branches, closely beset with narrow straight

leaves, alternately opposite, nearly an inch long, of a light green colour, and continuing in verdure all the year. The cones are black when ripe.—Native of the Cape of Good Hope. This is too tender to thrive while young in the open air of England, but would probably do well in warmer situations, after the plants have acquired considerable strength. Young plants, placed under a frame which had no glass, but only wooden shutters, were not injured by the cold, though the earth of their pots was frequently frozen hard. The practice now is, to keep them in pots, and house them in winter, till they are a yard in height. When they are committed to the open air, they must have a dry warm soil, and a well-sheltered situation ; nothing, however, can ensure them but the dry-stove.

5. *Cupressus Pendula* ; *Portuguese Cypress*. Leaves imbricate, glandulose ; fronds quadrangular, glaucous ; branches hanging down. This is a small tree, with a glaucous appearance. The leaves are glandulous. The flowers resemble those of the first species. It is at present rare in the English gardens, though there have been many plants raised here, which, as it is not quite so hardy as the common Cypress, have either perished, or been irrecoverably injured in severe winters. There are plenty of these trees growing at Busaco, near Coimbra in Portugal, where it is called the Cedar of Busaco, and grows to be a timber tree, so that from thence the seeds may be easily obtained.—It grows naturally at Goa, whence it was originally brought to Portugal, where it flourishes as above stated, although in England it seldom exceeds fifteen feet high. The branches extend horizontally to a great distance every way, quite from the ground ; they grow without much order, and the tree has a very different appearance from the other sorts. Thunberg describes the *Cupressus Pendula* of Japan, to be a tree of a man's height, or rather more, erect, and smooth ; and adds, that this handsome singular tree is easily distinguished from all the evergreens of this order, by its abundance of very long, dichotomous, pendent branchlets.—It may be propagated from seeds, in the same manner as the common Cypress, and the plants treated as directed for that species, with this difference only, that it will be proper to cover them during the two first winters after they are come up especially if the frost should be severe, which might destroy them while young and exposed. It may also be propagated by cuttings, which, if planted in autumn, and screened in winter, will take root ; but are generally two years before they will be rooted enough to transplant ; nor will the plants so raised thrive so fast as the seedlings, which are therefore greatly to be preferred whenever the seeds can be obtained.

6. *Cupressus Japonica* ; *Japan Cypress*. Leaves in four rows, sickled, compressed, furrowed, decurrent. This is a very lofty straight tree, with a trunk the thickness of the human thigh, or more. The wood is very soft, and is much used for cabinets, and other furniture, that are varnished or japanned, as it is termed.—Native of Japan.

7. *Cupressus Columnaris*. Leaves imbricate, subulate, furrowed ; strobiles cylindric, elongated.—Native of New Caledonia, and Norfolk Island.

Curatella ; a genus of the class Polyandria, order Digynia.—GENERIC CHARACTER. *Calix* : perianth five-leaved, rounded ; leaflets roundish, concave, the fifth interior, extremely like the petals. *Corolla* : petals three or four, roundish, concave, very like the calix. *Stamina* : filaments very many, filiform, shorter than the corolla : antheræ roundish. *Pistil* : germen two-parted, roundish ; styles two, filiform, erect, length of the stamina ; stigmas headed. *Pericarp* : capsule two-celled, two-parted : lobes roundish,

one-celled; seeds in pairs, oblong, shining. **ESSENTIAL CHARACTER.** *Calix*: five leaved. *Petals*: four. *Styles*: two. *Capsule*: two-parted, with two seeds in a cell.—The only known species belonging to this genus is,

1. *Curatella Americana*. It is of the stature of *Coccoloba*. Leaves alternate, oblong, subsessile, large, very rough; flowers in racemes, from the axils of the leaves which have already fallen, the division of the raceme having two bracts.—Native of South America.

Curculigo; a genus of the class Polygamia, order Monœcia. —**GENERIC CHARACTER.** *Hermaphrodite Flowers*, few, below. *Calix*: none. *Corolla*: petals six, oblong, spreading, withering. *Stamina*: filamenta six, very short; anthers linear, erect. *Pistil*: germen sessile, lanceolate; style very short; stigma large, tapering, with a three-cleft apex. *Pericarp*: capsule, when a germen, three-celled, with the rudiments of six or eight seeds in each cell; when ripe, appearing one-celled. *Seeds*: one to four, shining, black, beaked. *Male Flowers* several, above. *Corolla* and *Stamina*: as above. *Pistil*: wanting. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: six-petalled. *Filamenta*: six. *Pistil*: one. *Capsule*: seeds beaked.—The only known species is,

1. *Curculigo Orchioides*. Root tubercous, with many fleshy vermicular fibres; leaves numerous, all radical, petioled, sword-form, nerved, slender, with very few soft white hairs on them while young, from six to eighteen inches long, and half or three quarters of an inch broad; flowers pretty large, yellow, the one or two lowermost hermaphrodite, above all male.—Native of the shady uncultivated places about Samulcotah. It is the *nallatady* of the Telingas. Gærtner remarks, that it differs from all other plants in the singular structure of the style and capsule, and the roundish horny process from the outer and upper part of the seed, thickening upwards, and being slightly incurved.

Curcuma; a genus of the class Monandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth superior obscure. *Corolla*: tube of the petal narrow; border three-parted; divisions lanceolate, spreading, gaping more on the sinus; nectary one-leaved, ovate-acuminate, larger than the divisions of the petal, inserted into the more open sinus. *Stamina*: filamenta five, of which four are erect, linear, barren; one, (the fifth,) within the nectary, linear, petal-form, with a two-cleft tip; anthers adnate. *Pistil*: germen roundish, inferior; style length of the stamina; stigma simple, hooked. *Pericarp*: capsule roundish, three-celled, three-valved. *Seeds*: very many. **ESSENTIAL CHARACTER.** *Stamina*: four, barren, a fifth fertile. *Corolla*: four-parted. *Nectary*: three-lobed. *Filamenta*: flat.—These plants must be placed in the bark-stove; they are only propagated by parting their roots, in the spring, before they put out new leaves: plant them in rich kitchen-garden earth, and keep the pots constantly plunged in the bark-bed. In summer, when the plants are in a growing state, refresh them frequently with water, but not in large quantities, and admit a large share of air to them in warm weather. When the leaves are decayed, they should have very little wet, and be kept in a warm temperature. They usually flower in August, but strong roots only produce flowers.—The species are,

1. *Curcuma Rotunda*; *Round-rooted Turmeric*. Leaves lanceolate-ovate; lateral nerves very few. Root perennial, with a large ovate bulb, frequently as big as a goose's egg, covered with a thin rufescent pellicle, that has parallel rooting rings, within solid, fleshy, reddish-yellow, of a bitterish taste, and slightly aromatic smell. It creeps underground by means of little bulbs of the same ovate-form, growing by

the side of the maternal bulb. Stem none: leaves annual, three feet high, grooved, bright green; flowers in a loose spike, of a yellowish colour, enclosed in several spathes, or sheaths which drop off.—Native of the East Indies, and the mountains of China and Cochin-china.

2. *Curcuma Longa*; *Long-rooted Turmeric*. Leaves lanceolate; lateral nerves very numerous. Root perennial, creeping, fleshy, palmate, with columnar branches, and parallel rooting rings, the skin thin and pale, the flesh saffron-coloured, with a bitterish taste, and a smell of salve; stem none; leaves broad lanceolate, large, quite entire, smooth, annual, pale, green, grooved with oblique, slender, frequent lines; flowers sessile, white, with a yellow nectary, solitary, and inclosed within the scales of the spike; corolla one-petalled, funnel-shaped; tube slender, equal to the calix, widening above; seeds round, few; it has no barren filamenta.—Native of the East Indies, China, and Cochin-china, &c. It very seldom produces seed. It was much used formerly in cookery, to give things a colour, for which purpose it is still used in the East, as well as for dying. The root of this plant had the reputation of being a powerful aperient and resolvent, being commonly prescribed in obstructions of the liver, and other chronic complaints; the disease in which it has been thought to be most efficacious, is the jaundice; it is now, however, very rarely employed in Europe: it tinges the urine of a deep yellow colour. It is yet in high repute in the East. The first species being stronger, is seldom internally applied, but is used externally as a cataplasm, with the root of *Crinum Zeylanicum* and the leaves of *Artemisia*, and are esteemed a sovereign remedy in swellings of the abdomen, arising from a suppression of the menses. The English druggists, says Hill, keep the dried roots, which are good in the jaundice, and all obstructions, operating as a diuretic, and promoting the menses. Meyrick declares the root of *Turmeric* to be one of the most effectual remedies known in obstructions of the viscera and mesentery, as also of the menses, strangury, and affections of the kidneys. The dose in substance is from a scruple to a drachm, and three or four times as much in decoction or infusion.

3. *Curcuma Pallida*; *Pale Turmeric*. Bulbs knotted; scape long, bracted. An annual plant, without any stem, upright, three feet high. Root perennial, horizontal, creeping, oblong, columnar, twisted and knotty, within and without pale, fleshy, with little smell or taste; leaves lanceolate, large, with several oblique slender grooves; corolla yellowish white.—Native of China near Canton, and of Cochin-china.

Currants. See *Ribes*.

Curtisia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one leaved, four-parted; parts ovate, acute. *Corolla*: petals four, ovate, obtuse, sessile, longer than the calix. *Stamina*: filamenta four; inserted into the receptacle, subulate, shorter than the petals; anthers ovate. *Pistil*: germen superior, ovate; style subulate, the length of the stamina; stigma four or five cleft. *Pericarp*: drupe subglobular, smooth. *Seed*: nut roundish, bony, four or five-celled; kernels solitary, oblong. **ESSENTIAL CHARACTER.** *Calix*: four-parted. *Petals*: four. *Drupe*: superior, roundish, succulent, with a four or five-celled nut.—The only known species is,

1. *Curtisia Faginea*; *Beach-leaved Curtisia*, or *Hassagay Tree*. This is one of the largest trees in the African woods, with very diminutive flowers. The Hottentots and Caffres make the shaft of their javelins or assagays from the wood of this tree: they always carry one or two of these with them on their journeys; they consist of an iron spear hollowed out on each side about six inches long, with or without an

iron shaft, which is sometimes round and smooth, and sometimes grooved; it is fastened with thongs of leather to a slender round stick, five feet long, tapering towards the end, and made of this wood. With these lances, which they throw with great dexterity to the distance of an hundred paces, the Hottentots and Caffres defend themselves, and kill buffaloes and other wild animals. The Dutch call this tree *wite-else*, *stink-hout*, and *assaguay-hout*.

Cuscuta; a genus of the class Tetrandria, order Digenia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, cup-form, four-cleft, obtuse, fleshy at the base. *Corolla*: one-petalled, ovate, a little longer than the calix; mouth four-cleft, obtuse; nectary of four scales, which are linear, two-cleft, sharp, and growing to the corolla at the base of the stamina. *Stamina*: filamenta four, subulate, length of the calix; antheræ roundish. *Pistil*: germen roundish; styles two, erect, short; stigmas simple. *Pericarp*: fleshy, roundish, two-celled, cut round, or opening horizontally. *Seeds*: in pairs. **ESSENTIAL CHARACTER.** *Calix*: four-cleft. *Corolla*: one-petalled. *Capsule*: two-celled.—This genus consists of parasitical plants, fastening themselves to, and drawing their nourishment from others; the seed does not split into lobes, but opens and puts forth a little spiral body, which is the embryo: the stalk twines about some other plant, contrary to the apparent motion of the sun, sending out from the inner surface a number of little vesicles, which attach themselves to the bark of the plant. They have no leaves, except here and there a small membranaceous scale, close under a branch. They adhere to the ground by the original root, and at first draw a part of their nutriment thence; but the original root withers away as soon as the young stem has fixed itself to any other plant.—The species are,

1. *Cuscuta Europæa*; *Common Dodder*. Flowers conglomerate, sessile; corolla pitcher-shaped, with bluntish segments; number of parts generally four. Stem slender, filiform, smooth, four-cornered, reddish; a small, single, ovate-acute scale under each ball of flowers, where also it frequently puts forth a branch; corolla white, or with a tinge of purple; seeds generally two in each cell.—Native of Europe, in hedges, usually upon Hops, Brambles, Woody Nightshade, Fern, Thistles, Hemp; also on Flax, Nettles, Clover, Grass, &c. and lofty plants in general: it flowers in July and August. The whole plant is bitter; an infusion of it, according to Meyrick, in the proportion of an ounce to a pint of water, is a brisk purge, and is of considerable efficacy in obstructions of the viscera, as well as in the sciatica and scorbutic complaints. The fresh herb, bruised and applied externally, is excellent in dispersing scrofulous tumours. Dodder, says Hill, is best fresh gathered; it is to be boiled in water, with a little ginger and allspice, and the decoction works by stool briskly; it also opens obstructions of the liver, and is good in the jaundice, and many other disorders arising from the same cause. The Dodder which grows upon garden Thyme has been usually preferred to others, and supposed to possess peculiar virtues from the plant on which it grows; but this is imaginary, as experience shows it to be only a purge like the other, only less powerful; the common Dodder is preferable, because we can gather it fresh; while that which is imported loses a considerable portion of its virtues in passing through the hands of the druggist.

2. *Cuscuta Epithemum*; *Small Dodder*. Flowers conglomerate; corolla bell-shaped, deeply cloven with acuminate segments; number of parts constantly five. Corolla paler than that of the common sort, deeper cut; the segments sharper and smaller; the balls of flowers closer. From its destructive quality of suffocating plants, it has the opprobrious names

of *hell-weed*, and *devil's-guts*.—It is annual, and flowers from June to August. It is found in cultivated fields, particularly among pulse, nettles, and heath; it has been also often seen on beans, furze, flax, thyme, wild thyme, lavender, spurge, hops, grass, &c.

3. *Cuscuta Americana*; *American Dodder*. Flowers peduncled. This is a very branching, leafless, twining, parasitical plant, tender, shining, and yellowish; common peduncles very short; flowers small, without scent, aggregate, yellowish or greenish. Sloane says, the stems are very long and strong, stretching themselves over very large trees, and whole fields and pastures.—Native of America.

4. *Cuscuta Lupuliformis*; *Hop Dodder*. Flower racemed, sessile; number of parts four. Stem round, branching, very thick like hop-binds; bark reddish-green or brown-purple, rough and studded with stiff rising grains like millet; flowers on racemes, coming out laterally, an inch or two in length, sometimes branched; they are scattered, solitary, or only two or three together, not glomerate, sessile, not peduncled.—It is annual; a native of Silesia, and the Levant; and flowers in July and August.

Cussonia; a genus of the class Pentandria, order Digenia.—**GENERIC CHARACTER.** *Calix*: umbel none, but three or more peduncles, unbelled, collecting the flowers into a raceme or spike; involucre none, but scattered bractes at the base of the peduncles: perianth one-leafed, truncate, obscurely five-toothed, shorter than the corolla, permanent. *Corolla*: petals five, oblong, acute. *Stamina*: filamenta five, very short; antheræ ovate. *Pistil*: germen inferior, turbinate; styles two, filiform, patulous; stigmas simple, obtuse. *Pericarp*: twin, compressed, angular, crowned with the calix and styles, two-celled, two-valved. *Seeds*: solitary. **ESSENTIAL CHARACTER.** *Petals*: three-cornered; margin of the receptacle dilated into a five toothed calix.—The species are,

1. *Cussonia Thyrsiflora*. Leaves digitate; leaflets sessile, wedge-form, truncate, three-toothed; flowers racemed. Stem frutescent, at bottom scabrous, unequal, simple, the thickness of a finger, very simple at top. A shrub. There is a variety of this with jointed leaflets, the lowest joint dilated at the end into smaller lobes, whence the leaflets are as it were proliferous.—Native of the Cape of Good Hope.

2. *Cussonia Spicata*. Leaves digitate; leaflets petioled, spatulate; ligule three or five palmate, finely serrate; flowers in spikes.—Native of the Cape of Good Hope.

Custard Apple. See *Annona*.

Cyanella; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals six, cohering by their claws, oblong, concave, patulous, the three inferior ones hanging forwards. *Stamina*: filamenta six, contiguous at the base, very short, somewhat spreading, the lower one declined, and twice the length of the others: antheræ oblong, erect, gaping at the tip, with four obtuse teeth. *Pistil*: germen three-cornered, obtuse; style filiform, declinate, length of the lower stamina; stigma somewhat sharp. *Pericarp*: capsule superior, roundish, three-furrowed, three-celled, three-valved. *Seeds*: many, oblong. **ESSENTIAL CHARACTER.** *Corolla*: six-petalled, the three lower petals hanging forwards. *Stamina*: lower, declined, longer than the rest. The roots of these plants should be planted in pots filled with light earth, placed in winter in a frame, and treated in the same manner as is directed for *Ixia*.—The species are,

1. *Cyanella Lutea*; *Yellow-flowered Cyanella*. Leaves ensiform; branches erect.—It flowers in July, and by Sparrmann at the Cape of Good Hope.

2. *Cyanella Capensis*; *Purple-flowered Cyan*

waved; branches spreading very much. The root is shaped like that of the Spring Crocus; leaves long, narrow, with a groove on their upper side; the peduncle arises immediately from the root, supporting one flower of a fine blue colour, which appears in May, but the flowers are not succeeded by seeds in England. The roots are roasted and eaten in Africa.—Native of the Cape of Good Hope.

3. *Cyanella Alba*; *White-flowered Cyanella*. Leaves linear-filiform.—Found by Thunberg at the Cape.

Cycas; (the *Todda Panæ*) a genus of Palms, of the class Diœcia, order Polyandria, according to Jacquin.—GENERIC CHARACTER. *Male*. *Calix*: spathe none; spadix none; ament strobile-form, ovate, squarrose, imbricated with scales; scales spatulate-form, smooth, fleshy, coloured, keeled beneath, with a reflected point, distant. *Corolla*: none. *Stamina*: filamenta none; antheræ none; pollen spread within the upper surface of the scales of the ament, sessile, very plentiful, very crowded, somewhat globose, one-celled, bursting longitudinally on one side. *Female*, in a distinct individual. *Calix*: spathe none; spadix very simple, compressed, ancipital, long, sharpened; perianth none. *Corolla*: none. *Pistil*: germina solitary, immersed beyond the middle into the corners of the spadix, remote, roundish; style cylindric, very short; stigma simple. *Pericarp*: drupe oval, one-celled. *Seed*: nut woody, one-celled. ESSENTIAL CHARACTER. *Male*. *Ament*: strobile-form, with the scales covered every where beneath with pollen. *Female*. *Spadix*: sword-form. *Germin*: immersed into the corners of it, solitary. *Style*: one. *Drupe*: with a woody nut.—The trees of this genus require to be plunged into the bark-bed in the stove, which should be kept up fully to temperate heat in winter, but in summer should be much hotter. In hot weather they will require to be frequently refreshed with water, but must have it sparingly administered in autumn and winter.—The species are,

1. *Cycas Circinalis*; *Broad-leaved Cycas*. Fronds pinnate; leaflets linear, flat.—Native of the East Indies, the Friendly Islands, and the New Hebrides, in the South Seas.

2. *Cycas Revoluta*; *Narrow-leaved Cycas*. Fronds pinnate; leaflets linear, revolute about the edge. Trunk round, branched, a fathom or more in height, the thickness of the thigh, ferruginous, and hirsute from the falling off of the leaves; the stipe of the fronds has spines below: the leaflets are nearly opposite, linear, somewhat sickle shaped towards the inside; the fruit is an ovate, flat, red drupe, an inch and half in length. The fruit is eaten by the Japanese, but the pith of the trunk is most esteemed for its highly nutritive quality; they affirm that a soldier can subsist for a day on a very small piece of it. It is not used for food in China or Cochin-china, but is cultivated there for its beauty. In Tonquin, however, they make a sort of bread called *sagu*, from the pith of the trunk. Dampier says, that the inhabitants of Mindanao, one of the Philippine Islands, call the sago-trees *libby-trees*, and that they grow wild in great groves of five or six miles long, by the sides of the rivers. Its body and shape are much like the Palmieto or Cabbage-tree, but is not so tall as the latter; the wood is full of white pith, like that of Elder. They cut down the tree, split it in the middle, and scrape out all the pith, which they beat with a great pestle in a wooden mortar or trough, and then put it into a cloth or strainer held over a trough, and pouring water in among it, they stir it about, so that the water carries all the substance of the pith through the cloth, leaving a sort of husk behind, which is thrown away: that which runs into the trough settles to the bottom like mud, which, when the water is drawn off, they bake into cakes, and proves very good bread. The

Mindanese live three or four months of the year on this food. The native Indians of Ternate, Tidore, and all the spice islands, have plenty of these trees, and use them for food; the sago, which is transported into other parts of the East Indies, is dried in small pieces like little seeds or comfits, and commonly eaten with milk of almonds by those that are troubled with the flux.

Cyclamen; (Sow-bread) a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth half five-cleft, roundish, permanent; divisions ovate. *Corolla*: one-petalled; tube somewhat globose, twice as large as the calix, small, nodding; border bent upwards, five-parted, very large; divisions lanceolate; neck prominent. *Stamina*: filamenta five, very small, in the tube of the corolla; antheræ straight, sharp, in the neck of the corolla, converging. *Pistil*: germen roundish; style filiform, straight, longer than the stamina; stigma sharp. *Pericarp*: berry globose, one-celled, gaping five ways at the top, covered with a capsular cell. *Seeds*: very many, somewhat ovate, cornered. *Receptacle*: ovate, free. ESSENTIAL CHARACTER. *Corolla*. rotate, reflex, with a very short tube, and prominent throat. *Berry*: covered with a capsule.—All the sorts are propagated by seeds, which should be sown after they are ripe, in boxes or pots filled with light kitchen-garden earth, mixed with a little sand, and covered about half an inch deep, placing them where they may have the morning sun till the beginning of September, when they may be removed to a warmer exposure. The most proper time for removing these plants, is about the beginning of June, when the leaves decline; but they should not be often removed, as the roots do not lose their fibres, as in some others of the tuberous and bulbous-rooted kinds.

—The species are,

1. *Cyclamen Coum*; *Round-leaved Cyclamen*. Leaves orbicular, cordate, quite white. It has plane orbicular leaves, with short weak petioles; their under side is very red in the beginning of winter, but that colour goes off in the spring; their upper side is smooth, of a lucid green, and spread flat open; whereas the other sorts are hollowed, and reflex at the base. The flowers are very bright purple, and as they appear in the middle of winter, when there are few other flowers, they are the more valuable.—Native of the south of Europe. This, and the second and fourth species, may be plunged into the ground close to a south wall, a pale, or reed-hedge, in October, where, if the frost be very severe, it will be proper to cover them either with mats or pease-haulm, but in common winters they will not want covering.

2. *Cyclamen Europæum*; *Common Cyclamen*. Leaves orbicular, cordate, crenate. Root tuberous, oblatly spheroidal, white within, brown without; stem very short; leaves kidney-form, roundish, very blunt, slightly crenulate, deep green and spotted above, beneath commonly red purple, smooth, on very long round red petioles; flowers drooping, sweet-scented, purple; seeds large, rufous, kidney-form.—Native of Austria.

3. *Cyclamen Persicum*; *Persian Cyclamen*. Leaves oblong-ovate, cordate, crenate; leaves stiff, on strong fleshy petioles, nearly six inches long, of a purple colour, as are also the veins of the leaves underneath, but the upper side is veined and marbled with white; the corolla is pure white, with a bright purple bottom, but it varies in colour, and is sometimes entirely white: this variety smells very sweet. It flowers in March and April, and ripens seeds in August. It is admirably adapted to decorate the parlour or the study, and varies with fragrant flowers with the eye more or less red.—By its name it should be a native of Persia; but from Mr. Curtis we learn, that it comes from the East Indies; and Dr. John Sibthorp found it in the island of Cyprus. The

pots in which it is sown should be placed under a common hot-bed frame, where they may be protected from frost and hard rains, but the glasses may be taken off every day in mild weather, to admit the fresh air. This species is more impatient of cold than any of the others, and must be constantly preserved in pots filled with light sandy earth, or a mixture of loam and lime rubbish, and housed in winter, but should be placed near the glasses, where the plants may enjoy as much free open air as possible, when the weather will permit, for if they be crowded too closely under other plants, they are very subject to mould and rot.

4. *Cyclamen Hederæfolium*; *Ivy-leaved Cyclamen*. Leaves cordate, angular, toothletted. Root large, orbicular, compressed; leaves numerous, on petioles six or seven inches long, marked with black in the middle; the flowers appear before them on long fleshy scapes in August or September. Soon after, the leaves come out, continue growing all the winter and spring till May, when they begin to decay, and in June are entirely dried up. There are two varieties of this species, one with white, and the other with a purplish flower.—Native of Italy.

5. *Cyclamen Indicum*. Border of the corolla nodding. It differs only in having the divisions of the corolla not reflected but hanging down, and the whole corolla being much larger than in the European species.—Native of Ceylon.

Cycas; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved; tube short, turbinate; border four-parted, patulous; segments ovate-oblong, acute. *Corolla*: none. *Stamina*: filamenta ten, capillary, inserted into the neck of the calix, and longer; antheræ ovate. *Pistil*: germen ovate-oblong, villose, pedicelled; style capillary, flexuose; stigma obtuse. *Pericarp*: legume roundish, depressed, wrinkled, surrounded by an orbicular, membranaceous, broad, waving wing, one-celled, not opening. *Seed*: single, kidney-form. ESSENTIAL CHARACTER. *Calix*: four-parted, spreading, with a short turbinate tube. *Corolla*: none. *Filamenta*: inserted into the neck of the calix. *Style*: flexuose. *Legume*: roundish, winged, one-seeded.—The species are,

1. *Cycas Spicata*. Leaves pinnate. The trunk of this tree is from thirty to forty feet high, and a foot and half in diameter; the bark is gray and smooth, and the wood whitish; it has several large boughs at top spreading in all directions; leaves alternate, unequally pinnate; stipules in pairs at the base of the common petiole; flowers in long spikes, axillary and terminating, on short pedicels.—Native of the great forests of Guiana, flowering there in November, and fruiting in January. The Caribbee name is *apalatoua*.

2. *Cycas Aromatica*. Leaves ovate. The trunk of this tree is from forty to fifty feet high, and more, and about two feet in diameter; bark gray; branches very numerous, spreading in every direction; leaves alternate, large, stiff, ovate, acute, smooth, quite entire. The wood is light, and a little aromatic. The Caribbees call this tree *moutouchiraou*.—It is a native of marshy places in the great forests of Guiana, where it flowers in December, and fruits in May.

Cyclista; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, four-parted, very large, permanent, the upper division reflex, bifid, the rest erect, oblong, acute. *Corolla*: papilionaceous, a little longer than the calix, and permanent; banner roundish, emarginate, with a small lobe on each side of the base; wings oblong, obtuse, shorter than the banner, with a process on each side of the base; keel oblong, cleft at top and bottom, longer than the wings. *Stamina*: filamenta diadelphous, (simple and nine-cleft) ascending; antheræ roundish. *Pis-*

til: germen superior, ovate, compressed; style subulate, ascending; stigma subcapitate. *Pericarp*: legume ovate-oblong, compressed, one-celled. *Seeds*: two, oval. ESSENTIAL CHARACTER. *Calix*: very large, four-parted, the upper division cleft at the end. *Corolla*: permanent.—The only known species is,

1. *Cyclista Villosa*; *Hairy Cyclista*. A shrub, and requires the heat of a stove to preserve it; flowering in April and May.—Native country unknown.

Cymbachne; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite Flowers*. *Calix*: glume two-valved, one-flowered, so placed that each valve is pressed close to the rachis and parallel, not one hid by the other; outer valve linear, blunt, ciliate at the back; inner equal in length, semiovate, acute, boat-shaped, very much compressed, striated, coloured, ciliate at the back, inclosing the corolla. *Corolla*: two-glumed, hyaline, smaller than the calix. *Stamina*: filamenta three; antheræ black. *Pistil*: germen minute; style simple; stigmas two, black-bearded. *Female Flowers*. *Calix*: one-valved, ovate, slightly bifid at the tip, ciliate at the edge, opposite to the rachis, pressed close. *Corolla*: none. *Pistil*: as in the hermaphrodite, but with longer stigmas. ESSENTIAL CHARACTER. *Inflorescence*: half-spiked. *Hermaphrodite*: *Calix*: two-glumed, one-flowered, parallel to the rachis; outer valve linear, the opposite boat-form. *Female*. *Calix*: one-glumed, ovate, opposite to the rachis.—The only known species is,

1. *Cymbachne Ciliata*. This is a slender grass, a foot in height, with several culms, simple or branched, with a single leaf or leafless; leaf short, slender, ciliate on the edge above the sheath with long separate hairs; sheath truncate, with a pale brown mouth, and ciliate; spikes two, terminating, linear, an inch and half long, a line broad, some hermaphrodite, others female.—Native of Bengal.

Cymbaria; a genus of the class Didynamia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth ten-toothed, erect; two opposite teeth stronger and more spreading; the rest erect, linear, permanent. *Corolla*: one-petalled, ringent; tube oblong, bellied; border two-lipped, upper lip two-parted, reflex, obtuse, lower lip three-cleft, obtuse. *Stamina*: filamenta four, length of the tube; antheræ two-cleft, prominent. *Pistil*: germen ovate; style filiform, length of the stamina; tip incurved; stigma obtuse. *Pericarp*: capsule ovate, one-celled, two-valved; receptacle quadrangular. *Seeds*: very many, cornered, smooth. ESSENTIAL CHARACTER. *Calix*: ten-toothed. *Capsule*: cordate, two-celled.—The only known species is,

1. *Cymbaria Daurica*. The whole plant is hoary, and nearly allied to *Antirrhinum*; branches opposite, barren; flowers lateral, very few, subsessile, large; upper lip of the corolla vaulted; lower equal; palate gibbous; capsule marked with a groove on each side.—Native of the mountains of Dauria.

Cynanchum: (Base Dog's-bane) a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-toothed, erect, very small, permanent. *Corolla*: one-petalled; tube scarcely any; border five-parted, flat; divisions linear, long; nectary in the centre of the flower, length of the corolla, erect, cylindrical, with a five-cleft mouth. *Stamina*: filamenta five, length of the nectary, parallel; antheræ touching, within the mouth of the corolla. *Pistil*: germen oblong, two-cleft; style scarcely any; stigmas two, obtuse. *Pericarp*: follicles two, oblong, acuminate, one-celled, gaping lengthwise. *Seeds*: numerous, oblong, crowned with a down, placed in an imbricate manner. ESSENTIAL CHARACTER. Contorted. *Nectary*: cylindrical, five-toothed.—These are shrubs or under shrubs, com-

monly twining, with opposite leaves, and the flowers axillary or terminating, disposed in spikes, corymbs, or umbels. Those of the tropical climates are all tender, and will not thrive in this country, unless placed in a bark-stove. As they abound with a milky juice, they must have but little water in winter. They may be propagated by laying down the young shoots, which in three or four months will put out roots, and may then be transplanted into pots filled with light sandy earth, and plunged into the tan-bed, where the plants should continue all the year. They may also be increased by parting their roots, or by cuttings. Such as produce good seeds in Europe, which many of them do, may be propagated in that way.—The species are,

1. *Cynanchum Viminale*; *Naked Cynanchum*. Stem twining, perennial; leaflets. Naked. *Cynanchum* is so called from its having stems without any leaves on them. It sends out a great number of slender taper stalks, of a dark green colour, which are smooth, and twist about each other, or any neighbouring support, and then will rise to the height of ten or twelve feet, putting out branches at top, which also twine about the other stalks. It has not flowered in England.—Native of the Cape of Good Hope. This, and the eleventh, twelfth, and fifteenth species, come from the Cape, and must be preserved in the dry-stove. They may be increased either by layers or cuttings.

2. *Cynanchum Acutum*; *Acute-leaved Cynanchum*. Stem twining, herbaceous; leaves cordate-oblong, smooth. Root perennial, creeping; stems annual, twisting like hops round whatever plants are near them, and rising to the height of six or eight feet; leaves ending in acute points, flowers in small axillary bunches, of a dirty white colour.—It flowers in June and July, but does not produce seeds in England, occasioned probably by the roots creeping so far under ground; for most plants which propagate themselves so much by their roots become barren, especially if their roots have full liberty to extend. This, and the eighth species, being natives of the south of Europe, are hardy, and propagate too fast by their creeping roots, which are not easily extirpated, when they have once got possession of the ground. The roots may be transplanted any time after the stems decay, till they begin to shoot in the spring.

3. *Cynanchum Planiflorum*; *Flat-flowered Cynanchum*. Stem twining; leaves cordate, smooth, tomentose underneath; peduncles subracemed. This is a milky plant, with twining, round, smooth stems; leaves oblong-cordate, acuminate, quite entire, very soft, with a scarcely conspicuous nap underneath, smoothish on the upper surface, but bearded at the origin of the petiole, with abrupt, rigid, ferruginous cilia; common peduncles smooth, lateral, solitary, sustaining about five flowers, on pedicels elongated beyond the common one; flowers void of scent, very flat, half an inch indiameter; corollas veined and æruginose; calices greenish-white.—It flowers in July and August, and is a native of Carthage in New Spain.

4. *Cynanchum Racemosum*; *Racemed Cynanchum*. Stem twining; leaves cordate, smooth, acute; racemes simple. Stems herbaceous, twining, smooth, scandent, full of a white milky juice; leaves quite entire, shining, slightly waved, bright green on the upper surface, æruginose on the back, petioled; racemes lateral, three inches long, solitary; but by the side of the principal a smaller branch comes out, which is also loaded with flowers; they are scentless, small, and white.—It flowers in October and November, and is a native of Carthage.

5. *Cynanchum Maritimum*; *Sea Cynanchum*. Stem twining; leaves cordate, hirsute, tomentose underneath, peduncles

aggregate. A milky plant, with twining, round, hirsute stems; leaves acuminate, quite entire, petioled, from two to four inches long; peduncles one-flowered and shortish, springing aggregately from a tubercle among the leaves; flowers scentless, with a green calix, and a dark purple corolla.—It flowers in November, and is a native of the coast of Tierra Bomba.

6. *Cynanchum Suberosum*; *Cork-barked Cynanchum*. Stem twining, cork-barked at bottom, and cleft; leaves cordate, acuminate. Root perennial; stems slender, hairy, twining, and, if supported, rising six or seven feet high; the lower part is covered with a thick fungous bark, somewhat like cork, and full of fissures. At each joint is a pair of leaves, on long hairy footstalks. The flowers are in small axillary bunches; they are star-shaped, and green when they first appear, but afterwards change to a dusky purple colour.—Native of Carolina. It will live in the open air of England, if it be planted in a dry soil, and a warm situation. It may be increased by laying down the young shoots about Midsummer, which, if they are now and then refreshed with water, will put out roots, and may be transplanted in the autumn where they are designed to remain. The roots should be covered in winter with some rotten tan, to keep out the frost.

7. *Cynanchum Hirtum*; *Hairy Cynanchum*. Stem twining, shrubby, cork-barked, and cleft at bottom: leaves ovate-cordate. It rises to the height of twenty feet, or more, with a twining stem, if supported. The lower part is cork-barked, and full of fissures, like the preceding: leaves on long footstalks, smooth; flowers of a yellowish green colour, not succeeded by pods in England.—Native of Jamaica.

8. *Cynanchum Monspelicum*; *Montpellier Cynanchum*. Stem twining, herbaceous; leaves reniform, cordate, acute. Stems filiform, green, smooth, swelling at the joints, very long, climbing; leaves acute, glaucous, about the same length as the petioles; flowers on solitary peduncled racemes, between two petioles, the peduncles thickening toward the top; calix small, five-cleft; corolla deeply five-parted; segments linear, white above, pale rose-coloured beneath; in the centre is a white pitcher-shaped body, or nectary, ten-cleft at the top, with five broad shorter segments, and five sharp longer ones. Both this and the seventh species abound with a milky juice like the Spurge, which issues out wherever they are broken, and when concreted, has been frequently sold for Scammony, but is not as strong.—Native of the south of Europe.

9. *Cynanchum Extensum*; *Hairy-flowered Cynanchum*. Stem twining, frutescent; leaves cordate, acute; peduncles elongated; pedicels filiform; corollas hirsute at the edge; foliicles ramentaceous. From an annual root, divided into whitish fibres, a foot and a half long, and not so thick as a quill, arises a twining stem, very much branched, twelve feet high, round, villose, with longer hairs thinly interspersed, rough, glaucous, when far advanced slightly tinged with purple. The branches are the same; leaves quite entire, almost smooth on both sides, on a long round villose petiole; flowers pendulous, sweet-smelling, beginning to open about six o'clock in the evening, and closed by morning; they are of a greenish pale colour. The plant is elegant, and abounds with a white milk.—It flowers in July and August, and is a native of the East Indies.

10. *Cynanchum Undulatum*; *Wav'd-leaved Cynanchum*. Stem twining; leaves lanceolate, ovate, smooth; umbels globular. A milky plant, entirely smooth, with twining round stems; leaves quite entire, fat to the touch, on very short petioles, four inches long; flowers small, without scent, firm; calices ash-coloured; corollas nearly of the same

colour on the outside, and dirty purple within.—It flowers in July, and is a native of Carthage in New Spain.

11. *Cynanchum Capense*; *Cape Cynanchum*. Stem twining, conform on every side; leaves subcordate-ovate; peduncles many-flowered. Stem lofty, scarcely pubescent, even at top, by no means cork-barked; leaves petioled, mucronate, even; the younger ones ovate, the more advanced emarginate.—Observed by Kœnig and Sparrmann at the Cape. This and the next species must be preserved in the dry-stove, and may be increased by layers, cuttings, &c.

12. *Cynanchum Obtusifolium*; *Blunt-leaved Cynanchum*. Stem twining, herbaceous; leaves oblong, rounded at the tip, with a point; umbels lateral.—First observed by Thunberg at the Cape of Good Hope.

13. *Cynanchum Tenellum*. Stem somewhat twining, herbaceous; leaves ovate-oblong.—Found by Mutis in New Grenada.

14. *Cynanchum Erectum*; *Upright Cynanchum*. Stem erect, divaricated; leaves cordate, smooth. This is a perennial plant, which rises with slender upright stalks, about three feet high; leaves broad, smooth, ending in points; flowers axillary, in small bunches, on branching peduncles; they are small and white, greatly resembling those of the common white *Asclepias*.—It flowers in July and August, and is a native of Syria. It requires a warm situation to live abroad in England; and is propagated by parting the roots before they shoot in the spring.

15. *Cynanchum Filiforme*. Stem erect, quite simple; leaves linear; flowers verticilled, axillary.—Found by Thunberg at the Cape of Good Hope. It must be preserved in the dry-stove; and may be increased by layers, cuttings, &c.

16. *Cynanchum Crispiflorum*. Stem twining; leaves underneath villose, oblong, cordate, with the sinus closed; petals curled at the end.—It flowers in July; and is a native of South America and the West Indies.

17. *Cynanchum Reticulatum*. Stem twining, cork-barked at bottom, and chinky; leaves ovate, acute. Stem woody, covered with a thick whitish bark; the branches opening, striated, smooth; leaves far from each other, petioled, smooth, upper one lanceolate; flowers small, hairy on the outside, unequally pedicelled in peduncled axillary umbels.—Observed by Kœnig in the East Indies.

18. *Cynanchum Asperum*; *Rough-leaved Cynanchum*. Stem twining, shrubby; leaves cordate, acute, rough; flowers lateral. Stem twenty feet high, or more, very slender, and armed with small stinging hairs; leaves broad, on slender footstalks, covered underneath with rough hairs. The flowers are produced in small clusters, sitting close to the stalks; they are pretty large, yellow, and star-shaped, spreading open to the bottom.—Native of La Vera Cruz in New Spain.

19. *Cynanchum Carolinense*. Stem climbing, rough with hairs; leaves oblong-cordate, acuminate; corymbs axillary; segments of the corolla oblong, obtuse.—Native of Carolina.

20. *Cynanchum Rostratum*; *Beak-flowered Cynanchum*. Stem and petioles hirsute; leaves cordate-oblong; petals lanceolate, flat. Stem twining, shaggy, with reversed hairs, as are also the petioles: leaves two or three inches long, acuminate.—Found by Rohr on the island of Trinidad.

21. *Cynanchum Parviflorum*; *Small-flowered Cynanchum*. Stem twining, filiform; leaves ovate, subulate at the end; umbels subsessile.—Native of the West Indies.

22. *Cynanchum Prostratum*; *Prostrate Cynanchum*. Stem prostrate; leaves heart-shaped, orbiculate-acute, tomentose underneath. Stems a foot high, round, filiform, branched, knotted, tomentose, subherbaceous; leaves in pairs

at each knot, nearly equal to the petioles, quite entire, soft, glaucous underneath, having an unpleasant smell; flowers in solitary umbels; corolla deep green, deeply parted into five spreading segments, with a revolute border.—Native of Mexico.

23. *Cynanchum Grandiflorum*; *Great-flowered Cynanchum*. Stem twining; leaves heart-shaped, ovate-cuspidate, glaucous underneath; corollas coriaceous, before they expand rolled up in a spiral form, but afterwards spreading very much, deep green on both sides, divided into five lanceolate very sharp segments, nearly an inch in length. Stem very long, cylindrical, with a rufous nap at the joints; leaves with one branching nerve; flowers in short racemes.—Native of South America.

24. *Cynanchum Odoratissimum*; *Sweet Cynanchum*. Stem twining, corky, and cloven at bottom; leaves heart-shaped, acuminate, wrinkled; cymes reflex. Stem very long, round, shining, and very smooth, except at bottom, where it has a bark like cork; leaves waved, smooth, on long petioles; flowers yellow, very sweet-scented, in large hemispherical, axillary, reclining cymes. This plant is not inferior to the Arabian *Jasmin* in fragrance.—It is a native of Siam and Cochinchina, where the women of fashion use it to adorn their hair.

25. *Cynanchum Inodorum*. Stem twining, cork-barked, and chinked towards the bottom; leaves ovate-acuminate; peduncles subdivided. Root perennial; stem long, branched; leaves smooth, opposite; flowers numerous, small, yellow, scentless; peduncles short axillary; corolla rather salver-shaped; segments linear, longer than the tube, spreading; stigma large, sessile, ovate-oblong; follicles oblong, acuminate, downy, curved inwards.—Native of Cochinchina.

26. *Cynanchum Altissimum*; *Lofty Cynanchum*. Stem twining; leaves heart-shaped, tomentose on both sides; flowers umbelled. This is a milky shrubby plant, climbing trees to the height of fifty feet. Stems round; when old woody, smooth ash-coloured, leafless; when young, green, tomentose, leafy. Flowers thick, firm, scentless; calices greenish ash-colour; corollas dirty purple.—Native of New Spain, near Carthage.

27. *Cynanchum Longiflorum*; *Long-flowered Cynanchum*. Stem twining; leaves oblong, acute, villose; flowers umbelled; stems round, hairy, climbing to the height of fifteen feet; flowers destitute of either smell or beauty. The unusual elongation of the tube gives the flower a very different appearance from the others.—Native of Carthage in New Spain.

28. *Cynanchum Filiforme Americanum*. Stem twining; leaves ovate-acuminate, flat, shining; umbels globular. Stems round, filiform, branched, very numerous; flowers without scent, small; the petals and nectaries snow-white.—Native of Carthage in New Spain.

29. *Cynanchum Clausum*; *Close-flowered Cynanchum*. Stem twining; leaves acuminate, oblong, rolled back at the edge; flowers umbelled. Stems round, smooth, numerous; flowers scentless, with snow-white corollas and nectaries.—Native of Carthage in New Spain.

Cynara; a genus of the class Syngenesia, order Polygamia *Æqualis*.—GENERIC CHARACTER. *Calix*: common ventricose, imbricate; scales numerous, roundish, fleshy, increased by a membranaceous scale-formed appendicle, which is larger, roundish, channelled, and emarginated with a spine. *Corolla*: compound tubulous, uniform: corollas hermaphrodite, nearly equal; proper one-petalled, funnel-form; tube very slender; border erect, ovate, five-cleft; divisions linear, one more deeply serrated. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubu-

lose, length of the corollule, five toothed. *Pistil*: germen somewhat ovate; style filiform, longer than the stamina; stigma simple, oblong emarginate. *Pericarp*: none; calix converging but a little. *Seeds*: solitary, oblong-ovate, four-cornered, compressed; down sessile, long; receptacle bristly.

ESSENTIAL CHARACTER. *Calix*: dilated, imbricate, with fleshy scales, emarginate, with an acumen.—The species are,

1. *Cynara Scolymus*; *Common Artichoke*. Leaves somewhat spiny, pinnate, and undivided; calcine scales ovate. In its wild state, the Artichoke is said to attain the height of a man, but the cultivated Artichoke seldom exceeds four feet in height, with a stout, furrowed, leafy stem, slightly tomentose, sometimes a little branched at top. The root is large, thick, and perennial; root-leaves two to four feet long, petioled, irregularly pinnatifid, deeply cut, more or less spinous; stem-leaves simple, serrated or jagged; flowers terminating the stem and branches, on thick fleshy peduncles; heads subglobular, green or dark purple. Mr. Miller divides the Artichoke into two species. 1. The Green or French, and 2. the Globe Artichoke. The former, being the sort most commonly cultivated in France, is generally known here by the title of French Artichoke, and is the only sort in Guernsey and Jersey. Its heads are of a green colour, like those of the Globe Artichoke, but the bottoms are not near so thick of flesh; and they have a perfumed taste, which to many persons is very disagreeable, so that it is seldom cultivated in the gardea near London, where the Globe or Red Artichoke is the only sort in esteem.—The Artichoke is a native of the south of Europe, as in Italy, Sicily, and the south of France. In some parts it is eaten raw in its wild state, by the common people, and must certainly be a most wretched food. It is said to dye a good yellow; and the flowers are used instead of rennet, to turn milk for cheese. The whole plant has a peculiar smell, and a strong bitter taste. It was formerly in great repute for qualities which it is not now allowed to possess. It is reputed to be aperient, stomachic, and somewhat heating. According to Meyrick, the juice of the leaves, or a strong decoction of the roots, is powerfully diuretic, and of great efficacy in the jaundice and dropsy, which will frequently yield to this medicine. Hill also observes, that the root fresh gathered, sliced, and boiled in water in the proportion of six ounces to a quart, makes a decoction which works by urine, and which he has known to cure the jaundice alone. The Artichoke has the same name, with very little variation, in all the European languages. The Germans call it *artischoke*, corruptly *erdschocke*; the Dutch, *artisjok* or *artichok*; the Danes, *ærteskok*; the Swedes, *ærtskocka*; the French, *artichaut*; the Italians, *carciofo*; the Spanish and Portuguese, *alcachofa*; the Poles, *karciof*; and the Russians, *artitschok*.—*Propagation and Culture*. The way of propagating the common Artichoke is, from slips or suckers taken from the old roots in February or March, or rather some time in March or the beginning of April, which if planted in a good soil, will produce large fair heads in the autumn following. To make a new plantation, dig and bury some very rotten dung in the ground set apart for that purpose. Choose such plants as are taken from clear, sound, but not woody old stocks. Cut off with your knife the knobbed woody part that joined them to the stock; if that cuts crisp and tender, it is good, but if tough and stringy, through it away as useless. Cut off also the large outside leaves pretty low, that the middle or heart-leaves may be above them. If the weather be very dry, or the plants have been any time taken from the stocks, it will be expedient to set them upright in a tub of water, three or four hours before they are planted, which will greatly refresh them. To plant them, range a line across the ground, and

with a measure-stick place them at two feet distance from each other in the rows; and if designed for a full crop, five feet distance row from row. The plants must be set about four inches deep, and the earth closed very fast to their roots, observing, if the season prove dry, to water them two or three times a week until they are growing; after which they seldom require any. A thin crop of Spinach may be sown upon the ground before the Artichokes are planted, observing to clear it from about them after it appears. But whenever it is intended to plant any thing between the Artichokes, nine or ten feet must be allowed between the rows, which is the space left by the kitchen-gardeners near London, who sow the ground between with Radishes or Spinach, and plant two rows of Cauliflowers at four feet distance from row to row, and two feet and a half asunder in the rows, so that there are always five feet allowed for the Artichokes to grow; and in May, when the Radishes and Spinach are taken off, they sow a row of Cucumbers for pickling, exactly between the two rows of Cauliflowers, at three feet distance from each other; and between the rows of Cauliflowers and the Artichokes, plant a row of Cabbages or Savoys for winter use, which, when the Cauliflowers are drawn off and the Artichokes gathered, will have full liberty to grow; and by this means the ground is fully employed throughout the whole season. This has long been the practice of the kitchen-gardeners near London, who pay large rents for their land, and are obliged to get as many crops in a year from it as possible. In those which are planted at five feet distance from row to row, a line of Cabbages or Savoys may be planted for winter use in every other row, which will be gone by the time of landing them up; in doing this, you must lay the whole five feet of earth into one ridge, except the ground be extremely stiff, or the plants young, in both which cases you may lay only three feet and a half of the ground in the ridge over the roots, and the remainder may be laid in a small ridge between: the same compass of ground must also be allowed, where they are planted at a wider distance. If in the spring you find your stocks shoot very weak, which may be occasioned either by hard frost or too much wet, you must then cover them, and loosen and break the earth about them, raising a small hill round each stock; levelling the rest between the rows, which will greatly assist them, and in three weeks or a month after, they are commonly fit to slip. If any of the plants which are set in the spring should not fruit in autumn, you may, at the season of earthing up the roots, tie up the leaves with a small willow twig, and lay up the earth close to it, so that the top of the plant may be above ground; and when the frost come on, if you will cover the top with a little straw or pease-haulm, to prevent their being killed by the frost, these plants will produce fruit in winter, or early in the spring. If you intend to continue your Artichokes through a whole season, you must make a new plantation every year, otherwise you cannot possibly have fruit longer than two or three months. Those Artichokes which are planted in a moist rich soil, will always produce the largest and best fruit, especially in kindly seasons; so that where such a soil can be obtained, it will be advisable to make a fresh plantation every spring, to succeed the old stocks, and supply the table in autumn. But the roots will not live through the winter in a moist soil, so that the stocks which are intended to remain to supply the table early, and to furnish plants, should be in a drier soil, and ought always to be planted in an open situation, not under the drip of trees, where they will draw up very tall, and produce small insignificant fruit.—*Winter Dressing and Landing*. Since we have experienced, that in very severe frosts these roots are

sometimes destroyed, (though it rarely happens in dry ground) the earthing of Artichokes should be deferred till the latter end of November, or the beginning of December, provided the season continue mild; and towards Christmas, when there appears any danger of severe frosts, lay a quantity of long dung, pease-haulm, tanner's bark, or any other light covering, over the ridges of earth, which will keep out the frost, and, being at a distance from the roots, will not injure them; but this should be carefully removed in the beginning of February, or at least as soon as the weather is mild, otherwise the plants will be injured by its lying too long upon them. It will also be a good method, whenever any roots of Artichokes are dug up in autumn, either to bury them deep in the ground in a pit till spring, or lay them in a heap, so as that they may be easily covered in hard frosts; and these may be a supply, if those in the ground be destroyed. When you have thus earthed them up, you have nothing more to do till February or March, by which time they will have grown through the ridge of earth; and when the weather is favourable, must be dressed as before directed.—*Spring Dressing.* At the end of February, in March, or at the beginning of April, according to the earliness of the season, or forwardness of the old Artichoke roots, will be the proper time for dressing them, which must be thus performed: with the spade remove all the earth from about the stock, down below the part whence the young shoots are produced, clearing the earth by hand from between the shoots, so as to be able to judge of the goodness of each, with their proper position upon the stock; then make choice of two of the clearest, strongest, and most promising plants, that are produced from the under parts of the stock, which are much preferable to the strong thick plants, which generally grow upon the crown of the roots; for having these hard woody stems, never produce good fruit, but are generally what the market people call *rogues*, which have very little bottom, and the scales of their heads are irregularly placed. In slipping off the plants, be careful not to injure those which are to remain for a crop, but with your thumb force off all the other plants and buds also, close to the head of the stock whence they are produced, taking care not to overlook any of the buds, which would soon produce plants to the great detriment of those which are left; round which two you must draw the earth with a spade, and close it fast to each of them by hand, separating them as far as possible without breaking them, observing also to crop off the tops of the leaves that hang down with your hands. The ground being levelled between the stocks, you may sow thereon a small crop of Spinach, which will be taken off before the Artichokes can cover the ground. They must be kept clear from weeds; and towards the latter end of April, or the beginning of May, when your old plants begin to show their fruit, carefully inspect the stocks, and draw up all young plants from them, which may have been produced after their dressing, cutting off all suckers that are produced from the stems of the Artichokes, leaving only the principal head; which will increase the size of the fruit. When they are fit to gather, they ought not to be broken down close to the surface of the ground, that your stocks may make strong fresh shoots before the end of October: the season for earthing, or, as the gardeners term it, *landing* them up, is the middle or latter end of November, and is thus done: cut off all the young shoots quite close to the surface of the ground, then dig between every stock, raising all the earth between every row of stocks into a ridge, as is done in the common method of trenching ground, so as that the row of Artichokes may be exactly in the middle of each ridge; which will be sufficient to defend them from frost.

2. *Cynara Horrida*; *Madeira Artichoke*. Leaves pinnatifid, tomentose underneath, spiny; spines at the base of the leaves, and pinnae connate at bottom.—Native of the island of Porto Santo, near Madeira.

3. *Cynara Cardunculus*; *Cardoon Artichoke*. Leaves spiny, all pinnatifid; calcine scales ovate. Bauhin asserts, that this is a hybrid plant, or mule, from the seed of the common Artichoke. The corollas and pistils are of a deep blue colour, but the stamina are gray. Parkinson says, that he was assured by John Tradescante, that he saw three acres of land about Brussels planted with this kind of Artichoke, which the owner whited like Endive, and then sold them in the winter, but that "we cannot yet find the true manner of dressing them, that our country may take delight therein." In some parts of Spain they substitute the down of this plant for rennet, in making cheese; a strong infusion is made over night, and the next morning, when the milk is warm from the cow, they put nearly half a pint of the infusion to nearly fourteen gallons of milk. This plant has the same name, with slight variations, in all the languages of Europe, as *kardonen*, *kardon*, *cardone*, and *cardo*.—Native of Candia. The Cardoon or Cardoon, is propagated in the kitchen-gardens to supply the markets, being annually raised from seeds, which should be sown upon a bed of light earth in March; and when the plants come up they should be thinned where they are too close, transplanting those which are drawn out into a bed at about three or four inches' distance, where they should stay until finally removed to where they are to remain: these young plants must be kept clear from weeds, and should be transplanted out in the beginning of June, on a moist rich spot of ground, at about four feet asunder every way: the ground should be well dug before they are planted, and the plants should be well watered until they have taken new root; after which it must be very diligently weeded, to encourage the growth of the plants, and as they advance in height, there should be some earth drawn up about each plant; and when they are fully grown, their leaves should be closely tied up with a hay-baad, and the earth round them drawn up in hills, almost to the top, being careful to keep the earth from falling between the leaves, which may occasion the rotting of the plants: the earth should be smoothed over the surface, that the wet may run off, and not fall into the centre of the plants, which would also rot them. In about eighteen weeks after they have been thus earthed, they will be blanched enough for use, so that if a succession of them be wanted for the table, there should be but few plants earthed up at each time. Towards the middle or latter end of November, if the frost should be severe, it will be proper to cover the tops of those plants which remain with pease-haulm or straw, to prevent the frost from penetrating to the tender leaves, which frequently pinches them where they remain totally uncovered; whereas if the covering be only removed in fine weather, the plants may be thus preserved for use during most part of the winter. If a few of the plants be placed out in a warm situation to stand for seed, they should not be blanched, but only in a very hard frost some light litter or pease-haulm may be laid round them to keep out frost, which should be removed in the spring, and the ground gently dug between the plants, which will not only destroy the weeds, but also encourage the roots of the plants to shoot out on every side, and thereby add fresh strength to their stems. They will flower about the beginning of July, and if the season prove dry, their seeds will ripen in September; but in cold wet seasons they will not come to maturity in England. The stalk of the leaf, which is thick and crisp, and may be thought to be palatable, is the part eaten; it is rendered white and tender,

like celery, by the blanching, and is about a yard or more in length. The season for it is autumn and winter, when it is used in salads, soups, stews, &c.; it is not, however, in great estimation in England, and therefore not much cultivated. Never tie up the leaves for blanching before they be full grown, unless they are wanted in September or October, in which case they must be tied up and earthed in August, but then the stalk of the leaf will never be broad and thick, and in that its chief excellence consists. The proper time to begin blanching, is at the end of September or October, when the plants will come into use in December, and continue all the winter: observe also to tie up the leaves in a dry day, adding fresh hay-bands as the plants advance in height, taking care to cover their tops with long litter, if the frosts should be severe.

4. *Cynaris Humilis*; *Dwarf Artichoke*. Leaves spiny, pinnatifid, tomentose underneath; calicine scales subulate. The heads have some resemblance to those of the French Artichoke, but have no fleshy substance in their bottoms.—Native of Spain and Barbary. This may be planted in the same manner as the preceding species; the plants being set three or four feet apart; they require only to be kept clean from weeds; they will flower in the second year, and if the season prove dry, the seeds will ripen in September: they generally decay in the following winter, if it be severe, especially if they remain uncovered.

5. *Cynara Acaulis*. Stemless: leaves pinnate, unarmed, smooth above.—Native of Barbary.

6. *Cynara Integrifolia*. Leaves lanceolate, toothletted; calicine scales lanceolate-acuminate. It is a low smooth plant, with a simple striated stem; leaves petioled, broad, lanceolate; corollas blue.—Found by Barnadas in the mountains near Toledo in New Castile.

Cynoglossum: a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, oblong, acute, permanent. *Corolla*: one-petalled, funnel-form, length of the calix; tube cylindrical, shorter than the border; border half five-cleft, obtuse; mouth closed, with five squamules, which are convex, prominent, converging. *Stamina*: filamenta five, very short, in the mouth of the corolla; antheræ roundish, naked. *Pistil*: germina four; style subulate, length of the stamina, permanent; stigma emarginate. *Pericarp*: none, but four arils of the seeds, depressed, roundish, outwardly more obtuse, scabrous, not gaping, somewhat flattish on the exterior side, nixed by their tip. *Seeds*: as many; somewhat ovate, gibbous, acuminate, smooth. ESSENTIAL CHARACTER. *Corolla*: funnel-form, the throat closed with arches. *Seeds*. flat, affixed to the style by the inside only.—The species are,

1. *Cynoglossum Officinale*; *Common or Great Hound's-tongue*. Stamina shorter than the corolla; leaves broad-lanceolate, attenuated to the base, tomentose, sessile; calicine segments oblong. The whole plant is downy, and soft to the touch; root biennial; stem two or three feet in height, upright, grooved, angular, villose, very leafy, branched at top; root-leaves large, a foot or more in length, on petioles, ovate or lanceolate, pointed, covered with a silky down which gives them a grayish colour, veiny; stem-leaves, at least the uppermost, sessile, half stem-clasping, quite entire, with a waving edge, seven or eight inches long, crowded, placed irregularly on the stem, upright, lanceolate, and broadest at the base; flowers at first of a dull red, marone, or mulberry colour, afterwards becoming bluish, growing in racemes.—There are two varieties; the large Dutch Hound's-tongue, double the size of the common sort, but probably only a variety, from luxuriance of soil; and the Evergreen Hound's-

tongue, the leaves of which are nerveless, much narrower and rougher than the common sort, but entirely destitute of its hoariness, so that the leaves are therefore of a full green colour: it also wants that strong scent which distinguishes the common Hound's-tongue; the stem has a slight hairiness, and the flowers are blue and smaller. Hound's-tongue is frequently found with a white flower. The whole plant has a disagreeable smell, much resembling that of nice: it is suspected to possess narcotic qualities; and in the *Historia Ozoniensis*, vol. iii. p. 350, an instance is related, in which the leaves boiled by mistake for Comfrey, disordered a whole family, and proved fatal to one person; but many will not admit the fact. Mr. Ray informs us, from Dr. Hulse, that a decoction of the roots inwardly, and cataplasms of them outwardly, were used in his time to relieve strumous and scrofulous cases. It is, says Meyrick, a plant of very considerable virtues, being of an astringent balsamic nature, and excellently adapted to ease those coughs which proceed from a thin acrid humour falling upon the lungs, or other parts of the breast. A decoction of the roots drank freely, relieves the bleeding of the piles, and stops the overflow of the menses and the whites: the root powdered, and taken in doses of half a drachm twice or three times a day, is excellent against purgings and the bloody flux: an ointment made of its leaves, with honey and turpentine, is a good application to dress old fistulous ulcers. Cattle in general dislike this plant; the goat alone is said sometimes to eat it.—

It grows wild by road-sides in most of the uncultivated parts of Europe, particularly in Germany and Switzerland. In England it may be met with in the London road between Kelvedon and Witham in Essex, but more abundantly about Braxsted; about Southend, by Eltham; beyond Waltham Abbey, towards Harlow; at Norbury, near Leatherhead, in Surrey; and near Woreester. It flowers in April and May.

2. *Cynoglossum Virginicum*; *Virginian Hound's-tongue*. Leaves spatulate lanceolate, lucid, three-nerved at the base; bracte of the peduncles stem-clasping. This rises with an upright branching stem nearly four feet high, covered with rough hairs; the flowers grow scatteringly towards the ends of the branches; they are small and white, appear in June, and are succeeded by four small seeds, which ripen in autumn, and then the plants decay.—Native of Virginia, and other parts of North America. This, with the 3d, 4th, 5th, and 10th species, are hardy plants, which will grow plentifully without much care, if they only be permitted to scatter their seeds.

3. *Cynoglossum Cheirifolium*; *Silvery-leaved Hound's-tongue*. Corollas twice the length; leaves lanceolate; root perennial, branched; stems several, a foot high, round, branching; leaves half stem-clasping, obversely lanceolate, or spatulate, quite entire, covered on both sides with a white silvery down; flowers in racemes, without any bractes; corollas white, with red, blue, or purple veins.—Native of Silesia, Carniola, Italy, the south of France, Spain, Gibraltar, and the Levant.—It flowers in June and July.

4. *Cynoglossum Apenninum*; *Apennine Hound's-tongue*. Stamina equalling the corolla. The leaves of this species are much larger, the petal of the flower much shorter, and the stature taller, than the first sort; it also flowers earlier.—Biennial; flowering from April to June; and a native of the Apennines.

5. *Cynoglossum Lævigatum*. Leaves lanceolate-ovate, smoothish; calices tomentose; seeds glossy. Stem erect, a foot in height, striated, paniced at top; root-leaves petioled, soft; stem-leaves small, sessile.—Native of Siberia.

6. *Cynoglossum Lusitanicum*; *Portugal Hound's-tongue*, or *Venus's Navelwort*. Leaves heart-shaped, stem-clasping,

smooth, even about the edge. The whole of this plant is very smooth; stem erect, a foot high, round; branches axillary, alternate, quite simple; flowers red or violet, remote, in naked terminal racemes.—Native of Portugal. Both this and the seventh species are annual plants, commonly sown in gardens, with other low annual flowers, to adorn the borders of the flower garden; but the seeds should be sown in autumn, for those which are sown in the spring often fail, especially in dry seasons; and the autumnal plants always grow much larger, and flower earlier. The seeds should be sown where the plants are intended to remain, for they will not bear transplanting, except while they are young. The plants require no other culture but to be thinned where they are too close, and kept clean from weeds: they flower in June and July, and ripen seeds in autumn; but the autumnal plants appear a month earlier.

7. *Cynoglossum Linifolium*; *Flax-leaved Hound's-tongue*, or *Venus's Navelwort*. Leaves linear-lanceolate, smooth, toothletted, and rugged about the edge. It seldom rises more than five or six inches high, and the stalks do not branch nearly so much as those of the preceding; the leaves are very narrow and long, and of a grayish colour; the flowers grow in short loose panicles at the ends of the branches, they are white like those of the sixth species, but smaller, and have the seeds of the same form, namely, umbilicated, from which circumstance they both derive the name of Navelwort.—Native of Portugal.

8. *Cynoglossum Omphalodes*; *Comfrey-leaved Hound's-tongue*. Creeping: root-leaves cordate. Root perennial; branches trailing, and putting out roots from the joints; leaves bright green, on long slender footstalks; flowers shaped like those of Borage, but smaller, and of a lively blue colour. It flowers from March till May in England, and about Christmas in the woods of the south of Europe, of which it is a native.—This plant propagates very fast by its trailing roots, which require to be kept within compass, on this account it seldom produces seeds; it delights in a cool moist situation.

9. *Cynoglossum Japonicum*. Leaves oblong, villose; stems prostrate. Root annual; stems four or five, round, villose, flexuose, and erect, unequal; flowers terminating in racemes; calix wholly villose; corolla purple, longer than the calix; style simple, with an obtuse stigma.—Native of Japan.

10. *Cynoglossum Pictum*; *Painted Hound's-tongue*. Corollas nearly equal to the calix; segments roundish, dilated; leaves lanceolate, tomentose, the upper ones cordate at the base. Leaves much shorter, softer, and more hoary than those of the common sort; stems a foot and a half in height, more branched; seeds smaller. It agrees with the common species in habit, size, and manner of growth, and has therefore been confounded with it by those who have not seen both: it differs from it in having the leaves not narrowed but cordate at the base, and the flowers pale blue or pale purple, beautifully painted with darker veins. It is a perennial, and flowers in August. Mr. Miller informs us, that it grows naturally in Andalusia, and that he received the seeds from Gibraltar.—Native of the south of Europe, and of Barbary, and also of Madaira, where it was found by Masson.

11. *Cynoglossum Lanceolatum*. Leaves lanceolate, drawn to a point at both ends, rugged, with dots on the upper surface. Stem herbaceous, upright, angular, rough with hairs, hoary at top; lower leaves drawn out into a petiole an inch in length, upper ones sessile, veiny, nerved.—Native of Egypt and Arabia.

12. *Cynoglossum Myosotoides*. Airls basket-shaped, smooth, striated, tubercled, toothed on the edge; leaves

hairy, tubercled, entire; root-leaves spatulate-lanceolate. Root perennial; stems usually several, pipe-form, ascending, scarcely half a foot high, hairy, usually simple; leaves rough next the root, petioled; on the stem sessile, linear, lanceolate; calix hairy, with subovate segments; flowers in naked terminal racemes, small, alternate; corolla very small, scarcely longer than the calix, blue.—Native of the very summit of mount Lebanon.

Cynometra; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved, oblong, reflex, length of the corolla. *Corolla*: petals five, lanceolate, equal, acute. *Stamina*: filamenta ten, twice the length of the corolla; antheræ oval, two-cleft at the tip. *Pistil*: germen boat-form; style filiform, length of the stamina; stigmas simple. *Pericarp*: legume crescent-shaped, compressed, fleshy, tuberculate. *Seed*: single, kidney-form, large. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Antheræ*: bifid at the tip. *Legume*: fleshy, crescent-shaped, one-seeded.—These trees are natives of the East Indies. Their leaves are conjugated, and the peduncles many-flowered.—The species are,

1. *Cynometra Cauliflora*. Trunk floriferous. Roots knotty and large, appearing above ground, and having smaller ones between them, which are curled, and look like pigs' tails; trunk very irregular and short, seldom above two feet high; it is rugged, unequal, ugly, in hills and holes, covered with a thick hard cloven bark; the colour of Liverwort. The flowers come out on the trunk and large branches, and on the root when above ground. The corolla is small and white.

2. *Cynometra Ramiflora*. Branches floriferous. This is a lofty tree, sixty feet in height; trunk thick, solid, ash-coloured; bark blackish, within red; branches many, ash-coloured or greenish.—It is always green in Malabar, and bears flowers and fruit in August and November.

Cynomorium; a genus of the class Monœcia, order Monandria.—GENERIC CHARACTER. *Male flowers*, disposed in an imbricated ament with the female ones. *Calix*: ament erect, club-shaped, on every side covered with floscules; perianth proper, four-leaved; leaflets three, clavate, and the fourth inferior one larger, very obtuse, channelled. *Corolla*: none. *Stamina*: filamenta single, firm, straight, longer than the calicine scale; antheræ twin. *Female Flowers*, mixed with the males in the same plant, and scarce remote from them. *Calix*: ament commou with the males; perianth proper superior; leaflets four, club-shaped, tuberculated, equal, permanent. *Corolla*: none. *Pistil*: germen ovate, inferior; style single, erect, firm, spreading, length of the calicine scale; stigma obtuse. *Pericarp*: none. *Seed*: single, roundish. ESSENTIAL CHARACTER. *Male*. *Calix*: an imbricate ament. *Corolla*: none. *Female*. *Calix*: in the same ament. *Corolla*: none. *Style*: one. *Seed*: one, roundish.—The species are,

1. *Cynomorium Coccineum*. Stipe scaly; ament cylindrical; scales imbricate, ovate, retuse. This is a fungiform plant, the whole consisting of a long, thick, radical spadix, growing upon the roots of trees in salt-marshes under water. Stem commonly half a foot long, upright, solid, tough, as thick as the finger.—Native of Barbary, on the coast, at the roots of *Lentiscus*, *Myrtle*, &c. and Sicily, Malta, Cadiz, &c. on the *Halimus*, or *Portulaca Marina*, &c.

2. *Cynomorium Jamaicense*. Stipe scaly; ament elongated; scales imbricate, halved, rhomboidal. It grows in beds, and rises generally to the height of three, four, or five inches, but is commonly smallest towards the bottom. At first it is rather thickly covered with scales of the figure of a heart, which fall off gradually as it rises, and expose the body

of the plant, closely beset with little transparent denticles, intermixed with a few tubular trifold flowers that jet above the level of the surface. The stem is succulent and fleshy, and all the parts astringent.—It is seldom met with but in the most shady inland woods; and is a native of Jamaica.

3. *Cyanoorium Cayanense*. Stipe naked; ament sub-globular; scales roundish, peltate.—Native of Cayenne.

Cynosurus; a genus of the class Triandria, order Dignia. —GENERIC CHARACTER. *Calix*: receptacle common unilateral, often leafy; involucre in some one-leaved, lateral; glume many-flowered, two-valved; valves linear, acuminate, equal. *Corolla*: two-valved; the outer concave, longer; the inner flat, awnless; nectary two-leaved; leaflets ovate-acute, gibbous at the base. *Stamina*: filamenta three, capillary; anthera oblong. *Pistil*: germen turbinate; styles two, villose, reflex; stigmas simple. *Pericarp*: none; corolla closely coating over the seed, and not gaping. *Seed*: single, oblong, acuminate to each end. ESSENTIAL CHARACTER. *Calix*: two-valved, many-flowered. *Receptacle*: proper unilateral, leafy.—Several species of this genus are natives of the West Indies, and more of the East Indies. Few of them are known in Europe, otherwise than by specimens or descriptions. They must be propagated by seeds brought from their native places, and kept in the bark-stove. Those from the Cape of Good Hope, &c. are of course preserved in the dry-stove. For the culture of the European sorts, particularly the first, see *Grass*.—The species are,

1. *Cynosurus Cristatus*; *Crested Dog's-tail Grass*. Bractes pinnatifid; root perennial; culms from one to two feet in height, erect, strict, having three or four joints, smooth, and even; leaves narrow, flat, smooth on both sides, scarcely rough at the edge; spike obtuse, stiff, and straight.—It is common in dry pastures, flowering in July and August, and is called *Bent-grass*, in common with many others; and in Scotland, *Windle-straw Grass*. Most modern writers, echoing Stillingfleet, have celebrated this grass as excellent for sheep. Mr. Curtis justly thinks less favourably of it, and considers it as greatly inferior to many other grasses. It predominates on sheep-downs, and in many parks, but is late and unproductive. Mr. Ray sets down a variety of this species, which he calls *Square-crested Grass*, because the spike has four rows of flowers: it was found at Notley in Essex.

2. *Cynosurus Echinatus*; *Rough Dog's-tail Grass*. Bractes pinnate, chaffy, awned; raceme glomerate, pointing one way; bractes only on the outside of the flowers, alternately pinnate, one-flowered; the rays ending in an awn. Annual.—Native of Europe, and the Levant. Found near Sandwich, and in a sandy part of the island of Jersey; flowering in July. Of this grass, Villars remarks, that it is incorrectly named *echinate*, for the spike is rather lanuginous than beset with prickles; he adds, that it is sometimes very tall among the corn, but that on a rock he has seen it only two or three inches high.

3. *Cynosurus Lima*; *Imbricate Dog's-tail Grass*. Spike facing one way; the inner glume of the calix lying below the spikelets. Scarcely a span in height; leaf small, the sheath swelling a little; spike closely imbricate, oblong, composed of sessile flowers, compressed, and keeled, directed one way, in a double row; culms slender, upright; seed oblong, sharp at both ends.—It is annual; flowers in England during July and August; and in May in Spain, of which country it is a native.

4. *Cynosurus Durus*; *Rigid Dog's-tail Grass*. Spicules one-ranked, alternate, sessile, rigid, obtuse, pressed close; culms few, scarcely a palm in height, procumbent; leaves

even; florêts compressed, awnless; flowering-spike straight, stiff. The plant when adult is entirely of a brown bay-colour. Annual; flowering in May, June, and July.—Native of the southern parts of Europe; in Carniola, Switzerland, the Palatinate, Silesia, and other parts of Germany.

5. *Cynosurus Sphaerocephalus*; *Round-headed Cynosurus*. Bractes entire; spikes globular. The spike resembles a head of garlic; spikelets imbricate every way, and subsessile; calix two or three flowered; glumes nearly equal, at first longer than the corolla, but afterwards shorter, blue, with white edges, ending in a sort of crest, and ciliate on the middle of the back. There is a variety, with white flowers in large heads.—Native of the Alps.

6. *Cynosurus Cœruleus*; *Blue Dog's-tail Grass*. Bractes entire; spikes subovate. Culms oblique, surrounded at the base with a bundle of root-leaves, inclosed in a whitish-brown wrinkled skin, giving the appearance of a branched root; above bare of leaves; florets on short peduncles, purplish, livid, or brownish white, from half an inch to an inch in length; calix mostly two-flowered, sometimes just longer, and sometimes just shorter than the florets; edges and keel bearded; germen reddish brown; seed hairy. This flowers the earliest of all our grasses, and would well deserve to be extensively cultivated, if it were not for its low growth.—Native of Europe, in mountainous and boggy pastures; in the north of England, upon the highest limestone rocks, as Ingleborough in Yorkshire, &c.

7. *Cynosurus Uniola*. Without bractes: spike turned one way; spikelets in two rows, alternate, pressed close, ovate, keeled, oblique. A very smooth grass.—Native of the Cape of Good Hope.

8. *Cynosurus Coracanus*; *Thick-spiked Dog's-tail Grass*. Spike digitate, incurved; calix compressed; erect; leaves nearly opposite. Annual: culms four feet high; covered with leaf stalks; spikes four or six, terminating, (sometimes one below,) striated, almost erect, the length of the finger, growing broader as they ripen, often bent in; flowers ovate, oblong, compressed, awnless; seeds nearly globular, large, in four rows, swelling, naked.—Native of India and Japan, where it is cultivated for the eatable seeds. It flowers from July to September.

9. *Cynosurus Aegyptius*; *Creeping Dog's-tail Grass*. Spikes digitate, obtuse, in fours, spreading very much, mucronate; stem creeping; leaves opposite. Culm six to nine inches long, ascending, bent at the joints, leafy; leaves two or three lines broad, rough at the edges.—Annual; flowering from July to September; and a native of Asia, Africa, and America.

10. *Cynosurus Indicus*: *Indian Dog's-tail Grass*. Spikes digitate, linear; culm compressed, declined, knotty at the base; leaves alternate. Culm slender, almost upright, reddish, sometimes creeping, leafy; leaves many, small, stiff; spikes heaped, linear, four or six, from horizontal spreading, from a thick base growing gradually more slender to the top, floriferous at bottom; valves of the calix acute; the inner longer, ciliate, lanuginose.—It flowers in August, is annual, and a native of both Indies, Japan, and the Society Isles.

11. *Cynosurus Virgatus*; *Fine-spiked Dog's-tail Grass*. Panicle with simple branches; flowers sessile, six together, the last barren, the lowest sometimes awned. Height two feet and a half, with a spreading panicle at the top, generally composed of many delicate, simple, slender spikes.—It is perennial, flowering from July to August; and a native of Jamaica.

12. *Cynosurus Domingensis*. Panicle with simple branches; spikelets subsessile, six-flowered; all the flowers awned; root

perennial; culms several, erect, from two to three feet high, round, smooth, shining, slender, jointed, leafy, frequently putting out a single branch from one of the lower joints, otherwise quite simple. It flowers and seeds in the stove during the whole year.—Native of St. Domingo.

13. *Cynosurus Aureus*; *Golden-spiked Dog's-tail Grass*. Panicles with barren, pendulous, ternate spikelets; flowers awned. Annual.—Native of the south of Europe, among stones and rocks; and of the Levant; flowering in June and July.

14. *Cynosurus Erucaeformis*; *Linear-spiked Dog's-tail Grass*. Spike compound; spikelets scattered, the fruit-bearing ones erect; calices one and two-flowered; glumes obtuse, boat-shaped; keel obtuse; corollas acuminate.—It is annual, flowers in July, and is a native of Russia and Hudson's Bay.

15. *Cynosurus Retroflexus*. Spike compound; spikelets aggregate; calices two-flowered, awned; corollas awnless. Culms round, smooth; leaves awl-shaped, a span long, smooth; flowers on one side of the rachis, compressed, smooth.—Native of the East Indies.

16. *Cynosurus Filiformis*. Spike solitary, distich; calices awl-shaped, three-flowered; barren florets awnless. Culms creeping, branched, filiform, compressed at bottom; internodes an inch long; spike an inch long, linear; flowers small, alternate, compressed, smooth; awn a little longer than the calix.—Native of the East Indies.

17. *Cynosurus Monostachyos*. Spike terminating; calices awl-shaped, awnless, subtriflorous; florets awned, one-sided. Culm upright, a foot and a half high, smooth; leaves awl-shaped narrow; spike solitary, a span long; flowers alternate, imbricate on the inner side, smooth.—Native of the East Indies.

18. *Cynosurus Penicillatus*. Spikes digitate; calices four-flowered, awned at the back; outer petals of the hermaphrodite awned, with bearded pencils. Culm round, upright, very finely streaked, pubescent at top; spikes in threes, but sometimes solitary, on very short pedicels, bearded at the base, four or five inches long, upright, sometimes a little recurved at the end; flowers from the inner side only.—Native of the East Indies.

19. *Cynosurus Paspaloides*. Spikes digitate; calices two-flowered, subglobular; outer valve of the calix awned; corollas awnless. Culm very simple, almost leafless, a foot high; spikes five, sessile, an inch and a half long, and more woolly at the base, linear, narrow, ferruginous, shining.—Observed by Bulow at the Cape of Good Hope.

20. *Cynosurus Floccifolius*. Spikes linear, straight; leaves doubled together, alternately bearded on the edge; sheaths not ciliate; leaves not hairy. It differs from all the other species, in having all the single leaves folded together, and alternately bearded.—Native of Egypt.

Cyperus; (Greater Galengale) a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: spike imbricate two ways; scales ovate, keeled, flat, inflexed, separating the flowers. *Corolla*: none. *Stamina*: filamenta three, very short; antheræ oblong, furrowed. *Pistil*: germen very small; style filiform, very long; stigmas three, capillary. *Pericarp*: none. *Seed*: single, three-sided, acuminate, destitute of villus. ESSENTIAL CHARACTER. *Glumes*: chaffy, imbricate, in two rows. *Corolla*: none. *Seeds*: one, naked.—Most of these plants are natives of the East or West Indies, and will therefore require the protection of the bark-stove.—The species are,

*With a round Culm.

1. *Cyperus Articulatus*; *Jointed-stalked Cyperus*. Culm naked, jointed. Root tuberous, red, having a very grateful

smell, like that of *Calamus Aromaticus*; stalk three feet high, smooth, with very strong and frequent transverse partitions, or membranes. At the top several brown chaffy panicles, made up of small long spikes.—It is a native of the hills of the Savannah, beyond Two-mile Wood, in Jamaica; and of Egypt, on the banks of the Nile. This, if planted in a warm situation, will thrive in the open air.

2. *Cyperus Minimus*; *Least Cyperus*. Culm naked; spikes under the tip. Roots composed of many capillary brown fibres, whence arise many small narrow leaves, an inch long, and reddish underneath.—Native of Jamaica and Brazil. The roots of this should be planted in pots, and sheltered in winter.

3. *Cyperus Lateralis*; *Lateral-spiked Cyperus*. Culm roundish, naked; spike lateral, sessile. Culms the length of a needle, many, bristle-form, not stiff. Annual.—Native of the Cape of Good Hope.

4. *Cyperus Monti*. Culm round; umbel superdecompound; leaves even on the keel. Perennial.—Native of India; lately found wild in Italy.

5. *Cyperus Tenellus*. Culm naked, setaceous; spikes solitary, and twin sessile. Culm not a finger's length, the thickness of a horse-hair; spikes below the top of the culm, compressed, ancipitate, ovate, even, with ten or twelve scales.—Native of the Cape of Good Hope.

** With a three-cornered Culm.

6. *Cyperus Monostachyos*; *Single-spiked Cyperus*. Culm naked; spike simple, ovate, terminating; scales mucronate. Root-leaves numerous, linear, very narrow, even, loose, a span in length; culm filiform, weak, scarcely a foot high.—Native of the East and West Indies.

7. *Cyperus Levigatus*. Culm naked; head two-leaved; flowers levigated. Culms even, two feet high; leaves two, stiff, convolute, subulate. Perennial.—Native of Coromandel in the East Indies.

8. *Cyperus Haspan*. Culm leafy; umbel superdecompound; spikelets umbellate, sessile. Culm a foot high, lax, yellowish, striated, tender. Perennial.—Native of the East Indies, Ceylon, and the Cape of Good Hope.

9. *Cyperus Longus*; *Sweet Cyperus*, or *English Galengale*. Culm leafy; umbel leafy, superdecompound; peduncles naked; spikes alternate. Root long, odoriferous; peduncles sometimes twelve, umbelled; the rays gradually shortening to the middle; the outer one half a foot in length; spikelets corymbd, slender, acuminate, chesnut-coloured. The root is agreeably aromatic to the smell, warm and bitter to the taste; and although disregarded by modern practitioners, it is probably not inferior to some of the more costly medicines imported from abroad. The roots of *Cyperus* are attenuants, and deobstruents, promote urine and the menses, are good stomachics, and serviceable in the first stages of the dropsy. Perennial; flowering in July.—Native of France, Germany, Italy, Sicily, and Carniola, in bogs, marshes, and ditches. It has been found in the isle of Purbeck in Dorsetshire, and near St. David's in Wales. This, and the 11th species, may be propagated by dividing the roots in spring.

10. *Cyperus Esculentus*. Culm naked; umbel leafy; tubers of the roots ovate; zones imbricate. Roots fibrous, with small round tubers or bulbs hanging from them, of the size of peas or beans; stems about eighteen inches high. The radical tubers taste like sweet filberts, and are sold in the markets of Italy and the Levant. Perennial. Native of Montpellier, Italy, Sicily, and the Levant.

11. *Cyperus Rotundus*. Culm almost naked; umbel decompound; spikes alternate, linear. Culm scarcely a foot

high, having four alternate leaves at bottom. The round tuberos knobs attached to the roots, have a similar fragrance to the ninth species, and are used in Greece to keep insects from clothes.—Native of Arabia, India, Ceylon, and Japan.

12. *Cyperus Squarrosus*. Culm naked; umbel leafy, glomerate; spikes striated, squarrose. Culms several, one or two inches high, filiform, three-sided; leaves linear, bristle-shaped, longer than the culm, embracing the base of it with purple sheaths, glaucous when young, when old ferruginous.—Native of Tranquebar, and the Cape of Good Hope.

13. *Cyperus Difformis*. Culm naked; umbel two-leaved, simple, trifid; spikes cuspidate, the middle one sessile. Culm three-sided, flaccid, very weak, a foot high, having two linear soft leaves, two inches long, of a brownish green colour, above the base, in other parts naked.—Native of India.

14. *Cyperus Iria*. Culm half naked; umbel leafy; peduncles unequal, subumbellate; floscules distinct. Peduncles in the umbel very many, umbelliferous at top; umbel of three or four rays, alternately bearing spikelets, of three-cornered and very obtuse grains, covered with a scarcely discernible chaff, and little distant from each other: it is an elegant plant.—Native of India, China, and Japan.

15. *Cyperus Elatus*. Culms naked; umbel leafy, superdecompound; spikes a finger's length, imbricate; spikelets subulate. This is a large plant, with an even culm; umbel unequal.—Native of the East Indies.

16. *Cyperus Glomeratus*. Culm naked; umbels decompound, simple, leafy; pedicels spiked in a double row. Supposed to be a variety of the preceding.—Native of Italy.

17. *Cyperus Glaber*. Culm naked, even; umbel three-leaved; flowers glomerate, the lower brachiate; leaves smooth. Culm a palm in height: root-leaves erect, wholly smooth, the length of the culm; flowers ovate, compressed, imbricate, in two rows, growing brown by age.—Annual: found in wet places about Verona and Piedmont.

18. *Cyperus Elegans*. Culm naked; umbel leafy; peduncles naked, proliferous; spikes crowded, with spreading points. Root-leaves from two to three feet and a half in length; stalk two feet and a half high, with two or three leaves on the top, one whereof is a foot long.—Native of the sea marshes in Jamaica, also of the island of Santa Cruz.

19. *Cyperus Odoratus*. Culm naked; umbel decompound, simply leafy; pedicels spiked in a double row. Root long, roundish, frequently jointed, reddish on the outside, very odoriferous, creeping, and making a large tuft, whence rise many leaves with a prominent sharp cutting keel.—It is found by river-sides in Jamaica and most of the Caribbee islands; as well as in Surinam, and the Society Isles.

20. *Cyperus Compressus*. Culm naked; universal umbel three-leaved; glumes mucronate with the sides, membranaceous. This species is distinguished by its green panicle and spikes, by its mucronate glumes, not spreading, but the side-edges membranaceous.—Native of Jamaica, Virginia, and Malabar: it is generally found in sandy pastures.

21. *Cyperus Flavescens*; *Yellow Cyperus*. Culm naked; umbel three-leaved; peduncles simple, unequal; spikes crowded, lanceolate. Fibres of the root loaded with little tubers; culms obtusely three-cornered, smooth, from an inch to a hand and a span in height; root-leaves spreading, smooth, keeled, two or three inches long, mucronate; besides these there are two or three under the umbel of unequal lengths, narrower than the others, and longer than the umbel. It is biennial, flowering from July to September.—Native of France, Germany, Switzerland, Carniola, and Piedmont.

22. *Cyperus Fuscus*; *Brown Cyperus*. Culm naked; umbel trifid; peduncles branched, unequal; spikes crowded,

linear. It scarcely differs apparently from the foregoing, in having narrower brown spikelets, and the leaves more scabrous. Root annual; culms a span in height, smooth, with two or three leaves at the base, which are keeled, smooth, and the length of the culm. It flowers from July to September.—Native of Denmark, France, Germany, Switzerland, Carniola, Piedmont, and Egypt.

23. *Cyperus Pumilus*. Culm naked; umbel two-leaved, compound; spikelets alternate, digitate, lanceolate; glumes mucronate. Culm about three inches high, with a few leaves at bottom; involucre three-leaved, unequal.—Native of the East Indies.

24. *Cyperus Triflorus*. Culm naked; umbel three-spiked, the middle one sessile; spikelets even. Culms even, a foot high.—Perennial; and a native of the East Indies.

25. *Cyperus Strigosus*. Culm naked; umbel simple; spikelets linear, very much crowded, horizontal. Root roundish; culm striated, smooth, sheathed with leaves at the bottom, a foot high; leaves channelled, entire, smooth, shorter than the culm.—Native of marshes in Japan, Virginia, and Barbadoes.

26. *Cyperus Ligularis*. Spikelets of the umbel capitate, oblong, sessile; involucre very long, serrate, and rough. Leaves many, three feet long, nearly an inch broad at bottom, ending in a point, and making a large tuft; stalks as thick as the finger, three feet high; seeds brownish-red, and shining.—Native of Barbadoes, near Bridge Town; and also of Guinea, in Africa.

27. *Cyperus Papyrus*; *Paper Cyperus*, or *Egyptian Papyrus*. Culm naked; umbel longer than the involucre; involucre three-leaved, setaceous, longer; spikelets in threes. The stem is many feet in height, terminated by a very large and compound umbel of innumerable flowers; root large and creeping; leaves sword-shaped, sheathing the lower part of the stem.—Native of Egypt, Syria, Calabria, Sicily; and found, according to Strabo, in the lake Thrasimene, near Perugia. Papyrus was called *biblus* by the Grecians; in Egypt it had the name of *el berdi*; and is said to be known in Syria by the name of *babeer*, which very nearly approaches to the sound of papyrus and paper. The general figure of this plant, as Pliny has correctly stated, resembles a thyrus; the head is composed of many small grassy filaments, each about a foot long; about the middle, each of these filament parts into four, and in the point or partition are four branches of flowers; the head of this is not unlike an ear of wheat in form, but in fact is only a chaffy, silky, soft husk; these heads, or flowers, grow upon the same stalk alternately, and are not opposite to, or on the same line with, each other at the bottom. Pliny says it has no seed: the seed is indeed very small, and by its elevated situation, and the thickness of the head of the flower, requires the extraordinary covering which protects it from the violent hold the wind must have upon it. For the same reason the bottom of the filaments, composing the head, are sheathed in four concave leaves, which keep them close together, and prevent injury from the wind getting in between them. The stalk is of a vivid green, and of a triangular form; it has but one root, which is large and strong; Pliny says, as thick as a man's arm; which it probably was when the plant was fifteen feet high, but the whole length of the stalk, including the head, being little more than ten feet in the plants we now find, they are proportionally smaller: in the middle of this long root arises the stalk at right angles, the whole inverted having the figure of a T. From each side of the large root proceed smaller elastic roots or fibres in a direction perpendicular to it, and which, like the strings of a tent, steady it, and fix it to the earth at bottom: about two feet or little more of the lower part of the stalk is

clothed with long, hollow sword-shaped leaves, covering each other like scales, and fortifying the foot of the plant; they are of a dusky brown or yellow colour. It grows in the lakes of Ethiopia and Egypt; in the river Jordan, between Puncas and the lake of Tiberias; and at the confluence of the Tigris and Euphrates; but was not probably imported into Greece until the use of it, as manufactured into paper, was first known. It does not grow in the midst of the Nile, but in the calishes or places into which that river overflows, and is stagnant: the head is too heavy, the stalk too slender, tall, and feeble, and the root too short and weak, to resist the violent pressure of wind and current in an open plain country, and a deep rapid river. The Papyrus seems to have come down from Ethiopia at a very early period, and to have been used in Upper Egypt immediately after the discontinuance of hieroglyphics. According to Varro, it did not come into general use in Greece till after the conquest of Egypt by Alexander: yet it is plain from Anacreon, Alcæus, Æschylus, and the comic poets, that it was known in their time. Plato and Aristotle speak of it, and so do Herodotus and Theophrastus; we also know that it was anciently in use among the Ionians, who probably brought it in very early days directly from Egypt: Numa, who lived three centuries before Alexander, is said to have left a number of books written on Papyrus. The ancients divided this plant into three parts: the top, with the thyrses of flowers, adorned the temples, and crowned the statues of their gods; and Agesilaus, the Spartan king, preferred this crown before any other, on account of its simplicity. Antigonus made use of nothing else but the stalk, for ropes and cables to his fleets, before the use of spartum became known, which, though very little better, still serves that purpose in small ships on the coast of Provence to this day. The top of the Papyrus was likewise used for caulking the vessels, by forcing it into the seams, and afterwards covering it with pitch. Pliny tells us, that the whole plant together was used for making boats, a piece of the Acacia-tree being put in the bottom to serve as a keel, and this is still the only boat used by the Abyssinians, who call it *tancoa*. Probably the junks of the Red Sea, said to be made of leather, were first built with Papyrus, and covered with skins. The bottom, root, or woody part of this plant, before it turned hard, was chewed for the sweet juice contained in it; indeed the Abyssinians still chew it, as well as the root of the Indian corn, and every species of Cyperus. Herodotus states, that about a cubit of the lower part of the stalk was roasted over the fire and eaten. On account of the great scarcity of wood in Egypt, this lower part was likewise used in making cups, moulds, and other utensils, as also for boards or covers to their hooks. Paper was prepared from it in the following manner: the thick part of the stalk being cut in half, the pellicle between the pith and the bark, or perhaps the two pellicles, were stripped off, and divided by an iron instrument, which probably was sharp-pointed, but did not cut at the edges; this was squared at the sides, so as to be like a riband, then laid upon a smooth table or dresser after being cut into the lengths required for each leaf: these stripes or ribands were lapped over each other by a very thin border, and then pieces of the same kind were laid transversely, the length of these last answering to the breadth of the first; a weight was then laid on them while moist, and they were thus left to dry in the sun. It was supposed that the water of the Nile had a gummy quality in it; but this is without foundation, as the saccharine juice of the plants causes the adhesion of the stripes, and the water merely serves to dissolve and diffuse that juice. Paper, says the Abbé Rochon, is manufactured in Madagascar from the

Papyrus, which the natives call *sanga-sanga*. They pull off with great dexterity the inner bark, divide it into very thin filaments, which they moisten with water, and, having laid them across each other in various directions, press them well down; they are then boiled in a strong lye of ashes, and afterwards pounded in a strong wooden mortar till they are reduced to a paste: this paste is washed and drenched with water, upon a frame made of bamboos in the form of a grate. When this operation is finished, the leaves are spread out to dry in the sun, and are glazed with a decoction of rice-water. This paper is of a yellowish colour, but when it is well glazed does not imbibe the ink. The pens used by these islanders are made of the bamboo; their ink, from a decoction in boiling water of the bark of a tree which they call *arandrato*: this ink is not so black as the European, but more shining. As however, the Abbé Rochon unfortunately calls the Papyrus *Nilotica a tree*, we cannot judge with certainty from what materials the Madagascar paper is really made.

28. *Cyperus Spathaceus*. Culm clothed with sheaths of leaves; peduncles pinnate, lateral. Size of the Sugar-cane.—Perennial: native of Virginia, and the Cape.

29. *Cyperus Alternifolius*. Culm naked, alternately leafy at the end; peduncles lateral, proliferous. Culms a foot high; leaves at the top crowded, ensiform, half a foot long, even, roughish at the edge; a small subulate bracte from each axil. It flowers in February and March.—Native of the island of Madagascar. Perennial.

30. *Cyperus Denudatus*. Involucre scarcely any. Culm two feet high, with one sheath in the middle of it; umbel compound, not much expanded.—Native of the Cape.

31. *Cyperus Distans*. Culm naked; umbel leafy, superdecumbent; spikes alternate, filiform; floscules distant. Root tuberous; culm two feet high, three-sided, striated, yellowish; leaves alternate, lanceolate, keeled, reflex, glaucous, investing the lower half of the culm with their sheaths.—Native of Malabar.

32. *Cyperus Pannonicus*; *Dwarf Cyperus*. Culm obscurely three-cornered, prostrate; spikes about four together, sessile. Root annual; the whole plant smooth and shining; culms in a very thick tuft, from half an inch to six inches in length, leafless scales membranaceous, roundish, blunt, pale with green streaks; seeds pale bay, smooth.—Native of Hungary. Annual; flowering in July and August.

*** *New Species*.

33. *Cyperus Viscosus*; *Clammy Cyperus*. Culm three-sided, clammy; leaves rough, triangular at the tip. Perennial; flowering from May till August.—Native of Jamaica.

34. *Cyperus Pygmæus*. Culm round; umbel compound, involucred; spikes lanceolate; glumes mucronate. Root-leaves filiform, twice as long as the culm, which is striated, and scarcely an inch and half in height; umbel with five or six umbellulate peduncles; involucre four-leaved, three times as long as the umbel.—Native of the sands of Tranquebar.

35. *Cyperus Arenarius*. Culm compressed, naked; spikes of the head glomerate, sessile; involucre one or two-leaved. Roots jointed, creeping, from which proceed bunches of leaves sheathed at the base; leaves filiform, naked, from three to six inches long, compressed, striated, channelled on one side, yellowish-green.—Native of loose sands in the East Indies.

36. *Cyperus Capitatus*. Culm subangular, striated, leafy in the middle; head terminating, three-leaved; spikes sessile.—Culm four inches long, compressed, with a leaf or two at the base, and a bunch of leaves in the middle; glumes imbricate, scariose, ending in a recurved daggered point somewhat awned.—Probably a native of the East Indies.

37. *Cyperus Stoloniferus*. Culm naked, three-cornered; umbel compound, involucred; spikelets lanceolate. Root bulbous; leaves narrow, linear, complicate, a hand or half a foot in length; culm a span in height; involucre one or two-leaved, the longer an inch and half in length, the shorter half an inch long; besides these there is another leaf or two still shorter; they are all subulate and striated.—Native of Tranquebar in the East Indies.

38. *Cyperus Pangorei*. Culm three-cornered, leafy at the base; involucre three-leaved; universal umbel decomposed; partial ones subtrifid. Culm two feet and a half high.—Native of Tranquebar.

39. *Cyperus Cinnamomeus*. Culm three-cornered; leafy; umbel consisting of spikelets in a head, peduncled, and sessile; involucre five-leaved, serrulate-scabrous. Root annual; culms three feet high, solitary, leafy at the base, naked above; leaves longer than the culm, nearly half an inch broad, plaited, with an unarmed keel; heads ovate, compound, cinnamon-coloured.—Native place unknown.

40. *Cyperus Setaceus*. Culm setaceous, striated, angular, naked; spike terminating, with about four flowers, and naked. Culms in bunches, three or four inches long, very slender; leaves none; glume purplish; style trifid; seed whitish, turbinate, somewhat wrinkled; the angles rise above the seed with a truncated dagger point.—Frequently found in the neighbourhood of Calcutta.

41. *Cyperus Compactus*. Culm round, leafy; umbel decomposed; involucre five-leaved; spikelets heaped, subspiral. Culm two feet or more in height; leaves nearly as long as the culm, linear, with purplish sheaths, the edge and keel unarmed, striated; the longest leaf of the involucre a foot and half in length, the shortest three inches, all scabrous about the edge; umbellules three or five rayed.—Native of China.

42. *Cyperus Mucronatus*. Culm round, naked; spikes lateral, sessile; involucre one-leaved. Culms a foot high, with brown truncate sheaths at the base; one or two root-leaves short and narrow; head composed of a few sessile spikes, placed an inch and half from the end of the culm; involucre scarcely longer than the spikes; scales ovate, acute, convex, whitish.—Native of Visagapatnam in the East Indies.

43. *Cyperus Diphyllus*. Culm subtriangular, two-leaved; umbel superdecompound; spikelets roundish, subpinnate. Culm six feet high; umbel terminating, four inches long; involucre of many short acute leaves; peduncles compressed; a lanceolate whitish involucre under each partial peduncle; spikelets acute, pale, having about twelve flowers; scales imbricate, ovate, acute, striated.—Native of the East Indies.

44. *Cyperus Leucocephalus*. Culm setaceous, three-cornered, naked; head sessile; involucre four-leaved, or thereabouts, spreading very much; flowers one-stamined. Root bulbous, oblong; culms six inches high; leaves even, half the length of the culm; head small, snow-white; spikes eight to twelve, sessile, broad, ovate; scales linear, compressed, the lowest long, the upper ones gradually shorter, obtuse, striated; stigmas three, villose; seed long, linear, black.—Native of the East Indies.

45. *Cyperus Exaltatus*. Culm three-cornered, one-leaved at the base; umbel superdecompound, many-leaved; spikelets linear, peduncled. Culm five feet high, striated; root-leaf nearly three feet long, flat, striated, rough about the edge; umbel more than a foot high, fastigate; involucre many-leaved, the longest leaf two feet in length, the others decreasing to an inch, all rough about the edge; umbellules many-rayed, the rays unequally divided and compounded; involucre unequal in number, short, filiform; spikelets compressed, ferruginous on the sides, having twenty flowers in

them; there are two minute scales at the base of the pedicels; scales compressed, acute, keeled; seed white.—Native of Tranquebar in the East Indies.

46. *Cyperus Niveus*. Culm three-cornered, filiform, naked; umbel terminating, sessile, two-leaved; spikes compressed, lanceolate. Culms a foot and a half in height, striated; root-leaves few, short, narrow; sheath entire, with a short obtuse ligule opposite to the leaf; umbel composed of snow-white spikes, usually sessile; involucre reflex, longer than the head; spikes half an inch in length, with thirty flowers in some; glumes compressed, keeled, striated; seed black, like Buck-wheat.—Native of the East Indies.

47. *Cyperus Imbricatus*. Culm three-cornered, naked; umbel decomposed; rays of the umbellules imbricate; involucre six-leaved, with three leaves very long, and three very short. Umbel unequal, four inches long, some of the umbellules sessile, others on peduncles of three inches and a half in length; no involucre; spikelets convex on both sides, compressed longitudinally in the middle, lanceolate, scarcely two inches long, having from twelve to twenty flowers, yellowish brown and pedicelled; scales imbricate, broad, ovate, acute, with membranaceous edges.—Native of Tranquebar.

48. *Cyperus Cruentus*. Culm three-cornered, and one-leaved at the base; umbel terminating, two-leaved, very simple. Culm four or five inches high, filiform; leaf linear, shorter than the culm; spikelets from two to ten, lanceolate, sanguineous, brown, two to three lines long; involucre two-leaved, four times as long as the umbel.—Native of Tranquebar.

49. *Cyperus Nitens*. Culms three-cornered, leafy at the base; umbels almost simple; involucre three-leaved; flowers one-stamined. Culms many, an inch or two in height; leaves two to four, linear, longer than the culm; umbel glomerate, some of the spikes simple, others forming an almost sessile umbellule; the longest leaf of the involucre an inch and half in length, the others gradually shorter; spikelets linear, narrow, shining, whitish, but longitudinally brown in the middle, with the scales diverging at top, and from ten to fourteen flowers; scales ovate, compressed, keeled, striated, hyalinous, with a green keel, obtuse, with an acumen; stamina one; seed ash-coloured.—Native of Tranquebar.

50. *Cyperus Flavus*. Culm three-cornered, striated; umbel compound, three-leaved; spikes lanceolate; flowers one-stamined. Culms half a foot in height, one leaved; root leaves in bunches, short, narrow; some spikes of the umbel sessile, others in umbellules; involucre erect, three or four times as long as the umbel, linear; about twenty-six flowers in the spikes; scales scariosa, purplish on both sides, separate, narrow.—Native of Tranquebar.

51. *Cyperus Venustus*: 52. *Cyperus Stuppeus*: 53. *Cyperus Linctus*.—Native of the Society Islands.

Cyperus, Summer. See *Chenopodium Scoparia*.

Cypripedium; a genus of the class Gynandria, order Dianthia.—GENERIC CHARACTER. *Calix*: spathes vague; spadix simple; perianth none. *Corolla*: petals four or five, lanceolate-linear, very long, spreading, erect; nectary within the lower petal, slipper-form, inflated, obtuse, hollow, shorter than the petals, broader; upper lip ovate, flat, inflex, small. *Stamina*: filamenta two, very short, seated on the pistil; antheræ erect, covered by the upper lip of the nectary. *Pistil*: germen long, twisted, inferior; style very short, growing to the upper lip of the nectary; stigma obscure. *Pericarp*: capsule obovate, obtusely three-cornered, with three sutures, under which it gapes in the corners, three-valved, one-celled. *Seeds*: numerous, very small; receptacle linear, growing lengthwise to each valve of the pericarp.

ESSENTIAL CHARACTER. *Nectary*: ventricose, inflated, hollow.—Every plant of this genus is difficult to preserve in gardens: they must be planted in a mixture of bog-earth with much loam, in a shady moist situation, where they may have the morning sun only; they must be procured from the places where they naturally grow, for they cannot be propagated in gardens. The roots should be seldom removed, for transplanting them prevents their flowering. The American sorts require a little shelter in severe weather.—The species are,

1. *Cypripedium Calceolus*; *Common Lady's Slipper*. Roots fibrous; leaves ovate-lanceolate on the stem; petals acuminate; root composed of many fleshy black fibres, spreading obliquely near the surface, the fleshy part retaining the mark of the stalk produced the former year, a new root being annually formed on the side of the old one; stalks two, three, or more, in proportion to the strength of the root, nine, ten, or twelve inches high, and a little hairy; leaves from three to near four inches long, and near two inches broad at their base, of a deep green, and ending in acute points: four or five of these leaves are placed alternately along the stalk: in the bosom of the upper leaf is enclosed the flower-bud, supported by a slender peduncle, which generally turns a little on one side, and advances above the sheath before the flower opens; the corolla has four narrow petals of a dark purple colour, placed in the form of a cross, and spreading wide open: in the centre the nectary is situated, shaped like a wooden shoe, of a pale yellow colour, with a few broken streaks; the opening is covered with two ears, the upper one tender, white, and spotted with purple, the lower thick, and of an herbaceous colour. The lower leaves sheathe, the upper embrace the stem, they are marked with seven or nine principal parallel nerves, and numerous intermediate ones, fringed with short hairs on both sides. There is a variety which rises with a stalk nearly a foot and half high, which has longer and smoother leaves than the European sort, and is a native of Virginia, and other parts of America; where there is also another variety found, which is of the same height as the former, but has the leaves of an oblong oval form, and is called the *moccasin flower*. The old English name of this plant was *Our Lady's shoe* or *slipper*, from the Latin *calceolus Dominae Mariae*, or *Marianus*; and it is the same in the other European languages; in German, *Marienschuh*; in French, *sabot de la Vierge*, or *soulier de Notre Dame*; in Italian, *pontoffala*, or *scarpa della Madonna*, &c.—It is a native of Lapland, Sweden, Switzerland, Savoy, Piedmont, Germany, Hungary, Poland, &c. In the woods and thickets of the north of England, it is rarely found. Parkinson and Ray remarked its growing in Helk's wood, Lancashire, and near Ingleborough in Yorkshire; but Mr. Woodward has sought there for it in vain, a gardener of Ingleton having eradicated every plant for sale. Mr. Miller found it in the park of Borough Hall in Lancashire. Found also about Clapton and Ingleton, in the neighbourhood of Kilnsey, and about Kilnsey Crag, in Yorkshire; and near Castle Eden-dene in the county of Durham. It flowers at the end of May, and the stalks decay to the root in autumn, new ones rising in the following spring.—It succeeds very well in a pot, set under a hedge, where it has the morning sun only, and will last thus for many years; the roots will spread so as to fill the pot, and the plant may be propagated by parting the roots, but it must be done with caution. The gardeners, says Dr. Stokes, might make the botanists amend for rooting out these rare wild plants in their natural places of growth, and at the same time enrich themselves, if they would prove by experiment that one at least of the orchis tribe may be raised from seed.

2. *Cypripedium Bulbosum*; *Bulbous Lady's Slipper*. Bulb roundish; leaf roundish at the root. Root a bulb, throwing out a few thick fibres from its lower part, and invested with a semitransparent, acute, erect membrane, rising far above its top; leaf radical, solitary, petioled, oval, somewhat pointed, entire, ribbed, smooth, dark green, spotted with brown, very like the *Dog's-tooth Violet*; stalk three inches high, erect, round, one-flowered, invested with two tubular membranaceous sheaths; bracte solitary, not far from the flower, linear-lanceolate, acute, purplish; flower a little inclined; petals five, all pointing upwards, spreading, lanceolate, acute, three-nerved, purple, three on the outside of the other two; lower lip of the nectary as long as the petals, very large, pendulous, streaked with purple, having a prominent cloven point in the forepart beneath, gaping above, with a spreading, reflex, dependent margin, and bearded in the orifice with a little tuft of yellow hairs; the upper lip shorter than the petals, erect, broad, oval, entire, almost of the same substance and colour with the petals.—Native of Lapland, Russia, Siberia, and Nova Scotia.

3. *Cypripedium Japonicum*; *Japanese Lady's Slipper*. Leaves on the stem roundish, nearly opposite, nerved. Stem round, erect, villose, a foot high; leaves in the middle of the stem, two, embracing, acute, sinuate-waved, smooth, a hand broad; below the flower, a sessile, solitary, oblong, acute, entire leaflet, scarcely an inch in length; flower terminating, solitary, of the same size as in the common species.—Native of Japan, where it flowers in April and May.

4. *Cypripedium Album*; *White Lady's Slipper*. Roots fibrous; leaves ovate-lanceolate on the stem; petals obtuse. This species derives its name from the whiteness of its petals. The large nectary is tinged with purple. It is the most magnificent flower of the genus to which it belongs; and hence, Mr. Salisbury justly names it *spectabile*, for there are few flowers, that to such singularity of structure add such elegance and beauty.—It grows spontaneously in the woods, in various parts of North America.

5. *Cypripedium Acaule*; *Two-leaved Lady's Slipper*. Roots fibrous; leaves oblong at the root. It rarely has more than two radical leaves; a very short flowering stem, compared with the others; a large nectary in proportion to the size of the plant, divided on its upper part throughout its length, so as in a great degree to destroy that shoe or slipper-like form, from which this genus has taken its name.—It flowers with us in May; and is a native of North America.

Cyrilla; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth superior, five-leaved, permanent; leaflets linear-lanceolate, acute, spreading. *Corolla*: one-petalled, funnel-form; tube cylindrical, subcompressed, inflated, declined, straight, larger than the calix; border almost equal, inclined, five-parted; parts rounded, revolute, spreading; the three lower more produced. *Stamina*: filamenta four; the two lower longer, filiform; then capillary, incurved, converging, finally spiral, thickened at the base, inserted into the lower margin of the corolla, shorter than the tube; antheræ ovate, two-celled, peltate, distinct before flowering-time, but afterwards united into a square, white. *Pistil*: germen half emerging, conic at top, with a nectareous lid, below turbinate, villose; style filiform, pubescent, becoming bent down, the length of the stamina; stigma two-lobed. *Pericarp*: capsule turbinate, half two-celled; partitions two, extending half way, each ending in a two-parted receptacle. *Seeds*: numerous, small. **ESSENTIAL CHARACTER.** *Calix*: superior, five-leaved, linear-lanceolate. *Corolla*: declined, funnel-form; tube cylindrical, gibbous on its lower edge; throat tricallous; border inclined,

five parted; segments roundish, the three lower more produced; filaments inserted into the margin of the corolla, incurved, with a fifth barren; antheræ cohering. *Germen*: inferior, half emerging, with a nectareous lid; style bent down; stigma two-lobed. *Capsule*: half two-celled, with two parted receptacles; seeds numerous.—The only known species is,

1. *Cyrilla Pulchella*. A handsome plant: root branched, fibrose, stoloniferous. The young shoots resemble aments or catkins, are cylindric and closely imbricate, with ovate pubescent scales, thickened at the base, emarginate, and red; stems several, almost upright, branched, round, extremely villose, dusky purple, herbaceous; branches ternate, spreading; stem-leaves in threes, on the branches usually opposite, petioled, ovate or ovate-lanceolate, sharp at both ends, loosely serrate, entire at the base, with nerves prominent below, grooved above, villose on both sides, bright green, beneath paler, and very frequently blood-red; petioles round on one side, on the other flattish, and slightly channelled, one-third of the length of the leaves; flowers resembling those of *Ruellia*, axillary, solitary, peduncled, inclined, of the most vivid scarlet; peduncles spreading very much, round, villose, red, twice the length of the petioles; calix villose, ending in a turbinate germen, red at the base. It flowers in England at the end of summer and the beginning of autumn.—Native of Jamaica. It must be kept in the bark-stove, and may be propagated by suckers, but never produces seed in England. In the West Indies, where it thrives best in a cool moist gravel mixed with rich mould, it well deserves to be cultivated for its beauty and elegance.

Cyrtanthus; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: one-petalled, club-shaped, bent, six-cleft at top; segments ovate-oblong; the three inner blunt, the three outer terminating in a little horn. *Stamina*: filaments six, fastened to the tube, filiform-subulate, a little shorter than the corolla; antheræ oblong, erect. *Pistil*: germen inferior, ovate, obtusely three-cornered; style filiform; the length of the corolla; stigma trifid. **ESSENTIAL CHARACTER.** *Corolla*: tubular, club-shaped, crooked, six-cleft; segments ovate, oblong. *Filamenta*: inserted into the tube, converging at top.—These plants may be increased by offsets or seeds, but the former is much the best method; they require the same treatment as other bulbs from the Cape.—The species are,

1. *Cyrtanthus Angustifolius*; *Narrow-leaved Cyrtanthus*. Leaves obtusely keeled, straight; flowers drooping, narrow, purple, with a bent tube, from which latter circumstance it takes the name. The small glandular hook at the extremity of each alternate segment of the corolla, is deserving of notice.—It flowers from May to July; and is a native of the Cape.

2. *Cyrtanthus Obliquus*; *Oblique-leaved Cyrtanthus*. Leaves flat, oblique; flowers pendulous. This plant is singular for its oblique long leaves; flowers purple, variegated with orange and green; tube turbinate; border bell-shaped, erect.—It flowers from May to July, and is a native of the Cape.

Cytinus; a genus of the class Gynandria, order Octandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, tubular, bell-form, permanent; tube cylindric; border patulous, four-parted, somewhat obtuse, coloured. *Corolla*: none. *Stamina*: sixteen; filaments none; antheræ oblong, growing to the tip of the style under the stigma, oblong, two-valved. *Pistil*: germen inferior, rounded; style cylindric, length almost of the calix; stigma eight-cleft, gibbous, obtuse. *Pericarp*: berry crowned, roundish, coriaceous, eight-celled; seeds numerous, minute, roundish. **ESSENTIAL**

CHARACTER. *Style*: one. *Calix*: four-cleft, superior. *Corolla*: none. *Antheræ*: sixteen, sessile. *Berry*: eight-celled, with many seeds.—The only species is,

1. *Cytinus Hypocistis*; *Rape of Cistus*. A parasitical plant, growing at the root of the *Cistus*; leaves sessile, closely imbricate; flowers terminating, heaped; below the flowers are two opposite scales, becoming purple by age. The colour of the flower itself is a dirty yellow. The number of antheræ, and the divisions of the stigma, vary; the number of the antheræ is double the divisions of the stigma.—It is an annual plant, and a native of the county of Nice, Spain, Portugal, and Barbary.

Cytisus; (*Trefoil Tree*) a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, bell-form, short, obtuse at the base; mouth two-lipped; upper-lip two-cleft, acuminate, lower three-toothed. *Corolla*: papilionaceous; standard ovate, rising upwards, sides reflex; wings the length of the standard, straight, obtuse; keel somewhat bellied, acuminate. *Stamina*: filaments diadelphous, (single and nine-cleft), rising upwards; antheræ simple. *Pistil*: germen oblong; style simple, rising upwards; stigma obtuse. *Pericarp*: legume oblong, obtuse, attenuated at the base, stiff. *Seeds*: a few, kidney-form compressed. **ESSENTIAL CHARACTER.** *Calix*: two-lipped; upper lip two-cleft, lower three-toothed. *Legume*: attenuated at the base.—All the species of *Cytisus* are shrubs without spines, most of them very fit for ornamental plantations. They are chiefly hardy; the leaves ternate; the flowers, except in the twelfth, yellow, and growing in bunches.—The species are,

1. *Cytisus Laburnum*; *Laburnum*, anciently called *Beautrefoil Tree*. Racemes simple, pendulous; leaflets ovate oblong. The common height of the *Laburnum* is from eight to fifteen feet; but in a good ground, and when planted thick, it will run up much higher; leaves ternate, on long petioles, commonly three together from one point; leaflets quite entire, smooth, and pale green on the upper surface, glaucous, and covered with short appressed hairs on the lower, which has a strong prominent nerve or mid-rib. The flowers come out from the same short spurs with the leaves, in naked, handsome, villose racemes, a span in length; and beyond these, young shoots are produced, which are white, and bear the ternate leaves singly. Each flower hangs from a long pedicel; calix yellowish, small, two-lipped; the upper lip cloven, the lower having three minute teeth; corolla pale yellow; standard broad, emarginate, with dusky spots and dots within at the base; wings longer than the keel, hooked; keel in two parts; stamiferous sheath in one piece, the two upper filaments standing crosswise; germen smooth; legume from an inch to nearly two inches in length, covered with white appressed hairs, containing from one or two, to six or seven ripe seeds, which are black and shining, several at one or both ends are frequently abortive. There are two varieties of *Laburnum*: the first broad-leaved, which formerly was more common in the English gardens than it is at present; and the second, narrow-leaved, which having much longer spikes of flowers, makes a finer appearance, and has in a manner supplanted the other from our ornamental plantations. The first, however, grows to be the largest tree, and the wood of it is very hard, of a fine colour, and will polish very well; it approaches nearly to green ebony, and is called *ebony of the Alps* by the French, for the Swiss use it for many kinds of furniture; but in England there are few of these trees that have been suffered to stand long enough to arrive to any considerable size; for as they have only been looked upon as ornamental, the frequent alterations which

most of the gardens in England have undergone, have occasioned their destruction; but in some of the old gardens in Scotland, where they have been permitted to stand, there are large trees of this kind, fit to cut down for the use of the timber. Even where it had been broken and injured, it has been observed to girth more than a yard, at six feet from the ground; and if properly treated, would, of course, have been much larger. It grows fast, and is extremely hardy, and may therefore be well worth propagating upon poor shallow soils, and in exposed situations. The Duke of Queensbury sowed a great quantity of the seeds of this tree, upon the side of the downs, at his seat near Amesbury in Wiltshire, where the situation was very much exposed, and the soil so shallow that few other trees would grow; yet even here, the young trees were twelve feet high in four years' growth, and became a shelter to the other plantations, for which purpose they were designed; but as the hares and rabbits greatly injure these trees by feeding upon the bark in winter, they should be fenced, if possible, from these animals. On this account, however, Mr. Boucher ingeniously suggests, that the Laburnum is very proper to sow in plantations infested with hares and rabbits, who will not touch any other plant while a twig of Laburnum remains. And although they eat it to the ground in winter, yet it will spring again the next season, and thus constantly supply these mischievous animals, so that *five shillings worth* of Laburnum-seed will effectually secure a whole plantation from their destructive depredations. But the Laburnum is not only useful in preserving more valuable trees; the wood is very strong, and is much used for pegs, wedges, musical instruments, handles of knives, and a variety of furniture. Mr Boucher informs us, that he had seen a large table and a dozen chairs made of it, which judges of elegant furniture thought the finest they had ever seen. Pliny has remarked, that its wood is the hardest of any, next to Ebony; and Matthioli speaks of its being used for making the best bows. It chars remarkably well; and, if planted thick to run up tall, would make durable hop-poles. For this purpose, it might be planted in large clumps in parks, where it would be also very ornamental; the branches being generally loaded with long strings of flowers hanging down from every part of them in the month of May. Haller says, it is very bitter, and that the seeds purge and vomit violently. He also remarks that the Latin name *Laburnum* was evidently formed from the Alpine name *l'aubours*. It was formerly called *beau-trefoil*, and *peascod-tree*, in England; but the Latin name has superseded these. The Germans call it *bohnenbaum*; and the French, *cytise des Alpes*, *aubours*, and *faux-ebenier*.—It is a native of Switzerland, Austria, and Provence. It is easily propagated by seeds, which the trees produce in great plenty. If they be sown upon a common bed in March, the plants will appear by the middle or end of April, and will require no other care but to be kept clear from weeds during the following summer; and if the plants be too close together they should be transplanted in the autumn following, either into a nursery, where they may grow a year or two to acquire strength, or into the places where they are designed to remain. Where they are cultivated for timber, it will be the best method to sow their seeds upon the spot where they are intended to grow, because these trees send out long, thick, fleshy roots to a great distance, penetrating even gravel and rocks; and if their roots be cut or broken, it generally retards their growth; therefore, when they are not sown upon the intended spot, they should be transplanted thither young, otherwise they will not grow half so large, as the removing them twice will stop their growth, and cause them to be more productive in flowers: hence all trees intended for timber

are much better sown on the ground where they are designed to stand, than if transplanted into it from another place. If the seeds of these trees be permitted to scatter in winter, the plants will rise in abundance in the following spring; so that a few trees will soon supply any person with a sufficient number of the plants.—There is a variety with variegated leaves, which can only be continued by cuttings or layers; the cuttings should be planted in autumn, when the leaves begin to fall; and the plants must have a poor soil, for in good ground they are apt to become plain. The Laburnum however will thrive upon many different soils, and in such situations as few other trees will make any progress in, especially in a poor hungry soil, where, if there be any depth, it will increase surprisingly. Mr. Boucher recommends the seedling plants to be removed to the nursery in February or March, shortening their roots, which are not injured by cutting them freely when young, and planting them two feet and a half distant from row to row, and a foot asunder in the rows, there to remain during two seasons. Hence they may be removed either in October or February, still reducing the downright roots, and smoothing the extremities of those which spread, pruning off all ill-placed side-branches, but leaving some of the smallest at proper distances. The rows may now be five feet apart, the plants two feet asunder; and here they may remain three or four years: but these directions are more adapted to raising trees for ornamental plantations than for use. If they be designed for poles, they should be kept to smaller distances. The autumn after they are sown, they may be pricked out three or four inches apart, and the following spring to the distance of nine inches or a foot, there to remain three or four years, according to their growth; when they may be removed, being fourteen or sixteen feet high, to the places where they are designed to remain, only shortening the lateral roots, and just topping the tap-root, and they will then run up with few lateral branches, to the height of from twenty to forty feet.

2. *Cytisus Nigricans*; *Black Cytisus*. Racemes terminating, erect; calices hairy, with minute toothlets; leaflets elliptic, hairy underneath. This shrub seldom exceeds three or four feet high in England; it naturally puts out many lateral branches near the ground, which spread out on every side, forming a low shrubby bush, which is with difficulty raised to a stem. The branches are very slender, and their ends are frequently killed in severe winters. The leaves grow by threes, are equal in size, and of a dark green colour. The branches grow erect, and are terminated by bunches of yellow flowers, about four or five inches in length, and making a fine appearance.—Native of Austria, Hungary, Silesia, and Italy. This, with the third, seventh, ninth, eleventh, twelfth, thirteenth, and seventeenth species, may be propagated by seeds, which should be sown upon a bed of light earth in March, covering them about one-third of an inch with fine screened mould; and in the beginning of May the plants will appear, when they must be carefully weeded, which is all the culture they require till autumn, when it will be very proper to arch the bed over with hoops, that in frosty weather the plants may be covered with mats, to prevent their tender shoots from being killed; for as these young plants are apt to continue growing later in the autumn than those which are become woody, they are much more susceptible of cold; and if some care be not taken to cover them in severe winters, many of them may be entirely destroyed, and others killed to the ground. In the next spring after the danger of hard frost is over, they should be carefully taken up, and planted out at the distance of one foot row from row, and six inches asunder in the rows; they should

be placed in a sheltered situation, and as they do not shoot till late in the spring, they need not be transplanted before the end of March or the beginning of April; and if the season should then prove warm and dry, it will be proper to give the plants some water, to settle the earth to their roots; and if the drought continue, and the waterings are three times repeated at a week's interval from each, it will be of service to the plants. When they have taken new root, they will require no further care, but to keep them constantly clean from weeds: in this nursery, the plants may remain two years, in which time they will have acquired strength enough to be transplanted where they are to remain.

3. *Cytisus Wolgaricus*; *Winged-leaved Cytisus*. Hoary: racemes simple, erect; flowers pointing the same way; leaves pinnate; leaflets roundish; stipules subulate. This is a very handsome shrub, scarcely growing two feet high. The leaves have from three to nine, but usually six or seven pairs of leaflets, terminated by an odd one; they are smooth above, silvery beneath, and mostly orbiculate. The flowers are large, and of a deep yellow colour, in axillary and terminating racemes, erect on peduncles much longer than the leaves, about ten in number, generally opposite, or nearly so, in pairs, with a small acuminate bracte to each pedicel; calix and pedicels lanuginose, and having reddish glutinous glands scattered over them; seeds large, gray, testaceous, variegated.—Native of Siberia, in the deserts between the Tanais and the Wolga. See the second species.

4. *Cytisus Sessilifolius*; *Common Cytisus*. Racemes erect; calices with a triple bracte; floral leaves sessile. This rises with a woody stalk, putting out many branches, covered with a brownish bark; leaflets obovate, ternate, on very short petioles; flowers in close short terminating racemes, of a bright yellow colour; legumes short and broad. This shrub rises to the height of seven or eight feet, and becomes very bushy. It is easily known by its smoothness, the uprightness of the stalks and racemes, and particularly by the triple bracte immediately below the flower. Ruminating animals greedily devour the leaves and young branches of this species, while the goat alone will feed upon the Laburnum.—Native of the south of Europe. This is a hardy plant, that will thrive in any situation, and almost in any soil that is not too wet. It is propagated by seeds, which may be sown upon a common bed of light earth in the spring; in autumn the plants may be removed into the nursery, where they may remain two years to acquire strength, and should then be removed to the places where they are designed to grow.

5. *Cytisus Cajan*; *Pigeon Cytisus*, or *Pigeon Pea*. Racemes axillary, erect; leaflets sublanceolate, tomentose, the middle one on a longer petiole. This rises with a weak shrubby stalk, eight or ten feet high, sending out many side-branches, which grow erect. The flowers come out from the side of the branches, singly or in clusters; they are of a deep yellow colour, and about the size of those of the common Laburnum. The Pigeon-pea is frequently planted in the West India islands, chiefly in rows, as a fence to the sugar plantations, and will thrive on barren lands. The seed is much eaten by poor people and negroes, and is esteemed a wholesome pulse; even the better sort of people in the island of Martinico hold it in estimation, and prefer it to the European pea. In Jamaica it is chiefly used for feeding pigeons; whence its name. The branches, with the ripe seed and leaves, are given to feed horses, cattle, and hogs, which grow very fat upon them.—Native of both Indies, and of Africa, whence they are supposed to have been originally brought to the West Indies, where they are called *Angola-peas*, and *pois d'Angola*. It grows only in hot countries, and cannot be pre-

served in England, except in the bark-stove. It rises easily from seeds in a hot-bed, and will grow three or four feet high the first year, provided it have proper heat; and in the second year the plants will produce flowers and seeds.

6. *Cytisus Hirsutus*; *Hairy or Evergreen Cytisus*. Peduncles simple, lateral; calices hirsute, trifid, obtuse, ventricose, oblong. This plant has a soft shrubby stalk, dividing into many branches, which grow erect, and frequently rise to the height of eight or ten feet; the stalks, branches, and leaves are very hairy; the leaves are ternate, ovate, and placed closely on the branches; the flowers come out from the side of the stalk, in short racemes; they are of a pale yellow, appearing in June, and are succeeded by long, narrow, hairy legumes, which ripen in September.—Native of the south of Europe and Siberia. This may be propagated in the same manner as has been directed for the second sort; but as it is sometimes killed in severe frosts, it should be planted only on a dry soil, and in a warm situation; it is also very difficult to remove, when grown to any size.

7. *Cytisus Capitatus*; *Cluster-flowered Cytisus*. Flowers in heads; branches erect, strict, round, villose; leaves ovate-elliptic, villose; bracte linear beneath the calix. It differs from the preceding, in having most of the flowers terminating in a genuine head; the leaves more obtuse and hairy on both sides; the stems scarcely ever a cubit in height, and extremely hirsute. Native of Austria, Carniola, and Silesia. See the second species.

8. *Cytisus Austriacus*; *Siberian Cytisus*. Flowers in umbels terminating; stem erect; leaflets lanceolate. This has a shrubby stalk, which rises nearly four feet high, dividing into many branches, which, when young, are covered with a green bark; the flowers are produced in close heads at the ends of the branches, having a cluster of leaves under them; they are of a bright yellow colour, appear in the beginning of May, and are sometimes succeeded by short woolly legumes, containing three or four small seeds.—Native of Austria, Hungary, Silesia, Italy, and Siberia. This requires a cold situation, and a strong soil.

9. *Cytisus Supinus*; *Trailing Cytisus*. Flowers peduncled, about two together; leaves villose; stem decumbent, becoming shrubby. The stems of this are almost wholly procumbent, round, dusky, a little divided: the ends are closely beset with leaves and flowers, which come out together from spreading buds, formed of a few subovate simple bractes; the longer stems are frequently decorated with flowers for a foot in length; two flowers usually proceed from each bud, but sometimes only one, and rarely three or more, on short peduncles. The younger branches, the petioles, peduncles, and leaves, especially underneath, are covered with soft whitish hairs, which are frequently soft, and scarcely visible; flowers erect, deep yellow, but becoming reddish before they decay; seeds several, shining, brown. In the garden it becomes more pubescent, and by age more shrubby, branched, and diffused, rising to four feet in height, with long recurved branches loaded with flowers.—Native of the south of Europe and Siberia. See the second species.

10. *Cytisus Proliferus*; *Silky Cytisus*. Flowers in lateral umbels; stems erect; leaves elliptic, acute, silky underneath; calices woolly. The stems, but especially the small branches, are almost tomentose; leaves alternate, petioled; peduncles axillary, (four to eight,) equal, one-flowered, a little longer than the petiole, filiform, villose, with two opposite filiform bractes near the flower; corollas large, white. When the flowering is past, a branch grows out in the centre of the peduncles. It flowers in April and May, and is found in the mountain woods of Teneriffe. This, with the fourteenth,

fifteenth, sixteenth, and seventeenth species, will not bear the open air of our climate, but require the protection of a green-house, or dry-stove.

11. *Cytisus Argenteus*; *Silvery Cytisus*. Flowers generally two together, subsessile; leaves tomentose; stems decumbent; stipules minute. It has herbaceous stalks. The flowers are produced either single, or two, three, or more together, at the ends of the branches. It is a hoary shining plant; the branches towards the root become shrubby, but above they are herbaceous.—Native of the south of France, and Istria. See the second species.

12. *Cytisus Purpureus*. Flowers peduncled, solitary; leaves smooth; stems decumbent, becoming shrubby; legumes sickled above. This is suffruticose; stems the thickness of a goose-quill, naked, smooth, brownish, pliant, prostrate; from these spring slender, soft, ascending, branched twigs, at first slightly pubescent, but afterwards smooth; leaves scattered, alternate, petioled; leaflets sessile, ovate, sharpish, dark green, quite entire; flowers axillary, solitary, erect, on a short pedicel; calix tinged with purple; corolla large, bright red; standard obcordate, broad, villose, ciliate on the sides at bottom; wings oblong, oval, entire, converging; keel blunt; both that and the wings villose, ciliate at the base.—Native of Carniola, flowering in April and May. See the second species.

13. *Cytisus Glaber*. Flowers solitary, lateral, subsessile, pendulous; leaflets ternate, petioled; leaflets equal, lanceolate, elliptic, whitish about the edge, small, acute; peduncles shorter than the flowers; calix oblong, somewhat belying, trifid; corolla yellow, rather large.—Native of Austria.

14. *Cytisus Græcus*. Leaves simple, lanceolate-linear; branches angular. It rises with a woody stalk, six or seven feet high, sending out many angular lateral branches. The flowers are produced in short bunches from the sides of the branches; they are small, yellow, and appear in July and

August, but are not succeeded by seeds in England. It is propagated by cuttings, which if planted on a bed of light earth in the beginning of July, and closely covered with a bell or hand glass, shaded from the sun in the middle of the day, will put out roots by the middle or end of September, when they should be carefully taken up, planting each in a separate small pot, carefully watering and shading them until they have taken new root; after which they may be exposed in a sheltered situation until the end of October, when they must be removed into shelter.

15. *Cytisus Tener*. Leaves simple, lanceolate; branches round. This is an erect shrub, branching very much, three feet high, with a trunk the thickness of a finger, round, and upright; leaves quite entire, subpetioled, pale beneath, somewhat villose on both sides, scarcely half an inch long; flowers few, in terminating racemes on short pedicels, smelling sweet; legumes hirsute; seed few.—Native of Madeira.

16. *Cytisus Foliolosus*; *Leafy Cytisus*. Racemes terminating, erect; calices villose; segments sickle shaped; leaflets obovate, oblong.—It flowers in July and August; and was found in the Canary Islands.

17. *Cytisus Divaricatus*; *Clammy Cytisus*. Racemes terminating, erect; calices villose and legumes ramentaceous, viscid; leaflets oblong; leaves ternate, with ovate oblong leaflets, on short petioles; racemes simple; flowers peduncled, solitary, supported by one or two subulate bracts. Before the corolla opens, the whole is tawny; but when open, the standard about the middle only is of that colour; the rest is then yellow; the calix is also tawny. It flowers in July and August, and is a native of the south of France, Spain, and Madeira. See the second and tenth species.

18. *Cytisus Biflorus*. *Smooth Cytisus*. Peduncles generally in pairs, lateral; calices oblong, villose, two lipped; upper lip bifid; leaflets oblong, elliptic. It flowers in May and June.—Native country unknown.

D A C

DACTYLIS; a genus of the class Triandria, order Dignia.—**GENERIC CHARACTER.** *Calix*: glume many-flowered, two-valved, collecting the floscules into an ovate-oblong spicule; valves concave, keeled; on one side convex, broader, half ovate; on the other narrow, the inner largest. *Corolla*: two-valved; the lower valve larger, concave, acute, mucronate, or awned, the inner lanceolate, acutely bifid, scarcely shorter than the lower; nectaries two, lanceolate, acuminate, gibbous at the base. *Stamina*: filaments three, capillary, longer than the corolla; antheræ oblong, two-forked. *Pistil*: germen ovate; styles two, spreading; stigmas feathered. *Pericarp*: none; corolla including the seed, and dropping it. *Seed*: single, oblong, grooved on one side. **ESSENTIAL CHARACTER.** *Calix*: two-valved, compressed, one valve larger, keeled. For the propagation and culture of this genus, see *Grass*.—The species are,

1. *Dactylis Cynosuroides*; *American Cock's-foot Grass*. Spikes scattered, numerous; flowers closely imbricate, and pointing one way; culm erect, two feet high, reedy; leaves on the culm six lines broad, longer than the culm, very glossy, scabrous about the edge, bent in, more glaucous on their inner surface; spikes six or more, diverging, chaffy; floscules scabrous behind; calices one-flowered, scabrous on the keel,

D A C

mucronate, longer than the floscule, sessile, turned one way; pistils villose, very long.—Native of Virginia and Canada: perennial.

2. *Dactylis Glomerata*; *Rough Cock's-foot Grass*. Panicle turned to one side, glomerate. Root perennial; culms from two to three feet high, acipital, naked, and rugged at top, having four or five smooth purplish knots or joints, and three leaves with ancipital, villose, or rugged sheaths, sharply keeled; leaves six inches or more in length, and three or four lines broad, spreading, somewhat glaucous, very rugged on both sides, with extremely minute spinules; ligule white, oblong, obtuse, cloven; panicle close, often coloured; peduncles solitary, alternate, angular, stiff, rugged, with a callous tumor at the base, twice and thrice cloven, the lowest sometimes two more, remote, longer, spreading, at length becoming horizontal, and even somewhat reflex; spikelets all turned the same way, subsessile, twin-glonierate, oblong, very obtuse, having two, three, and sometimes four flowers, pressed close, and diverging during florescence; seed dropping. It is a rough coarse grass, and hence has the names of *rough grass* and *hard grass*; as well as that of *orchard grass*, from its flourishing particularly under the shade of trees. No grass is more common than this: it is extremely hardy,

but unproductive: its flourishing under the drip of trees may be a recommendation; but the head is so large, that in heavy rains it is apt to be laid.—It is rather early, flowering from June to August; and should always be cut while young and tender, either for hay or fodder.

3. *Dactylis Ciliaris*; *Hairy Cook's-foot Grass*. Spike in a head, turned to one side; calices three-flowered; stem creeping. Root filiform, creeping, with long white fibres; culms a palm high, ascending, very simple, even, with one joint; root-leaves involute, filiform, even, the length of the culm; stem-leaf one, even, the length of the head; sheath somewhat bellying; head terminating, ovate, with many sessile flowers; glume of the calix, three-flowered, compressed, mucronate, the length of the corolla, having scattered hairs on the back under the tip.—Native of the Cape.

4. *Dactylis Lagopoides*. Spikes roundish, pubescent; culm prostrate, branched. Root perennial, fibrous; culms a palm high, several, covered on every side with the sheaths of leaves; leaves spreading, subulate, like spines, contracted at the base narrower than their sheaths; spike glomerate, ovate, pubescent; flowers sessile, many together, pointing nearly one way; calix eight-flowered, but often only four-flowered, nearly equal.—Native of the fields of Malabar.

5. *Dactylis Capitata*. Spikes in a head, even; culm prostrate, branched. Root perennial; leaves even, three on the culm, which is of the thickness of a fowl's quill, a foot and half in height, and even; panicle in form of a spike, as it were conglomerate, narrower at top, a palm in length, the colour of chaff; flowers always twin, depressed; calix nearly the length of the flower, containing about five flowers.—Found by Sparrmann at the Cape.

6. *Dactylis Stricta*; *Sea Cook's-foot Grass*. Spikes terminating, usually twin; flowers remote, pressed close; culms and leaves strict. The calix contains one floret only, which has but one style, and the style is longer than the stamina. It is perennial, and flowers from July to September.—Native of the marshes in Essex, and very common on the sea-coast, and also in Portugal.

7. *Dactylis Patens*; *Spreading Cook's-foot Grass*. Spikes scattered, turned one way, few; flowers closely imbricate; culm, decumbent; leaves spreading very much.—This is a perennial, flowering in August; and a native of North America.

Daffodil. See *Narcissus*.

Daffodil, *Sea*. See *Panocratium*.

Dahlia; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common double; the outer of several leaves, six or seven, ovato-spatulate, reflexed; inner of one leaf, cup-shaped, in several ovate segments. *Corolla*. compound radiant; florets of the centre perfect, with a tubular, stalked, five-cleft petal; those of the radius fertile, with an ovate three-toothed petal, equal in number to the segments of the calix. *Stamina*: in the perfect florets; filamenta five, broadest at the base inserted into the bottom of the petal; anthera united into a tube. *Pistil*: germen somewhat spatulate, obscurely triangular, notched at the top; style thread-shaped; stigmas somewhat spreading, pubescent. *Seeds*: solitary, shaped like the germen. *Receptacle*: flat, chaffy; the scales large, the middle ones keeled, the rest flat; down none. ESSENTIAL CHARACTER. *Calix*: double, the outer of many leaves. *Corolla*: radiant, its rays equal in number to the segments of the calix, ovate, three-toothed. *Receptacle*: chaffy. *Stigmas*: downy. *Seed-down*: none.

There are several species of *Dahlia*, all natives of the mountainous parts of the Spanish settlements of South Ame-

rica: their flowers are large and handsome, like those of the Sunflower, but the rays mostly red or purple, like the China Aster, and likewise variable in this respect: the herbage is coarse and rank, with compound leaves.—Mr. Salisbury, who has written a history of this genus, recommends the cultivation of some species in poor gravelly soil, in the open ground, by which means they grow less luxuriantly, and flower earlier and more copiously.

Dais; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre four-leaved, sessile, many flowered; leaflets scarious, erect; perianth none. *Corolla*: one-petalled, funnel-form, longer than the involucre; tube filiform, rude; border five cleft; divisions lanceolate, obtuse. *Stamina*: filamenta ten, inserted into the throat, shorter than the border, the alternate ones shorter; anthera simple. *Pistil*: germen somewhat oblong, growing on the base of the corolla; style filiform, length of the tube; stigma globose, ascending. *Pericarp*: berry ovate, one-celled. *Seed*: single, ovate. ESSENTIAL CHARACTER. *Involucre*: four-leaved. *Corolla*: four or five-cleft. *Berry*: one-seeded.—The species are,

1. *Dais Cotinifolia*; *Cotinus-leaved Dais*. Flowers five-cleft, ten-stamined. Leaves opposite, obovate, quite entire, smooth, petioled; flowers in a bunch, aggregate, terminating, pubescent, with a gemmaceous four-valved involucre. The fruit is a small nut, of an ovate acuminate form, with a thin bark over it, and clothed with a permanent corolla; the epidermis is membranaceous, pale, diaphanous, thickening on each side into a prominent whitish edge, easily separating; shell bony, thin, brittle, livid white on the outside, black within, one-celled, and valveless.—Native of the Cape. This ornamental deciduous green-house shrub, has not yet seeded in England, as it does in Holland. The seeds should be sown in pots of light earth in the spring season, and plunged into a good hot-bed: when they have attained a good growth, they must be removed into a larger, and placed in the green-house. It sometimes succeeds by layers and cuttings, if made from young shoots. The difficulty of raising it, enhances its price among the nursery-men.

2. *Dais Octandria*. Flowers four-cleft, eight-stamined. Leaves opposite, elliptic oblong, acuminate, petioled, even; involucre one or two, terminating, peduncled, shorter than the flowers, which are smooth; stamina placed upon the tube, and longer than the corolla.—Native of the East Indies.

3. *Dais Disperma*. Flowers eight and ten stamined. Leaves ovate-lanceolate, acuminate, nerveless.—Native of Tongataboo.

Daisy. See *Bellis*.

Daisy, *Great*, or *Oxeye*. See *Chrysanthemum*.

Daisy, *Blue*. See *Globularia*.

Dalbergia; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, five-toothed; teeth bluntish. *Corolla*: papilionaceous; standard large, ascending, cordate-ovate, emarginate, retuse, with a linear claw; wings oblong, straight, obtuse, with a reversed tooth above; keel scarcely shorter than the wings, two-parted at the base, straight, obtuse. *Stamina*: filamenta ten, united in two equal lateral bodies, free at top, ascending; anthera roundish. *Pistil*: germen oblong, compressed, pedicelled; style subulate, ascending or reflex; stigma simple. *Pericarp*: legume oblong, compressed, flat, pedicelled, not gaping, one-celled. *Seed*: single, or few, remote, kidney-form, compressed. ESSENTIAL CHARACTER. Filamenta two, four-cleft at top. *Fruit*: pedicelled, not opening, leguminose, membranaceous, compressed.—The species are,

1. *Dalbergia Lanceolaria*. Leaves pinnate; leaflets elliptic, hairy underneath; fruits lanceolate. This is a tree with wand-like, pendulous, hairy branches; leaves alternate, unequally pinnate; leaflets elliptic, alternate, remote, from ten to sixteen, quite entire, wavy, smooth underneath, hirsute above, veinless, small; petioles hairy; racemes axillary, hairy, branched; flowers ferruginous; calix rough with hairs; corolla larger than in the second sort. The fruit is a membrane, exactly the figure of a little lance, attenuated at the base, not opening, not divisible into two skins by a knife, the length of a finger or less: in the middle of this membrane, a single, compressed, oval seed is immersed; and when there are two seeds, they are placed longitudinally, at a distance from each other.—Observed by Kœnig in Ceylon and Malabar.

2. *Dalbergia Monetaria*. Leaves ternate; leaflets smooth, ovate; fruits oval, veinless. This is a shrub; leaflets petioled, quite entire, veined, acuminate, alternate; peduncles several, axillary, spiked, directed one way, toothed at bottom, where the flowers have fallen; flowers extremely minute, white; calix blunt, with five small equal teeth; filamenta two, lateral, equal, four-cleft at top, with a third, which is single, below the germen, hence there are nine filamenta; antheræ nine, globular, twin; style filiform, erect; stigma headed. The fruit is of an oval form, like a piece of coin, compressed, cartilaginous within, one-celled, deciduous, not opening; seed single, compressed, kidney-form. The root when cut yields a purple juice; the wood is red, and yields a resin resembling Dragon's-blood.—Native of wet parts of Surinam.

Dalechampia; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Involucre*: common exterior smaller; leaflets four, lanceolate, spreading: interior very large; leaflets two, heart-shaped, three-cleft, converging. For the *male flowers*, a foot-stalked umbel, simple, ten-flowered, shorter than the interior involucre. *Calix*: involucre two-leaved, erect, blunt; leaflets somewhat three-lobed; scales numerous, obovate, pressed in an imbricate manner to the exterior side of the involucre, and of the same length with it; perianth proper five-leaved, footstalked; leaflets ovate, acute, deciduous. *Corolla*: none. *Stamina*: filamenta very many, growing together into a column longer than the calix; antheræ roundish. In the *females*, three florets within the same common involucre, approximate to the inferior side. *Calix*: involucre three-leaved; leaflets emarginate, small; perianth proper, inferior; leaflets eleven, linear, toothed, acute, converging, permanent. *Corolla*: none. *Pistil*: germen roundish, shorter than the perianth; style filiform, ascending, length of the males; stigma somewhat headed, perforated. *Pericarp*: capsule roundish, three-berried, three-celled; cells two-valved. *Seeds*: solitary, globose. ESSENTIAL CHARACTER. Outer common involucre with four leaflets, inner with two trifid leaves. *Male*: umbellule ten-flowered; involucre two-leaved, with numerous chaffs; proper perianth five-leaved. *Corolla*: none; filamenta very many, connate. *Females*: floscules three; involucre three-leaved; proper perianth with eleven leaflets. *Corolla*: none; style filiform. *Capsule*: tricoccus.—These plants are propagated by seeds, sown early in the spring on a hot-bed, transplanted into small pots when three inches high, plunged into a bark-bed, and frequently watered; they should be afterwards removed into larger pots, and placed at the back of the bark-stove, where they may have an espalier or trellis to run upon. They seldom continue more than two years.—The species are,

1. *Dalechampia Colorata*; *Coloured Dalechampia*. Leaves quite entire. This resembles the second species, and the

leaves are three-lobed, but less deeply cut, and not serrate; the involucre is more oblong, resembling a petal, or coloured, not cordate at the base, or green. Found in New Granada, by Mutis.

2. *Dalechampia Scandens*; *Climbing Dalechampia*. Leaves trifid, serrate. Stem branched, climbing, hairy, the hairs standing out; leaves alternate, petioled, remote, cordate, three-lobed, much veined, wrinkled, pubescent; flowers axillary, green, on long stalks; bractes large, three-cleft, serrated, inclosing the flowers and seeds. (Miller has a variety, native of Jamaica, having a smooth fruit, with a hispid calix.)—It flowers in June and July; and is a native of the West Indies.

Damasonium; a genus of the class Hexandria, order Hexagynia.—GENERIC CHARACTER. *Calix*: spathe one-leaved, oblong, five-winged; wings wavy, two running down into the petiole; mouth five-toothed, teeth sharp, membranaceous at the edge; perianth one-leaved, three parted, superior; leaflets lanceolate, blunt, surrounded by a membranaceous edge, spreading. *Corolla*: petals three, roundish; wavy, spreading, longer than the perianth. *Stamina*: filamenta six, very short; antheræ linear, erect, blunt, emarginate at the base, shorter than the corolla. *Pistil*: germen oblong, inferior; styles six, linear, emarginate, erect, longer than the stamina; stigmas, villose hairs on the side of the styles. *Pericarp*: berry oblong, ten-celled, crowned by the calix; seeds very many, oblong, small. ESSENTIAL CHARACTER. *Spathe*: one-leaved. *Perianth*: one-leaved, three-parted. *Petals*: three. *Berry*: ten-celled, inferior.—The only known species is,

1. *Damasonium Alismoides*. Leaves heart-shaped, nerved, floating, unarmed; scape naked, quadrangular, one-flowered. There are only six stamina in the flower, with six bifid styles.—Native of the East Indies, Malabar, Ceylon, &c.

Dame's Violet. See *Hesperis*.

Dandelion. See *Leontodon*.

Danewort. See *Sambucus*.

Daphne; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: one-petalled, funnel-form, withering, including the stamina; tube cylindrical, imperforate, longer than the border; border four-cleft; divisions ovate, acute, flat, spreading. *Stamina*: filamenta eight, short, inserted into the tube, the alternate ones lower; antheræ roundish, erect, two-celled. *Pistil*: germen ovate; style very short; stigma headed, depressed, flat. *Pericarp*: berry roundish, one-celled. *Seed*: single, roundish, fleshy. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: four-cleft, corollaceous, withering, including the stamina. *Berry*: one-seeded.—The species are,

* *Flowers lateral*.

1. *Daphne Mezereum*; *Mezereon*. Flowers sessile, in threes on the stem; leaves lanceolate, deciduous. It is a shrub growing in gardens, to the height of five or six feet, with a strong woody stalk, putting out many woody branches on every side, so as to form a regular head; the flowers come out before the leaves very early in the spring, in clusters surrounding the shoots of the former year. The leaves are smooth, about two inches long, and three quarters of an inch broad in the middle, placed without order. In its wild state it is only from one to two feet in height, and the branches then are not numerous, they are very flexible; the leaves are entire, and of a pale green. The fruit is a superior berried drupe, first green, then red, of an ovate-globular form, with a thin succulent pulp, and a crustaceous, thin, brittle, black, shining shell; it is, however, commonly called a berry. There are two principal varieties of the *Mezereon*; one with a white

flower, succeeded by yellow berries; the other with peach-coloured flowers and red fruit; the latter has sometimes flowers of a much deeper red. There is also a variety with variegated leaves; the flowers of which appear in February and Mareh, and even in January, when the season is mild; the berries will be ripe in June, if they be not previously devoured by birds. Villars mentions another variety, with the leaves a little villose, or having small hairs at their base, and the flowers four together: he remarks, that the parts of fructification are so perfectly formed the year before the flowers unfold themselves, that the character may be easily determined by the naked eye.—Mezereon is a native of Lapland, Sweden, Denmark, Germany, Switzerland, France, Carniola, Savoy, Piedmont, and great Britain. Mr. Miller is the first who declared it to be a native of our island, namely, near Andover in Hampshire; since that it has been found at Laxfield, in Suffolk; in Selborn-hanger, Hants; and frequently observed in the beech-woods of Buckinghamshire. As it has escaped all our old herbarists, and even the indefatigable Ray and his immediate successors; and birds are remarkably fond of the berries, there is reason to suspect that they may have disseminated this beautiful shrub; unless we can suppose that it remained unnoticed, on account of its flowering before the time at which the herbarists sally out upon their vernal excursions. Gerarde informs us, that he had plenty thereof for his garden from Elbing in Poland: he calls it German Olive-spurge, or Spurge-olive, Spurge-flax, and Dwarf-bay, and says that the Dutch call it *Mezereon*. Parkinson calls it Dwarf-bay, or Flowering-spurge: the Germans have named it *kellerhals*, *kellerbere*, *kellerkraut*, &c. the Dutch, *peperboompje*; the Danes, *kielderhals*; the Swedes, *kiellerhals*; the French, *laureole gentille* or *femelle*, *bois gentil*, *bois joli*; the Italians, *laureola femina*, *dafnoide*, *camelea*, *calmolea*, *biondella*; the Spaniards, *laureola hembra*; the Portuguese, *loireola femea*, or *mezeroe major*; and the Russians, *woltschje-luke*. The branches afford a good yellow dye.—The whole of this vegetable is extremely acrid, especially when fresh, and, if retained in the mouth, excites great heat and inflammation, particularly of the throat and fauces: the berries, when swallowed, prove a powerful poison, not only to man, but to many quadrupeds. A woman gave only twelve of the berries to her daughter, who laboured under a quartan ague, and she, after vomiting a good deal of blood, expired immediately. Both the bark and the berries of Mezereon, in different forms, have been long used externally in cases of obstinate ulcers, and ill-conditioned sores. In France, the bark is used as an application to the skin, which, under certain circumstances, produces a serous discharge without blistering, and is thus rendered very useful in chronic cases of a local nature, answering the purpose of what is called a perpetual blister, while it occasions less pain and inconvenience. In England, the Mezereon has been principally employed in syphilitic cases; and in this way, Dr. Donald Monro was the first who testified its efficacy in the successful use of the Lisbon diet-drink. Several cases were afterwards published by Dr. Russel, then physician to St. Thomas's hospital, fully establishing the utility of the bark of Mezereon, in venereal nodes. In the above cases, the decoction of the root was made use of, but it has been found necessary in some cases to join with it a solution of sublimate. Dr. Cullen informs us, that Dr. Home has not only found the decoction of Mezereon to cure schirrhous tumours, which remain after the lues venerea, and after the use of mercury, but that it has also healed them when proceeding from other causes. The considerable and long-continued heat and irritation that is produced in the throat when Mezereon is chewed, induced Dr. Withering to give it

in a case of difficulty of swallowing, apparently the effect of a paralytic affection: the patient was directed to chew a thin slice of the root as often as she could bear to do it, and in about two months she recovered her power of swallowing: she had suffered the above complaint upwards of three years, and was greatly reduced, being totally unable to swallow solids, and liquids but very imperfectly. An ointment prepared from the bark or the berries has been found serviceable to sore ulcers. A decoction made of a drachm of the bark of the root, in three pints of water till one pint is wasted, and this quantity taken daily for a considerable time together, has been found very efficacious in resolving and dispersing venereal swellings and excrescences. Dr. Russel prescribes two drachms of the Mezereon and half an ounce of Liquorice-root, boiled with three pints of water to a quart: four to eight ounces of this decoction to be given four times a day. The bark of the root, says Hill, or the inner bark of the branches, is to be used, but it requires caution in the administration, and must only be given to persons of robust constitutions, and even to them very sparingly, for if it be given in too large a dose, or at all to a weakly person, it will cause vomiting and bloody stools; but to the robust it acts only as a brisk purge, and is excellent in dropsies and other stubborn disorders; a light infusion is the safest and most efficacious mode of giving it.—Mezereon is propagated by seeds, which should be sown on a border exposed to the east, soon after the berries become ripe; for if they be not sown till the spring following, they often miscarry, and always remain a year in the ground before the plants appear; whereas those which are sown in August will grow the following spring, so that a year is saved; and these never fail. When the plants come up, they will require no other care, but to keep them clean from weeds; and if the plants be not too close together, they may continue in the seed-bed to have the growth of two summers, especially if they do not make great progress the first year; then at Michaelmas, when the leaves are shedding, they should be carefully taken up, so as not to break or bruise their roots, and planted into a nursery, about sixteen inches row from row, and eight or nine inches asunder in the rows. In this nursery they may remain two years, by which time they will be fit to remove to the places where they are designed to remain for good. The best season to transplant these trees is in autumn, for as these plants begin to vegetate very early in the spring, it is hazardous to transplant them in that season. They grow best in a light, dry, sandy earth, but become mossy, and make little progress, in cold wet lands, so that upon such soils they are small, and produce but few flowers. Notwithstanding the berries of this tree are so very acrid as to burn the mouth and throat of those who may incautiously taste them, yet the birds greedily devour them as soon as they begin to ripen; so that unless the shrubs be covered with nets to preserve the berries, they will all be destroyed before they are fit to gather. The Mezereon is a very ornamental shrub in gardens, flowering before others, very early in the spring; and when there are plenty of them growing together, perfuming the air to a considerable distance.

2. *Daphne Thymelæa*. Flowers sessile, axillary; leaves lanceolate; stems very simple. This plant rises to the height of three or four feet, with a single stalk, covered with a light-coloured bark; the flowers come out in clusters on the sides of the stalk, and being of an herbaceous colour, make but little appearance. They come forth early in the spring, and are succeeded by small berries, which are yellowish when ripe.—Native of Spain, Italy, and the south of France. Vahl found it in great abundance, on the confines of New Castile. This species, together with the fifth and twelfth, are hardy

and will live through the winter, in England in the open air provided they are placed in a dry soil and a warm situation. They should be planted on a very warm dry border, where, if there be a foundation of lime-rubbish or chalk under the upper surface of the ground, the plants will thrive better, and continue much longer, than in better ground; and all the culture they require, is to keep the place clear from weeds, for the less the ground is stirred near the roots, the better the plants will thrive; for they grow naturally on poor shallow land, and out of crevices in rocks, and therefore the nearer the soil approaches to this, the more likely the plants are to succeed.

3. *Daphne Pubescens*. Flowers sessile, aggregate; leaves lanceolate-linear; stem pubescent, simple; leaves alternate, remote, almost naked, annual, submucronate; flowers axillary, narrow, five, or fewer, with a filiform pubescent tube, shorter than the leaves.—Found by Jacquin in Austria.

4. *Daphne Villosa*. Flowers sessile, solitary; leaves lanceolate, flat, ciliate, hairy, crowded. This is a shrub with alternate branches; leaves like those of Knotgrass, scarcely petioled, with white remote hairs on both sides, fewer on the upper surface, and more towards the edges; in the axils are very many rudiments of branchlets, whence it is as if were verticilled; flowers narrow, small, shorter than the leaves.—Observed by Alstroemer in Spain and Portugal.

5. *Daphne Tartonraira*; *Silvery-leaved Daphne* or *Tartonraira*. Flowers sessile, aggregate, lateral, imbricate with scales at the base; leaves obovate, nerved, silky. This is a long shrubby plant, which sends out several weak stalks from the root, about a foot long, and spreading about irregularly; these seldom become woody in England, but are tough and stringy, covered with a light bark; the leaves are small, very soft, white, and shining like satin, and sit pretty close to the stalks; between these, white flowers come out in thick clusters; they are commonly two or three together, very seldom solitary, bell-shaped, silky on the outside, but yellowish within, imbricated at the base with four or more ovate keeled scales.—Native of the south of France. See the second species.

6. *Daphne Alpina*; *Alpine Daphne*. Flowers sessile, aggregate, leaves lanceolate, somewhat obtuse, tomentose underneath. This species rises about three feet high; the flowers come out in clusters from the sides of the branches early in the spring, and are succeeded by small roundish berries, which turn red when ripe; the root fixes itself deeply in the crevices of the rocks; the little stems are shrubby and upright, scarcely a palm in height, as if were brachiate, leafy, and flowering at the top; leaves lanceolate or obovate, usually emarginate hoary with hairs when viewed with a glass, as are also the calices and fruits; the younger leaves appear hirsute to the naked eye, but afterwards appear bald, unless to the magnifier.—Native of the south of France, and of the mountains near Geneva, Austria, and Italy. This sort is a beautiful sweet shrub, and deserves a place in gardens as much as any of those we cultivate for ornament. Both this and the eleventh species may have a cooler situation than the second species; if these be sown where they can only have the morning sun, they will thrive better than in a warmer situation, and the ground near the roots of these should not be disturbed; therefore in the choice of the situation, there should be regard had to this, not to sow them near other plants which may require transplanting, or to have the ground dug and loosened. The seeds of these plants coming from distant countries, rarely arrive here time enough to sow in autumn; so that when they are sown in the spring, the plants do not appear till the succeeding spring; and have sometimes remained even till

a second spring in the ground: but as this may be too long for many people to leave the ground undisturbed, they had better put the seeds into small pots of earth, and bury them in the ground the first summer, and take them up in autumn, and sow them where they are to stand; by this method the seeds will be forwarded so as to vegetate in the following spring. They are both very difficult to keep in gardens, because they will not bear to be transplanted: they are as hardy as the common Mezereon, and are not in danger of being hurt by the frost in England, but have always died upon being removed, though they have been transplanted at different seasons and with the greatest care; and even when plants of all sizes, from the youngest seedling to the oldest plants have been tried. Those therefore who desire to have these plants in their gardens, must procure their seeds from the countries where they naturally grow, which should be sown as soon as they arrive in the place where they are designed to remain.

7. *Daphne Laureola*; *Spurge-Laurel*. Racemes axillary, five flowered; leaves lanceolate smooth. This is a low evergreen shrub, rising with several stalks to the height of two or three feet, dividing at top into several branches: the leaves come out irregularly on every side, sit pretty close to the branches, are thick, smooth, and of a lucid green; among these, towards the upper part of the stalks, come out the flowers in small clusters, they are of a yellowish green, and appear soon after Christmas, if the season be not very severe: they are succeeded by oval berries, which are green till June, when they ripen, turn black, and soon afterwards fall off. The flowers are of a dull colour, with an unpleasant scent, and they appear at a gloomy season.—It is a native of Britain, France, Switzerland, Austria, and Carniola. Gerard did not know that it grows wild in England, although it is common enough in our woods and hedges; and, notwithstanding Linneus's censure, the Spurge-Laurel is a shrub of some value, on account of the lucid green of its leaves, which continuing all the year, render it ornamental in winter, but particularly because it flourishes under trees, and is therefore very proper to fill up spaces in plantations.—Very happy effects have been produced by the use of this plant in rheumatic fevers; it is a rough purgative, and an efficacious medicine in worm-cases, but requires some caution in the administration, and might be productive of dangerous consequences in unskilful hands. The whole plant has the same qualities, but the bark of the root appears to be the strongest, and should never be given in a dose of more than ten grains. An infusion of the leaves is a good medicine for those of robust constitutions, who are subject to dropsical complaints; it operates by vomit and stool, but so roughly that few constitutions can bear it; dried and reduced to powder, the leaves are useful in the venereal disease. Some other species of this genus possess nearly similar powers with the Mezereon and Spurge-Laurel, and are used in similar cases; but, like the former, require caution in their use, and should not be trusted to inexperienced hands. The plants may be easily obtained from the woods, and is propagated by seeds, layers, or cuttings.

8. *Daphne Pontica*. Peduncles two-flowered; leaves lanceolate-ovate; stem about two feet high, branched sometimes from the very bottom, about three lines in thickness, very pliable, covered with a grey bark; leaves towards the top without order, of the figure and consistence of those of the Lemon, the largest four inches long, and two wide, pointed at each end, smooth, bright green, and shining, having a thick mid-rib underneath. At the end of April, young shoots, terminated by new leaves, push from the extremities of the

stems and branches, among which spring the flowers commonly in pairs, on a short peduncle. The corolla is of a greenish yellow, inclining to lemon colour, and has a sweetish smell, which is soon lost.—It flowers in autumn, and is a native of Pontus and Siberia.

9. *Daphne Dioica*; *Diocous Spurge Laurel*. Flowers axillary, twin; leaves linear-lanceolate. This is a shrub, a foot in height, stiff, and branched, with a corky bark; branches alternate, erect, stiff, roughened by the scars of fallen leaves; leaves crowded, so as almost to be imbricate, very smooth, resembling those of Myrtle, four lines long, and hardly a line broad, not ciliate; flowers sessile, always two together, one flowering later than the other, diœcous; corolla yellowish white, or pale sulphur colour, with a bellying tube.—Native of the Pyrenees.

** *Flowers terminating.*

10. *Daphne Indica*; *Chinese Daphne*. Head peduncled; leaves opposite, oblong-ovate, smooth. A small shrub; leaves commonly acute, quite entire, petioled; peduncle very short, from six to eight sessile flowers at top.—Native of China near Canton, but probably from Nankin, since it is commonly called the Nankin shrub.

11. *Daphne Cneorum*; *Trailing Daphne*. Flowers in bunches, sessile; leaves lanceolate, naked, mucronate. It is a very humble shrub, seldom more than one foot high; stems branched; leaves narrow, lanceolate, placed without order. The branches are terminated by small clusters of purple flowers, which stand erect. The tube of the corolla is longer and narrower than in the Mezereon. The flowers emit a pleasant odour, and appear early in the spring.—Native of France, Germany, Switzerland, Austria, Monte Baldo, the Pyrenees, and Hungary. See the sixth species.

12. *Daphne Gnidium*; *Flax-leaved Daphne*. Panicle terminating; leaves linear-lanceolate, acuminate. It rises with a shrubby stalk, two feet high, dividing into small branches, terminated by panicles of flowers, which are much smaller than those of the Mezereon, having swelling tubes, contracted at the mouth, and appearing in June. The stems spread on the ground; the leaves are annual, and smooth; the flowers heaped, surrounded with leaves, sweet-smelling, red above. It flowers twice a year. Gerarde calls it *Spurge flax*, or *Mountain Widow-wayle*. Parkinson names it *Spurge Olive*.—Native of the south of France, Spain, and Italy. See the second species.

13. *Daphne Squarrosa*; *Square Daphne*. Flowers peduncled; leaves scattered, linear, spreading, mucronate. It rises to the height of five or six feet, dividing at top into several erect branches, covered with a white bark, and terminated by woolly heads, out of which come the flowers in small clusters; they are white, have oblong tubes, and the segments of the border are obtuse and spreading.—Native of the Cape. It requires a good green-house to preserve it, and is very difficult to keep in our gardens.

14. *Daphne Oleoides*; *Oily Daphne*. Flowers twin, sessile; leaves elliptic, lanceolate, smooth; stem rather shrubby, compound.—Native of the Levant. This and the three following species, require the protection of a green-house to preserve them in England.

15. *Daphne Fœtida*; *Stinking Daphne*. Smooth: flowers heaped, sessile; leaves opposite, petioled, ovate, oblong, acute.—Native of the Society Isles. It is not certain whether this be different from *Daphne Indica*.

16. *Daphne Rotundifolia*; *Round-leaved Daphne*. Hirsute: flowers heaped, sessile; leaves opposite, elliptic, sub-petioled, obtuse, smooth; branches tomentose, hoary.—Native of Tongataboo or Namoka in the South Seas.

17. *Daphne Odora*; *Sweet-smelling Daphne*. Head sessile, many-flowered; leaves scattered, oblong-lanceolate, smooth. Stem becoming shrubby, dichotomous, smooth, naked, erect; branches like the stem, from divaricating erect; leaves at the top of the last branches approximating, sessile, acute, quite entire, spreading, bent back at the tip, deep green on the upper surface, with a groove along the middle, paler underneath, unequal, thick, evergreen, an inch in length; flowers about eleven; corolla smooth; tube purple; filaments inserted below the mouth; antheræ oblong, four, included, and four standing out; seed ovate, smooth.—Native of Japan, where it flowers in February; and also of China, where it is cultivated on account of the grateful odour of its white flowers, which, in England, appear from December to March. It must be protected by a green-house; though hardy enough to bear our climate, it scarcely ever flowers in the open ground.

*** *New Species.*

18. *Daphne Pendula*. Heads lateral, peduncled, involucred, nodding; leaves lanceolate-elliptic, alternate, smooth. A tree or shrub, with alternate round branches, leafy at the end, covered with a smooth brown outer bark, and very filamentous, silky, white inner bark, as in most of the other species; leaves on short petioles, acute, quite entire, veined, paler underneath, deciduous; the primordial ones minute, like stipules, silky on the back, and abortive; flowers in solitary heads, from the axils of the leaves of the former year. Found by Thunberg in the island of Java. It is a stove plant, and must be treated in the same manner as Coffee. See *Coffea*.

19. *Daphne Altaica*. Flowers in bundles, terminating, sessile; leaves oblong-ovate, smooth. Stems straight, slender, covered with an even testaceous bark; the lower branches are short, flowering, hairy next the flowers; the upper ones, which continue the growth of the shrub, are smooth. The leaves are alternate, quite entire, drawn to a point at the base, sessile; on the flowering twigs oblong-ovate, smaller, growing up to the flowers; on the barren branches more oblong, very like the leaves of Mezereon, and emulating their consistence. Flowers mostly five together, collected into a head, without any bractes or stipules; corolla white, with a longish tube, swelling at the base, pubescent, with many hairs, and a spreading border, with lanceolate smooth segments; antheræ in a double row in the tube on very short filaments; germen subglobular, with an obtuse stigma.—This elegant shrub was discovered by Patrin on the Altaic Alps.

20. *Daphne Triflora*. Flowers sessile, axillary, heaped; calices three-flowered; leaves lanceolate, scattered. Stem three feet high, simple, with ascending branches; leaves quite entire, smooth, on short petioles; flowers yellowish.—Native of China, in the suburbs of Canton.

21. *Daphne Cannabina*. Umbels terminating; leaves lanceolate, opposite. This is a tree, ten feet high, with ascending branches, and a very tough bark, like that of Hemp; leaves ovate-lanceolate, quite entire, smooth; flowers yellow, in subterminating umbels; corolla salver-shaped, with a long tube, and a small border, with ovate segments; berry ovate, red, small.—Native of the woods of Cochinchina. An excellent writing paper is made from the bark, prepared like hemp. Shapeless, heavy, brown, resinous, woody fragments, resembling the wood of Aloe, and having somewhat of its smell in the fire, are frequently found within the trunk of this tree near the root. The bark and root may be medicinally used in dropsical complaints, without incurring any of those ill effects which are too often produced by the other species.

22. *Daphne Colina*; *Neapolitan Mezereon*. Flowers in bundles, terminating, sessile; leaves obovate, obtuse, very smooth on the upper surface, villose on the lower. Stems three feet high, much branched; the branches often forked; bark tough, wrinkled, void of down or hair, except on the younger branches; leaves evergreen, alternate, on short footstalks, a little revolute on the edge, having a silky down underneath.—Native of the low hills in the south of Italy. It covers the hills and fields on the banks of the Vulturnus, as Furze does on commons in England; and, since it thrives here like the Myrtle, becomes a valuable addition to our shrubs.

23. *Daphne Lagetto*; *Lace-bark Daphne*. Spikes paniced, terminating; leaves ovate, acute. This is a tree the wood of which is white; leaves about four inches long, and two and a half broad, broadest near the base, having one middle and several transverse ribs, of a yellowish green colour, shining, thick and smooth. The outer bark is smooth, light brown, or gray and striated; the inner is solid and white, of a very fine texture, tough, and divisible into several coats or layers, which may be drawn out into thin webs resembling lace, and have been worn instead of it. King Charles II. had a cravat of it, which was presented to him by Sir Thomas Lynch, then governor of Jamaica; where it is principally used for rope-making, but would undoubtedly make fine paper, if properly prepared.—Native of Jamaica, where it is called *Lagetto*, or *Lace-bark Tree*; and of Hispaniola, where it is known by the name of *bois dentelle*. It is a stove plant, and must be treated in the same manner as the Coffee shrub.

24. *Daphne Tinifolia*. Racemes compound, erect; flowers terminating, crowded; leaves oblong. It rises with a woody stalk to the height of twenty feet, dividing into many branches, covered with a gray rough bark. The leaves of this tree are about two inches long, and one inch broad, rounded at the top, and entire, on very short footstalks.—Native of Jamaica. It is a stove plant, and must be treated like Coffee. See *Coffea*.

25. *Daphne Occidentalis*. Peduncles axillary; flowers terminating, in umbellets, diœcous; leaves alternate, lanceolate, smooth.—Native of Jamaica. It is a stove plant, and requires the same propagation and culture as Coffee.

26. *Daphne Vermiculata*. Flowers sessile, lateral, solitary, smooth; leaves linear-lanceolate, villose. This is an humble, stiff, and very branching shrub; branches purple, warted, villose at top; leaves sessile, crowded, thick, obtuse; flowers axillary, opposite, shorter than the leaf.—Native of the kingdom of Arragon in Spain.

27. *Daphne Sericea*. Flowers aggregate, terminating, sessile; leaves lanceolate, villose underneath; segments of the corolla obtuse. It is a very branching shrub; branches round, brown, villose at top; leaves towards the ends of the branchlets crowded, sessile, lanceolate, elliptic, veinless, quite entire, acute, smooth above, villose underneath; flowers purple, five.—Native of Candia and Naples.

28. *Daphne Buxifolia*. Flowers aggregate, sessile, terminating; leaves oblong, very blunt, villose underneath. This shrub has round, villose, naked branches; leaves towards the ends of the branchlets approximating, sessile, a little narrower at the base, rounded at the end, the younger ones villose on both sides, the rest only underneath, veinless; flowers six; tube of the corolla villose, silky on the outside, gibbose at the base; segments oblong, obtuse. It differs from the foregoing in the form of the leaves, and the whiteness of the corolla.—Native of the Levant.

Darnel Grass. See *Lolium*.

Date Plum. See *Diospyrus*.

Date Tree. See *Phoenix*.

Datisca; a genus of the class Diœcia, order Dodecandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth five-leaved; leaflets linear, acute, equal. *Corolla*: none. *Stamina*: filamenta scarcely any; antheræ about fifteen, oblong, many times longer than the calix, obtuse. *Female*. *Calix*: perianth two-toothed, the third tooth wanting, erect, very small, superior, permanent. *Corolla*: none. *Pistil*: germen oblong, inferior, longer than the calix; styles three, two-parted, short; stigmas simple, oblong, shaggy, length of the germen. *Pericarp*: capsule oblong, triangular, three-valved, three-horned, one-celled. *Seeds*: numerous, small, adhering longitudinally in three to five directions to the capsule. ESSENTIAL CHARACTER. *Male*. *Calix*: five-leaved. *Corolla*: none. *Antheræ*: sessile, long, fifteen. *Female*. *Calix*: two-toothed. *Corolla*: none. *Styles*: three. *Capsule*: triangular, three-horned, one-celled, pervious, many-seeded, inferior.—These plants should be propagated by parting the roots, which may be performed in autumn, when the stalks decay; but they must not be parted too small. They may be planted in any open beds, where they are not under the drip of trees, and will require no other culture but to keep them clean from weeds. They may also be propagated by seeds; but these should be taken from such plants as grow in the neighbourhood of male plants, or they will not succeed; and if the seeds be not sown in autumn, they seldom grow the first year. When the seeding plants appear, they will require no other care than to be kept clean from weeds till autumn, when they may be transplanted whither they are to grow.—The species are,

1. *Datisca Cannabina*; *Smooth-stalked Bastard Hemp*. Stem even. This plant has a perennial root, from which rise several herbaceous stalks, about four feet high, with pinnate leaves placed alternately, each composed of three pairs of leaflets, terminated by an odd one; these are two inches long, and half an inch broad, ending in acute points, deeply serrate, and of a light green. The flowers come out in long loose spikes from the upper part of the stalks, at the axils, but having no petals make a poor appearance: the antheræ of the male flowers being pretty long, and of a bright yellow colour, are most visible at a distance. It flowers in June or July, and the seeds ripen in September.—Native of Candia or Crete.

2. *Datisca Hirta*; *Rough-stalked Bastard Hemp*. Stem hirsute, larger. The stem rough on every side with hairs that stand out; leaflets larger, more alternate, more decurrent, and confluent at the base.—Found in Pennsylvania. This is as hardy as the first species, but requires a shady situation, and a moister soil.

Datura; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, oblong, tubular, bellied, five-cornered, five-toothed, horizontally deciduous near the base, the remaining circular part permanent. *Corolla*: one-petalled, funnel-form; tube cylindrical, almost longer than the calix; border erect, expanding, five-cornered, five-plaited, almost entire, with five acuminate teeth. *Stamina*: filamenta five, subulate, length of the calix; antheræ oblong, compressed, obtuse. *Pistil*: germen ovate; style filiform, straight; stigma thickish, obtuse, two-plaited. *Pericarp*: capsule somewhat ovate, two-celled, four-valved, seated on the base of the calix; receptacles convex, large, dotted, affixed to the dissepiment. *Seeds*: numerous, kidney-form. ESSENTIAL CHARACTER. *Corolla*: funnel-form, plaited. *Calix*: tubular, angular, deciduous. *Capsule*: four-valved.—Most of the plants of this genus have a strong aromatic smell, are natives of hot countries, and therefore require a stove or glass-case.—The species are,

P. 457.

Common Thornapple.

DATURA STRAMONIUM.

P. 454.

DAPHNE LAUREOLA — Spurge Laurel.

1. *Datura Ferox*; *Rough Thornapple*. Pericarps thorny, erect, ovate; the upper thorns very large, and convergent. It seldom rises more than a foot and a half high, spreading out into many branches. Fruit round, armed with very strong sharp thorns: seeds black when ripe. Annual; flowering from July to September; and a native of China. This, and the fourth and fifth species, may be raised by sowing the seeds upon a gentle hot-bed in the spring, and treating them afterwards in the same manner as the *Marvel of Peru*, and other hardier kinds of annuals, transplanting them into the full ground in the latter end of May: they will flower in July; and if some of the plants be placed in a glass case, will produce ripe seed in autumn.

2. *Datura Stramonium*; *Common Thornapple*. Pericarps thorny, erect, ovate; leaves ovate, smooth. Stem from one to six feet in height, according to the soil, but seldom more than two feet, round, smooth, dividing into many strong irregular branches, which are hollow, and covered with a fine down; leaves from the forking of the stem and branches, single, scarcely six inches long, petioled, pointed, deep green on the upper surface, paler beneath, and on the edges, with strong ribs or nerves, unequally sinuated, and toothed about the edge, extending farther down the petiole on one side than on the other; flowers single from the axils, on short peduncles, upright; calix pale green; corolla white; seeds blackish. At night the leaves, particularly the upper ones, rise up and inclose the flowers: these appear from July to September.—Gerarde says, the Thornapple was brought in seed from Constantinople. Mr. Miller thinks it was probably first introduced from Italy or Spain. It is, however, now become so common about London and other towns, as to appear like a native plant, there being few gardens or dunghills without it in summer. That it is a native of America, we have however, the most undoubted proof; for in the earth brought with plants from various parts of that extensive country, we are sure to have the Thornapple come up. Kalm says, that it grows about all the villages, and that it and the *Phytolacca* are the worst weeds that infest that continent. Our old writers call it *Thorny-apple of Peru*. Gerarde declares that he first "dispersed the seeds through this island, and that he made great use of it in chirurgerie as well in burnings and scaldings, as also in virulent and maligne ulcers, apustemes, and such like."—An ointment prepared from the leaves gives ease in external inflammations and hæmorrhoids, being cooling and repelling. The leaves, stalks, and apple of this plant, when smoked, has been found efficacious in asthmatic and consumptive cases. The Edinburgh College direct an extract from the leaves, which has been given with great advantage for convulsions and epilepsies, in doses from two to sixteen grains a day. These and the seeds, when internally given, are liable to bring on delirium, tremors, swelling, itching, eruption, and inflammation on the skin. Baron Stoerck informs us, that the juice pressed out of the fresh plant, and inspissated to an extract, has been given in doses from half a grain to the amount of a drachm every twenty-four hours, in epileptic disorders, convulsions, and madness, and proved to be a medicine of singular efficacy in those deplorable maladies, several persons being cured by it, whose disorders were both violent and of long standing. Hill observes, that the leaves are used externally by the country people, who lay them upon burns and inflammations; but this is not always safe. The root and seeds are of a sleeping nature, and ought not to be taken internally; opium itself being considerably less dangerous. The whole of this plant is powerfully narcotic and poisonous.—This species is well adapted to the large borders of pleasure-grounds, where it

will have a good effect, mixed with others of similar growth: it is easily propagated; for it is together with the next species, very hardy, and if only permitted to seed, will furnish a supply of plants for several years to come, for the seeds will lie long in the ground, and when turned up to the air, soon begin to vegetate.

3. *Datura Tatula*; *Blue Thornapple*. Pericarps thorny, erect, ovate; leaves cordate, smoothed, toothed. This resembles the common sort, but is twice the size; stems purplish, with white dots, divided at an acute angle, smooth, and even; corollas pale blue; leaves more finely toothed, and, if they be flattened, cordate.

4. *Datura Fastuosa*; *Purple Thornapple*. Pericarps tubercled, nodding, globular; leaves ovate, angular. This rises with a finely polished purple stalk, four feet high, dividing into several branches; leaves large, smooth sinuated, on pretty long footstalks. The flowers are produced at the divisions of the branches; they have largeswelling tubes, which spread very broad at the top, their brims having ten angles each, ending in a long slender point; they are of a beautiful purple on their outside, and a satiny white within; some of them are single, others have two or three flowers, standing one within another, and some are double, having four or five petals within each other, of equal length, so as to appear a full flower at the brim: they have an agreeable odour at first, but if long snelt to, becomes less so, and are narcotic.—Native of Egypt, and the East Indies. For its propagation and culture, see the first species.

5. *Datura Metel*; *Hairy Thornapple*. Pericarps thorny, nodding, globular; leaves cordate, almost entire, pubescent. It has a strong stem, three feet high, divided into many woolly branches. The flowers have long tubes, which extend beyond the bifid calix; they then spread out very broad, where the brim is divided into ten obtuse angles, and are of a pure white above, but the tubes have a tincture of green within; they are succeeded by roundish fruit, closely covered with thorns.—Native of Asia, Africa, and the Canary Islands. See the first species.

6. *Datura Arborea*; *Tree Thornapple*. Pericarps smooth, unarmed, nodding; stem arboreous. It rises to the height of twelve or fourteen feet, with a woody stalk, dividing into several branches; leaves oblique, six inches long, two inches and a half broad in their widest part, growing narrower at each end, downy, on long footstalks, which stand nearer to one side than the other. The flowers come out at the divisions of the branches; they have a loose tubular calix, nearly four inches long, which opens at the top on one side like a spathe; the tube of the flower is narrow; but above, it swells very large, nearly six inches in length, then spreads open at the brim, where it is divided into five angles, which terminate in very long points; they are white, with some longitudinal stripes of a pale yellow on their outside; and are succeeded by round smooth capsules, filled with kidney-shaped seeds.—Native of South America; and one of the greatest ornaments to the gardens of Chili, where the inhabitants propagate it with great care. When the flowers are fully blown, they make a fine appearance; and a single tree will perfume the air of a large garden. This and the seventh species are both too tender to endure the open air of our climate, and must be sheltered in the stove.

7. *Datura Lævis*. Pericarps smooth, unarmed, erect; leaves smooth; stem fistular, herbaceous; corollas white.—Native of Africa; flowering from July to September.

8. *Datura Innoxia*. Pericarps ovate, nodding, set with harmless spines; leaves cordate, pubescent. This species rises three or four feet high, with a purplish stem, dividing

into several strong branches; leaves oblong, heart-shaped. Stems, branches, and leaves, covered with soft hairs. The flowers come out at the divisions of the stalk and branches, standing erect; they are large, white, and are succeeded by oval fruit, covered with long, soft, innocuous spines, and opening within in four cells, full of brown seeds.—Native of Vera Cruz. In favourable seasons, this will rise in the spring, from scattered seeds; and when the summer proves warm, will flower, and even perfect its seeds.

Daucus; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal manifold, flowering, flat, fruiting concave-converging; partial manifold, similar. *Involucre*: universal many-leaved, length of the umbel; leaflets linear, pinnatifid; partial more simple, length of the umbellule. *Perianth*: proper, scarce manifest. *Corolla*: universal difform, somewhat rayed; floscules of the disk abortive; proper of five petals, inflex-hearted, the exterior ones larger. *Stamina*: filamenta five, capillary; antheræ simple. *Pistil*: germen inferior, small; styles two, reflex; stigmas obtuse. *Pericarp*: none; fruit ovate, often hispid on every side, with stiff hairs, bipartite. *Seeds*: two, somewhat ovate, on one side convex, hispid, on the other flat. ESSENTIAL CHARACTER. *Corolla*: subradiate, all hermaphrodite. *Fruit*: hispid with hairs; according to Gärtner, mucronate with prickles, forming longitudinal crests.—The species are,

1. *Daucus Carota*; *Wild Carrot*, or *Bird's Nest*. Seeds hispid; petioles nerved underneath. In its wild state, the common Carrot has a slender, hard, whitish, or brownish fusiform root; stem upright, grooved, hispid, two feet high, with alternate branches, which are commonly from seven to nine or ten inches long, have one leaf on them, except the primary or terminating one, which is naked, and a single umbel of flowers at top. The flowers are white, those in the middle sometimes tinged with purple, and fertile; but those in the circumference, which are irregular and larger than the others, are frequently either neuter, or have pistils only. The fruit is spheroidal, composed of two plano-convex seeds, on the back of which are four membranaceous narrow crests, pectinated with linear-setaceous, innocuous, flexible teeth; and between these, three raised nerves, having very minute prickles on them along each side, bowing outwards; the belly is flat or slightly concave, marked with obscure longitudinal streaks.—It is common in pastures, on balks and headlands; and is a biennial, flowering from June till August. Carrot seeds have been recommended as a powerful diuretic, and an infusion of them has been found to give relief in fits of the gravel and stone. They have a slight aromatic smell, and a warm pungent taste. They communicate an agreeable flavour to malt liquor, if infused in it while working in the vat, and render it an useful drink in scorbutic disorders. They have not only been used as diuretics, and in the stone and gravel, but to disperse wind in the stomach; and, as they operate very powerfully by urine, they are excellent in obstructions of the viscera, in the jaundice, suppressions of the menses, and in the beginning of dropsies. A poultice made of the roots, has been found to mitigate the pain of foul cancerous ulcers, and remove the intolerable stench. Mr. Miller informs us that the shops are supplied with old seeds of the garden Carrot, instead of fresh seeds of the wild plant. This is one of the many ways in which efficacious medicines are brought into disrepute; but the remedy consists in every person's gathering wild Carrot seeds fresh for himself—He informs us, that he cultivated the wild Carrot for many years, but could never get the seeds which were sown in the spring to grow, but that part of the seeds which he sowed in autumn came up well. These plants he treated in

the same manner as the garden Carrot, but could not in the least improve the root, for they invariably continued to be small, sticky, and of a hot biting taste; from whence he inconclusively infers, that the wild Carrot and the garden Carrot are specifically different. This conclusion, however, is not to be admitted; for the improvement has probably been the effect of accident, or of time and care in a warmer climate; and the uncultivated plants, if left to themselves in a dry undunged soil, would probably relapse into their primitive state. Mr. Ray observed a variety of the wild Carrot on the sea-shore near Dover, with leaves of a dark green and glossy colour. Dr. Stokes adds, that in a specimen from the coast of Cornwall, the leaflets are remarkably broad, and but slightly cut. Moles are so fond of the roots, that Carrots are a proper bait to ensnare them with; but garden Carrots answer best for that purpose, as well as for destroying crickets, being made into a paste with powdered arsenic and wheat-meal. The females of this *polished* age will smile at the simplicity of ancient times, when they are informed, that the autumnal beauty of Carrot leaves allured many *gentlewomen* formerly oftentimes to stick them in their hats or heads, or pin them on their arms, instead of feathers.—The *Garden Carrot* is three feet high in its flowering state, and differs but little from the wild one, except in the largeness and succulency of the plant, and particularly of the root, which, with its superior size, usually takes a tincture of yellow, in different shades, as far as a deep orange, and becomes of a softer texture, without any of that acrimony and aromatic flavour, which are found in the wild root. There are several varieties, differing in the colour of their roots, as white, yellow, orange, and dark red or purple, which variations may be perpetuated by simply observing not to mix them together in the same garden. In London, the orange Carrot is most generally esteemed. Mr. Miller conceives the red or purple Carrot to be a distinct sort; it is much more tender than the others, insomuch that the roots were all destroyed by the first frosts in autumn: the seeds were sent from Aleppo, and the roots were smaller than the common sort, and purple, like a deep-coloured radish, very tender and sweet, with leaves more finely cut and less hairy than those of the common Carrot.—*Propagation and Culture*. The Carrot is commonly cultivated in gardens for the kitchen: they are propagated at two or three different seasons, and sometimes oftener, where people are fond of young Carrots. The first season for sowing the seeds is soon after Christmas, when the weather is open; they should be sown in warm borders, near walls, pales, or hedges, but not close to them, which would draw them up weak, and prevent them from producing any tolerable roots; they delight in a warm, light, sandy soil, which should be dug pretty deep, that the roots may be better run down, for if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral roots, especially where the ground is too much dunged in the same year that the seeds are sown, which will also cause them to be worm-eaten: it is best therefore to dung the ground intended for Carrots the year before they are sown, that the manure may be consumed and mixed with the earth; but in such places where there has not been ground so prepared the year before, and there may be a necessity for dunging it in the same year that the Carrots are sown, the dung should be well rotted, and thinly scattered over the ground; while in digging it into the ground, care should be taken to distribute it equally, and not to bury it in heaps, which would stop the roots of the Carrots in their downright growth, and cause them to be short and forked. Where the ground is inclined to binding, too much trouble cannot be taken to break and divide the parts; hence in digging land for Carrots, large

apits should never be taken, but thin ones that the elods may be well broken, which if not attended to by the master himself, is very seldom properly performed by workmen. The ground, when thus dug, must be laid level; or, when it is raked over after the seeds are sown, part of them will be too deeply buried, and others will run the risk of being drawn up into heaps, which will compel the plants to come up in bunches, while large plots of ground will be left unoccupied; all of which should always be carefully avoided. The seeds have a great quantity of small forked hairs upon their borders, by which they adhere so closely, that it is difficult to sow them so as to prevent them from coming up in patches; they should therefore be rubbed well through both hands, whereby the seed will be separated before it is sown: a calm day should be chosen to sow it in, for it is impossible to sow it equal when the wind blows, as the seeds being very light will be blown into heaps. As soon as it is sown, the ground should be trodden pretty closely with the feet, that the seed may be buried, and then the surface may be raked to make it level. When the plants are come up, and have got four leaves, the ground should be hoed with a small hoe about three inches wide, cutting down all young weeds, and separating the plants to four inches' distance each way, that they may acquire strength; and, in about a month or five weeks after, when the weeds begin to grow again, the ground should be hoed over a second time, in which two Carrots ought not to be left close to each other, but should be separated to a greater distance, cutting down every weed, but slightly stirring the surface of the ground in every place, the better to prevent young weeds from springing, as well as to facilitate the growth of the young Carrots: in about a month or five weeks afterwards, they must be hoed a third time, and the weeds removed as before. The Carrots should now be cut out to the distance they are to remain, which must be proportioned to the size at which it is intended they should arrive: if they be intended for drawing young, five or six inches asunder will be sufficient, but if to grow large before they are pulled up, they should be left eight or ten inches every way apart; the weeds must also be again removed, as they will greatly retard the Carrots, if suffered to grow among them. The second season for sowing is in February, on warm banks situated near the shelter of a wall, pale, or hedge; but those which are intended for the open large quarters should not be sown before the beginning of March, nor any later than the end of that month, for those sown in April or May will run up to seed before their roots have any bulk, especially if the weather should prove hot and dry. In July you may sow again for an autumnal crop, and at the end of August some more to stand for the winter, by which method you will have early Carrots in March, before the spring sowing will be fit to draw; but these are seldom so well tasted, and are often very tough and sticky: however, as young Carrots are generally expected early in the spring, most people sow some at this season; but these should be sown upon warm borders and dry land, otherwise they are seldom good. If the winter should prove very severe, it will be proper to cover the young Carrots with pease-haulm, the haulm of Asparagus, or some such light covering, to prevent the frost from destroying the roots; but if in very hard winters all the Carrots should be killed, a hot-bed may be made early in the spring, to sow some, which will be fit for use long before any that are sown in the full ground; these beds, however, should be earthed fifteen or sixteen inches deep, that the roots may have a proper depth of soil to run down. If these beds be lined with hot dung twice, at such times when their heat begins to decline, it will greatly forward the growth

of the Carrots, but great care should also be taken to avoid drawing the plants up too weak: these may be allowed to grow closer together than those sown in the full ground, because they will be drawn up for use when very young. Many persons mix several other sorts of seeds, as Leek, Onion, Parsnep, Radish, amongst their Carrots, and others plant Beans; but none of these methods are good, for if there be a full crop of one of these plants, there can be no room for any thing else amongst them; so that what is got by one is lost by another. It is not only more sightly, but actually better for the plants of each kind to be sown separate; for by this means the ground will be clear when the crop is gone, to sow or plant any thing else; but when three or four kinds are mixed together, the ground is seldom at liberty before the succeeding spring; besides where tall-growing plants are introduced among the Carrots, they are apt to make them grow more in top than root. The covetousness of some gardeners will not permit them to cut out their Carrots to a proper distance when they hoe them, so that by leaving them too close they draw each other up weak, and never recover their strength when so drawn, as those do which are properly thinned at the first hoeing; therefore where the Carrots are designed to have large roots, they must never stand too close, nor should they have any other crop mixed with them.—*Culture in the Field.* It is only of late years that the Carrot has been cultivated for cattle in the fields, although it has been long cultivated in gardens for the table. Even now there are not many parts of England where field-culture is practised; which is much to be regretted, for where the soil is suitable, there is scarcely any root yet known which more deserves the attention of the farmer. One acre of Carrots, if well planted, will fatten a greater number of sheep or bullocks than three acres of turnips, and the flesh of the animals will at the same time be firmer and better tasted. Horses are extremely fond of them; and there cannot be a better food for hogs. They have been cultivated in parks for feeding the deer, and have been found an excellent resource in hard winters, when great numbers of deer must otherwise have perished through the scarcity of other food, and when even those which have survived without them have been so much reduced as not to recover their flesh during the following summer; while those fed upon Carrots have been kept in good condition all the winter, and upon the growth of the grass in the spring have been fat early in the season; which is an important advantage wherever the grass is generally backward in its growth. There is also a material advantage in the cultivation of this root beyond that of the Turnip, because the crop is not so liable to fail; for as the Carrots are sown in the spring, the plants generally come up well; and unless the months of June and July turn out very unfavourable, there is no danger of the crop succeeding; whereas Turnips are frequently destroyed by the flies at their first coming up, and in dry autumns they are attacked by Caterpillars, which in a short time devour whole fields, while the Carrots remain unmolested by these vermin. Carrots have other advantages over Turnips, besides the principal one already mentioned, of their being better adapted to that sort of soil which best suits them both; they are less liable to be damaged by frost, are not subject to the same distempers and accidents, and last till April, the season of great difficulty, when farmers frequently know not what to provide for their stock, especially sheep; being also a spring crop, if the plant fail, the seed only is lost, and the land is in perfect order for Turnips at midsummer; or if scattered plants only be produced, the intervals may be filled by sowing Turnips or planting Cabbages. Carrots are also an excellent preparation for barley in sands and sandy loams, that are not foul

with quick or spear grass, for in such lands the hoeing for Carrots increases rather than destroys the quick, by hacking it in pieces. No crop, when such lands are clean, can be better for them than Carrots; because it admits no summer ploughing whatever, and is put on one earth given with a trench-plough in March, so that as much tenacity is given to these naturally loose soils as possible: the crop may be left late in the ground, and if the soil be very sandy, a crop of Buck-wheat may follow, for which any degree of cleaning from quick may be given if required. Every farmer therefore, who has a stock of cattle or sheep, if he have land proper for the purpose, which must be light, and of a proper depth to admit of the roots running down, should always have a supply of these roots. In preparing the land for Carrots, if it have never been in tillage before, it should be ploughed early in autumn, and then across again before winter, laying it up in high ridges to mellow by the frost; and if the ground be poor, some rotten dung should be spread over it in winter, and ploughed in at the beginning of February. The ground should be ploughed again in March to receive the seeds; to perform which, some employ two ploughs, one following the other in the same furrow, so that the ground is loosened a foot and a half deep; others have men with spades following the plough in the furrows, turning up a spit of earth from the bottom, which they lay upon the top, levelling it smooth, and breaking the clods; the latter method is attended with a little more expense, but is much preferable to the former, because the clods are better broken, and the surface left more even. If the land should have been in tillage before, it will require but three ploughings: the first just before winter, when it should be laid in high ridges, for the reasons before given; the second cross-ploughing should be in February, after which, if it be well harrowed to break the clods, it will be very beneficial; the last time must be in March, to receive the seeds as above directed. If great clods of earth remain unbroken after this third ploughing, it will be necessary to harrow it well before the seeds be sown. One pound and a half of seeds will be sufficient for an acre of land, but as they are apt to adhere together, it renders them more difficult to sow even than most other sorts, therefore some mix a quantity of dry sand with their seeds, rubbing them well together, so as to separate the Carrot seed from each other, which is a very judicious method; after the seeds are sown, they must be gently harrowed in to bury them; and when the plants come up, they should be hoed in the manner before directed.—The field-culture of Carrots is best carried on in a tract of Suffolk, called from the nature of its soil the *Sandlings*; it is a triangle formed by Woodbridge, Bawdsey Cliff, and Orford, at the three angles. They sow five pounds of seed to the acre, on a double furrow about fourteen inches deep; the time of sowing is about Lady-day, and they begin to hoe at Whitsuntide; they give three hoeings in all, which cost from fifteen to eighteen shillings an acre, sometimes more. Ten loads, of forty bushels each, topped clean, on an acre, in good land, is reckoned to be a middling crop: they feed with them from before Christmas, and continue sometimes till Whitsuntide, taking them up, and housing them in the latter part of the season, to have the land clear for Barley-sowing. The time of sowing among the sandy-field gardeners, is the first week in March; some sow in the middle, and others again at the end of March, but the time must in some measure be regulated by the season, and the convenience of the farmer. The time of sowing is by some extended from the beginning of February till the end of April; but this is too wide a range, if it can be avoided. New seed will appear a week sooner

than the old; and the crop depends very much upon the quality of the seed. Mr. Miller recommends only a pound and a half of seed to be sown on an acre, which is certainly too little; on the other hand, in the *Sandlings* we have seen that they sow five, eight, ten, and some even twelve pounds, which is generally a waste of seed. The common rule for the first hoeing is seven weeks after the seed is sown, or generally at the beginning of May; and the second at the middle of June, or somewhat later, according to the state of the crop. The usual produce on poor lands is 200, and on good land 400 bushels per acre; we have had accounts of 250, 300, 312, 326, 340, 352, 368, 400, 460, 482, and even 640, and 700 bushels produced from an acre; but let the husbandman always beware of calculating upon great crops, which are commonly produced on a small scale, or on very rich land, or by extraordinary tillage and manuring, or by some unusually fortunate and unforeseen circumstances. Several methods are prescribed for preserving Carrots during winter: it is the practice in the *Sandlings* to take up the Carrots as they are wanted, only keeping a store beforehand in case of frost; but this way of proceeding in some years leaves many to rot upon the ground. Soon after Michaelmas, in dry weather, they may be taken up with a common dung-fork, and piled up, or stacked in a corner of the field in the following manner: lay a platform of earth six inches above the level, two feet and a half wide, and of a length proportioned to the quantity of the crop, suppose from ten to twenty yards; on this earth scatter a light layer of straw, upon which place a row of Carrots, with their tops on, and turned outwards; the tails lapping over one another, so that the width covered with Carrots be about two feet; top the small roots, and lay them in the middle crosswise, to keep the two sides from parting, by pressing the weight more on the centre; on every two or three rows scatter a little straw, and thus continue to build up about four feet high; then cover the tops carefully with dry straw, and lay some sedge or other coarse material over all, by way of thatch; then begin another line parallel to the first, just leaving room to pass between them, and so continuing until the whole crop is taken up; fill the alleys with dry straw, and guard the outside with bundles of straw staked down, or set fast with hurdles, to prevent the wind from removing the straw and covering. Other persons take up their Carrots during some dry days in October, put them directly into small upright cocks of ten bushels each, entirely covered with the tops cut off, and being thus dried, carry them into a barn or shed, throwing some straw over them, but taking care not to pack them too close. Another way is, to leave them in cocks well covered over with straw or fern till they are quite dry, and then cover them with earth, beaten smooth with a spade: some twist off the tops with the hand, and others take off an inch of the roots to keep them from sprouting: but these attentions can only be bestowed on small crops. If they be barrellled up with very dry sand, after being previously well dried, they may be preserved a considerable time at sea.—Long experience has confirmed what Mr. Miller asserts, that they are a hearty food for sheep, cattle, horses, hogs, and deer, particularly for horses: they may also be applied to feeding hounds and pointers when boiled, and mixed with milk and barley-meal. A very good spirit may also be distilled from Carrots, and the refuse will be excellent for feeding hogs. One ton eight stone, after being exposed a few days to dry, weighed 160 stone, and measured forty-two bushels; after being washed, topped, and tailed, they lost eleven stone in weight, and seven bushels in measure. From this quantity fifty gallons were distilled, which were rectified, and twelve gallons of unexceptionable spirit were

obtained. The refuse weighed forty-eight stone, and the wash from the still measured 112 gallons, so that the refuse greatly exceeds that of an acre of Barley: and an acre of Carrots, allowing the produce to be twenty tons, will yield 240 gallons of spirit, which is considerably more than can be obtained from five quarters of Barley. But the produce of an acre ought not to be estimated at more than from ten to fourteen tons; and therefore the quantity of spirit extracted from an acre of Carrots will not exceed 168 gallons. Carrot-seed has been for many years raised at Weathersfield in Essex, perhaps because it possesses two soils best adapted to this culture; rich sand to raise the Carrots the first year, and strong loam for the year of seeding. The preparation of the soil consists in making it very fine by repeated ploughings and harrowings; usually three or four earths are given; and twenty pounds of seed per acre (apparently too great a quantity) are sown in April: they hand-hoe twice, setting the plants out seven inches asunder. At Michaelmas they dig up, cut off the tops to the length of an inch, and pack up the roots in barns with straw, taking care that they are dry enough when laid up. Securing them is a work of some difficulty, for the air must be admitted, and the frost at the same time excluded. The crops are large; a good produce is three bushels on a rod, but four have been known. For replanting in the spring, they choose a piece of fresh land, if there be any on the farm; if not, such as is in good heart, but they never manure it: the preparation is, to throw two three-foot ridges together in a dry season, in February or March; cut the top end of the Carrots off, to the amount of one-third of the root, and plant a double row upon each ridge, at three feet between the plants, and two feet row from row, in a quincunx order, so that the plants of one row may be ranged against the spaces of the other: they are twice hoed, and twice earthed up, the second time very high. The heads are cut off when quite dry, as they ripen, by women, and being laid on pack-cloths, are thrashed and dressed by men.

The other species are,—2. *Daucus Mauritanicus*; *Fine-leaved Carrot*.—Biennial.—3. *Daucus Visnaga*; *Spanish Carrot*, or *Pick-tooth*. Annual. The rays which sustain the umbel, being long and stiff, are used by the Spaniards and others, for picking their teeth: when they have served this purpose, they are chewed, and thus are supposed to be of service in cleansing and fastening the teeth; however this may be, they have a pleasant aromatic taste in the mouth.—4. *Daucus Gingidium*; *Shining-leaved Carrot*. Annual.—5. *Daucus Muricatus*; *Prickly-seeded Carrot*. *Daucus Maritimus*. A maritime variety of the last-mentioned species.—6. *Daucus Lucidus*; *Shining Carrot*. Biennial.—7. *Daucus Hispanicus*; *Viscous Carrot*. Biennial.—These are all natives of the south of Europe and Barbary; and flower from June to August.

Day Lily. See *Hemerocallis*.

Deadly Carrot. See *Thapsia*.

Deadly Nightshade. See *Atropa*.

Deadnettle. See *Galeopsis* and *Lamium*.

Decumaria; a genus of the class Dodecandria, order Monogynia; or, according to the *Hortus Kewensis*, of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth superior, with about ten leaves, very small; leaflets ovate, coloured, acute, reflex. *Corolla*: petals ten, lanceolate, obtuse, equal, disposed in a single circle, expanding. *Stamina*: filamenta from sixteen to twenty-five, filiform, length of the corolla; antheræ twin, depressed. *Pistil*: germen top-shaped, inferior; style cylindrical, shorter than the corolla; stigma gibbose, lobed with about ten little swellings. *Pericarp*: capsule eight-celled, many-

seeded. *Seeds*: solitary. ESSENTIAL CHARACTER. *Calix*: eight to twelve leaved, superior. *Petals*: eight to twelve. *Capsule*: eight-celled, with many seeds.—The only known species is,

1. *Decumaria Barbara*; *Climbing Decumaria*. A shrub, whose stem clinging by means of fibres to the trunks and branches of trees, climbs to a great height; leaves opposite, petioled, leathery, veined, towards the base remotely serrate; no stipules; buds pubescent; panicle corymbed, terminating; flowers like those of the lime-tree, whitish, and very sweet-scented.—Native of Carolina.

Delima; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, obtuse, equal, permanent. *Corolla*: none. *Stamina*: filamenta numerous, capillary, nearly equal to the calix; antheræ roundish. *Pistil*: germen superior, somewhat ovate; style cylindrical, length of the flower; stigma simple, permanent. *Pericarp*: berry larger than the calix, ovate, acuminate, two-valved; capsule coriaceous, one-celled. *Seeds*: two, arilled. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: none. *Berry*: with two seeds.—The only known species is,

1. *Delima Sarmantosa*. A tree, with scabrous leaves, resembling those of Beech; flowers peduncled, loosely panicled, both axillary and terminating; fruit a coriaceous swelling capsule, ending in an incurved beak, very smooth, of a yellow bay colour, opening on one side only by a longitudinal cleft; seeds two, globular, crooked next the base, berried, red, becoming blackish when ripe, fixed to the bottom of the capsules; their aril is incomplete, spongy, membranaceous, snow-white, torn at the edge, scarcely covering the lower half of the seed.—The leaves, being very thick and rugged, are used by the inhabitants of Ceylon, where it naturally grows, for polishing; and hence they name it *korosawael*, or *karossawael*, from *korossa*, to smooth or polish.

Delphinium: a genus of the class Polyandria, order Trigenia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals five, unequal, disposed in a circle, of which the uppermost in some is more obtuse than the rest in front, and is extended behind into a tubular, straight, long, obtuse horn, and the rest ovate-lanceolate, spreading, nearly equal; nectary two-cleft, seated in front within the circle of petals on the upper part, behind stretched out, involved within the tube of the uppermost petal. *Stamina*: filamenta very many, (fifteen or thirty) subulate, wider at the base, very small, inclined towards the upper petal; antheræ erect, small. *Pistil*: germen three or one, ovate, ending in styles the length of the stamina; stigmas simple, reflex. *Pericarp*: capsules as many, ovate-subulate, straight, one-valved, gaping inwards. *Seeds*: very many, cornered. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: five. *Nectary*: cloven, produced into a horn behind. *Siliques*: three or one.—These are mostly specious hardy annuals or perennials; the lower leaves digitate or palmate, the upper less divided, and sometimes even entire; the flowers are in loose spikes or panicles at the ends of the stem and branches, of various colours, chiefly blue, never yellow.—The species are,

* *Unicapular*.

1. *Delphinium Consolida*; *Branching Larkspur*. Nectaries one-leaved; stem subdivided. Root annual; stalk upright, a foot high or more, round, pubescent, divided into alternate dividing branches; leaves alternate, the lower ones on petioles half an inch long, the upper ones sessile or nearly so; corolla blue, varying to purple, pink, and white, and in gardens to striped, and many different shades of colour. In English, it is called *Wild* or *Corn Lark's-spur*, *Lark's-claw*, and

Lark's-toes; in French, *pied d'allouette*; in German, *rittersporn*; in Danish and Swedish, *ridderspore*; in Italian, *sporonella*; and in Spanish, *espuela de caballero*. It grows wild in the corn-fields in Germany, France, Switzerland, Carniola, Italy, and Spain; it was observed by Sherard in Swaffham-fields, Cambridgeshire, and found there by professor John Martin in 1730, and has been seen in abundance in most of the open fields round Cambridge, with pink, purple, and white flowers, ever since the year 1752. The expressed juice of the petals, with the addition of a little alum, makes a good blue ink. The seeds are acrid and poisonous.—Meyrick informs us, that a decoction of the leaves is good for the bleeding piles; stopping the hæmorrhage, and cooling the body at the same time, contrary to most of the other restraining medicines. A conserve made with the flowers is an excellent medicine for children, who, from a redundancy of acrid humours in the intestines, are subject to violent purgings. Hill also prescribes the juice of the flower, and an infusion of the whole plant, against the colic, and pains in the bowels.—The first, second, third, fourth, and fifth species, (which are annuals,) are propagated by seeds, which must be sown where the plants are designed to remain, for they do not bear transplanting well, especially when they are not removed while very young. Those seeds which are sown in autumn, produce the strongest plants and most double flowers, and ripen their seeds better than those which are sown in the spring, as they come earlier to flower; but to obtain a succession of these flowers, there should be some seed sown in the spring. When they are sown upon the borders of the flower-garden for ornament, they should be in patches of about a foot in diameter, in the middle of the borders, at proper distances; in each of these patches may be scattered ten or a dozen seeds, covering them over about a quarter of an inch with earth, and in the spring the plants may be thinned, leaving about five or six of the upright sort in each patch to stand for flowering, but of the branching sort not more than three or four, because they occupy so much more room. The plants will now require nothing farther, except careful weeding; and when they begin to flower, should be supported by flower-sticks, to prevent their being broken by the wind, especially if they be in an unsheltered situation. If the seeds be well chosen, there will be very few ordinary flowers among them; and if different coloured flowers spring up in each patch, they will make a pleasing variety; but the upright sort should never be mixed in the same patches with the branching, because they do not flower at the same time. But in order to preserve the two sorts fine, without degenerating to single or bad colours, there should be a bed of each sort sown in autumn, in some separate part of the garden, where the plants should be properly thinned, and kept clean from weeds till they begin to show their flowers; they should then be carefully looked over every other day, to pull out all those plants whose flowers are not very double, nor of good colours, for if these be permitted to stand among the others till their farina has impregnated them, it will certainly cause them to degenerate: hence those persons who are contented with only marking their good flowers for seed, and suffer the others to stand for seed among them, will always find themselves disappointed in the goodness of their flowers the following season: therefore those who propose to have these flowers in perfection, should never gather the seeds of such as grew in the borders of the flower-garden, because there it will be almost impossible to preserve them so true, as when they are in beds of a distance from all other kinds. When the seed-vessels turn brown, they must be carefully watched, to gather them before they open and discharge their

seeds; because those which are situated on the lower part of the stalk, will open long before the others on the upper part are ripe; hence the pods ought to be gathered as they ripen, and not suffered to stand till the stalks are pulled up, which is often practised. Those pods which are situated on the lower part of the stalks, are much preferable to such as grow near the top, for which reason those who are very curious in the choice of their seeds, crop off the upper part of the spikes of flowers, and never suffer them to seed. As these plants are so very hardy, and require so little care in their culture, they deserve a place in every good garden; and during their continuance in flower, there are few plants which make a better appearance.

2. *Delphinium Ajacis*; *Upright Larkspur*. Nectaries one-leaved; stem simple. The stalk is eighteen inches and more in height, and seldom branched; leaves finely divided, commonly by threes, on broad petioles; segments linear, quite entire, channelled above; spike of flowers erect and more dense than the preceding; commonly only one capsule or silique. This species affords a great variety of colours in both the single and double flowers, some of which are very large and numerous, in close spikes, making a fine appearance from the end of June until August.—Native country unknown. See the preceding species.

3. *Delphinium Aconiti*. Nectaries one-leaved, with four teeth in front; branchlets one-flowered. Stem a foot high, panicled, branching, hoary, pubescent; leaves pedate, multifid, linear, becoming hoary; the upper ones only three-parted; flowers terminating, solitary, peduncled, small, livid, variegated within with purple and green.—Annual: Native of the Dardanelles. See the first species.

** *Tricapsular*.

4. *Delphinium Ambiguum*; *Doubtful Larkspur*. Nectaries one-leaved; corollas six-petalled; leaves many-parted. Corollas blue, with a green outside; stalk three feet high or more; the branches come out horizontally at first, but afterwards turn up so as to make an acute angle with the stalk; the leaves are long, and finely divided; the flowers also are placed thinner in the spikes than those of the upright sort, are large, and some of them very double and of various colours. It flowers later than the Upright Larkspur.—Native of Barbary. See the first species.

5. *Delphinium Peregrinum*; *Broad-leaved Annual Larkspur*. Nectaries two leaved; corollas nine-petalled; leaves many-parted, obtuse. This has a very branching stalk, about two feet high; the lower leaves are divided into many broad obtuse segments, but those which are upon the stalks are generally single; the flowers grow scatteringly towards the upper part of the branches, are small, and of a deep blue colour; they are succeeded by very small seed-vessels, which are single or double, rarely three together.—Native of the south of Europe and the Levant. See the first species.

6. *Delphinium Grandiflorum*; *Great-flowered Larkspur*. Nectaries two-leaved, with entire lips; flowers usually solitary; leaves compound-linear, many-parted; they are of a light green above, and hoary beneath. It has a perennial root, which puts out two or three branching stalks every spring, rising a foot and a half high. The flowers come out towards the upper part of the stalks singly, each on a long naked peduncle; they are large, and of a fine azure colour, appearing in June and July, and ripening seed in autumn.—Native of Siberia. The sixth, seventh, eighth, ninth, and tenth, (which are perennials) are propagated by seed, which, if sown in autumn, will more certainly succeed than those which are sown in the spring; when the plants come up, they should be weeded and thinned; in the following autumn they must be

planted where they are to remain : they will flower in the following summer, and the roots continuing to increase in magnitude for many years, will produce a great number of flower-stalks.

7. *Delphinium Intermedium*; *Palmated Bee Larkspur*. Nectaries two-leaved, with ovate cloven lips and ovate divisions; leaves three-parted, with trifid gashed divisions. Root perennial, with annual stems growing to the height of six or seven feet; leaves broad, divided into five or seven parts, cut into many narrow segments towards the top; flowers in long spikes, terminating; corollas of a fine blue colour.—Native of Silesia. See the sixth species.

8. *Delphinium Elatum*; *Common Bee Larkspur*. Nectaries two-leaved, with ovate emarginate lips, and very short unequal divisions; leaves subpeltate, three-parted, with multifid divisions. It is six feet high; root perennial; leaves slightly villose, becoming smooth by age, half five-lobed, petioled; lobes acute, often half three-lobed, sharply serrate; spikes of flowers very long and handsome; peduncles one-flowered, languinose; corollas deep blue, with a wrinkled spur. It flowers from June to September, and is a native of Switzerland and Siberia. See the sixth species.

9. *Delphinium Exaltatum*; *American Larkspur*. Nectaries two-leaved, with oblong cloven lips and lanceolate equal divisions; leaves three-parted, with trifid divisions. Root perennial; stem upright, five or six feet high, branching; lower leaves large, divided into three lobes to the petiole, and these cut on their borders into acute segments; they are a little hairy, and of a grayish colour, standing upon pretty long petioles; stem-leaves smaller, and not so deeply divided; the principal stalk is terminated by a long loose spike of flowers; the flowers are not much larger than those of the common Larkspur, and are of a pale blue colour. The bearded nectary has, at first sight, the appearance of a large fly in the tube of the flower. It flowers at the end of June or beginning of July, and in cool seasons there is frequently a succession of flowers till the end of August.—Native of most parts of North America, where it occasions great disorders in the cattle that feed upon the leaves. See the sixth species.

10. *Delphinium Puniceum*; *Scarlet-flowered Larkspur*. Lips of the nectary two-parted, hairy; horn straight; leaves many-parted; no calicine bractes. It differs from all the other sorts in the dusky red colour of the flowers. Perennial.—Native of Siberia. See the tenth species.

11. *Delphinium Staphisagria*; *Palmated Larkspur*, *Stavesacre*, or *Lousewort*. Nectaries four-leaved, shorter than the petal; leaves palmate, with the lobes obtuse. This is an annual plant, rising with a strong hairy stalk about two feet high; leaves hairy, composed of five or seven oblong lobes, which have frequently one or two acute indentures on their sides; the flowers form a loose spike at the upper part of the stalk, each on a short peduncle, and are of a pale blue or purple colour. A variety with leaves veined with white, differs in having the leaf gashed, seven-parted, the divisions acuminate, the horn or spur of the corolla not obscure, but the length of the pedicel. The common people use the powder of the seed to kill lice; whence it is named *Lousewort*.—The seeds are kept by druggists, and have been given in small doses against rheumatic and venereal disorders; they vomit and purge, and that in so rough a manner, that it is not safe to take them internally; when chewed in the mouth, they excite a very large discharge of watery humours from adjacent parts, and frequently prove serviceable in disorders of the head; but are chiefly used to destroy the lice with which children's heads are

generally infested, and the seeds, coarsely powdered and strewed among the hair, never fails to remove them.—The seeds of this sort should be sown where the plants are designed to remain, and require no other treatment than the common Larkspur.

Dentaria; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets ovate-oblong, converging from parallel, obtuse, deciduous. *Corolla*: four-petalled, cruciform.—*Petals*: roundish, obtuse, scarcely emarginate, flat, ending in claws the length of the calix. *Stamina*: filamenta six, subulate, length of the calix, of which two are shorter; antheræ cordate-oblong, erect. *Pistil*: germen oblong, length of the stamina; style very short, thick; stigma obtuse, emarginate. *Pericarp*: silique long, columnar two-celled, two-valved, bursting open elastically, with the valves rolled back; dissepiment a little longer than the valves. *Seeds*: many, somewhat ovate. ESSENTIAL CHARACTER. *Silique*: bursting elastically, with the valves rolled back. *Stigma*: emarginate. *Calix*: converging lengthwise.—These plants are propagated by seeds, or parting their roots: the seeds should be sown in autumn, soon after they are ripe, in a light sandy soil, and a shady situation; in the spring the plants may be taken up where they grow too close, and transplanted out into the same kind of soil and situation, where, after they have taken root, they will require no farther care, but to keep them clear from weeds; in the second year they produce their flowers, and sometimes perfect their seeds. The best time for transplanting the roots is in October, when they should be planted in a moist soil and a shady situation; for they will not live in a dry soil, or when they are exposed to the sun. The bulbs produced on the stalks of the second sort, if planted, will grow, and produce other plants.—The species are,

1. *Dentaria Enneaphylla*; *Nine-leaved Toothwort*. Leaves three together, ternate, serrated, without any glands between the leaflets. Root perennial, white, toothed, long, of a pleasant taste; stem a foot, or a foot and a half in height, branched, round, and smooth; leaflets lanceolate, serrate, acuminate, smooth; flowers from three peduncles, forming a panicle or raceme, erect, fascicled; calix pale green or yellowish; petals reddish yellow, or yellowish red: most of the upper flowers are abortive. Gerarde calls it *Coral-toothed Violet*.—It flowers in April and May, and is a native of the woods of Hungary, Austria, Silesia, &c.

2. *Dentaria Bulbifera*; *Bulbiferous Toothwort*, or *Coral-wort*. Lower leaves pinnate; upper simple. Stem simple; corollas flesh-coloured. The scaly bulbs in the axils of the upper leaves falling off, take root, and propagate new plants, so that it rarely produces seed. Root perennial; petals purple, white, or reddish. It flowers in April and May. Gerarde calls it the *Toothed*, or *Dog-toothed Violet*.—Native of Germany, Carniola, Piedmont, and England, in moist woods and shady places. It is but rare in England, having only been observed in Highreed and Foxholes woods, near Mayfield, Sussex; in Old Park wood, near Harefield; and between Beaconsfield and Wycomb, Bucks.

3. *Dentaria Pinnata*; *Seven-leaved Toothwort*. All the leaves pinnate: lower leaves with seven, and the upper with five leaflets. It may be fairly separated from the fourth species, there being a permanent difference in the leaves, although they agree in the flowers.—Native of Switzerland, the south of France, and Silesia, Mount Jura, and Saleya.

4. *Dentaria Pentaphylla*; *Five-leaved Toothwort*. Leaves digitate. This rises with a strong stalk, a foot and a half high, with a leaf at each joint, composed of five lobes, four

inches long, and nearly two broad in the widest part, ending in acute points, and deeply serrate; the flowers which are small and of a bluish colour, grow in loose spikes at the top of the stalks. Ray observed this plant in abundance on Mount Jura.—Native of Switzerland, Savoy, the south of France, Carniola, and Silesia.

Dentella; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, superior; segments subulate. *Corolla*: one-petalled, funnel-form, longer than the calix; tube gradually widening into a five-cleft spreading border; segments acute, three-toothed; the middle toothlet more produced. *Stamina*: filamenta five, short, awl-shaped, inserted at the base of the tube; antheræ oblong. *Pistil*: germen roundish, inferior, villose; style cylindrical, short, thickish; stigmas two, thicker than the style, longer, spreading. *Pericarp*: capsule globular, crowned by the calix, two-celled. *Seeds*: very many, ovate. ESSENTIAL CHARACTER. *Corolla*: tubular, five-cleft, with three-toothed segments. *Calix*: five-parted. *Stigmas*: two. *Capsule*: globular, inferior, two-celled, many-seeded.—The only known species is,

1. *Dentella Repens*.—A native of various parts of the East Indies, and of New Caledonia. It is considered as a weed in the gardens of Amboyna.

Devil-in-a-Bush. See *Nigella*.

Devil's-Bit. See *Scabiosa*.

Devil's-Guts. See *Cuscuta*.

Deutzia; a genus of the class Decandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, somewhat bell-form, one-third of the length of the corolla, tomentose, five-cleft, seldom six-cleft; divisions ovate, obtuse, erect. *Corolla*: five-petalled, seldom six-petalled; petals inserted on the outside of the edge of the germen, oblong, obtuse, entire, white. *Stamina*: filamenta ten, placed without the edge of the germen, linear, filiform at the tip, below the tip emarginate, trifid, white, the length of the corolla, alternately somewhat shorter; antheræ globular, twin. *Pistil*: germen superior, like a wreath, concave in the middle; styles three, seldom four, filiform; a little longer than the corolla; stigmas simple, club-shaped. *Pericarp*: capsule globular, truncate, perforated, somewhat three-cornered, callous, scabrous, three-awned with the permanent bases of the pistils, three-valved, three-celled, seldom four-celled, the size of a pepper-corn, ash-coloured, gaping at the base. *Seeds*: several in each cell. ESSENTIAL CHARACTER. *Calix*: one-leafed. *Capsule*: three-celled. *Filamenta*: three-cusped.—The only species hitherto discovered is,

1. *Deutzia Scabra*. A tree, about the height of a man, and very much branched; branches alternate, round, even, purplish; branchlets villose, scabrous, spreading; leaves opposite, petioled, ovate, acuminate, serrate, veined and wrinkled, scabrous with hairs in stars, spreading, an inch or more in length; flowers on the outer branchlets in compound panicles, on alternate pedicels; peduncles and pedicels angular, tomentose, and scabrous.—It flowers in May and June, and is a native of Japan, where the leaves are used by joiners in smoothing and polishing.

Deuberry. See *Rubus*.

Dialium; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals five, equal, sessile, elliptic, obtuse, deciduous. *Stamina*: filamenta two, conic, very short, situated at the upper side of the receptacle; antheræ oblong, obtuse, as if of two conjoined. *Pistil*: germen superior, ovate; style subulate, declined, length of the stamina; stigma simple, ascending towards the tip of the antheræ. *Pericarp*: legume, inter-

nally pulpy. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: five-petalled. *Stamina*: at the upper side of the receptacle.—The only known species of this genus is,

1. *Dialium Indum*. A tree with alternate pinnate leaves, having seven ovate, oblong, acuminate, petioled, even leaflets, a hand in length; flowers paniced, nodding.—Native of the East Indies.

Dianthera; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted, tubular; divisions lanceolate, equal, length of the tube, permanent. *Corolla*: one-petalled, ringent; tube short; upper lip flattish, reflex, cloven, very obtuse; lower lip three-parted; divisions oblong, equal, obtuse, distant, the middle one wider. *Stamina*: filamenta two, filiform, shorter than the corolla, growing to the back of it, length of the upper lip; antheræ on each filamenta double, oblong, the one a little higher. *Pistil*: germen oblong; style filiform, length of the stamina; stigma obtuse. *Pericarp*: capsule two-valved, two-celled, compressed above and below, but alternately, with boat-like valves, bursting asunder with an elastic nail. *Seeds*: solitary, in form of a lens. ESSENTIAL CHARACTER. *Corolla*: ringent. *Capsule*: two-celled, bursting with an elastic nail. *Stamina*: each a pair of alternate antheræ.—All these plants, except the first species, being natives of the East or West Indies, and other hot countries, must be preserved in the bark-stove.—The species are,

1. *Dianthera Americana*. Spikes solitary, alternate. It is a low herbaceous plant, with a perennial root, which sends out several weak stalks about four inches long; the leaves are roundish, hairy, sessile, of a dark green colour, and an aromatic odour; the flowers are produced from the side of the stalks in small spikes, and are in shape and colour very like those of *Clinopodium*. They come out at the end of July, but rarely produce seeds in England.—Native of Virginia and other parts of North America. This plant is very difficult to preserve in England; for although it be hardy enough to endure the open air, yet it is very subject to rot in winter; and if it be placed under shelter, is apt to draw up weak, and soon after to decay.

2. *Dianthera Comata*. Spikes filiform, verticilled, the lower umbelled. Stem herbaceous, a foot high, somewhat branched and erect, angular, jointed, smooth; the joints swelling. According to Brown, it generally rises to the height of two or three feet, and is plentifully furnished with slender subdivided branches near the top; seeds two in each cell.—Native of the low lands of Jamaica, where it is called *balsam herb*.

3. *Dianthera Japonica*. Peduncle axillary, solitary, sustaining from two to four flowers; bractes oblong, ciliate. Root annual; stem herbaceous, erect, six-cornered, very finely villose, kneed, swelling above the knee, but little branched, a foot in height; corolla purple, a little longer than the bractes, with a curved cylindrical tube.—Native of Nagasaki in Japan; flowering in August.

4. *Dianthera Cœrulea*. Umbel fascicled, sessile, quite simple.—Native of Botany Island, near New Caledonia.

5. *Dianthera Clavata*. Panicle subumbelled, compound; peduncles dilated at the end.—Native of the Society Islands.

6. *Dianthera Paniculata*. Panicles axillary; leaves lanceolate, tomentose. A shrub, five feet high, with an erect stalk and brachiate branches; leaves quite entire, opposite; segments of the calix filiform; corolla white, with a long slender tube.—Native of Cochin-China.

7. *Dianthera Punctata*. Stem herbaceous; spikes termi-

nating; leaves lanceolate-ovate, acuminate; antheræ awnless. Stem erect, roundish, even, jointed; joints three inches long, narrowed at bottom; branchlets axillary, filiform, the length of the joints; flowers in whorls, two or three on each side, on very short pedicels and small, the lower ones more remote; bractes lanceolate, acuminate, a line in length; corolla twice as long as the calix, smooth on the outside, the throat dotted with violet.

8. *Dianthera Sulcata*. Stem herbaceous, grooved; leaves cordate-ovate; spikes terminating; lower antheræ awned. Stem erect, angular, six-grooved, pubescent, jointed; the internodes two or three inches long, and the joints swelling; leaves opposite, obtuse, scarcely crenate, somewhat rugged along the nerves, a little villose, paler underneath, an inch and half long, with alternate veins; petioles the length of the leaves; corolla villose on the outside, white, veined with purple; lower lip three-lobed; the lobes oblong, obtuse, equal.—Native of Arabia Felix.

9. *Dianthera Flava*. Suffruticose: leaves elliptic-lanceolate; spikes terminating; lower antheræ awned. Stem shrubby, roundish, the thickness of a goose-quill; branches obscurely quadrangular, subpubescent, scored with a line along the sides; the internodes an inch long; the joints swelling; leaves opposite, quite entire, thinly hairy, twice as long as the internodes, with alternate veins, on short petioles.

10. *Dianthera Debilis*. Stem shrubby; spikes solitary, imbricate, axillary, and terminating; bractes ovate, ciliate. Branches obscurely quadrangular, four-grooved, with hairs pointing backwards; leaves opposite, lanceolate, narrowed at the base into a very short petiole, quite entire, bluntish, veinless, having four parallel villose nerves underneath, and being only half the length of the internodes.

11. *Dianthera Violaacea*. Stem shrubby; spikes terminating, imbricate; bractes lanceolate, ciliate; flowers bicaricled. Branches powdered and villose, obscurely quadrangular; the angles scarcely scored with a line; the internodes an inch and half long; leaves opposite, lower oblong, upper lanceolate, rounded at the base, quite entire, smooth, bright green, veinless nearly the length of the internodes, on short petioles; spike cylindrical, half an inch long, on a very slender peduncle.

12. *Dianthera Bicaliculata*. Flowers paniced, bicaricled; panicles dichotomous. Stem herbaceous; leaves opposite, ovate, acuminate, quite entire, petioled, paniced, axillary; pedicels bifid, often trifid; corolla purple, bilabiate, divided; antheræ divaricated. It is annual; and flowers here in August.—Native of the East Indies and Arabia Felix.

Dianthus; a genus of the class Decandria, order Digynia. —GENERIC CHARACTER. *Calix*: perianth cylindric, tubular, striated, permanent, five-toothed at the mouth, surrounded at the base with four scales, of which the two opposite are lower. *Corolla*: petals five; claws length of the calix, narrow, inserted into the receptacle; border flat; the plates outwardly wider, obtuse, crenate. *Stamina*: filamenta ten, subulate, length of the calix, with spreading tips: antheræ oval, oblong, compressed, incumbent. *Pistil*: germen oval; styles two, subulate, longer than the stamina; stigmata bent back, acuminate. *Pericarp*: capsule cylindrical, covered, one-celled, gaping open at top four ways. *Seeds*: a great many, compressed, roundish; receptacle free, four-cornered, shorter by half than the pericarp. ESSENTIAL CHARACTER. *Calix*: cylindric, one-leaved, with four scales at the base. *Petals*: five, with claws. *Capsule*: cylindrical, one-celled.—These beautiful plants are chiefly herbaceous; some few, however, are suffruticose. Most of them are hardy and perennial, or biennial; some of the smaller wild sorts only are annual.—The species are,

* *Flowers aggregate.*

1. *Dianthus Barbatus*; *Bearded Pink*, commonly called *Sweet-william*. Flowers in bundles; calicine scales ovate-subulate, equal to the tube in length; leaves lanceolate. It has a perennial fusiform root; stem upright, jointed, smooth, a foot and half high, branched; leaves soft, veined, connate, from half an inch to almost an inch broad in the widest part, bright green; bundles of flowers compact, umbelled, sessile; petals serrate when wild, red, either plain or spotted with white, smaller than in many of the genus. The variations of colour are numerous, and might have been more so if this species had attracted the same minute attention as the *Pink* and *Carnation*. The principal varieties are, 1. Broad-leaved *Sweet-william*; 2. Narrow-leaved, or *Sweet-john*: each of these have the flowers one single and two double. The principal variations of colour are, 1. deep red; 2. pale red, rose-coloured, flesh-coloured; 3. purple, inclining to blue; 4. purple and white; 5. white-spotted; 6. red with white borders, and purple with white borders; 7. pure white, with all the intermediate shades of the above colours, both single and double. The broad-leaved, with very double flowers of a deep purple, inclining to blue, bursting the calix, is not so much esteemed. The double-rose *Sweet-william*, with flowers of a fine deep rose-colour, and smelling sweet, is much valued, for it does not burst. The mule, or *Fairchild's Sweet-william*, is one of the narrow-leaved sorts; it is supposed to have been produced from the seeds of a *Carnation*, impregnated by a *Sweet-william*; the flowers are of a brighter red than either of the former, and have an agreeable odour, but their bunches are not quite so large.—Native of Germany and Carniola. Some of the single flowers have very rich colours, which frequently vary in those of the same bunch; there are others with fine variegated flowers, and others whose middles are of a soft red bordered with white, which are called *Painted Ladies*; but whoever is desirous of preserving any of these varieties in perfection, should particularly mark the best flowers of each, and permit no other to stand near them, lest their farina should impregnate them. That which is called the *Painted-lady Sweet-william*, is a very beautiful variety; the stalks of this do not rise so high as most of the others; the bunches of flowers are larger, and produced more in the form of an umbel; the flowers standing equal in height, make a better appearance: there are others whose stalks rise three feet high, and the flowers of a very deep red or scarlet colour. These all flower at the same time as the *Carnations*, which reduces their value, as they have no scent. They must be renewed annually, to retain them in perfection. The single sorts are generally propagated by seeds, which must be sown in the latter end of March or the beginning of April, in a bed of light earth, and in June they will be fit to transplant out; at which time prepare some beds ready for them, and set them at six inches' distance every way: in these beds they may remain till Michaelmas, and ought then to be transplanted into the borders of the pleasure-garden or wilderness. They will flower the next year in June, and perfect their seed in August. The seeds should be saved from the best-coloured flowers for a supply. They may also be propagated by slipping their roots at Michaelmas; but this is seldom practised, because seedling roots always blow the strongest, and produce new varieties. Double *Sweet-williams* are propagated by cuttings, (or, as the florists term them, pipings) or layers, like *Pinks* and *Carnations*; they love a middling soil, not too light, nor too heavy or stiff, nor too much dunged, which very often occasions their rotting. They continue flowering a long time, and are extremely beautiful, especially the mule, which produces two full blooms of

flowers, one in June and the other in July; it is very subject to canker and rot, especially if planted in a soil too wet or dry, or if watered with sharp spring water.

2. *Dianthus Carthusianorum*; *Carthusian Pink*. Flowers subaggregate; calicine scales ovate, awned, shorter than the tube; leaves linear, three-nerved. This differs from the foregoing sort, in having the leaves narrower by half, stiffer, and marked with three principal nerves, not one only, as in that. The stem is a little scabrous, not perfectly smooth as in the former; the petals are distant and villose, not smooth, on their upper surface. In a fertile soil there will be fifteen flowers on a stem; in a barren soil fewer, and sometimes only one: this, therefore, is an intermediate species between the aggregate and one-flowered *Dianthi*. There are sometimes seven calicine scales. The petals are of a deep-red colour, ovate, and five-toothed. It does not flower till July.—Native of Germany, Switzerland, and Italy.

3. *Dianthus Atrorubens*; *Red Pink*. Flowers aggregate; calicine scales ovate, awned, shorter than the tube; leaves connate, striated. Height from two to three feet; leaves smooth, flat, lanceolate, erect. The head of flowers at the end of the stem is formed in this manner: a pair of elliptic leaves emitting a long awn, has two short peduncles rising from it on each side; hence the stem, rising a little higher, has three other very short peduncles, each bearing three flowers; petals scarlet, rhomb-shaped, with few unequal teeth.—It has hardly any smell; is perennial; and a native of Piedmont, in dry hilly places by the sides of woods.

4. *Dianthus Ferrugineus*; *Rusty Pink*. Flowers aggregate; petals bifid; segments three-toothed. This species very much resembles the third; but the stem is narrower, and the leaves are more grassy and keeled. It has the entire habit of Sweet-william; the flower-stems are upright, and about a foot and half high; the leaves are somewhat like those of Carnations, but of a darker green; the bundles of flowers are close; some of the corollas yellow, and others of a rusty iron colour, in different bundles, and sometimes even in the same bundle. They flower in July; but when the weather proves cool and moist, there will be a succession of flowers till the end of September. The roots will abide two or three years, but the young plants of the second year produce the most flowers.—Native of Italy and Spain.

5. *Dianthus Armeria*; *Deptford Pink*. Flowers in bundles; calicine scales lanceolate, villose, equal to the tube in length. Root annual; stems erect, a foot or a foot and half in height, round, pubescent, roughish, swelling at the joints, towards the upper part a branch comes forth at each joint, terminated with a small bundle of from two to four flowers; leaves linear-lanceolate, connate, bright green, erect, entire, pubescent on both sides and roughish, three-nerved, three inches long, and two lines broad; claws of the petals long; border purple, dotted with red and white, smooth, except that they are slightly hairy towards the throat, obtuse and finely notched at the end, acuminate, with one or two teeth; antheræ violet-coloured; stigmas red, purple, flexuose, pubescent. It flowers in July and August.—Native of Gothland, Denmark, Upper and Lower Silesia, the Palatinate, and other parts of Germany, France, Switzerland, Italy, Spain, and England. From having been found in a meadow near Deptford, it obtained the name of *Deptford Pink*; and is met with in Charlton-wood, and other parts of Kent; near Croydon, between Dorking and Mickleham, Dulwich, Oak-ouhonour Hill, and Streatham, in Surrey; in Norfolk; about Pershore and Eckington, in Worcestershire; near Ketley in Shropshire; and at Clarkson-leap, near Worcester. It is also found near Reading in Berkshire; near Caversham; on the

road from Harefield to Chalfont St. Peter's; in a little wood near Highgate; and in Tuddington-fields.

6. *Dianthus Japonicus*; *Japan Pink*. Flowers in bundles; calicine scales acute, ciliate, shorter than the tube. Stem decumbent at base, then erect, round, even, smooth, simple, or very rarely divided at top, a foot in height; leaves opposite, petioled, ovate, acute, entire, smooth, nerveless, erect, an inch in length, the upper ones smaller; petioles broad, stem-clasping; flowers terminating, fastigiate; calix the length of the tube of the corolla, striated, smooth; calicle ovate at the base, then lanceolate, acuminate, keeled, half the length of the calix; corolla crenate.—Native of Japan.

7. *Dianthus Prolifer*; *Proliferous Pink*. Flowers in heads; calicine scales ovate, obtuse, awnless, exceeding the tube in length. Root annual; stem usually single, erect, decumbent only at bottom, very smooth, swelling at the joints, a span or a foot high, sometimes more; flowers in a crowded head on the summit of the stalks, three or four together, surrounded by large scaly bractes nearly hiding them; they open one at a time, the uppermost first, rising up from the bractes, when they fade, drying up and withdrawing again, so that they are a considerable time in flowering; corollas small, slightly bifid, not crenate, red or rose-coloured, sometimes varying to white; they expand about eight in the morning, and close about one in the afternoon. It flowers in July and August; and is known by the name of Childing Sweet-william or Childing Pink.—Native of Denmark, Germany, France, Switzerland, Carniola, Italy, Sicily, Spain, and England. With us it is rare, in sandy pastures, and has been observed at Selsey Island in Sussex; near Norwich, on Landridge-Hill, at Hanley Castle, in Worcestershire; and between Hampton Court and Tuddington.

** *Flowers solitary, several on the same stem.*

8. *Dianthus Diminutus*; *Small Pink*. Calicine scales eight, longer than the flower. This seems evidently to be a mere variety of the preceding species: Linnæus affirms it to be the daughter of the Childing Pink. It is a very diminutive plant, seldom rising six inches high, terminated by a single flower, of a pale-red colour: the leaves are short and narrow, and grow in close heads. Annual.—Native of Germany and Switzerland.

9. *Dianthus Caryophyllus*; *Clove Pink*, and *Common Carnation*. Calicine scales subrhomboid, very short; petals crenate, beardless. This species, so well known by the gardener in its improved state, is thus described by Haller in a state of nature: Root large, woody, branched; stem a foot or eighteen inches high, decumbent at bottom, jointed, branched; leaves glaucous, smooth, linear, a line in breadth; every branch is terminated by one, two, or three flowers; the petals have long claws, which are green, with a rose-coloured border. This flower has a pleasant smell, but not the spicy odour of the garden plant. It grows on rocks, walls, and in dry soils. This fine flower, which has long been deservedly esteemed, both for its superior beauty and rich spicy odour, must have been unknown to the ancients in its cultivated improvement; otherwise it would have been described by the naturalists, and sung by the poets, as well as its rival the Rose. Carnations and Pinks have, however, been cultivated from time immemorial in Europe, and were among the few favourite flowers of our remote ancestors. Parkinson recites nineteen sorts of Carnations, and thirty of Gillyflowers. Though these have been supplanted by modern flowers, and the florists are daily producing new ones, yet it may not be unacceptable to the curious, to recite the names of those which were in favour almost two centuries ago.—*Carnations*.

Gray, red, and blue hulo; grimelo, or prince; white, or delicate; French; grand, or great Harwich, or old English; chrystall or chrystalline; red chrystall; fragrant; striped savage; blush and red savage; Oxford; king's or ordinary Bristow; greatest Granado; grand pere; cambersine; great Lombard red.—*Gillyflowers*. Lusty gallant, or Westminster; Bristol blue; Bristol blush; red Dover; light, or white Dover; fair maid of Kent, or ruffling Robin; qucen's dainty; Brazil; Granado; Turkey; Poole; light or pale pageant; sad pageant; Bradshaw's dainty lady; best white; London white; Stamell; purple; gredeline; blue; blush; John Wittie his great tawny; divers other tawnies; many sorts of blushes; some varieties of reds; striped tawny; marbled tawny; Master Tuggie's princess; flaked, feathered, and speckled tawny; Master Tuggie his Rose Gilliflower. This Master Tuggie appears to have been the most famous man of his time for the cultivation of those fine flowers; and Johnson, referring to the work of his friend Parkinson, says, "if they require any further satisfaction, let them, at the time of the year, repair to the garden of Mistress Tuggie, the wife of my lately deceased friend Mr. Ralph Tuggie, in Westminster, which, in the excellency and variety of these delights, exceedeth all that I have ever seen."—Modern florists distinguish the Carnation into four classes. First, *flakes*, of two colours only, and their stripes large, going quite through the leaves. Second, *bizarrs*, with flowers striped or variegated with three or four different colours, in irregular spots and stripes. Third, *piquettes* or *piquettees*, having a white ground, and spotted or pounced with scarlet, red, purple, or other colours. Fourth, *painted ladies*, which have the petals of a red or purple colour on the upper side, and are white underneath. Of each class there are numerous varieties, but chiefly of the third, which some years ago was in most esteem with the florists; but of late years the flakes have been in greater request. To enumerate the varieties would be useless, as they are not permanent, and every country produces new flowers almost every year, which, though at first raising they may be greatly valued, in two or three years become so common as to be of little worth, especially if they prove defective in any one property; and are turned out to make room for new comers. For the variety of pompous names, we refer, therefore, to the lists published yearly by florists and nurserymen, who either raise these flowers from seeds, or import them from abroad. The following are what the florists call the good properties of a Carnation: 1. The stem of the flower should be strong, and able to support the weight of the flower without hanging down; 2. the petals should be long, broad, and stiff, and pretty easy to expand, or, as the florists term it, should make free flowers; 3. the middle of the flower should not advance too high above the other parts; 4. the colours should be bright, and equally marked all over the flower; 5. the flower should be very full of petals, so as to render it, when blown, very thick in the middle, and the outside perfectly round. To this we may add, that the stem should not only be strong, but straight, and not less than thirty, or more than forty-five inches high. The flower should be at least three inches in diameter, and the petals well formed, neither so many as to appear crowded, nor so few as to appear thin. The lower or outer circle of petals, commonly called the guard-leaves, should be particularly substantial, rise perpendicularly about half an inch above the calix, and then turn off gracefully in a horizontal direction, supporting the interior petals, which should decrease gradually in size as they approach the centre, which should be well filled with them; all the petals ought to be

regularly disposed, and lie over each other in such a manner as their respective and united beauties may meet the eye all together; they should be nearly flat, or at most have a small degree of inflection at the broad end; their edges should be perfectly entire, without notch, fringe, or indentation: the calix should at least be an inch in length, and sufficiently strong at top to keep the bases of the petals in a close and circular body: the colours ought to be distinct, and the stripes regular, narrowing gradually to the claw of the petal, and there ending in a fine point: almost one half of each petal should be of a clear white, free from spots.—*Pinks* do not seem to have been much noticed by our ancestors; and it is only within the present century, and particularly of late years, that they have been so much improved and varied as to be highly valued by the florists; the principal varieties are the damask, white shock, pheasant's eye, common red, Cob's, Dobson's, white Cob, and Bat's. The old man's head, and painted lady Pinks, rather belong to the Carnation. The damask Pink is the first of the double sorts in flower; it has but a short stalk, and the flower is not very large, nor so double as many others; the colour is of a pale purple, inclining to red, but the scent is very sweet. The next which flowers is the white shock, which was so called from the whiteness of its flowers, and the borders of the petals being much jagged and fringed; but the scent of it is not so agreeable as of some others. After this appear all the varieties of pheasant's eye, of which new varieties are frequently raised, which are either titled from the persons who raised them, or the place where they were raised; some of these have very large double flowers, but those which burst their pods are not so generally esteemed. The Cob Pink comes out next, the stalks of which are much taller than any of the former; the flowers are very double, and of a bright red colour, and as it has the most agreeable scent of all the sorts, it well deserves a place in every good garden. The old man's head, and the painted lady, do not flower till July, coming out at the same season with the Carnation, to which they are more nearly allied than to the Pink: the first, when it is in its proper colours, is purple and white, striped and spotted, but this frequently is of one plain colour, which is purple, and will continue flowering till stopped by the autumnal frost; it has an agreeable scent, for which it is esteemed; while the painted lady is chiefly admired for the liveliness of its colour, being neither so sweet nor of so long continuance as the other. The times of flowering for the Pinks is from the latter end of May till the middle of July; and that sort of Pink which is called Bats will frequently flower again in autumn.—*Propagation and Culture of Carnations*. Having obtained some good seeds, prepare a proportionable number of pots or boxes, filled with fresh earth mixed with rotten cow-dung, incorporated well together: then sow the seeds, but not too thickly, in them, covering them with about a quarter of an inch of the same kind of light earth, placing the pots or boxes so as to receive the morning sun till eleven o'clock, observing also to refresh the earth with water as often as it may require. In about a month's time the plants will come up, and, if kept clear from weeds, and duly watered, will be fit for transplanting about the end of July; at which time prepare some beds of the same sort of earth as they were sown in, in an open airy situation, in which plant them about three inches square, observing to water and shade them until they have taken new root, taking care to keep them clear from weeds; in these beds they may remain till the end of August, by which time they will have grown so large, as almost to meet each other; then prepare some more beds of the like good earth, in quantity proportionable to the flowers you

have raised, in which plant them at six inches' distance each way, and not above four rows in each bed, for the more conveniently laying such of them as may prove worth preserving, for in these beds they should remain to flower; the alleys between these beds should be two feet wide, to afford room for passing between and clearing them. If the season should prove very dry, they ought not to be transplanted till there is some rain, so that in some years it may happen to be the middle or end of September, before there may be wet enough to moisten the ground for this purpose; but if there be time enough for the plants to strike root before the frost commences, that will be sufficient. If the winter should prove severe, the beds must be arched over with hoops, that they may be covered with mats, otherwise many of the plants may be destroyed, for the good flowers are not so hardy as the ordinary ones. They will only require weeding, and to be supported by sticks to prevent their breaking when they shoot up their stalks to flower: they ought to be attentively looked after as soon as they begin to blow, to ascertain which of them promise to be good flowers, as all the layers should be laid down upon them. Those which are well marked, and blow whole without breaking their pods, should be reserved to plant in borders, in order to secure seed; and those which burst their pods, and seem to have good properties, should be planted in pots, to try what their flowers will be when managed according to art, for until the second year no one can pronounce what the value of a flower will be. Having chosen such flowers as promise well for the large sort, mark them separately for pots, and the round whole-blowing flowers for borders: pull up all single or ill-coloured flowers, to allow the rest more air and room. When these have been laid at a proper season, as soon as they have taken root, which will be some time in August, they should be taken off and planted out; those that blow large, in pots, and the others in borders. The whole-blowing flowers have been latterly much more esteemed than those large flowers which burst their pods, but especially those round flowers which have broad stripes of beautiful colours and round rose-leaves, of which kind there have been a great variety introduced from France within these few years; but as the French flowers are extremely apt to degenerate into plain colours, and are much tenderer than the English, less prices are now given than for some years past: from the present taste for the whole-blowing flake flowers, many of the old varieties have been revived, and large prices paid for such as some years before were sold for one shilling a dozen, or even less; so variable is the taste, so capricious the fancy, of the florists. To propagate these plants by *layers*, (the best time for doing which is in June,) strip off the leaves from the lower part of the shoot intended to be laid, making choice of a strong joint about the middle part of the shoot, not too near the heart of it, nor yet in the hard part next to the old plant; then with a small knife make a slit in the middle of the shoot from the joint upwards, half way to the other joint, or more, according to their distance; then with your knife cut the tops of the leaves, and remove the swelling part of the joint where the slit is made, so that the part slit may be shaped like a tongue; for if that outward skin be left on, it would prevent their pushing out roots; then having loosened the earth about the plant, and, if necessary, raised it with fresh mould that it may be level with the shoot intended to be laid down, lest by the ground being too low, by forcing down the shoot you should split it off; then make a hole in the earth with your finger, just where the shoot is to come, and bend it with your finger and thumb gently into the earth, observing to keep the top as upright as possible, that the slit may be open, and being provided with forked sticks for

that purpose, thrust one of them into the ground, so that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the shank of the layer with the same sort of earth, giving it a gentle watering to settle the earth about it, which should be repeated as often as is necessary to promote their rooting. They will have taken root in about five or six weeks afterwards; and may then be transplanted into earth proper for them, which should have been previously prepared in the following manner: Select some good upland pasture, or a common that is of a hazel earth, or light sandy loam; dig eight inches deep from the surface, taking all the turf, and laying the whole in a heap to rot and mellow for one year: this heap must be turned once a month to sweeten, and ought then to have about a third part of rotten cow-dung, or rotten dung from a Cucumber or Melon bed, well mixed with it six or eight months before it be used, the better to incorporate their parts. They should be removed from the pots or beds, with balls of earth about their roots, in the beginning of autumn, into small pots, to have shelter during the winter. In the middle or latter end of February, if the season be good, you must transplant these layers into pots for their bloom; the pots should be full eight inches over at the top, and should have the holes stopped with oyster-shells or potsherds, to draw off the water; these pots should be filled about half way with the same good compost as was before directed: the plants should then be shaken out of the small pots with all the earth about their roots, and you must take off some of the earth round the outside of the ball, and from the surface removing the fibres of the roots on the outside of the ball of earth, plant one good plant exactly in the middle of each pot, but neither so low as to bury the leaves of the plant, nor so high that the shank may rise above the rim of the pot, which must now be filled up with the before-mentioned earth, closing it gently to the plant with your hands, and giving it a little water in dry weather, to settle the earth about it, and placing it afterwards where it may be sheltered from the north wind, and watered as the season may require: here they are to remain till the middle of April, when a stage of boards should be prepared to set the pots on. This stage should be so ordered that the plants may have little cisterns of water round their pots, to prevent insects, particularly the earwig, from attacking the flowers in bloom: as those insects never fail to destroy the petals of the flowers, which are very tempting to them on account of their sweetness. But since the making of these stages is somewhat expensive, and not very easy to be understood by such as have never seen them, we shall here describe a very simple one, which will answer the purpose as well as any other. First, prepare some common flat pans about sixteen inches over, and three deep; place these two and two opposite to each other, about two feet distance, and at every eight feet lengthways two of these pans; in each of these whelm a flower-pot (which should be about six inches over at the top), upside-down, and lay a flat piece of timber about two feet and a half long, and three inches thick across, from pot to pot, till you have finished the whole length of your stage; then lay your planks lengthways upon these timbers, which will hold two rows of plants in the pots, of the size ordered for Carnations; and when you have set your pots upon the stage, fill the flat pans with water, replenishing them whenever it decreases, which will effectually guard the flowers against insects. The stage should be placed in a situation open to the south-east, but defended from the west winds, which would probably blow the plants down, being particularly violent at the season in which the flowers begin to appear.

The stage indeed should be defended by trees, at some distance, from the wind of every point; but care ought to be taken that the trees be not too near. In the middle of April the layers will begin to shoot up for flower, when some square deal sticks, about four feet and a half long, which should be thicker toward the bottom, and planed off taper at the top, should be carefully stuck into the pots as near to the plants as possible without injuring them; then fasten the spindle to the stick with a slender piece of bass-mat, to prevent its being broken; repeating this as the plant advances in height, observing also to pull off all side-spindles as they are produced, never suffering more than two spindles to remain upon one root, nor above one when you wish the flower to blow exceeding large. Towards the beginning of June, the flowers will have attained their greatest height, and their pods begin to swell, and some of the earliest begin to open on one side; observe therefore to open it in two other places at equal angles, which must be done as soon as you perceive the pod break, otherwise your flower will run out on one side, and be in a short time past recovering so as to make a complete flower, and in a few days after the flower begins to open, you must cover them up with glasses, which are made for that purpose, in the following manner: Upon the top of the glass, exactly in the centre, is a tin collar or socket, about three-fourths of an inch square, for the flower-stick to come through; to this socket are soldered eight slips of lead at equal distances, which are about six inches and a half long, and spread open at the bottom about four inches asunder; into these slips of lead are fastened slips of glass, cut according to the distances of the lead, which when they are fixed in, are bordered round the bottom with another slip of lead quite round, so that the glass has eight angles, with the socket in the middle, and spread open at the bottom, about eleven inches wide. When the flowers are open enough to be covered with these glasses, make a hole through your flower-stick, exactly to the height of the under part of the pod, through which put a piece of small wire about six inches long, making a ring at one end of the wire to contain the pod, into which ring fix the stem of the flower; then cut off all the tyings of bass, and thrust the stem of the flower so far from the stick, as may give convenient room for the flower to expand without pressing against the stick, to which distance you may fix it by turning your wire so as not to draw back through the hole; then make another hole through the stick, at a convenient distance above the flower, through which put a piece of wire, an inch and a half long, which is to support the glasses from sliding down upon the flowers; and be sure to observe that the glasses are not placed so high as to admit the sun and rain under them to the flowers, nor so low as to scorch their leaves with the heat. At this time also, or a few days after, as you shall judge necessary, cut some stiff paper, cards, or some such thing, into collars about four inches over, and exactly round, cutting a hole in the middle of it about three-fourths of an inch in diameter, for the bottom of the flower to be let through; then place these collars about them to support the petals of the flower from hanging down, this collar should be placed withinside the calix of the flower, and should be supported thereby: then observe daily what progress the flowers make, and if one side come out faster than the other, turn the pot round with that side towards the sun, and shade the glasses with cabbage leaves in very hot weather during the heat of the day, to prevent their being scorched or forced out too soon; and when the middle pod begins to rise, take out the calix thereof with a pair of nippers made for that purpose, but this should not be done too soon, lest the middle part of the flower should advance

too high above the sides, which will greatly diminish its beauty: you must also observe whether there be more leaves in the flower than can be properly expanded in the space allotted to it, and if that be the case, put out some of the lowermost to spread, drawing out and expanding the others at the same time; and when the flowers are fully blown, if you cut them off, put on a fresh collar of stiff paper, which should be cut exactly to the size of the flower, that it may support the petals to their full width, but not to be seen wider than the flower in any part: when this is put on, draw out the widest leaves to form the outside of the flower, which although they should be in the middle, yet by moving the other leaves, they may be drawn down, and then the next longest leaves upon them again, that the whole flower may appear equally globular, without any hollow parts: in the doing of this some florists are so curious as to render an indifferent flower very handsome; and on this, in a great measure, depends the skill of the artist to produce large fine flowers. During the flower season, particular care should be taken not to let them suffer for want of water, which should on no account be raw spring water, nor compound waters, such as are enriched with various sorts of dung; but the best and most natural water is that of a fine soft river; next to that is pond-water, or standing water; but if you have no other than spring water, it should be exposed to the sun and air two days before it is used, otherwise it will give the flowers the canker, and spoil them. The directions here introduced are chiefly intended for the management of those large Carnations, which require the greatest skill of the florists, although of late years they have been less esteemed than formerly, and those flowers which do not break their pods, and are termed *whole-blowers*, have now the preference. These are generally planted in pots, and treated in the same way as the large flowers, but do not require so much trouble to blow them; all that is necessary to be done for these, is to fasten their stems up to flower-sticks, to prevent them from being broken, and to take off the pods which proceed from the side of their stalks, leaving only the top-bud to flower, if they be intended to be large and fair; and when the flowers begin to open, if they be screened from the sun in the heat of the day, and also from the wet, they will continue much longer in beauty. But although the most valuable of these flowers are usually planted in pots, and thus carefully treated, yet many of these whole-blowing flowers may be planted in beds, or borders of the flower-garden, where they form a principal ornament during their continuance in flower, which is from the beginning of July till the middle of August, especially if the several colours be properly intermixed; for the flakes and bizarrs should be intermixed with the picquettes, and not planted separately, unless where they are designed for saving the seeds, in which case, those which are the finest of each sort should be planted in beds at a distance from each other, especially where persons are desirous to keep them distinct; for where the sorts are blended together, there will be an admixture of their farina, so that the seeds will vary, and not produce the particular kinds: the flowers that are planted in the full ground, generally produce such seeds better than those in pots. But whoever proposes to raise a supply of new flowers from seeds, must always observe to save the best of their seedling flowers for this purpose; for it is well known, that after any of these flowers have been a few years propagated by layers, they become barren, and do not seed; which is also the case of most other plants that are propagated by slips, layers, or cuttings, so that the young plants which have been newly obtained from seeds, are always the most productive of seeds: the plants which are propagated by layers or slips, will

always continue to produce the same flowers, so that when a fine variety is obtained, it is thus propagated and maintained; but all the new varieties come from seed, so that every person that is curious in these flowers must sow the seeds annually. Carnations may also be increased by cuttings and pipings as pinks are, but not so successfully in general as by layers, unless the operation be performed on a hot-bed under glasses; the cuttings for piping should have two joints, which ought to be thrown into water for a few minutes, and planted not more than half an inch deep; they are to be gently watered, and to continue open till their leaves are dry before they are covered; after this, they are to be kept moist till they have rooted, and to have only the morning sun and air admitted occasionally; but notwithstanding every precaution, success will be very uncertain, and many of the cuttings will frequently perish.—*Propagation and culture of Pinks.* The common Pinks are propagated by seeds, which is the best way to obtain new varieties; or by layers, as is practised for Carnations; or by slips, or pipings as they are commonly called, which, if carefully managed, will take root very well. In raising them from seed, care should be taken to save only the sorts which will produce the finest flowers; the seeds may be sown in the spring, and the plants treated in the same way as is above pointed out for the Carnation: the Old Man's Head and Painted Lady Pinks, are commonly propagated by this method, and most of the others. The time most proper for piping, will vary with the season, but it should always be done immediately before or during the bloom, or indeed as soon as the young shoots are of a sufficient length for that purpose, that is, to form pipings from two to three inches in length; the striking will be much facilitated by covering the beds or pots with glasses, after having given them a good watering; not taking off the glasses till the cuttings or pipings begin to grow, but applying the water, when necessary, round the outside of the glasses. In a month or six weeks they may be rooted, and grow, though they may be fully exposed. The only difference between cuttings and pipings is, that the former are cut through a joint horizontally, and the latter are drawn out at the joint from their sockets, so that they leave a hollow like a pipe, and thence derive their name. At the time of planting, if any rain should fall it will be of great service, but should the weather prove dry, the cuttings or pipings will require to be watered every other day until they have taken root; they should be planted in a shady border, and the ground should be dug well, and all the clods broken; and if no rain falls, it should be well soaked with water a few hours before they are planted; they ought then to be taken from the plants, all their lower lips stripped off, and planted as soon as possible after, for if suffered to lie long, they will wither and spoil. They need not be planted at a greater distance than three inches square, with the ground closed very hard about them; after which, watering and weeding is all they will require. Pinks may also be increased by slipping off the young shoots from the sides of the main ones, any time in the spring from February to April; the slips ought to be from three or four to six or eight inches in length.

10. *Dianthus Pomeridianus; Afternoon Pink.* Calicine scales ovate, acute, very short, upper half of the calix striated; petals emarginate, almost entire. The stem has only three or four simple, long, one-flowered branches; the corolla is yellow, and underneath pale green. The flowers open at half after twelve at noon, and close at ten at night.—Found near Constantinople, and in Palestine.

11. *Dianthus Deltoides; Maiden Pink.* Calicine scales ovate-lanceolate, acute, about two; petals crenate; leaves

bluntish, subpubescent. Barren stems numerous, reclining; putting forth roots; flowering-stems six to eight inches high; columnar below, square at top, slender, weak, but usually erect, sometimes simple, sometimes branched or dichotomous, swollen at the joint, slightly pubescent; the petals vary much in colour, being sometimes of a very pale flesh-colour, sometimes deep red, but always marked with a ring of deeper red dots near the centre of the flower. Dillenius distinguished this species by the scales of the calix being much more pointed; the corolla of a deeper colour, with numerous silvery dots; and its flowering later, namely, in June, and July. It continues flowering till late in autumn. There is a variety of this species common in gardens, which has white flowers with a beautiful purple ring, and leaves rather more glaucous than in the common sort.—It is found on pastures and heaths on a light soil in Sweden, Denmark, Germany, Spain; and is not uncommon in England, being found on Hampstead Heath, Dupper's Hill near Croydon, about Hampton Court Park, Beacon's Hill, near Feversham in Kent; not far from Slough, near Windsor; near Sandy, in Bedfordshire; in Cambridgeshire, Suffolk, and Norfolk; at Clay, near Hillborough in the way from Brandon, &c. in Nottinghamshire, Derbyshire, Westmoreland, Shropshire, Somersetshire; and at King's Park, Edinburgh.

12. *Dianthus Rupestris; Field Pink.* Calicine scales two, very obtuse; petals crenate. Leaves linear, very narrow, three-sided, channelled, stiffish, connate, in tufts, scabrous on the edge and keel; stem filiform, prostrate, bearing one or two flowers, which are remote, and sweet-scented; petals blood-red, crenate, not feathered or villose.—Perennial; native of mountains in the south of Europe.

13. *Dianthus Cæsius; Mountain Pink.* Flowers sub-sultry; calicine scales roundish, short; petals crenate, pubescent; leaves rugged at the edge. The circle is purple, and there is a purple tinge on the upper surface, from a number of very fine lines. Root woody; stalks several, a span high, erect, simple, smooth, quadrangular, having two or three pairs of leaves on them, one-flowered, scarcely ever two-flowered; petals flesh-coloured, with a double row of blunt notches, marked with lines, and bearded at the base. The flowers have no scent.—Native of Switzerland; and in England it is found on Cheddar rocks, in Somersetshire.

14. *Dianthus Albens; Cape Pink.* Calicine scales lanceolate, four, short; corollas emarginate. Petals white above, greenish white underneath, with the tip violet-coloured on both sides.—It is a perennial, flowering in August; and native of the Cape of Good Hope. This is the only plant of the genus which will not bear the open air of our climate.

15. *Dianthus Chiensis; China Pink.* Calicine scales subulate, patulous, leafy, equalling the tube; corollas crenate, leaves lanceolate. The flower-stems rise from six to eight or nine inches high, branching out on every side; the branches grow erect, and are terminated each by one flower, which possesses no scent, but exhibits a great variety of colours. They are a considerable ornament to the flower-garden from July till autumn, when the frost stops them. They have been greatly improved by culture; some flowers being as full of petals as the best double Pinks, and displaying the most glowing and vivid red colours: it is known in the nursery-grounds by the name of *Indian Pink*, and was originally imported from China by way of Paris. It is generally supposed to be an annual plant, because the plants which are raised from seeds, flower and produce ripe seeds in the same season, so that their roots are not often preserved; but, where they are planted on a dry soil they will continue two years, and the second year will produce a greater number of flowers than

the first. There is a great variety of very rich colours in these flowers, which annually vary when raised from seeds. The double flowers are most esteemed, though the colours of the single ones are most distinct and beautiful; for the multiplicity of petals in the double flowers in a great measure hides the deep shades which lie towards the lowest part of the petals. These plants are propagated by seeds, which should be sown upon a gentle hot-bed about the beginning of April: this moderate heat is merely intended to accelerate the vegetation of the seeds; therefore, when the plants come up, they must have a large share of air admitted to them; to prevent their drawing up weak; and, as soon as the weather will permit, they should be exposed to the open air. Three weeks or a month afterwards, they will be fit to remove, and should then be carefully taken up with good roots, and planted in a bed of rich earth, at about three inches asunder, being careful to shade them from the sun until they have taken new root, and in dry weather to water them three or four times a week; they will then only require weeding till the end of May, at which time they may be transplanted to the places where they are designed to remain for flowering, when they may be taken up with large balls of earth to their roots, so as scarcely to feel their removal, especially if it happen to rain at that time. As they do not grow large plants, so when they are planted singly in the borders of the flower-garden, they do not make so fine an appearance as where they are planted by themselves in beds, or if they be planted in small clumps of six or eight roots each, where the flowers being of different colours, will set each other off to advantage. Those who are curious in these flowers, take particular care in saving their seeds, never permitting any single flowers to stand among the double, but pull them up as soon as they display their flowers, and also draw out all those which are not of lively good colours. Where this is observed, the flowers may be kept in great perfection; but where the seeds can be exchanged once every two or three years, with trusty friends who live at some distance, it is much better to change than to continue sowing seeds in the same place many years in succession.

16. *Dianthus Monspelicius*; *Montpellier Pink*. Calicene scales subulate, straight, a little shorter than the tube; corollas many-cleft; stem erect.—It is a perennial plant, and grows wild about Montpellier, Verona, and in Piedmont.

17. *Dianthus Plumarius*; *Feathered Pink*. Calicene scales subovate, very short, much blunted and awnless; corollas many-cleft. Stems ascending a foot or eighteen inches in height, branched; flowers, one, two, seldom three, at the ends of the branches, sweet-scented; petals large, light red, or bright purple, sometimes white, with a circle of red deeply jagged, having a red down at the base of the lamina or border; anthers red. It flowers from June to August, and is perennial.—Native of rocks, mountain pastures, and dry woody places, in North America.

18. *Dianthus Crinitus*; *Hairy Pink*. Calicene scales, oval, mucronate, subdiverging, one-third of the length of the tube; petals many-cleft, beardless. Stalks a span high, smooth and even; flowers two or four on a stalk, erect; petals narrow, irregularly cut to the base in very fine segments. It varies with a white flower.—Found by Tournefort in Armenia.

19. *Dianthus Superbus*; *Superb Pink*. Flowers panicled; calicene scales very short, acuminate; petals cloven into many capillary segments. Stem erect. The stem is a foot or eighteen inches in height, procumbent at the base, and then erect; round, somewhat two-edged on the upper part, smooth, branching only at top; leaves like those of the narrow-leaved Sweet-william; petals pale-red colour, sometimes

white, hairy at the base of the border, sprinkled with bloody spots. The flowers smell very sweet, especially in the evening; capsule cylindrical, a little longer than the calix, glittering like gold-dust, smooth, four-parted. According to some, it is perennial, while others reckon it biennial, and even annual. Mr. Miller asserts, that the roots will live three or four years, but that the flowers are in their greatest beauty the second year from seeds.—Native of Denmark, Lapland, Germany, Switzerland, France, Italy, and Spain: flowering from July to September. This deserves a place in every garden, on account of the elegance and delicious fragrance of the flowers. It grows naturally in a calcareous soil, and will thrive luxuriantly in a garden, if chalk be mixed with the common mould, but not otherwise.

20. *Dianthus Attenuatus*; *Diminished Pink*. Calicene scales short, lanceolate, acuminate, about six; tube attenuated at the top; petals crenate. Stalks diffused, woody at bottom, twisted, branching very much; flowering-branches ascending a foot long, leafy, round, smooth, divided at top into two or three branches, which are one-flowered; flowers flesh-coloured, void of scent.—Native of the south of France, near the coast.

*** *Stem one-flowered, herbaceous.*

21. *Dianthus Arenarius*; *Sand Pink*. Stem bearing one or two flowers; calicene scales ovate, obtuse; petals many-cleft; leaves linear. Stem a span in length, sustaining one flower; root-leaves abundant, in bundles, smooth, narrow, obtuse, stiffish; petals white, not crenate, smelling very sweet, especially in the evening. Mr. Miller says that the flower is sweet, but pale-coloured and small.—It flowers in May and June; and is a native of Scania, in drifting sand; of Silesia, on the borders of Saxony; of the mountains of Carniola, and Piedmont; and is found on old walls and buildings in any part of England.

22. *Dianthus Alpinus*; *Alpine Pink*. Corollas crenate; outer calicene scales leafy, almost equalling the tube. Root woody, perennial, putting forth many stems of a finger's length, having three joints; leaves on the stem linear, bluntish, flat; root-leaves in tufts, linear-lanceolate.—Native of the Alps, Silesia, Austria, Stiria, and Siberia, in rough stony places; flowering in June and July.

23. *Dianthus Virgineus*; *Upright Pink*. One or two inodorous flowers on the stem; petals crenate; calicene scales very short and blunt, in pairs. Root perennial; lower leaves copious, erect, in an imbricate tuft, acuminate, like those of Thrift; stems few, a span in height, having four very simple joints with smaller leaves, the uppermost very small, arising from a perfoliate sheath, decumbent, not prostrate. It flowers in June and July.—Native of the Alps, the south of France, Austria, Carniola, &c.

**** *Shrubby.*

24. *Dianthus Arboreus*. Stem shrubby; leaves oblong, somewhat fleshy; calicene scales numerous, blunt, closely imbricate, very short. Stalks eighteen inches and more in height, white, round, smooth, jointed, woody, branched; leaves glaucous, an inch and half long, narrow, rigid, mucronate; petals pale purple, striated a little beyond the middle marked with a dark-red dotted line, forming a ring, below which they are lanuginous; they are also cut about the edge.—Native of the island of Candia. This, with the two following species, are noble ornamental plants, which, it is to be lamented, are lost to our gardens.

25. *Dianthus Fruticosus*. Stem shrubby, twisted, two feet high, brittle, hard, covered with a dark cloven bark; leaves lanceolate, an inch long, and three or four lines broad, obtuse, fleshy, brittle, bitter as gall, growing in tufts; flowers

commonly solitary, but sometimes several together; petals an inch and half long.—Native of Seriphos, in the Levant.

26. *Dianthus Juniperinus*. Stem shrubby, with a lacerated chinky bark, very much branched; leaves awl-shaped; calicine scales about four, obovate, mucronate and pungent, patulous, only half the length of the tube; flowers two or three at the tops of the branchlets, pedicelled, small.—Native of the island of Candia.

***** *New Species.*

27. *Dianthus Pungens*; *Prickly-leaved Pink*. Flowers solitary; stems full of alternate branches, few-flowered; calicine scales very short, mucronate, spreading; tube gibbous; petals entire. The stem-leaves are connate and sheathing at the base, crowded and covering the branches with their sheaths; the leaves on the branches are slightly connected with distant sheaths; all are flattish, acuminate, and somewhat prickly; the peduncles arise from the ends of the lateral branchlets; the pedicels sustain from one to three flowers, which appear from August until October.—It is a native of the coast of Spain.

28. *Dianthus Hispanicus*. Stem usually one-flowered; calicine scales ovate; petals linear, quite entire. Plant a span in height; root woody; root-leaves in a tuft, linear, subulate; stems seldom two-flowered, smooth. There is a variety with roundish petals, white and red.—Native of the province of Arragon in Spain.

29. *Dianthus Libanotis*. Flowers subaggregate; calicine scales six, acuminate, recurved; corollas multifid-capillary, bearded at the throat; stem erect. Root perennial, thickish, and somewhat branched; stem herbaceous, a foot high; leaves lanceolate, glaucous, those next the root obtuse, on the stem acute, recurved; flowers paniced; calicine scales six, sometimes eight, seldom four, awl-shaped, dilated at bottom, membranaceous, a little shorter than the tube of the calix; petals yellowish, with a few hairs and red dots within at bottom; the claws are the length of the calix; filamenta filiform, a little longer than the calix; styles swelling at the base, scarcely the length of the stamina.—Native of Mount Libanus.

30. *Dianthus Pumilus*. Stemless; leaves linear. This plant grows in a tuft; the leaves are acute, smooth, and half an inch long; flowers sessile, solitary; petals toothed.

Diapensia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth eight-leaved; the five interior leaflets placed in a circle, the rest leaning upon them in an imbricated manner, all equal, ovate, obtuse, erect, permanent. *Corolla*: one-petalled, salver-shaped; tube cylindric, open, length of the calix; border five-cleft, obtuse, flat. *Stamina*: filamenta five, compressed, linear, erect, terminating; the tube at the incisures of the border short; antheræ simple. *Pistil*: germen roundish; style cylindric, length of the stamina; stigma obtuse. *Pericarp*: capsule roundish, three-celled, three-veined. *Seeds*: very many, roundish. ESSENTIAL CHARACTER. *Corolla*: salver-shaped. *Calix*: five-leaved, imbricate with three other leaflets. *Stamina*: placed on the tube of the corolla. *Capsule*: three-celled.—The species are,

1. *Diapensia Lapponica*. Root perennial; stem rising immediately from the root, and divided into several simple diffused branchlets, clothed all round with leaves at most a finger's height; leaves linear, blunt, almost membranaceous, having a longitudinal nerve, concave above, prominent beneath, perennial, the lower ones finally withering, but not falling; peduncle from the top of the branch straight, slender, one-flowered; corolla shining, snowy white.—Native of the mountains of Lapland, among stones covered with moss; also found on the coast of Labrador, and in Norway.

2. *Diapensia Barbulata*. Leaves somewhat wedge-shaped, downy beneath; antheræ spurred at the base.—Found on the mountains of North Carolina.

Dicera; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four or five parted; leaflets equal. *Corolla*: petals four or five, obovate, trifid; segments obtuse, the middle one longest; nectary of four or five small emarginate corpuscles surrounding the germen. *Stamina*: filamenta (twelve to twenty) several between the nectary and the germen, capillary, short; antheræ linear, two-horned at top. *Pistil*: germen roundish; style awl-shaped, longer than the stamina; stigma simple. *Pericarp*: berry, ovate, two-celled. *Seeds*: very many. ESSENTIAL CHARACTER. *Petals*: four or five, obovate, trifid. *Nectary*: of four or five emarginate corpuscles. *Antheræ*: two-horned.—The species are,

1. *Dicera Dentata*. Style one; leaves oblong, acuminate, toothed; racemes simple, axillary, loose. This is an elegant tree, bearing at the extremities of the branches abundance of leaves, which are alternate, oval, or oval-oblong, bluntish, smooth, veined, bluntly serrate, petioled with a double gland at their base; racemes axillary, simple, loose, solitary, the length of the leaves; flowers on very minute pedicels, nodding; stamina sixteen when there are four, and twenty when there are five petals. Fruit an oval berry, with a hard stone in it; while unripe, it is preserved after the manner of olives. Linneus remarked twenty stamina in the Ceylonese plant, and only eight in that from Java.—Native of New Zealand.

2. *Dicera Serrata*. Styles four; leaves opposite, cordate-ovate, unequally serrate; racemes lateral, compound. This agrees with the preceding species in the structure of the flowers, but differs in the fruit.—Native of New Zealand.

Dichondra; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: five-leaved; leaflets obovate, netted nerved, hairy without, smooth within, permanent. *Corolla*: monopetalous, inferior, rotate, subcampanulate, five-cleft, the length of the calix. *Stamina*: filamenta five, subulate, spreading, placed alternately between the divisions of the corolla, and only half the length; antheræ roundish. *Pistil*: germina two, hairy; styles two, divaricate, setaceous, the length of the stamina, arising on the inside from the base of the germina; stigmata capitate. *Pericarp*: capsules two, globular, subhirsute, one-celled. *Seeds*: one in each cell, globular. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: rotate, inferior. *Capsule*: dicoccous.—The only known species is,

1. *Dichondra Repens*. Stem prostrate, creeping, branched, round, leafy; leaves alternate, petioled, erect, kidney-shaped, sometimes emarginate, above almost naked, below silky, radiate-veined; flowers small, rather nodding, on axillary filiform, simple, silky peduncles, scarcely the length of the petioles, and usually solitary. The specimens from different countries differ in having the leaves naked above, or silky on both sides; also in the length of the petioles and peduncles; but these seem only to be varieties. Mutis sent it to Linneus from New Granada; Commerson found it at Buenos Ayres, and in the island of Mauritius; and it is likewise known to be a native of Peru, Jamaica, and New Zealand.

Dicksonia; a genus of the class Cryptogamia, order Filices.—GENERIC CHARACTER. Fructifications, kidney-shaped, lying under the edge of the frond at the lower surface; outer valve formed of the substance of the leaves itself, inner membranaceous.—The species are,

1. *Dicksonia Arborecens*; *Tree Dicksonia*. Fronds superdecompound, villose; leaflets almost entire; stem

P. 449.

DIGITALIS PURPUREA — *Purple Foxglove.*

DELPHINIUM GRANDIFLORUM — *Great-flowered Larkspur.*

arboreous.—It flowers during the greater part of the winter; and was found by Sir Joseph Banks and Dr. Solander, in the island of St. Helena.

2. *Dicksonia Culcita*; *Shining-leaved Dicksonia*. Fronds superdecompound, smooth; leaflets serrate. Found in the island of Madeira, where it is called *feila brom*; and in the island of San Miguel, one of the Azores. The inhabitants make pillows and cushions of the roots. There is little doubt but that this plant, and the *barometz*, or Scythian Lamb, are one and the same, though they come from countries so remote.

Dictamnus; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, very small, deciduous; leaflets oblong, acuminate. *Corolla*: petals five, ovate-lanceolate, acuminate, with claws, unequal, of which two are bent upwards, two placed obliquely at the sides, one bent downwards. *Stamina*: filamenta ten, subulate, length of the corolla, situated between the two lateral declining petals, unequal; small point-like glands scattered over the filamenta; antheræ four-sided, rising upwards. *Pistil*: germen five-cornered, elevated from the receptacle; style simple, short, bent downwards, incurved; stigma sharp, rising upwards. *Pericarp*: capsules five, conjoined inwardly at the border, compressed, acuminate, with distant tips, two-valved. *Seeds*: in pairs, ovate, very smooth, within a common aril, which is two-valved, and cut down. ESSENTIAL CHARACTER. *Calix*: five. *Petals*: five, patulous. *Filamenta*: having glandulous dots scattered over them. *Capsule*: five, conjoined.—The species are,

1. *Dictamnus Albus*; *Frazinella*. Leaves pinnate; stem simple. Root perennial, striking deep into the ground, and the head annually increasing in size; stalks many, two or three feet high, round, here and there slightly grooved, sometimes subcapitulate, not branched, at bottom green and beset with white hairs, ferruginous, red towards the top, with resinous glands; leaves alternate, the larger above a foot in length, spreading out horizontally, ascending towards the end; the midrib flat at top and edged on both sides, convex beneath, and hairy; leaflets from two to five pairs, with an odd one at the end, most of them alternate; the whole somewhat resembling an ash-leaf; flowers in a long pyramidal loose spike or raceme, nine or ten inches in length; corolla large and handsome, the common natural colour pale purple, with dark purple veins, but varying to white; filamenta pale purple, concealing the germen and style, ascending or turning up at the end, glandular, especially at top; antheræ green; germen covered with pedicelled glands; style with white hairs; stigma blunt, dark purple. The whole plant, especially when gently rubbed, emits an odour like that of lemon-peel; but when bruised, has something of a fine balsamic scent, which is strongest in the pedicels of the flowers, which are covered with glands of a rusty red colour, exuding a viscid juice or resin, which exhales a highly inflammable vapour, and in a dark place, in hot weather explodes, on the approach of a candle, without injuring it. Gerard calls it *Bastard* or *False Dittany*; and Parkinson, *False* or *White Dittany*. It flowers with us at the end of May and in June, and the seeds ripen at the end of September.—Native of Germany, France, Spain, Italy, &c. in shady mountainous places. Its beauty and fine scent should introduce it into every good garden. The roots are the parts chiefly used in medicine, and they are of a cordial sudorific nature, and are good in fevers, and in nervous hysteric complaints. A strong infusion of the young tops is a pleasant and efficacious medicine for the gravel: it works powerfully by urine, and gives ease in those colicky pains which so frequently attend that

disorder.—It is propagated by seeds, which, if sown in the autumn, soon after they are ripe, the plants will appear the following April; but when they are kept out of the ground till the spring, the seeds seldom succeed; or if they do grow, it is the following spring before the plants appear, so that a whole year is lost. When the plants come up, they must be constantly kept clean from weeds; and in the autumn, when their leaves decay, should be carefully taken up, and planted in beds at six inches' distance every way: these beds may be four feet broad, and the paths between them two, that there may be space left for weeding them. The plants may stand two years in these beds, during which time they must be constantly kept clean from weeds; and if they thrive well, they will be strong enough to flower. In the autumn they should be carefully taken up, and planted in the middle of the borders of the flower-garden, where they will continue thirty or forty years, producing more stems of flowers in proportion to the size of the roots. All the culture these require, is to be kept clean from weeds, and the ground about them dug every winter.

2. *Dictamnus Capensis*. Leaves simple; stem branching. The simple leaves are alternate, and like the leaflets of the preceding; the raceme is the same in both.—Native of the Cape of Good Hope.

Didelta; a genus of the class Syngenesia, order Polygamia Frustranea.—GENERIC CHARACTER. *Calix*: common, double, permanent; outer three-leaved or three-parted, unbilobed at the back; leaflets cordate, acuminate, much expanded, tomentose-hoary above; inner placed on the disk of the outer, shorter, composed of eleven or twelve leaflets, which are linear-lanceolate, very acute, serrate, prickly, one-nerved, spreading, five or six, alternately shorter by half than the others, the twelfth often wanting. *Corolla*: compound, radiated; corollets hermaphrodite, numerous, shorter than the calix, barren in a deltoid disk, fertile in the outer triangles of the receptacle; females eleven or twelve in the ray, each opposite to one of the calicine leaflets, and double the length of the calix; proper in both hermaphrodites funnel-shaped, half five-cleft; border five-parted, linear, acute, patulous, revolute, brown at the tip; female ligulate, four or three toothed, three-furrowed, tubular at the base, spreading. *Stamina*: in both hermaphrodites; filamenta five, capillary, very short, inserted into the tube; antheræ cylindric, tubular, five-toothed, brown at the tip, the length of the corollet: in the females, the rudiment of one stamen inserted at the top of the tube. *Pistil*: in the perfect hermaphrodites, germen inferior, immersed in the receptacle, oblong, compressed, crowned with a thin short pappus or down, like the eye-lashes; style slender, finally standing out; stigma two-parted, subulate, revolute; in the barren hermaphrodites, germen roundish, very small, immersed; in other respects as in the fertile; females scarcely any rudiment of a germen. *Receptacle*: deltoid, flat, honey-combed, with labyrinthed membranes, distinct, and finally resolvable into four partial deltas or triangles; the central naked, barren; the side ones producing seeds, roughened with stiff brown bristles, becoming hard, and in separating from each other forming a pericarp; nuts three, bony, three-cornered, flattened, stiff, bristly, from the outer triangles of the receptacle gaped and hardened, each retaining an outer leaf and the opposite inner calicine leaflets, or one-third part of the calix, and many-celled. *Seeds*: small kernels, as many as there were germina, but some abortive, oblong; down simple, thin, short, stiffer than in the flower. ESSENTIAL CHARACTER. *Calix*: expanding, outer leafy. *Receptacle*: honey-combed, dividing into many parts which retain the seeds. *Down*.

chaffy, many-leaved.—These plants may be propagated both from seeds and cuttings, must have the protection of a dry-stove or a glass-case, and may be managed like other Cape plants.—The species are,

1. *Didelta Carnosa*; *Succulent-leaved Didelta*. Leaves alternate, lanceolate-oblong, fleshy. Stem herbaceous, very much branched, erect, round, eighteen inches in height; branches alternate, diffused, fleshy, smooth, green, the thickness of a quill, the extreme branchlets woolly; leaves from an inch to two inches long, thick and juicy, entire, obtuse, somewhat downy beneath; flowers solitary, terminating, on long peduncles, scarcely nodding, yellow. It is an annual; but, like some other annuals, will last several years in the stove, and become somewhat shrubby.—It flowers in July; and is a native of the Cape of Good Hope.

2. *Didelta Spinosa*; *Opposite-leaved Didelta*. Leaves opposite, somewhat stem-clasping, ovate. Stem shrubby, erect; leaves broad-ovate, somewhat heart-shaped, smooth, with prickles above their insertion; calix entire, the outer of five leaves or segments. This plant is very smooth.—It flowers in June and July; and is a native of the Cape.

Didymodon, one of Hedwig's genera of Mosses.

Dier's-broom, or *Dier's-weed*. See *Genista*.

Dier's-weed. See *Reseda*.

Digitalis; a genus of the class Didymia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth five-parted; divisions roundish, sharp, permanent; the superior longer than the rest. *Corolla*: one-petalled, bell-form; tube large, expanding, bellied downward; cylindric, and close at the base; border small, four-cleft; upper division more expanding, emarginate, inferior division larger. *Stamina*: filamenta four, subulate, inserted into the base of the corolla, bent downwards, of which two are longer; antheræ two-parted, acuminate on one side. *Pistil*: germen acuminate; style simple, in the situation of the stamina; stigma sharp. *Pericarp*: capsule ovate, length of the calix, acuminate, two-celled, two-valved; valves bursting in two directions; according to Gærtner, partition double from the inflex edges of the valves. *Seeds*: very many, small; Gærtner says, subprismatic. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: bell-form, five-cleft, bellying. *Capsule*: ovate, two celled.—The species are,

1. *Digitalis Purpurea*; *Purple Foxglove*. Calicine leaflets ovate, acute; corollas obtuse, upper lip entire, according to Withering very slightly notched. Root biennial; stem three to six feet high, simple, upright, leafy, round, pubescent; leaves alternate, ovate-acute, serrate, veiny, wrinkled underneath, whitish with pubescence, gradually lessening to both ends; petioles short, winged; flowers in a long spike, nodding, imbricate, all directed the same way; peduncles one-flowered, pubescent, thickest at top; calix also pubescent; corolla purple; the bellying part sprinkled in the inside with spots like little eyes, or elegantly mottled; upper segment entire and truncate; lower bent in, obtusely lobed above, and four-cleft, the lower segment somewhat longer; filamenta a little broader at top, crooked at bottom; antheræ at first large, turgid, ovate, cloven almost to the base, yellowish, and often spotted, afterwards changing both their form and situation in a singular manner; germen rather conical, very hairy; stigma bifid; nectary a gland surrounding the base of the germina; the lowermost valve of the capsule splits in two; seeds dark-brown, truncate at both ends. The corolla is generally of a fine purple; but it varies into different shades of that colour, and is frequently white or cream-coloured. Some, says Parkinson, thinking Foxglove to be a foolish name, do call them Finger-flowers,

because they resemble the fingers of a glove with the ends cut off.—It flowers from June to August, and is a native of Denmark, Germany, Switzerland, and Britain. It is found in sandy and gravelly soils, and grows plentifully about Charlton-wood, and Norwood, near London. The *Digitalis Purpurea*, or common Purple Foxglove, has long been considered as a plant possessed of very powerful virtues. A drachm of the powdered leaves, taken inwardly, excites violent vomitings. It is certainly a very active medicine, and merits great attention; and it is singular that a plant, so powerful in its operations, should not sooner have been introduced into the modern materia medica. The country people in Somersetshire are said to have been long in the habit of using it, in decoction, for fevers, to purge and vomit, which it often brings on in too violent a degree. The Italians call this plant *aralda*, and have a proverb concerning it, *aralda tutte piaghe salda*, "Foxglove cures all sores." Parkinson declares it to be effectual in the falling sickness, if two handfuls of it be boiled in ale with four ounces of Polypody of the Oak, and the decoction drank by the patient; and that they who had laboured under that disease twenty-six years, falling down twice or thrice every month, were perfectly restored by the use of this decoction, and did not fall into a fit for the space of fourteen or fifteen months after. The dried leaves applied, or the juice made into an ointment, has been highly commended in ulcers, king's evil, &c. as well as the bruised flowers made into an ointment with fresh or May butter. The diuretic effects of Foxglove, for which it is now so deservedly celebrated, and on which account, as well as for its other powers, it is so much used in drop-sical cases, seem to have been first ascertained by Dr. Withering; yet he observes, that it seldom succeeds in men of great natural strength, tense fibre, warm skin, and florid complexion, or in a tight cordy pulse. If the belly in ascites be tense, hard, and circumscribed, or the limbs in anasarca be solid and resisting, we have but little hope. On the contrary, if the pulse be feeble or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, the anasarcaous limbs readily pitting under pressure of the finger, we may expect the diuretic effects to follow in a kindly manner. In hydrothorax, or water in the chest, striking proofs are said to have been afforded of the efficacy of Foxglove. The dose of the dried leaves in powder is from one to three grains a day; but if a liquid medicine be preferred, a drachm of the dried leaves is to be infused for four hours in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. The first dose of this infusion for an adult may be about half an ounce three times a day, increased by about a drachm daily till the desired effect follows, unless the reduction of the pulse, and other symptoms, arise to an alarming degree.—If the seeds of this plant be permitted to scatter, the young plants will come up in the spring, and require only to be weeded out where they are too numerous. The seeds of this, and of the other sorts, should be sown in autumn; for those which are sown in the spring seldom succeed, or at least lie a year in the ground before they grow.

2. *Digitalis Minor*; *Small Foxglove*. Corollas obtuse; upper lip slightly two-lobed; leaves entire, according to Withering very slightly notched; stem even, shorter by half than that of the first species; peduncles villose; flowers very like those of first species in form, size, and colour, but the dots of the palate are more copious and without the pale iris; the upper lip is more deeply two-lobed, the lower very obtuse, and the lateral segments reflex.—Native of Spain; perennial.

3. *Digitalis Thapsi*; *Spanish Foxglove*. Leaves decurrent, tomentose, veined, serrate; the lower lanceolate-ovate, the upper broad-lanceolate, all decurrent, and having the decurrent sides reflex. The bunch or spike of flowers the same as in the first species; the corolla purple, with a pale throat, over which are sprinkled blood-red dots; border four-cleft; the upper lobe undivided, the lower longer and ciliate.—Perennial; flowering from June to August; and a native of Spain.

4. *Digitalis Lutea*; *Small Yellow Foxglove*. Calicine leaflets lanceolate; corollas acute; upper lip bifid. It has very long obtuse leaves near the root; the stalk is small, and rises from two to three feet high. It is distinct from the next species, in having the leaves smooth, harder, and narrower; the flowers small, thicker in the spike, pale, not spotted; the segments of the calix and corolla acute, triangular; the spike long and dense, of small yellow flowers. Perennial; flowering in July and August.—Native of France, about Geneva, in Switzerland, Silesia, Carniola, and about Salerno and Naples.

5. *Digitalis Ambigua*; *Greater Yellow Foxglove*. Calicine leaflets lanceolate; helmet of the corolla emarginate; leaves pubescent underneath. The upper part of the stalk is adorned with large yellow flowers, nearly of the same size with those of the first sort, the brim having acute points, and the upper lip being entire; the stem is two feet high, and pubescent. It flowers in July and August.—Native of Germany, Switzerland, Geneva, Austria, and Piedmont.

6. *Digitalis Ferruginea*; *Iron-coloured Foxglove*. Calicine leaflets ovate, obtuse, spreading; lower lip of the corolla bearded. Stem strict, even, six feet high; leaflets sessile, lanceolate, even, marked with lines, quite entire; flowers in an upright raceme from each of the upper axils; bractes linear-lanceolate, reflex; pedicels very short, solitary; the three upper leaves of the calix approximating; corolla a little longer than the calix, pubescent, yellowish within; the two upper divisions obscure, the side ones sharp, the lowest longer; stamina flexuose, without any rudiment of a fifth; style the length of the flower, which expands in June, and has the colour of rusty iron.—Native of Italy, and found about Constantinople.

7. *Digitalis Obscura*. *Willow-leaved Foxglove*. Leaves linear-lanceolate, quite entire, growing together at the base. Stem undershrubby, with a few opposite branches; flowers on terminating racemes; corollas drooping, obtuse, yellowish within, reticulated, and rufous at the bottom, pale rufous on the outside, especially at the back; upper lip half cleft and recurved, lower three-parted, the middle part a little longer than the others.—It flowers in July and August; and it a native of Spain.

8. *Digitalis Canariensis*; *Canary Shrubby Foxglove*. Calicine leaflets lanceolate; corollas two-lipped, acute; stem shrubby. It rises sometimes four, and even five or six feet high, dividing into several branches; leaves lanceolate, rough, nearly five inches long, and two broad in the middle, gradually decreasing to both ends, having a few short serratures on their edges, placed alternately on the branches, each of which is terminated by a loose spike of flowers, nearly a foot in length: they are of an orange colour, intermixed with yellow, and are shaped somewhat like the flowers of *Acanthus*.—Native of the Canary Islands. It begins to flower in May, and there is generally a succession of flowers on the same plant till the winter puts a stop to them, which renders the plant more valuable. It is propagated by seeds, which should be sown in pots filled with light earth, in the autumn, soon after the seeds are ripe. Those pots ought to be

plunged into an old bed of tanner's bark, the heat of which is exhausted, and in mild weather the glasses ought to be drawn off to admit the air; but in hard rains and frosts they must be kept on, to protect the seeds from both which frequently destroy them when exposed in our climate. The plants will come up in the spring, and should enjoy the free air in mild weather, but must be protected from the cold. When these are large enough to transplant they should be each planted into a separate small pot filled with light earth, and placed under the frame till they have taken new root, and ought then to be gradually inured to the open air. They must have a sheltered situation during the summer, but in the winter must be placed in a green-house, for they will not live abroad in England. They must not be kept too warm and close in the house, for they only want protection from the frost, and in mild weather require abundance of free air and frequent waterings.

9. *Digitalis Sceptrum*; *Madeira Shrubby Foxglove*. Calicine leaflets subulate; bractes linear, longer than the flowers; corollas obtuse; leaves elliptic, serrate; stem shrubby. This is a very handsome plant, the branches of which are rough with hairs; peduncle terminating the branch, solitary, round, upright, a hand or more in length, porous on the inside, ending in an ovate spike, with the flowers hanging down. It flowers in July and August.—Native of Madeira, in woods. For the propagation and culture of this plant, see the preceding species.

10. *Digitalis Orientalis*; *Oriental Foxglove*. Calicine leaflets acute; leaves oval-lanceolate, nerved. Root leaves many, smooth; among these arises the stalk about a foot high; the leaves on it are smooth, from four to five inches long, and one inch and a half broad in the middle, half stem-clasping; spike terminating, short, loose: corollas yellow, almost as large as those of the fifth species, but shorter. It flowers in May, and the seeds ripen in Autumn.—Native of Tartary.

11. *Digitalis Cochinchinensis*. Leaves lanceolate, rough; flowers solitary, axillary; calices acute; corollas obtuse, emarginate at top. Stem herbaceous, a foot and half high, almost upright; capsule ovate, acute, two-celled.—Native of Cochinchina.

12. *Digitalis Sinensis*. Leaves ovate, hairy on both sides; flowers solitary, axillary; segments of the calix awl-shaped; corollas obtuse, entire at top. Stem cespitose, erect, a foot and half high, round, smooth; stigma screw-shaped.—Native of China.

Dilatris; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: six-petalled, superior; petals ovate-lanceolate, concave, from erect spreading, equal, hirsute on the outside, permanent. *Stamina*: filamenta three, subulate, shorter than the corolla, the third less than the other two; antheræ ovate-lanceolate, two-furrowed, that on the smaller filamenta larger. *Pistil*: germen inferior; style filiform; stigma simple, obtuse. *Pericarp*: capsule globular, extremely hirsute, three-celled, three-valved. *Seeds*: solitary, orbicular, compressed, smooth, perpendicular. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: six-petalled, hirsute. *Filamenta*: one less than the others. *Stigma*: simple.—For the propagation and culture of this genus of plants, see *Wachendorfia*.—The species are,

1. *Dilatris Umbellata*. Petals ovate; corymb fastigiata, hirsute. The whole plant hoary, and very villose, except the inside of the flower; root fibrous; root-leaves like those of *Cyperus*, even, strict, erect, one or two only on the stem, lanceolate, short, orange at their base; flowers numerous, pale lilac; stalks red, hairy.—Native of the Cape

2. *Dilatris Viscosa*. Petals linear; corymbs fastigiata,

villose, viscid. This species is larger than the preceding with broader leaves ; the stem and inflorescence more hairy and viscid.—Native of the Cape.

3. *Dilatris Paniculata*. Petals lanceolate ; panicle oblong, villose, viscid ; flowers of a yellowish purple colour.—Native of the Cape of Good Hope.

Dill. See *Anethum*.

Dillenia ; a genus of the class Polyandria, order Polygynia.—**GENERIC CHARACTER.** *Calix* : perianth five-leaved ; leaflets obovate, obtuse, concave, leathery, smooth within, villose without, permanent. *Corolla* : petals five, obovate, narrowed at bottom, very blunt, very finely subrenate, somewhat concave, longer than the calix, deciduous. *Stamina* : filamenta scarcely any ; antheræ very numerous, inserted into the base of the germen, linear, orange with a black line, shorter than the calix. *Pistil* : germen superior, ovate ; styles several, erect, simple, longer than the antheræ ; stigmas simple. *Pericarp* : roundish, outwardly coated with as many oblong capsules, which are longitudinal, and divided by a furrow, inwardly by a columnar, very large, pulpy receptacle. *Seeds* : numerous, very small, nestling under the capsules. **ESSENTIAL CHARACTER.** *Calix* : five-leaved. *Petals* : five. *Capsules* : many seeded, connate, filled with pulp.—This genus consists of beautiful trees, natives of the East Indies ; their leaves are large, and of a leathery substance ; their flowers axillary or terminating, sometimes very large ; the fruit approaching to that of *Clusia*.—The species are,

1. *Dillenia Integra*. Leaves obovate, obtuse, almost entire ; peduncles one-flowered. Branches alternate, wrinkled, dusky, smooth ; flowers terminating on the extreme branchlets, subsolitary, peduncled.—Native of Ceylon ; where the inhabitants use a decoction of the leaves for cleansing foul ulcers, and have named the tree *gudapara* and *rununidade*.

2. *Dillenia Speciosa*. Leaves oblong, round-acute, toothletted ; peduncles one-flowered. This is a lofty tree, with thick, wrinkled, ash-coloured, smooth branches ; leaves a foot in length, and a hand in breadth ; petioles thick, scarcely an inch in length ; flowers on the branchlets terminating.—Native of Java and Malabar

3. *Dillenia Elliptica*. Leaves elliptic-ovate, acute, serrate ; peduncles one-flowered ; flowers terminating. Native of Amboyna, Celebes, and Macassar.

4. *Dillenia Retusa*. Leaves obovate, truncate, serrate ; peduncles one-flowered. Branches alternate, wrinkled, dusky, smooth ; petioles semi-cylindric, channelled, hirsute at the base, scarcely an inch long ; flowers terminating.—Native of the woods of Ceylon.

5. *Dillenia Serrata*. Leaves elliptic-ovate, acute, serrate ; peduncles three-flowered. pedicelled.—Native of Celebes, Macassar, and Java.

6. *Dillenia Dentata*. Leaves ovate, retuse, toothed ; peduncles three-flowered. Branches alternate, wrinkled, ash-coloured, smooth ; petioles angular, smooth, a little shorter than the leaf ; pedicels alternate, smooth, half an inch long. According to Vahl, the peduncles are frequently from four to eight flowered, branching at the base.—Native of Ceylon, where the natives call it *diapura*.

7. *Dillenia Pentagynia*. Leaves ovate-lanceolate, serrate, sharp ; flowers pentagynous. It is a large tree, with numerous ascending branches ; leaves from twelve to twenty inches long, and four to six broad ; flowers small, yellow, on simple stalks, growing many together in bundles along the branches ; pericarp pendulous, size of a small nutmeg ; seeds reniform.—It flowers in March and April, and is a native of the mountainous parts of Coromandel.

Dimorpha : a genus of the class Diadelphia, order De-

candria.—**GENERIC CHARACTER.** *Calix* : perianth one-leaved, rounded at the base, deeply three or four-cleft, obtuse. *Corolla* : petals very wide, ventricose, convolute at the sides, crenulate, inserted into the calix below the stamina, placed at the lower side. *Stamina* : filamenta diadelphous, (single at the opening of the petal, and nine-cleft, incumbent on the middle of the petal,) ascending, longer than the corolla ; antheræ paralleliped, incumbent. *Pistil* : germen pedicelled, compressed, short ; style longer than the stamina ; stigma simple. *Pericarp* : legume large, oblique, compressed, one-celled. *Seed* : single, or few. **ESSENTIAL CHARACTER.** *Petal* : one, large, convolute, in place of the keel ; standard and wings none.—The species are,

1. *Dimorpha Falcata*. Leaves pinnate ; pods falciform. A tall tree, upwards of sixty feet high, very much branched at top, and branches much scattered ; flowers numerous, spiked ; spikes alternate, extremely long, pendulous, axillary, and terminal.—Native of the woods of Guiana ; where it flowers in September.

2. *Dimorpha Grandiflora*. Flowers larger than in the other species. A large tree, with a trunk more than two feet in diameter ; the wood is reddish, solid, and compact, and is used for various important purposes : it flowers in September.—Native of Guiana.

3. *Dimorpha Tomentosa*. Legume tomentose. A tree upwards of twenty feet high, very much branched at top, and branches much scattered ; flowers scattered, terminal, axillary, appearing in September.—It grows on the banks of the rivers in Guiana.

Diodia ; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix* : perianth two-leaved ; (according to Gærtner, two or four leaved ;) leaflets subovate, superior, equal, permanent. *Corolla* : one-petalled, funnel-form ; tube slender, long ; border small, spreading, four-parted ; divisions lanceolate. *Stamina* : filamenta four, bristle-shaped, upright ; antheræ versatile. *Pistil* : germen roundish, four-sided, inferior ; style filiform, length of the stamina ; stigma two-cleft. *Pericarp* : capsule ovate, four-cornered, crowned, larger than the calix, two-celled, two-valved ; (according to Gærtner, valveless, bipartite, eight-furrowed.) *Seeds* : solitary, ovate-oblong, polished, convex, and furrowed on the outside, flat on the inner. **ESSENTIAL CHARACTER.** *Corolla* : one-petalled, funnel-form. *Capsule* : two-celled, two-seeded.—The species are,

1. *Diodia Virginica*. Stem branching, procumbent, smooth and even, red ; branches alternate ; leaves opposite ; flowers white. The calix in some is two-leaved only, in others unequally four-leaved, that is, with two very minute leaves placed in the interstices of the larger, and this even seems to be the more natural number.—Native of Virginia.

2. *Diodia Simplex*. Stem herbaceous, simple, almost erect, smooth, and even ; leaves ovate-lanceolate.—Native of the island of Jamaica.

3. *Diodia Prostrata*. Stem suffruticose, subdivided ; branches prostrate, filiform ; leaves linear, somewhat hirsute, revolute.—Native of Jamaica.

4. *Diodia Scandens*. Stem scandent, suffruticose ; leaves ovate-lanceolate, rigid, rugged.—Native of Hispaniola.

5. *Diodia Sarmentosa*. Stem flaccid, shrubby ; branches opposite, spreading ; leaves oblong, acute, somewhat rugged.—Native of Jamaica.

6. *Diodia Verticillata*. Smooth : leaves lanceolate, in whorls, rugged at the edge ; stem herbaceous, erect, simple, a foot high, smooth, as is the whole plant, and even ; flowers several together in whorls, inclosed by the stipule ; the terminating whorl larger than the others ; capsule two-celled,

DIONEAE MUSCIPULA - Venus's Fly Trap.

DRACONTIUM PECTUSUM - Leaved Dragon.

linear, somewhat compressed, ciliate on both sides at top, crowned with two teeth.—Native of Santa Cruz.

Dionæa; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, upright; leaflets oblong, acute, permanent. *Corolla*: petals five, sessile, oblong, obtuse, concave. *Stamina*: filamenta ten, subulate, shorter; antheræ roundish; pollen tricoccus. *Pistil*: germen roundish, depressed, crenate; style filiform, shorter than the filamenta; stigma spreading, fringed on the edge. *Pericarp*: capsule one-celled, gibbous. *Seeds*: very many, subovate, very small, affixed to the base of the capsule. *Observe*. The number of stamina is not always constant. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: five. *Capsule*: one-celled, gibbous, containing many seeds.—The only known species is,

1. *Dionæa Muscipula*; *Venus's Fly Trap*. This is a very singular plant: root squamous, sending forth but few fibres, like those of some bulbs, and perennal; stalk about six inches high, round, smooth, without leaves, ending in a spike of flowers; leaves many, ciliated, inclining to bend downwards, and placed in a circular order, jointed, succulent; the lower joint, which is a kind of stalk, is flat, longish, two-edged, and inclining to heart-shaped; in some varieties they are serrate on the edges near the top; the upper joint consists of two lobes, each semioval, the margins furnished with stiff hairs, like the eye-lashes, embracing or locking into each other when they are close: this they do when they are irritated within: the upper surface of these lobes is covered with small red glands, appearing, when highly magnified, like the compressed fruit of the *Arbutus*; among the glands, about the middle of each lobe, are three very small erect spines. The lobes are so remarkably irritable or sensitive, that if a fly settles on the leaf, the lobes immediately close, and never open again while it continues there; if it can be extracted so as not to strain the lobes, they expand again, but if force be used to open them so strong has nature formed the springs of their fibres, that one of the lobes generally snaps off rather than yield. The flowers are milk-white, on peduncles, with a little pointed bracte at the bottom of each. What Mr. Ellis calls the lower joint of the leaf, Linneus looks upon as the petiole winged in the same manner as in the orange. The stem is a scape; the flowers grow in a corymb, resembling an umbel; the petals are marked with seven streaks, and bending at the end. Linneus asserts, that when the entrapped insect ceases to struggle, and is quiet, the leaf opens and permits it to escape; which disagrees with Ellis's account, for the latter affirms, that the lobes never open again, so long as the animal continues there. He thinks it probable that a sweet liquor discharged by the red glands, tempts the insect to its destruction; and adds, that if a straw or pin be introduced between the lobes, they will grasp it as fast as if it were an insect.—It is a native of the swamps of North Carolina, near the confines of South Carolina, where the winters are short, and the summers very hot: it flowers in July and August. Being a swamp plant, a north-east aspect will be the most proper to plant it in, to avoid the direct rays of the meridian sun; and in winter it will be necessary to shade it with a bell-glass, which should be covered with straw or mat in hard frosts. Its sensitive quality will be in proportion to the heat of the weather, and vigour of the plant. It may also be planted in pots of light moorish earth, for in such the plants are imported, and should be placed in pans of water in an airy stove, where the heat of such a situation, being like that of its native country, will make it surprisngly active; but the heat of our summers is not sufficient to ripen the seed.

Dioscorea; (Indian Yam) a genus of the class Diœcia, order Hexandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, bell-form, six-parted; divisions lanceolate spreading at top. *Corolla*: none, unless the calix be so termed. *Stamina*: filamenta six, capillary, very short; antheræ simple. *Female*. *Calix*: perianth as in the male. *Corolla*: none. *Pistil*: germen very small, three-sided; styles three, simple stigmas simple. *Pericarp*: capsule large, triangular, three-celled, three-valved. *Seeds*: in pairs, compressed, girt with a large membranaceous border. **ESSENTIAL CHARACTER** *Male*. *Calix*: six-parted. *Corolla*: none. *Female*. *Calix*: six-parted. *Corolla*: none. *Styles*: three. *Capsule*: three-celled, compressed. *Seeds*: two, membranaceous.—These plants may be propagated by laying their branches into the ground, where in about three months they will put out roots, and may then be taken from the old plants, and put into separate pots, which should be plunged into the tan-bed in the stove: during winter they should have a little water, but in summer, when they are growing vigorously, they should be watered three or four times a week, and have their glasses open, to admit a large portion of free air in warm weather. When seeds are received, they should be immediately sown in pots, and plunged into a hot-bed, where, if it be early in the spring, the plants will come up in the same season; but when they are sown late, the seeds often remain in the ground till the following season before they vegetate, in which case the pots must be screened from frost during the winter, and put into a new hot-bed in the spring. They may also be increased by cutting the roots in pieces, as is practised for potatoes, putting each piece in a pot filled with fresh earth, and plunged into the bark-pit, giving them little water until they shoot, lest they should rot. The roots do not grow to any great size in our climate; and the plants having little beauty, seldom flowering, and requiring much care and room, are not often allowed a place in our stores, except in very curious collections.—The species are,

1. *Dioscorea Pentaphylla*. Leaves digitate. Root very large and thick; stalks spiny, slender; flowers first yellow, then turning blackish.—Native of the East Indies and the Society Isles.

2. *Dioscorea Triphylla*. Leaves ternate. The leaves are above dusky green, beneath smooth and shining, with whitish prominent nerves, on long petioles; stalks round, slender, smooth, spiny; seeds in pairs, semielliptic, about an inch long, of a cinnamon colour.—Native of Malabar.

3. *Dioscorea Trifida*. Leaves cordate, trifid; stem winged, bearing tubers.—Native of Surinam.

4. *Dioscorea Aculeata*. Leaves cordate; stem prickly, bulb-bearing, suffruticose, turning round, slender, very much branched, with many straight, short, scattered prickles; flowers in long, spiked, lateral racemes; the calix has from three to six acute, very short, unequal, spreading leaflets; the corolla exhibits six ovate concave petals, almost closed, and of a dusky purple colour; filamenta awl-shaped, equal to the corolla, with roundish antheræ; germen inferior.—Native of Malabar and Cochin-china.

5. *Dioscorea Alata*. Leaves cordate; stem winged, bulb-bearing. Root a foot or more long, as big as a man's leg or thigh, brown on the outside, within white, or reddish purple, viscid, but when boiled very mealy; stalk the size of a goose-quill, square, with a thin reddish membrane at each corner, winding itself round poles nine or ten feet high, and putting out leaves at every three inches' distance, opposite, on square winged footstalks, two inches long; peduncles axillary, an inch or more in length, with small flowers of a yellowish green colour.—Native of both Indies, where it is cultivated

for food, as well as the sixth and seventh species. The roots are frequently three feet long, and weigh thirty pounds.

6. *Dioscorea Bulbifera*. Leaves cordate; stem even, bulb-bearing. Stalks slender, somewhat woody.—Native of both Indies, and of the islands in the South Seas.

7. *Dioscorea Sativa*; *Cultivated Dioscorea*, or *Yam*. Leaves cordate, alternate; stem even, round. It has slender stalks, climbing to the height of eighteen or twenty feet, not winged, but round. There is much confusion in the synonyms of this plant. It is a native of the East and West Indies, and of Japan. The Yam is largely cultivated for food in Africa, and in the East and West Indies, especially by the negroes of the latter; the roots grow to a considerable size, are mealy, and esteemed to be easy of digestion; they are palatable, and not inferior to any roots now in use, either for delicacy of flavour, or nutritive qualities; they are eaten instead of bread, either roasted on the embers or boiled, and the flour of them is also made into bread and puddings. In Otaheite they make a dish which the natives esteem very delicious, from the roots of the Yam, with the kernel of the cocoa-nut scraped, and the pulp of the banana. There are many varieties of the roots, some spreading out like the fingers, others twisted like a serpent, others again very small, scarcely weighing more than a pound, with a whitish ash-coloured bark, whereas the bark is commonly black. The flesh of the raw Yam is white or purplish, and viscid, but becomes farinaceous, or mealy, when dressed. The above-named varieties were found in Otaheite.—The Yam is a native of Florida and Maryland.—*Cultivation of the Yam*. The roots (according to Brown) must be cut so as to have a little of the skin to each piece, for by that alone they germinate, the roots having no apparent buds or eyes, but casting out their weakly stems from every part of the surface alike; two or three plants are put into each hole, which holes are dug pretty regular, a foot and a half or two feet square; these are afterwards filled from the adjoining banks, and the whole piece is covered with cane trash, which serves to keep the ground cool and fresh, and to prevent the growth of weeds, from which they must be carefully preserved, until they grow sufficiently to cover the mould. They are planted commonly in August, and are ripe about November and December following: care should be taken to wound the roots as little as possible in digging them up, for such as are cut throw out their sprouts very early, and are therefore seldom fit for any thing but planting. They should be rubbed over with ashes, and piled regularly on beds or hurdles raised above the floor, that the air may come easily between them; or if they be piled in heaps, some ashes should be strewed between the layers.

8. *Dioscorea Villosa*. Leaves cordate, alternate, and opposite; stem even. The flowers come out on long loose strings on short pedicels.—Native of Florida and Maryland.

9. *Dioscorea Opositifolia*. Leaves opposite, ovate, acuminate. Stem round, woody, twining, unarmed; racemes of male flowers axillary, opposite, solitary, subvillose, composed of three cylindric aments; the flowers are almost sessile.—Native of the East Indies, Japan, and Cochin-china; where the roots are preferred to all others.

10. *Dioscorea Septemloba*. Leaves cordate, seven-lobed, seven-nerved. The whole of this plant is smooth; stem round, climbing; flowers axillary, in racemes, very small; capsule ovate, triangular, with the corners winged, emarginate, with the style permanent.—Native of Japan.

11. *Dioscorea Quinqueloba*. Leaves cordate, five-lobed, nine-nerved. Stem filiform, twining, very long, with the rest of the plant smooth; petioles swelling at top and bottom,

reflex, a finger's length; racemes axillary, two or three, loose, near a span in length; flowers on patulous pedicels, a line in length, three or four together; bractes ovate, acute; calix saffron-coloured; germen inferior, smooth.—Native of Japan.

12. *Dioscorea Japonica*. Leaves cordate, acuminate, nine-nerved. The whole plant is smooth; stem filiform, angular, twining, branched; branches scattered, few, resembling the stem; petiole somewhat angular, reflex, spreading, nearly the length of the leaf; spikes axillary, one or two together, spreading, longer than the leaves; the rachis regular.—The root of this species is cut into slices, boiled, and eaten, in Japan; where it is a native.

13. *Dioscorea Hastata*. Leaves hastate; stem even; racemes very long. This differs from the seventh species in the shape of its leaves, which have two round ears at their base, but the middle extends to an acute point, like an halbert; the bunches of flowers are also longer and looser than those of the seventh species.

14. *Dioscorea Eburina*. Leaves heart-shaped, seven-nerved, alternate; flowers hermaphrodite, in simple long racemes. Stem shrubby, unarmed, long, twining; the branches and petioles four-cornered; calix three-leaved, with ovate erect leaflets; corolla three-petalled, ovate, fleshy, yellow, concave, nearly equal to the calix; filamenta hardly any; antheræ roundish, two-celled, very small; germen inferior, oblong, three-sided, without any style, but three oblong reflex stigmas; capsule oblong oval, the angles entering deep; seeds ovate, few. Root vertical, consisting of one or two tubers, three feet long, round, angular, sharpish, curved a little in shape and whiteness resembling elephants teeth, whence the vernacular name *khoai ngu*, and the trivial, *eburina*.—Native of Cochin-china.

15. *Dioscorea Cirrhosa*. Leaves ovate-lanceolate, three-nerved; flowers hermaphrodite, three-stamined; stem cirrhose. Stem shrubby, long, slender, climbing; flowers very small, axillary, on three-flowered peduncles; calix six-leaved, superior; leaflets ovate, thick, curved, almost closed, permanent, in a double row, of which the inner is smaller; corolla and filamenta none. The root a middle-sized irregular tuber.—Native of Cochin-china.

Diosma; (African *Spiræa*) a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate, acute, permanent. *Corolla*: petals five, ovate, obtuse, sessile, erect, spreading; nectaries five, placed on the germen. *Stamina*: filamenta five, subulate; antheræ subovate, erect. *Pistil*: germen crowned with the nectary; style simple, the length of the stamina; stigma obscure. *Pericarp*: capsules five, ovate-acuminate, compressed, conjoined inwardly at the margin, distant at the tips, gaping at the upper suture. *Seed*: solitary, oblong, ovate-depressed, acuminate at the point; an elastic aril, gaping on one side, involving each seed. **ESSENTIAL CHARACTER.** *Corolla*: five-petalled. *Nectary*: five on the germen. *Capsule*: three or five, conjoined. *Seeds*: veiled.—All these plants are propagated by cuttings, which may be planted during any of the summer months, in pots filled with light fresh earth, and plunged into a very moderate hot-bed, where they should be shaded in the day-time from the sun, and frequently refreshed with water. In about two months the cuttings will have taken root, when they should be each transplanted into a small pot, and placed in a shady situation, until the plants have taken fresh root, when they may be placed in a sheltered situation with other plants; they may remain abroad until the beginning of October, or later, if the season continue favourable; for they only require to be sheltered from frost, so that in a very dry airy green-house they may be

preserved very well in winter, and in summer they may be exposed to the open air with other green-house plants. The great beauty of the bloom, and the fragrant smell, of many of these plants, particularly entitle them to a place in collections of the shrub kind.—The species are,

1. *Diosma Oppositifolia*; *Opposite-leaved Diosma*. Leaves subulate, acute, opposite. It rises to the height of three feet; the branches are very long and slender, and are very irregularly produced from the stem; the leaves are placed cross-wise, in pairs, and are pointed; every evening they close up to the branches: the flowers are produced along the branches from between the leaves, and in the evening, when they are expanded, and the leaves closely embrace the branches, the whole plant appears as if covered with spikes of white flowers; and as it continues a long time in flower, it makes a fine appearance when intermixed with other exotics in the open air.—Native of the Cape.

2. *Diosma Hirsuta*; *Hairy-leaved Diosma*. Leaves linear, hirsute. This sort makes a very handsome shrub, growing to the height of five or six feet; stalks woody, sending out many slender branches; the leaves come out alternately on every side; flowers in small clusters at the ends of the shoots, they are white, and are succeeded by starry seed-vessels, having five corners, like those of the starry Anise; each of these corners is a cell, containing one smooth, shining, oblong, black seed: these seed-vessels abound with a resin which affords a grateful scent, which is common to the whole plant. This species frequently ripens its seeds in England; but if they are not sown soon after they are ripe, they rarely grow, or at least lie a whole year in the ground.—Native of the Cape.

3. *Diosma Rubra*; *Red-flowered Diosma*. Leaves linear, mucronate, smooth, keeled, dotted in two rows beneath. This plant seldom exceeds three inches in height, and spreads out into many branches, with leaves resembling those of Heath; flowers in clusters at the ends of the branches, like those of the second species, but smaller, and the bunches not so large. The leaves, when bruised, emit a strong balsamic odour.—Native of the Cape.

4. *Diosma Ericoides*; *Sweet-scented Diosma*. Leaves linear-lanceolate, convex beneath, imbricate in two rows. It is a low bushy shrub, which seldom rises above two feet high, but spreads out its branches far on every side; the leaves are narrow and smooth, of a light-green colour, and being ranged on each side the branches, appear flat on the upper and under side, and when bruised, emit a very strong penetrating odour; the flowers are produced singly from between the leaves; they are white, and tinged on their upper surface.—It is a native of the Cape.

5. *Diosma Capensis*; *Cape Diosma*. Leaves linear, three-sided, dotted beneath, opposite; flowers white in a corymb. The barren stamina have almost the appearance of petals.—Native of the Cape.

6. *Diosma Capitata*; *Headed Diosma*. Leaves linear, imbricate, scabrous, ciliate; flowers in spiky heads. Stem proliferous, two feet high, erect, brown, having the appearance of a large Heath; flowers purple, sessile, and forming a head; calix imbricate; leaflets (the inmost and true ones only five) ovate, pubescent at the edge; petals roundish, with the claws the length of the calix; nectaries very small, awnless.—Native of the Cape.

7. *Diosma Unicapularis*; *One-capsuled Diosma*. Leaves linear-lanceolate; capsules one-celled; branches wand-like, even; leaves alternate, subpetioled, linear-lanceolate, even above, longitudinally wrinkled underneath, smooth, quite entire at the edge, but as it were serrate with pellucid dots; peduncles lateral, few-flowered, much shorter than the leaves; flowers minute; capsules usually solitary, bent

in, and having a beak of the same length.—Native of the Cape.

8. *Diosma Latifolia*; *Broad-leaved Diosma*. Leaves ovate-crenate; peduncles axillary, solitary; stem villose. Branches somewhat pubescent; leaves petioled, crenulate above the edge with pellucid dots, every notch dotted on the disk, bluntish, scarcely acute.—Native of the Cape.

9. *Diosma Marginata*; *Margined Diosma*. Leaves cordate-attenuated, membranous-edged, erect, with the branches scarcely pubescent; leaves remote; flowers from the upper axils of the leaves, solitary or in pairs; the peduncles longer than the leaf; stamina five, real; nectaries five from alternate filamenta, having at the tip a black larger antherine gland, bifid at the base, with a small yellow head.—Native of the Cape.

10. *Diosma Barbiger*; *Bearded Diosma*. Leaves cordate, stem-clasping; petals bearded, branching. Leaves sessile, opposite, mucronate, even, dotted underneath; corymbs terminating, subsessile; calix five-cornered; petals small, and bearded with white.—Native of the Cape.

11. *Diosma Tetragona*; *Quadrangular Diosma*. Leaves cordate, retuse, folded together and keeled, ciliate; branches one-flowered. This species is singular, and is distinguished from the rest by the leaves being so closely together, that the whole stem is covered with them; by the branches being quadrangular and thicker toward the top; and by the large, solitary, and terminating flower.—Native of the Cape.

12. *Diosma Cupressina*; *Heath-leaved Diosma*. Leaves ovate, three-cornered, imbricate; flowers solitary, terminating, sessile. Branches filiform, erect, alternate, covered with alternate minute leaves like those of Heath, subsca-brous, sessile, erect, terminating in a coloured callosity; calix membranaceous, lanceolate, erect; petals often four, obovate, twice as long as the calix, attenuated gradually into the claws; stamina erect, the length of the calix.—Native of the Cape.

13. *Diosma Imbricata*; *Imbricated Diosma*. Leaves ovate, mucronate, imbricate, ciliate. The petals are purplish and roundish, with the claws three times the length of the calix.—Native of the Cape.

14. *Diosma Lanceolata*; *Spear-shaped Diosma*. Leaves elliptic, obtuse, smooth. They have a few hairs on both sides.—Native of the Cape.

15. *Diosma Ciliata*; *Ciliated Diosma*. Leaves lanceolate, ciliate, wrinkled. Petals oblong, with the claws scarcely longer than the calix. Native of the Cape.

16. *Diosma Crenata*; *Crenated Diosma*. Leaves lanceolate-oval, opposite, glandular-crenate; flowers solitary. Leaves of the calix subulate and crenate.—Native of the Cape.

17. *Diosma Uniflora*; *One-flowered Diosma*. Leaves ovate, oblong; flowers solitary, terminating. Leaflets of the calix ovate, large, and almost broader than the leaves.—Native of the Cape.

18. *Diosma Pulchella*; *Oval-leaved Diosma*. Leaves ovate, obtuse, glandular-crenate; flowers twin, axillary. The flowers are hermaphrodite, but the fruit is three-celled. The horns of the germen are each of them terminated by two glands. The Hottentots use the leaves of this species dried and powdered, under the name of *bucku*, to mix with the grease with which they anoint themselves, which gives them so rank an odour, that the chevalier Thunberg declares he could not bear the smell of the men who drove his wagon.—Native of the Cape.

19. *Diosma Asiatica*; *Asiatic Diosma*. Leaves lanceolate, alternate; racemes subterminating. It is a small tree, six feet high, spreading, and very much branched; leaves quite entire, smooth; flowers yellow, in compound racemes; an-

theræ sessile, linear, at the side of the nectary, converging at top; capsules somewhat kidney-form, each on its proper peduncle; seeds destitute of an aril.—Native of Cochin-china.

Diospyros; a genus of the class Polygamia, order Diœcia; or, according to Thunberg, of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Hermaphrodite female*. *Calix*: perianth one-leaved, four-cleft, large, obtuse, permanent. *Corolla*: one-petalled, pitcher-shaped, larger, four-cleft; divisions sharp, spreading. *Stamina*: filamenta eight, bristle-form, short, almost inserted into the receptacle; antheræ oblong, unproductive. *Pistil*: germen roundish; style single, half four-cleft, permanent, longer than the stamina; stigma obtuse, two-cleft. *Pericarp*: berry globose, large, eight-celled, sitting on a very large spreading calix. *Seeds*: solitary, roundish, compressed, very hard. *Male*, in a distinct plant. *Calix*: perianth one-leaved, four-cleft, sharp, upright, small. *Corolla*: one-petalled, pitcher-shaped, leathery, four-cornered, four-cleft; divisions roundish, rolled back. *Stamina*: filamenta eight, very short, inserted into the receptacle; antheræ double, long, sharp, the interior shorter. *Pistil*: rudiment of a germen. **ESSENTIAL CHARACTER.** *Hermaphrodite*. *Calix*: four-cleft. *Corolla*: pitcher-shaped, four-cleft. *Stamina*: eight. *Style*: four-cleft. Berry eight-seeded. *Male*. *Calix*, *Corolla*, and *Stamina*: of the other.—The species are,

1. *Diospyros Lotus*; *European Date-plum*. The two surfaces of the leaves of different colours. The smaller branches spread a little, and are yellowish; leaves oval-lanceolate, large, quite entire, paler underneath, somewhat hoary, with the veins somewhat hairy; flowers small, reddish-white, rotate; fruit the size of a cherry, yellow when ripe, astringently sweet, sessile in the bosom of the leaves, within the calix, which is increased, somewhat cartilaginous, flattened, usually five-cleft, seldom four-cleft. These berries are recommended as a cure for the diarrhœa. Loureiro describes it as a small tree, six feet high, with spreading branches. The broad-leaved variety grows up into very large trees in the southern parts of Caucasus. It is also abundant in the woods of Hyrcania, and along the whole coast of the Caspian sea. Gesner was informed that it grows upon the mountains in the neighbourhood of Verona; and Mr. Ray is pretty confident, that he saw it in his way from Lerici to Lucca, and not far from the latter place. It is also found in the woods on the hills about Turin, plentifully about Lyons, and upon the eastern coast of Africa, whence it is supposed to have been first imported into Europe. Gerarde says, that, in English, it is called *Bastard Meynwood*, which name is now quite lost; and Parkinson calls it *India Date-plum*.—This, and the second species, are both propagated by seeds, which will come up well in the open ground, but will appear much sooner if sown upon a moderate hot-bed, as well as make a greater progress: in this case the seeds should be sown in pots or boxes of earth, and plunged into the hot-bed, because the plants will not bear transplanting till autumn, when the leaves fall off; so that, when the plants are up, and have made some progress, they may be inured by degrees to the open air; and in June they may be wholly exposed, and may remain abroad until November, when it will be proper to set the pots under a hot-bed frame, to protect them from hard frost, which might kill the tops while they are very young, but they must have as much free air as possible in mild weather. The following spring, before the plants begin to shoot, they should be transplanted into a nursery, in a warm situation, where they may be trained up for two years, and then removed to the places where they are designed to remain. They are both hardy enough to resist our severest winters.

2. *Diospyros Virginiana*; *American Date-plum*. The two surfaces of the leaves of the same colour. In England it rises to the height of fourteen or sixteen feet, but generally divides into many irregular trunks near the ground, so that it rarely forms a handsome tree. The branches are many, and grow slender to the end, covered with a thin greenish bark; leaves many, broad, green, without dent or notch on the edges; and is so like the first sort, that it seems, to a slight observer, to be the same. Our European Lotus has a lighter-coloured bark, inclining to yellow on the branches, and yellow and shining on the twigs; the American has a dark-brown bark on the branches, and on the twigs it is grayish from pubescence, so that they are soft to the touch, whereas the others are smooth: fruit, in form, size, and firmness, like a date, and almost as sweet, with a great flat thick kernel within. In England it produces fruit in abundance, but never brings it to perfection. Captain Smith, in the Discovery of Virginia, says, if it be eaten while it is green, it draws the mouth awry by its harsh and binding taste, but is pleasant when ripe; which, however, is not the case till it has been mellowed by the frost, being then very sweet and glutinous, with a little astringency; and a considerable quantity may be eaten without inconvenience. The Americans extract a spirit from it, and make a palatable liquor with it and malt. The time of ripening is from the end of September to December. The wood is very hard, but brittle, rather white, and very suitable for joiners' tools, such as planes, handles to chisels, &c. but it soon rots if exposed to the weather. It spreads very much, and is not easy to extirpate; but in the northern provinces of the American states it is often killed by frosts in hard winters. In Virginia and Carolina it is called *pishamin* or *persimon*, and there is plenty of it in the woods; as well as in Pennsylvania, New Jersey, Philadelphia, &c. where it is generally found in wet places, round water pits. See the first species.

3. *Diospyros Kaki*; *The Kaki*. Peduncles three-parted. A middling-sized tree, very branching; branches and twigs alternate, round, dotted, smooth, tomentose at the ends, spreading; leaves alternate, petioled, ovate, acuminate, quite entire, paler underneath, scarce apparently villose, netted-nerved, smooth above, an inch or more in breadth, from an inch to three inches in length, spreading; petioles semicylindric, subtomentose, half an inch long; flowers axillary; peduncles tomentose, half an inch in length; pedicels one-flowered, like the peduncles; fruit a subglobose pome, obscurely four-cornered, smooth, when unripe green, when ripe yellow, truncate at the base, where the calix remains, obtuse, with the stigma also permanent, eight-valved, eight-celled, the size of a middling apple, having nearly the taste of a sweet white plum, fleshy; seeds half-mooned, compressed at one edge, smooth, some of the cells are occasionally barren. The fruit eaten plentifully occasions a diarrhœa in the autumnal months. It is preserved in the same manner as the fig, by sprinkling meal or sugar over it. There is a variety of this species, in which the leaves are oblong-ovate, acute, nerved, a finger's length; the petioles channelled; pome ovate, very obtuse, yellow, with a soft astringent pulp like that of the orange, usually eight-celled, sometimes ten-celled, but very seldom nine-celled, the size of a pigeon's egg, and always barren.—Native of Japan, China, and Cochin-china, with other parts of the East Indies. It differs from the American sorts in its branches, and the pubescence on the lower surface of the leaves.

4. *Diospyros Hirsuta*. Branches and leaves villose underneath; leaves elliptic, obtuse; flowers axillary, heaped, sessile.—Found by Thunberg, in Ceylon.

5. *Diospyros Ebenaster*; *Ebony*. Leaves oval-oblong, leathery; buds smooth. This is a very large tree, very smooth in all its parts, and the timber very hard. The small branches have an ash-coloured bark, those which bear the leaves are blackish; the leaves are alternate, on very short petioles, quite entire, obtuse, shining, often spotted, beneath wrinkled with small veins, and as it were a little hoary; berry sessile, ovate, on the four-cleft reflex calix; seeds six to eight, ovate, black, somewhat compressed. It is very like the first species, but the leaves are more ovate, and more hoary underneath. The wood is heavy, compact, and hard, whitish next the bark, but towards the middle very black; this blackness gradually tinges the whole body, in the same manner as the resinous part of the Fir pervades the body by the decaying branches. This is the true Ebony, according to Kœnig and Thunberg: but Loureiro describes the real Ebony as a distinct genus, by the name of *Ebenoxylum*.—Native of the vast woods of Ceylon, Amboyna, Cochin-china, and the East Indies.

6. *Diospyros Ebenum*; *Green-leaved Ebony*. Leaves ovate-lanceolate, acuminate; buds rough with hairs; leaves about three inches in length, thin, flexible, dark green.—Native of Ceylon; and observed in the woods near Calcutta.

7. *Diospyros Lobata*. Leaves ovate-lanceolate, smooth on both sides; peduncles one-flowered, axillary; berries eight-lobed. This is a small tree, eight feet high, with spreading branches; flowers white, hermaphrodite; berry pale yellow, an inch in diameter, compressed, eight-celled, one-seeded, with a sweetish austere pulp, without any smell.—Native of Cochin-china.

8. *Diospyros Dodecandra*. Flowerstwelve-stamined, axillary; berries lenticular. This is a large tree; leaves broad-lanceolate, quite entire, alternate; flowers white; berry pale, compressed, shaped like a lens, one-celled, with eight compressed-ovate, bony, large seeds; the pulp is sweetish, astringent, eatable, but not pleasant. The wood is like that of the fifth species, but has not the black veins. This tree is much used for supporting the black-pepper shrubs.—Native of Cochin-china.

9. *Diospyros Tetrasperma*. Leaves membranous, shining, wedge-form; berries four-seeded.—Native of Jamaica.

10. *Diospyros Menaloxylon*. Trunk erect, in large trees from 20 to 25 feet to the branches, and about eight or ten in circumference; bark scabrous or deeply cracked, somewhat spongy; berry round, size of a small apple, yellow, pulpy, astringent, and not very palatable. This tree is the *tumida* of the Telingas.—Native of the mountainous parts of the Circars, on the coast of Coromandel.

11. *Diospyros Sylvatica*. Leaves three to six inches long, two to three broad; berry the size of a nutmeg, round, smoothish. This is the *tellagada* of the Telingas.—It grows on the uncultivated hills of the Circars.

12. *Diospyros Montana*. Trunk crooked, covered with dark rust-coloured pretty smooth bark; leaves three to four inches long, two broad; flowers howing, small, greenish-white. This is the *yerragada* of the Telingas.—It is common among the mountains in the Circars: its timber is variegated with dark and white coloured veins, is hard, and very durable.

13. *Diospyros Chloroxylon*. Leaves an inch and a half or two long, one broad; flowers small, white; berry the size of a cherry, which when ripe is very palatable. The *nella-woolymera* of the Telingas.—A middle-sized tree among the Orixia mountains; but in the low lands towards the coast only a large bush.

14. *Diospyros Cordifolia*. Leaves two inches long, three-quarters broad; berry round, size of a small crab-apple.

The *kal-woolymera* of the Telingas.—A pretty large tree among the mountains of the Circars; but towards the sea much smaller.

Diphysa; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, slightly compressed, half five-cleft; the two upper segments roundish, obtuse, plane, spreading very much: the two lateral ones ovate, acute, erect, flattish; the lowest lanceolate, acuminate, concave, erect, a little longer than the rest. *Corolla*: papilionaceous; standard obovate-oblong, emarginate, plane, broad, reflex, on a claw the length of the calix; wings shorter than the standard, oblong, obtuse, ascending, converging behind, diverging in front; keels sickle-shaped, acuminate, compressed, ascending, shorter than the wings. *Stamina*: filamenta ten, diadelphous, simple, and nine-cleft, ascending; antheræ ovate, small. *Pistil*: germen subcylindrical, pedicelled; style capillary, rising; stigma simple, acute. *Pericarp*: legume linear, compressed, flat, obtuse, augmented longitudinally on each side by a membranaceous, very large, inflated bladder, closed all round, one-celled. *Seeds*: several, oblong, obtuse, compressed, furnished with a little hook. ESSENTIAL CHARACTER. *Calix*: half five-cleft. *Legume*: with a bladder on each side. *Seeds*: hooked.—The only species is,

1. *Diphysa Carthaginensis*. A small, unarmed, inelegant, erect, branching tree, ten feet in height, and approaching to the arborescent Mimosas. Leaves pinnate, smooth, two inches long, on the younger branches; there are usually five leaflets on each side, with an odd one, though not unfrequently more or less: they are oblong, emarginate, small, some alternate, others opposite; common peduncles two-flowered or three-flowered, axillary, filiform, the length of the leaves; flowers yellow, with scarcely any smell; legumes have thin, dry, whitish bladders to them, and hence the name. They continue long upon the tree without opening, till at length they fall in transverse pieces at the joints; seeds five or six, yellowish.—It flowers in August and September, and is a native of Carthage in New Spain.

Dipsacus; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth common many-flowered, many-leaved; leaflets longer than the floscule, loose, permanent; perianth proper scarce manifest, superior. *Corolla*: proper universal equal, one-petalled; tubular; border four-cleft, upright; outer division larger, more acute. *Stamina*: filamenta four, hair-form, longer than the corolla; antheræ incumbent. *Pistil*: germen inferior; style filiform, length of the corolla; stigma simple. *Pericarp*: none. *Seeds*: solitary, columnar, crowned by the entire calicine margin. *Receptacle*: common, conical, separated by longer chaffs. ESSENTIAL CHARACTER. *Calix*: common many-leaved; proper superior. *Receptacle*: chaffy.—These are biennial, tall, herbaceous plants, prickly or rough, terminated by rough heads of flowers; the leaves sometimes connate at the base, and forming a basin containing rain.—The species are,

1. *Dipsacus Fullonum*; *Cultivated Teasel*. Leaves sessile, serrate; involucre short, horizontal; chaffs bent back. This plant is cultivated in great quantities in the west of England, for raising the nap upon woollen cloths, by means of the crooked awns or chaffs upon the heads, which in the wild sort are straight, or at least not hooked; for this purpose they are fixed round the circumference of a large broad wheel, which is turned round while the cloth is held against them. These heads are collected in August. Parkinson calls it *Fuller's Thistle*; and Gerarde, *Tame*, or *Garden Teasel*. The root of this plant is bitter, and given in a strong infusion, strengthens the stomach and creates an appetite, and

is also good for obstructions of the liver, and the jaundice. Many people erroneously think that the water contained in the basin formed by the leaves is a good cosmetic.—Teasel is propagated by sowing the seeds in March, upon a soil that has been well ploughed; about a peck of seed will sow an acre, for the plants should have sufficient room to grow, or the heads will not become either so large or so numerous. When the plants are come up, hoe them in the same manner as is practised for turnips, cutting down all the weeds, and singling out the plants to about six or eight inches' distance; and as the plants advance, and the weeds begin to grow again, hoe them a second time, cutting out the plants to a wider distance, for they should be finally left at least a foot asunder; and you should be particularly careful to clear them from weeds, especially during the first summer, for when the plants have spread so as to cover the surface of the ground, the weeds will not so readily grow between them. The second year after sowing, the plants will shoot up stalks with heads, which will be fit to cut about the beginning of August, and should afterwards be tied up in bunches, setting them in the sun if the weather be fair, but if not, placing them in rooms to dry. The common produce is about one hundred and sixty bundles or staves upon an acre, which they commonly sell for about one shilling a stave. Some persons sow Caraway and other seeds among their Teasels, but it is not a good method, for the one spoils the other; nor can you so easily clear them from weeds as when alone: this, however, is still the common practice in Essex, where the Teasel is chiefly cultivated, on account of the neighbouring manufactories of ordinary cloth and baize, in which it is used for raising the nap. Old pasture-land, the soil of which is a strong clayey loam, is best adapted to the culture of Teasel. The method of managing the land for their compound crop, has already been given under the article *Carum*, or Caraway; we have only to add therefore, for the instruction of the hoers, that the first appearance of Teasel is much like that of a Lettuce; that the heads being ready about the middle of September, the second year, are to be cut as soon as they begin to turn brown, with a stalk a foot long, and tied up in bundles or bunches, twenty-five in each; twenty-four of these bunches are fixed on a small stick, and called a row, two hundred and forty of which make a load, in bulk equal to a ton of hay from the meadow. The work of cutting and bunching the Teasel can only be done by those who are well acquainted with it; the crop must be looked over, and the heads cut at several times as they ripen; the produce is sometimes a load on an acre, the average price of which is twelve pounds, but it often happens that there is not more than one-fourth of a load.

2. *Dipsacus Sylvestris*; *Wild Teasel*. Leaves connate, crenate, uppermost entire; involucre long, bending up; chaffs straight. Root biennial, simple, with large fibres; stem from three to six feet high, branched, round, striated, hollow, spinous, but the spines few near the base, very numerous near the heads, long and sharp; root-leaves of the first year's plant spread on the ground in a circular form, ovate-oblong, bluntish, notched, wrinkled, and rough, with spines thinly scattered over the leaf; stem-leaves, at least the lowermost, less wrinkled, uniting at the base so as to form a large cavity containing water after rain, and hence the name of *dipsacus*, and *labium Veneris*. The flowers are blue purple, first breaking forth about the middle of the heads; chaffs of the receptacle the length of the stamina, rigid, bearded; some of the lower chaffs bowed downwards, but not hooked at the points.—Native of most parts of Europe, on the edges of pastures, in cultivated places, and by road-sides, flowering

from June or July to September. The water contained in the basin formed by the leaves, is said to cure warts, and to serve as a beauty-wash for the face; it is also supposed to be good for the eyes. Cattle in general, even asses, appear to avoid this plant; a small moth, earwigs, and other insects, take refuge in the head. Linneus thought this to be a mere variety of the first species; but Mr. Miller, after having cultivated both for nearly forty years, hesitates not to declare them to be distinct species.

3. *Dipsacus Laciniatus*; *Cut-leaved Teasel*. Leaves connate. Root biennial, long, branching; stem three feet high, upright, angular, prickly, branched; leaves pinnatifid, lacinate or sinuate, bright green, smooth above, pubescent beneath, having short prickles along the nerve, and being ciliate on the edge; heads ovate, obtuse, terminating the stem and branches, with an involucre at the base, consisting of stiff prickly leaves, spreading out like a star; chaffs lanceolate, straight, ending in a stiff prickle; flowers whitish; antheræ reddish. It differs from the common Teasel, not only in the leaves being cut so deeply, but in the prickles being weaker, and having lateral flowers, rising higher than those in the middle. The goldfinch is fond of the seeds, as well as those of the common sort.—Native of Germany, France, Alsace, Austria, and Carniola.

4. *Dipsacus Pilosus*; *Small Teasel*. Leaves petioled, with little appendages. It differs from its congeners in having a fragile stem, from two to six feet high, sharp, with short prickles pointing upwards, angular, and grooved; leaves with little appendages at the base, but these are sometimes wanting, and the upper leaves are nearly entire, slightly hairy on both sides, and with short prickles along the midrib underneath; scales of the receptacle longer than the corollas, ciliate, in hemispherical heads; corollas white, sometimes with a purple tinge; antheræ dark purple; seeds ovate-quadrangular, crowned with the calix; stigma sometimes simple, but most frequently trifid, with the lower lobe shorter than the upper, as it is likewise in the common sort; sometimes it is slightly cloven into three parts. The heads of flowers hang down during the time of flowering, but afterwards become upright. This plant is called *Shepherd's Rod*, and *Shepherd's Staff*; it flowers in July, and in September ripens seeds. They are eaten by the small birds; and the flowers are frequented by great numbers of moths after sun-set. It is the handsomest species of the genus, and very distinct from the three others, which are very nearly allied.—It is a native of France, Germany, Switzerland, and Austria; in England, it is found in moist and watery places, by brooks and damp hedges and ditches; between Deptford and Lewisham; at Edgecombe, near Croydon; at Guildford, and Godalmin, in Surry; in Beckenham church-yard near Chislehurst, Foot's-eray, Farnborough &c. in Kent; about Finchley in Middlesex; at Fulham, between the bishop's palace and the field; at Morehall, &c. near Harefield; near Thame Park in Oxfordshire; at Littlehall abbey, in Shropshire; at Eversham in Worcestershire; in the way from Braintree to Hedingham, and from Dunmow to London; in Garanton park, and Hollinghall wood, in Leicestershire; and in Scotland.

Dipteryx; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leafed, turbinate: two upper segments wing-shaped, oblong, concave, spreading; the third lower, small, entire, or three-toothed. *Corolla*: papilionaceous; standard longer, obovate, bent in at the sides, erect; wings two, oblong, shorter than the standard; keel shorter, two petalled. *Stamina*: filaments eight to ten, united into a cylinder, cloven at top; antheræ small, roundish. *Pistil*: germen pedicelled, oblong; style

awl-shaped, ascending; stigma acute. *Pericarp*: legume large, ovate, compressed, thick, one-celled. *Seed*: single, ovate. **ESSENTIAL CHARACTER.** *Calix*: two, upper segments winged. *Legume*: ovate, compressed, one-seeded.—The species are,

1. *Dipteryx Odorata*; *Coumarouna*. Leaves alternate. This is a large tree, sixty feet high, very much branched at top; leaves large and pinnate; leaflets perfectly entire, two or three on each side, affixed alternately on the midrib. The flowers are borne on racemes, which are axillary and terminal; their colour purple, dashed with violet. The almonds or fruits are fragrant, and are put by the Creoles into chests, in order to drive away insects, as well as for the sake of their smell: they are known in London by the name of Tongo Beans, and are used to give a flavour to snuff.—It grows in the large forests of Guiana.

2. *Dipteryx Oppositifolia*; *Taralea*. Leaves opposite. This, like the former, is a tall tree, and very branching at top; the leaves are opposite, and pinnate; the leaflets large, ovate, sharp, strong, and perfectly entire; the flowers are panicle, axillary, and terminal, and when blown, their fragrance is very diffusive.—Native of the woods of Cayenne.

Dirca; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: one-petalled, club-shaped; tube bellying above; border obscure, with unequal margin. *Stamina*: filamenta eight, capillary, inserted into the middle of the tube, longer than the corolla; antheræ roundish, upright. *Pistil*: germen ovate, with oblique tip; style filiform, longer than the stamina, crooked at the tip; stigma simple. *Pericarp*: berry one-celled. *Seed*: single. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: tubulous, with an obscure border. *Stamina*: longer than the tube. *Berry*: one-seeded.—The only known species is,

1. *Dirca Palustris*; *Marsh Leatherwood*. Height five or six feet, but in Europe seldom exceeding three: it sends out many jointed branches near the root; leaves oval, pale yellowish, and smooth; the flowers come out from the side of the branches, two or three upon each peduncle; they are of a greenish white colour, and appear early in the spring, when the leaves begin to shoot. It is a little shrub, growing on hills towards swamps and marshes in North America: the bark is very tough, as is also the shrub itself, insomuch that the branches cannot easily be separated without cutting. The twigs are used for rods, and the bark for ropes, baskets, &c. for which it is very suitable, being equal in strength and toughness to the bark of the Lime-tree. The French in Canada call it *bois de plomb*, or leaden-wood.—This shrub is very difficult to propagate in Europe, where it does not produce seeds, and can therefore only be propagated by layers or cuttings, and these are generally two years before they put out roots, and as it naturally grows in very moist places, it is with difficulty preserved in gardens, unless it be planted in wet ground: it is seldom injured by cold.

Disa; a genus of the class Gynandria, order Diandria.—**GENERIC CHARACTER.** *Calix*: spathe one-valved, acuminate, oblong, gaping longitudinally on one side. *Corolla*: petals three, ovate, spreading, large, nearly equal; the upper one unequal, somewhat horned obtusely at the base behind. *Stamina*: filamenta subulate; antheræ two, connected into a lanceolate form, a little shorter than the corolla, subulate at the base, gaping, mounted on the style; dorsal petal of the stamina two-parted, shorter than the stamina; divisions oblong, obtuse, converging. *Pistil*: germen inferior, length of the spathe; style tongue-shaped, short, hollowed at the base, two-horned backwards. *Pericarp*: capsule oblong,

three-valved. *Seeds*: numerous, minute. **ESSENTIAL CHARACTER.** *Spathe*: one-valved. *Petals*: three; the third less, two-parted, gibbous at the base.—The species are,

1. *Disa Grandiflora*. Horn shorter than the petals, with about two flowers on the stem. Stem a foot high, erect, quite simple, even; leaves shorter than the stem, those next the root lanceolate-linear; those on the stem sheathing, alternate, three in number; the disk shorter than the sheath, acuminate at the end; flower terminating, peduncled, inclined, sometimes two, and then the second comes out on a longer peduncle from the spathe of the former; this flower is red, and elegantly veined; it is very conspicuous and beautiful.—Native of the Cape of Good Hope.

2. *Disa Racemosa*. Horn shorter than the petals; flowers in racemes.—Native of the Cape of Good Hope.

3. *Disa Longicornis*. Horn longer than the petals; scape one-flowered. Flower blue, beautiful, and singular in its form.—Native of the Cape of Good Hope.

4. *Disa Maculata*. Horn conical, very short; scape one-flowered. Root-leaves oblong; stem and sheath spotted with red; flowers blue.—Native of the Cape of Good Hope.

Disandra; a genus of the class Heptandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, from five to eight parted; divisions straightish, permanent. *Corolla*: one-petalled, wheel-shaped; tube very short; border five-parted; divisions ovate. *Stamina*: filamenta from five to eight, bristle-form, from erect, becoming patulous, shorter than the corolla; antheræ sagittate. *Pistil*: germen ovate; style filiform, length of the stamina; stigma simple. *Pericarp*: capsule ovate, length of the calix, two-celled. *Seeds*: several, ovate. **ESSENTIAL CHARACTER.** *Calix*: seven-leaved. *Corolla*: seven-parted, flat. *Capsule*: two-celled.—The species are,

1. *Disandra Prostrata*. Leaves reniform, crenate; peduncles in pairs. Stems from a foot to two feet in height, prostrate, round, pubescent; leaves alternate, petioled, pubescent; peduncles axillary, usually two together, but sometimes one or three, erect, filiform, one-flowered, higher than the petioles; corollas yellow. The foliage greatly resembles that of Ground-ivy; the branches also trail upon the ground in a similar manner, to the length of several feet. It varies extremely in the number of stamina, and in the divisions of the calix and corolla; seven is thought to be the most usual number of the former, and five the most natural.—It flowers during most part of the summer, and is a native of Madeira. It grows readily from cuttings; in the winter it must be kept in the green-house, but will bear the open air in summer; it should be planted in rich earth, and plentifully watered in dry weather: it appears to most advantage in a pot placed upon a pedestal, or in some elevated situation, where its branches may hang carelessly down.

2. *Disandra Africana*. Leaves orbiculate, entire, crenate, peduncles solitary. It is doubtful whether this be a distinct species.—Native of Africa.

Dittander. See *Lepidium*.

Dittany of Crete. See *Origanum*.

Dittany, White. See *Dictamnus Fraxinella*.

Dock. See *Rumex*.

Dodartia; a genus of the class Didynamia, order Angiosperma.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-form, five-toothed, with ten corners, tubular, nearly equal, flat, permanent. *Corolla*: one-petalled, ringent; tube cylindric, bent downwards, much longer than the calix; upper lip small, emarginate, ascending; lower lip spreading, wider, three-cleft, twice longer, obtuse; middle division narrower. *Stamina*: filamenta four, ascending

towards the upper lip, and shorter than it; antheræ small, roundish, twin. *Pistil*: germen roundish; style subulate, length of the corolla; stigma compressed, oblong, obtuse, two-cleft, the lamellas converging. *Pericarp*: capsule globose, two-celled. *Seeds*: numerous, very small. *Receptacle*: convex, growing to the dissepiment. **ESSENTIAL CHARACTER.** *Calix*: five-toothed. *Corolla*: lower lip twice as long as the upper. *Capsule*: two-celled, globular.—The species are,

1. *Dodartia Orientalis*; *Oriental Dodartia*. Leaves linear, quite entire, smooth. It has a perennial root, which creeps far under the surface, and sends out new stalks at a great distance from the parent plant; these stalks are firm, a little compressed, and grow a foot and half high, sending out several side-branches; leaves long, narrow, fleshy, opposite, of a deep green colour, those on the lower part of the stalk are shorter and broader than those above: the flowers come out singly on each side the stalk, sitting close to it; they are nearly an inch long. The flower is of a deep purple colour, and appears in July, but rarely produces seeds in England.—First discovered by Tournefort near Corvirap, not far from the foot of mount Ararat, in Armenia. This plant propagates very fast by its creeping roots, so that when it is once established in a garden, it will multiply fast enough; it loves a dry light soil, and may be transplanted, either in autumn when the stalks decay, or in the spring before the new stalks arise.

2. *Dodartia Indica*. Leaves ovate, serrate, villose; stems roundish, villose, somewhat branching; raceme terminating with small leaves; flowers opposite, pointing one way, subsessile; calix obtuse, villose; corolla yellow, with the outer lip straight and short.—Native of India.

Dodder. See *Cuscuta*.

Dodecas; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, turbinate, permanent, half four-cleft, superior; divisions ovate, spreading. *Corolla*: petals roundish, sessile, inserted into the calix. *Stamina*: filamenta twelve, capillary, shorter than the calix, inserted into the receptacle: antheræ oblong. *Pistil*: germen half superior; style filiform, longer than the stamina; stigma simple. *Pericarp*: capsule ovate, one-celled, inferior, growing to a patulous calix, within which the apex is naked and four-valved. *Seeds*: numerous, oblong, minute. **ESSENTIAL CHARACTER.** *Corolla*: five-petalled. *Calix*: half four-cleft, bearing the corolla superior. *Capsule*: one-celled, connate with the calix.—The only known species is,

1. *Dodecas Surinamensis*. A shrub, somewhat four-cornered, even; the branches opposite, short; leaves opposite, obovate-oblong, or wedge-shaped, subpetioled, even, obtuse, quite entire; peduncles axillary, one-flowered, short, solitary, the length of the calix; bractes in pairs, minute under the calix; calix before it unfolds four-cornered, four-valved, turbinate at bottom, columnar; petals inserted into the calix at the divisions; stamina inserted into the receptacle, next the germen, not into the calix.—Native of Surinam.

Dodecatheon; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: involucre many-leaved, many-flowered, very small; perianth one-leaved, half five-cleft, permanent; divisions reflex, finally longer, permanent. *Corolla*: one-petalled, five-parted; tube shorter than the calix, naked at the throat; border reflex; divisions very long, lanceolate. *Stamina*: filamenta five, very short, obtuse, seated on the tube; antheræ sagittate, converging into a beak. *Pistil*: germen conic; style filiform, longer than the stamina; stigma obtuse. *Pericarp*: capsule oblong, one-celled, gaping at the tip; (according to Gärtner, subcylindric,

opening into five parts.) **ESSENTIAL CHARACTER.** *Corolla*: rotate, reflex. *Stamina*: placed on the tube. *Capsule*: one-celled, oblong.—The only known species is,

1. *Dodecatheon Meadia*; *Virginian Cowslip*, or *Meadia*. This plant has a yellow perennial root, from which come out in the spring several long smooth leaves, nearly six inches in length, and two and a half in breadth, at first standing erect, but afterwards spreading on the ground, especially if it be much exposed to the sun; from among the leaves arise two, three, or four flower stalks, in proportion to the strength of the roots, which reach to the height of eight or nine inches, and are smooth, naked, and terminated by an umbel of flowers, of a purple, inclining to a peach-blossom colour. The flowers appear at the end of April, or the beginning of May; and the seeds ripen in July; soon after which the stalks and leaves decay, and the roots remain inactive till the following spring.—Native of Virginia. It is propagated by offsets, which the roots put out pretty freely when they are in a loose moist soil and shady situation; the best time to remove the roots, and take away the offsets, is in August, after the leaves and stalks are decayed, that they may be fixed well in their new situation before the frost comes on. It may also be propagated by seeds, which the plants generally produce in plenty, and which should be sown in autumn, soon after they are ripe, either in a shady moist border, or in pots, which should be placed in the shade. In the spring the plants will come up, and must then be kept clean from weeds, and, if the season prove dry, be frequently refreshed with water; nor should they be exposed to the sun, for while the plants are young they are very impatient of heat. The young plants should not be transplanted till their leaves are decayed, then they may be carefully taken up and planted in a shady border, at about eight inches' distance from each other, where the soil is loose and moist, where they may remain for a year, by which time they will be strong enough to produce flowers, and may then be transplanted into some shady borders in the flower-garden, where they will appear very ornamental while they continue in flower. This plant is not only very elegant, but also hardy.

Dodonæa; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, flat; leaflets ovate, obtuse, concave, deciduous. *Corolla*: none. *Stamina*: filamenta eight, very short; antheræ oblong, bowed, converging, length of the calix. *Pistil*: germen three-sided, length of the calix; style cylindrical, three-furrowed, upright; stigma slightly three-cleft, a little acute. *Pericarp*: capsule three-furrowed, inflated, three-celled, with large membranaceous corners. *Seeds*: in couples, roundish. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: none. *Capsule*: three-celled, inflated. *Seeds*: in couples.—The species are,

1. *Dodonæa Viseosa*; *Broad-leaved Dodonæa*. Leaves oblong. A tree ten or twelve feet high, according to Sloane, with fibrous deciduous bark; branches round, when young unequally quadrangular; leaves deciduous, alternate, nearly sessile, obovate with a taper base, nearly entire, bluntish with a little point, about two or three inches long, very glutinous, especially when young, destitute of all pubescence; flowers greenish, in little terminal, often branched clusters. The taste of the whole plant is acrid and bitterish. In Jamaica it is called the *switch sorrel*.—Native of the countries between the tropics, in sandy ground. It is propagated by seeds, which, if obtained fresh from abroad, will rise easily upon a hot-bed. When the plants are fit to remove, they should be each planted in a separate small pot filled with light loamy earth, and plunged into a hot-bed of tanner's

bark, shading them from the sun until they have taken new root; they then may have free air every day admitted to them, in proportion to the warmth of the season, and must neither be drawn up weak, nor should they have too much water. In the autumn the plants must be removed into the stove, where they should have a temperate warmth in winter, but during that season little water should be given them, nor should they have too much heat; for either of these will soon destroy them. As the plants obtain strength they will become hardier, and may be set in the open air for two or three months in the heat of summer, but should always be placed in a sheltered situation; in winter they must be placed in a stove, kept to a moderate temperature of warmth, for the plants will not live in a green-house here. This plant was formerly shewn for the Tea-tree, in many parts of the European gardens; and passed for it during many years, among those who knew no better.

2. *Dodonæa Angustifolia*; *Narrow-leaved Dodonæa*. Leaves linear. It resembles the foregoing: the fructification is polygamous.—It flowers from May to August; and is a native of the Cape of Good Hope. The second sort is less tender than the first, and requires only the protection of a green-house or glass-case.

Dogberry Tree, Dogwood. See *Cornus*.

Dog's Bane. See *Apocynum*.

Dog's Grass. See *Triticum*.

Dog's Mercury. See *Mercurialis*.

Dog's-tail Grass. See *Cynosurus*.

Dog's Tooth. See *Erythronium*.

Dolichos, a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*; perianth one-leaved, very short, four-toothed, equal; the superior tooth emarginate. *Corolla*: papilionaceous; standard roundish, large, emarginate, the whole reflex; two calluses oblong, parallel and longitudinal, growing to the standard beneath towards the base, compressing the wings, not hollowed on the back; wings ovate, obtuse, length of the keel; keel lunulate, compressed, beneath converging closely, length of the wings, ascending at the tip. *Stamina*: filamenta diadelphous, simple and nine-cleft, the simple one curved at the base; antheræ simple. *Pistil*: germea linear, compressed; style ascending; stigma bearded, running on inwardly from the middle to the tip of the style, which on the fore part is callous, obtuse. *Pericarp*: legume acuminate, large, oblong, two-valved, two-celled. *Seeds*: several, elliptic, usually compressed. **ESSENTIAL CHARACTER.** Two parallel oblong calluses at the base of the standard, compressing the wings underneath.—Most of these species come from the East and West Indies, are tender, and seldom perfect their seeds in England; they are principally annual plants, and are frequently lost in our stoves. Several species are cultivated for the table in warm countries, but seldom perfect their seeds in England; and were they to thrive here as well as in the warm countries, they would be little esteemed, because we already have much better sorts in our gardens; for the scarlet-flowering kidney-bean is preferable to all of them for eating, and deserves to be cultivated more than any other.—The species are,

* *Twining.*

1. *Dolichos Bengalensis*. Shrubby; legumes ending in long dagger-points. This is perennial; the stem is rather roughish to the touch, and scandent, as well as producing several branches; leaves roundish, ovate, ending in a point, furnished with a bristle; stipules lanceolate; peduncles racemose, four or five inches long; flowers seated on very short peduncles, uncertain as to number, snow-white, and slightly

odorou; legume oblong, pointed, compressed, first green, afterwards growing pale; seeds few, roundish-oblong, compressed, brown, with deeper-coloured points, and with a long protuberant, snow-white hilum.

2. *Dolichos Lablab*; *Black-seeded Dolichos*. Legumes ovate, salver-shaped; seeds ovate, with a bowed eye towards one end. Stems and branches round, scabrous backwards; peduncles forming half-whorls; seeds three or five, flattened a little, smooth, but not shining, black or ferruginous, edged on one side with a fungous snow-white callous, proceeding from the umbilicus, they have no albumen. Alpinus says, that this plant grows wild in Egypt: Hasselquist, however, is certain it does not grow wild in Lower Egypt, but is only cultivated there in gardens. The Egyptians call it *ful Frangi*, or European bean; and thence we may conjecture that the Europeans first brought it into Egypt. The natives make pleasant arbours of it, not only supporting it with trellis work, but fastening it with twine, by which means the leaves form an excellent covering and an agreeable shade.

3. *Dolichos Sinensis*; *Chinese Dolichos*. Legumes pendulous, cylindrical, torulose; peduncles erect, many-flowered. Stem annual, long, round, slender, twining, somewhat branched; leaves ternate, broad-lanceolate, smooth, with two or three lanceolate stipules at the base of the common petiole; flowers pale violet, on few-flowered, suberect, axillary peduncles; standard ascending, very blunt.—Native of Amboyna, China, Cochin-china, and the East Indies generally.

4. *Dolichos Uncinatus*; *Hook-podded Dolichos*. Legumes cylindrical, hirsute, with a hooked subulate claw at the end; peduncles many-flowered; stem rough with hairs.—Native of Jamaica.

5. *Dolichos Luteolus*. Legumes in several cylindrical heads; seeds rounded. Stem rather angular, branched, round. A scandent plant; branches three or four cubits long; leaves ovate, entire, subacute, glossy; stipules small, and roundish; peduncles axillary, supporting from six to ten elegant yellow flowers; the stigma bearded.—Native of the Society Isles.

6. *Dolichos Unguiculatus*; *Bird's-foot Dolichos*. Legumes in subcylindrical heads, recurved, and concave at the tip. This is an annual smooth plant, with a climbing stem; leaves lance-ovate, and sharp; peduncles upright, supporting but few flowers; flowers whitish; stigma long and bearded; seed whitish, with a snow-white hilum.—Native of the West Indies. Loureiro says it is a native of China, and was imported into Portugal.

7. *Dolichos Tranquebaricus*. Legumes few, in cylindrical heads, with a straight dagger-point. The whole plant is very smooth; the vexillum, or standard of the flowers, pale yellow behind, and blush red in front, the wings more blue, and the keel white.

8. *Dolichos Ensiformis*; *Horse Bean*. Legumes gladiated, three-keeled at the back; seeds arilled. Stem three or four feet high, with shoots running much farther; the legumes are between ten and fourteen inches in length, and generally contain ten or eleven seeds. This species is distinguished by its large falcated legume and white seeds, with a saffron-coloured scar.—Native of Jamaica.

9. *Dolichos Tetragonolobus*. Legumes quadrangular-membranaceous. Stem herbaceous, round, slender, scandent, long, branching; leaflets broad-lanceolate, smooth, pale green; stipules lanceolate, minute; flowers pale blue, on long, lateral, few-flowered peduncles; seeds about eight.—Native of the East Indies, China, and Cochin-china.

10. *Dolichos Sesquipedalis*; *Long-podded Dolichos*. Legume subcylindrical, even, very long; standard of the flower pale above, reddish within; legume more than a foot and a

half in length, roundish, with a little obtuse gibbous hook at the end.—Native of the West Indies.

11. *Dolichos Altissimus*; *Tall Dolichos*. Legumes racemed, rough-haired, equal; seeds surrounded with a scar; leaves smooth on both sides. This climbs the highest trees, whence hang elegant wreaths of flowers in close racemes, on peduncles frequently more than twelve feet in length. The flowers are void of scent, an inch and a half long, with a ferruginous calix, a violet blue standard and wings, and a yellowish keel; the whole of the stamina and pistilla rise surprisingly, and are inclosed within the convoluted standard.—Native of the island of Martinico.

12. *Dolichos Pruriens*; *Horse-eye Bean*. Legumes in racemes; valves somewhat keeled, rough-haired; peduncles by threes. Leaflets rough with hairs underneath; calix campanulate, five-toothed, the middle tooth shorter; banner very short, three times less than the other petals, ovate; keel linear, acute, boat-shaped at the end; legume compressed, inflex at the base, reflex at the tip. Common in all parts of the West Indies, and rising to the top of the tallest trees or spreading wide among lower bushes. The flowers dark purple, in spikes at the axils of the ribs. A decoction of the roots is reckoned a powerful diuretic and cleanser of the kidneys; and a vinous infusion of the pods in beer, (twelve pods to a quart) is said to be a certain remedy for the dropsy: the dose is half a pint. In the Windward Islands they make a syrup of the pods, which is said to be very effectual against worms.—Native of both Indies, and of Cochin-china. This, and the next species, are sometimes preserved in botanic gardens, especially the latter, whose pods are closely covered with stinging hairs, commonly known by the name of *cow-itch*. Both these plants are too tender to thrive in the open air of our country; so that whoever desires to have them, should sow their seeds in a hot-bed in March; and when the plants come up, they should be each planted in a separate pot, and plunged into the hot-bed again, taking care to shade them until they have struck root; after which they must every day have fresh air admitted to them, in proportion to the warmth of the season; and when the plants are too tall to remain in the hot-bed, they should be removed into the bark-stove, where, if they be allowed room to run, they will flower and perfect their seeds.

13. *Dolichos Urens*; *Cow-itch Dolichos*. Legumes in racemes, with furrows transversely lanceolate; the seeds surrounded with a scar. Stems round; leaves subovate, quite entire, acuminate, the upper surface smooth, the lower covered with a shining silvery down that is hardly perceptible; racemes simple, pendulous, scarcely ever longer than the leaves; proper peduncles one-flowered, in threes, placed closely at the end of the raceme, and hence forming a very elegant pendulous wreath of about eighteen flowers, which are scentless, about two inches long, having a ferruginous calix, and a yellow corolla, with the lower edge of the wings red. The seeds, from their resemblance to an eye, are called by the French *yeux bourrique*, or ass's eye; and in the British West India islands, they are for the same reason named *ox-eye bean*. This plant climbs to the top of the tallest trees, throwing down its long slender flower-stalks to a moderate distance from the axils of the upper ribs, whence they generally rise, and are not above the thickness of a common packthread, but seldom under four or five feet in length, and bear the flowers in clusters at their extremities. The outside of the pods are densely covered with sharp hairs, which penetrate the skin when touched, and cause a most excessive and troublesome itching.—Native of the West Indies. See the preceding species.

14. *Dolichos Minimus*; *Small Dolichos*. Legumes in racemes, compressed, with four seeds in them; leaves rhomb-shaped. This climbs three or four feet in height, and has numerous branches; leaves glaucous; racemes stiff; wings of the corolla yellow; standard brownish red, turning blue as it withers. Brown calls it *small fetid dolichos*; and in Curaçoa, it has the name of *vrattekruyt*, or wart-herb, the leaves bruised with salt being reputed to cure warts.—Native of Jamaica.

15. *Dolichos Lineatus*. Legumes in racemes, oblong, three-keeled. Stem subangular, smooth; leaflets smooth, ovate, obtuse, with a point, marked with lines, equal, an inch and half in length, the side ones short, the middle ones on a long petiole; stipules very small, bristle-form; legumes rounded in front, straight at the back, marked with three lines, the side ones larger than the middle line, acute, smooth, two inches long.—Native of Japan.

16. *Dolichos Capensis*. Peduncles with one or two flowers; legumes elliptic, compressed; leaves smooth. Stem filiform, angular, even; stipules ovate, acute, striated, very small; leaves petioled; leaflets ovate-oblong, acuminate, veined; peduncles long; legumes acute at both ends, the back suture straight, smooth, containing usually two seeds.—Native of the Cape of Good Hope.

17. *Dolichos Scarabæoides*; *Silvery-leaved Dolichos*. Leaves ovate, tomentose; flowers solitary; seeds two-horned. Stem scabrous; leaves petioled; leaflets obtuse, veined underneath, soft; flowers single, from the axils.—Native of the East Indies.

18. *Dolichos Incurvus*. Legumes solitary, incurved, three-keeled. Stem striated, smooth; leaflets oblong, acute, entire, smooth, paler underneath, nerved, two inches broad, a hand in length, equal, the side ones on very short petioles, the middle leaflet on a longer; flowers axillary, solitary, peduncled.—Native of Japan.

19. *Dolichos Bulbosus*; *Bulbous Dolichos*. Leaves smooth, many-angled, toothed. Stem perennial, suffruticose, long, round, smooth, branched, without any stipules; leaves roundish, petioled; flowers terminating in long racemes; calix cup-shaped, four-cleft, the upper segment shorter, emarginate; corolla pale violet, with an ovate, entire, converging standard. The root consists of roundish, tailed, juicy, white tubers, in bundles; they are eaten both raw and dressed, but the seeds are refused.—Native of both Indies.

20. *Dolichos Trilobus*. Lateral leaflets gibbous on the outside, the middle one three-lobed. Stem perennial, suffruticose, round, very long, branched, twining, or creeping, when it lies on the ground, hirsute; leaves petioled, with two horned stipules; leaflets three-lobed, acuminate, pubescent; flowers purple, in long terminating and lateral spikes, with a large yellow spot on the middle of the standard. The root is composed of a few long tubers in bundles; they are two feet long, subcylindric, fibrose, fleshy, of a pale colour, and eatable when boiled, but not the legumes.—Native of the East Indies, and cultivated in China and Cochin-china.

21. *Dolichos Aristatus*. Peduncles two-flowered, axillary; legumes linear, compressed, ending in a straight awn. Stem round; leaflets even, ovate-oblong, acuminate.—Native of America.

22. *Dolichos Filiformis*; *Cat's-claw Dolichos*. Leaflets linear, obtuse, mucronate, smooth, pubescent underneath. This grows among bushes, but seldom stretches beyond three or four feet in length; the pods are long and compressed; the stigma or top of the style almost naked. It is used as a purgative ingredient in diet-drinks, and is said to answer well in dropsical cases.—Native of Jamaica.

23. *Dolichos Purpureus*; *Purple Dolichos*. Stem smooth; petioles pubescent; wings of the corolla spreading. Leaflets subcordate, smooth, netted underneath with purple veins; calices covered with two bractes; corolla bright purple; keel violet below the tip. The legumes, when young and fresh, are sapid and salubrious; seeds compressed, ovate, surrounded with a scar.—Native of both Indies: cultivated in China and Cochinchina.

24. *Dolichos Regularis*. Leaves ovate, obtuse; peduncles many-flowered; petals equal in size and alike in form.—Native of Virginia.

25. *Dolichos Lignosus*; *Woody Dolichos*. Stem perennial; peduncles forming a head; legumes stiff and straight, linear. Root woody, perennial; leaves alternate, on long foot-stalks, ternate, or rather binate, with an odd leaflet; common footstalk roundish, channelled above, unbelling, and purplish at the base; partial ones very short, swollen, incurved; leaflets rhomboid, elongated, acute, entire, obsoletely three-nerved, bright green and shining above, glaucous beneath; racemes axillary, solitary, erect, having from three to six flowers in a little head; flowers nodding a little, rose-coloured, with a purplish keel; seeds black.—Native of the East Indies. It is easily propagated by seed, and produces abundance of flowers during summer in a stove.

26. *Dolichos Polystachios*; *Many-spiked Dolichos*. Stem perennial; racemes very long; pedicels in pairs; legumes acuminate, compressed. Stem becoming shrubby, often round, smooth, very long; leaves alternate, unequally pinnate, smooth; leaflets about six pairs, opposite, on very short petioles, ovate, acuminate, entire, smooth, pale underneath, an inch long, the odd lobe on a longer petiole; the flowers from the same bud with the leaves, in racemes often a foot in length; pedicels scattered, opposite, and alternate, short, one-flowered. It varies with white and with purple corollas, with larger hirsute, and with smaller smooth legumes. Native of Japan, where it is frequently cultivated for arbouris; and also of Virginia.

27. *Dolichos Reticulatus*; *Netted-leaved Dolichos*. Leaves ovate, acute, wrinkled, netted, villose; racemes few-flowered. Shrubby.—Native of New South Wales.

28. *Dolichos Luteus*. Twining; flowers in a sort of spike; legumes subcylindric, smooth; leaves roundish, rhomboid, obtuse, entire, smooth.—Native of Jamaica.

29. *Dolichos Montanus*; *Mountain Dolichos*. Stem shrubby, climbing; leaflets ovate, rhomboid; five filamenta with oblong antheræ, and five alternate, roundish. Roots subtuberous, hard, long, in bundles; stem long, branched; leaflets large, tomentose, entire; flowers wholly purple, in long lateral spikes; stamina five, longer, with oblong antheræ, five alternately shorter, with roundish antheræ; legume linear, straight, compressed, separated between the seeds, which are compressed and suborbiculate.—Native of the mountain woods of Cochinchina.

30. *Dolichos Hastatus*. Stem procumbent; leaves subhastate; peduncles many-flowered, erect. Stem annual, long, round, branched; flowers yellow, axillary, on long striated peduncles; legume linear, straight, subcylindric; seeds ovate, pale, esculent.—Native of Africa.

31. *Dolichos Rotundifolius*. Legumes racemed, compressed, somewhat hairy, sword-shaped; leaflets oval, roundish, smooth. Stem smooth, woody, angular at top; leaflets oval, the end one roundish, entire, emarginate, veined; petiole a little longer than the leaflets, scarcely hairy; petiolules purple, hairy; racemes axillary, half a foot long; flowers two or three at each tubercle, on very short pedicels; bractes two, roundish, caducous, at the

base of the flower; calix bell-shaped, smooth; corolla large, purple.—Native country unknown.

** *Erect*.

32. *Dolichos Ensiformis*; *Scymetar-podded Dolichos*. Stem suberect; legumes scymetar-shaped, three-keeled; seeds arilled. Leaflets acute, wrinkled, smooth; stipules bristle-shaped, very small; flowers violet-coloured, on many-flowered axillary peduncles; calix tubular, two-lipped, upper lip bifid, lower three-toothed, shorter. There is a variety with legumes twice as long, and flatter, with blunter leaves, and other minute differences.—Native of China and Cochinchina, where it is cultivated for arbouris, but not for food.

33. *Dolichos Soja*. Stems flexuose; racemes axillary, erect; legumes pendulous, hispid, containing about two seeds. Stem round at bottom and smooth; above, striated, very hirsute, a foot or more in height; leaves petioled, hirsute; leaflets petioled, ovate, obtuse, with a point, entire, the middle leaves on a longer petiole, and larger, an inch in length; petiole striated, hirsute, a finger's length; flowers in short, erect, hirsute racemes; subsessile, from three to five together; corollas purple, scarcely bigger than the calix.—Native of the East Indies, Ceylon, and Japan.

34. *Dolichos Catiang*. Legumes double, linear, somewhat erect. Stem annual, a foot and a half high, roundish, rugged, branched; leaflets broad-lanceolate, smooth; common petiole long; stipules lanceolate, minute; flowers subterminating, two or three together, on a very long peduncle; seeds oblong, ovate, somewhat compressed, with a scar of a different colour. There are several varieties differing in the colour of the flower and seed, all of which are much cultivated for food.—Native of the East Indies.

35. *Dolichos Biflorus*; *Two-flowered Dolichos*. Stem perennial, even; peduncles two-flowered; legumes erect. Root an ovate brown tuber; leaves linear-lanceolate, quite entire, veined, pubescent on both sides, subsessile; flowers yellow, axillary.—Native of China and India.

36. *Dolichos Repens*; *Sea-side Dolichos*. Stem creeping; leaves pubescent, ovate; flowers racemed, in pairs; legumes linear, columnar.—This is a common plant by the sea-side, in Jamaica: the root is a strong purgative.

37. *Dolichos Roseus*. Stem creeping, ascending; leaflets roundish, shining; flowers in racemes; legumes three-keeled at the back.—Native of Jamaica.

38. *Dolichos Fabæformis*; *Bean-shaped Dolichos*. Stem erect, angular; leaves villose, glaucous; legumes stiff and straight, subquadrangular. Root annual; petioles three-sided, channelled; stipules linear, very acute, villose, erect, permanent; spikes axillary, solitary, erect, villose, shorter than the petioles; flowers subsessile, erect, purple.—Native of the East Indies.

Doliocarpus; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets oblong, rounded, concave, unequal, coloured, permanent. *Corolla*: petals three, roundish, concave, plaited. *Stamina*: filamenta very many, inserted into the receptacle, capillary; antheræ compressed. *Pistil*: germen globular; style long, incurved; stigma compressed, flat, subbifid. *Pericarp*: berry globular, one-celled, crowned with the style. *Seeds*: two, arilled, oblong, rounded, flat on one side, convex on the other. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: three-petalled, plaited. *Stigma*: subbifid. *Berry*: globular, crowned with the style, one-celled, two-seeded.—The species are,

1. *Doliocarpus Rolandri*. Stem stiff and straight: leaves

ovate-lanceolate, toothed; flowers terminating. A stiff erect shrub, with pendulous leaves.—Found in Surinam.

2. *Dolioscarpus Major*. Stem scandent; leaves ovate, toothed; peduncles lateral, one-flowered. The flowers are aromatic, but rather nauseous, and the berries positively pernicious; stem slender and flexuose; branches at right angles; leaves spreading.—Found in Surinam.

3. *Dolioscarpus Calinea*. Stem scandent; leaves ovate, quite entire; flowers axillary, in bundles. This is a shrub with several knotty spreading twigs, scattering over the neighbouring trees; the branches are garnished with alternate, oval, shining, green leaves, terminating in a point, the largest are four inches long. The flowers spring from the bosoms of the leaves, on the branches, and are arranged alternately in little heaps; the corolla consists of three white petals, which are large and rounded.—Native of Guiana.

Dombeya; a genus of the class Diccæia, order Monadelphia.—GENERIC CHARACTER. *Male*. *Calix*: ament ovate-cylindric, imbricate, with very many woody short scales, each terminated by a lanceolate, acute, coriaceous leaflet, concave at bottom, narrower and recurved at top. *Perianth* and *Corolla*: none. *Stamina*: filamenta none, except the amentaceous scales; antheræ ten or twelve, heaped about each amentaceous scale, linear, grooved, the length of the scale, fastened to the top of it, below the leaflet by the upper extremity, approximating and converging round the scale, separating by the lower extremity when the scale is broken. *Female*. *Calix*: ament large, roundish, ovate, closely imbricate, with very many germina, resembling scales. *Perianth* and *Corolla*: none. *Pistil*: germen each wedge-form, oblong, subcompressed, contracted at the base into a point, with a broad, thick, callous termination; style none; stigma bivalve, the valves unequal, the inner very small, obtuse, the outer very large, broad at the base, thick, curved inwards above the inner one, terminated by a linear, acute, slender, ascending strap, almost the length of the germen, bent in at a right angle above it. *Pericarp*: none. *Seeds*: very many, heaped into a roundish strobile, imbricate, each oblong, sub-cylindric, towards the base obtusely four-cornered, with a short broad spatulate wing or strap at the top, thickened at the edge, incurved, ascending; the shell coriaceous, coloured, valveless; the kernel oblong, subangular at the base. *Receptacle*: naked, villous, here and there alveolate. **ESSENTIAL CHARACTER.** *Male*. *Calix*: the scales of an ament, terminated by a leaflet. *Corolla*: none. *Antheræ*: ten or twelve, without filamenta. *Female*. *Calix*: ament with many germina. *Corolla*: none. *Stigma*: bivalve, unequal. *Seeds*: many, in a roundish strobile.—The only species hitherto discovered is,

1. *Dombeya Chilensis*. Turbinate, imbricate leaves, mucronated on one side; the branches quaternate and cruciate.—This tree is very little known: it is a native of Chili, of a resinous nature, in some respect allied to Protea; and also to the Pines in some particulars of its fructification. The trunk is straight, and of considerable height; the wood white, solid, and clothed with a kind of double bark; the boughs are covered with very numerous leaves, sessile, oval, very pointed, entire, smooth, and coriaceous, a little concave inwards, and convex outwards; they have a sharp point, and are ranged on the branches in the manner of scales; the flowers are male and female, borne on different individuals, and hang in solitary catkins from the tops of the branches.

Donatia; a genus of the class Triandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets awl-shaped, short, remote. *Corolla*: petals nine,

or eight to ten, linear, oblong, twice as long as the calix, spreading. *Stamina*: filamenta three, awl-shaped, the length of the calix; antheræ subglobular, twin. *Pistil*: germen inferior; styles three, filiform, a little longer than the stamina; stigmas bluish. **ESSENTIAL CHARACTER.** *Calix*: three-leaved. *Petals*: nine, twice as long as the calix, linear, oblong. *Antheræ*: subglobular, twin.—The only known species is,

1. *Donatia Fascicularis*. This is a simple undivided plant, a finger's length, with imbricate leaves.—Native of moist rocky places in Terra del Fuego.

Doræna; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, shorter than the corolla; divisions ovate, concave. *Corolla*: one-petalled, subcylindric, wheel-shaped; border five-cleft; segments ovate, obtuse, erect. *Stamina*: filamenta very short, so as to be scarcely any, inserted into the tube of the corolla; antheræ oblong, subquadrangular, included. *Pistil*: germen conic, smooth, superior; style filiform, the length of the corolla; stigma truncate, emarginate. *Pericarp*: capsule ovate, acute, one-celled. *Seeds*: very many. **ESSENTIAL CHARACTER.** *Corolla*: five-cleft. *Stigma*: emarginate. *Capsule*: one-celled.—The only species hitherto discovered is,

1. *Doræna Japonica*. A tree about six feet high; branches alternate, round, ash-coloured, smooth, divaricate; leaves alternate, petioled, oblong, acuminate, remotely and obscurely serrate, nerved, smooth, spreading, the length of a finger; petioles semicylindric, grooved on the upper part, smooth, half an inch in length; flowers in racemes, white, minute; racemes axillary, scarcely half an inch long; capsule the size of a pepper-corn.—Native of Japan.

Doronicum; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common with leaflets lance-subulate, about twenty in number, equal, upright, of a double series, length generally of the rays of the corolla. *Corolla*: compound, rayed; corollules hermaphrodite, tubular, numerous in the disk; females ligulate; of the number of calicular leaves, in the ray; proper of the hermaphrodite funnel-form; border five-cleft, patulous; female ligulate, lanceolate, three-toothed. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; anther cylindric, tubular. *Pistil*: in the hermaphrodites; germen oblong; style filiform, length of the stamina; stigma emarginate: in the females, germen oblong; style filiform, length of the hermaphrodites; stigmas two, reflex. *Pericarp*: none; the calix slightly converging. *Seeds*: in the hermaphrodite solitary, obovate, furrowed, a little compressed; down hairy: in the females solitary, obovate, furrowed, a little compressed; down none. *Receptacle*: naked, flat. **ESSENTIAL CHARACTER.** *Calix*: scales in two rows, equal, longer than the disk. *Seeds*: of the ray naked, and destitute of down; down to those of the disk simple. *Receptacle*: naked.—The species are,

1. *Doronicum Pardalianches*; *Great Leopard's Bane*. Leaves cordate, obtuse, toothletted, those next the root petioled, on the stem embracing. Roots thick, fleshy, divided into many knots, sending out strong fleshy fibres, which penetrate deep into the ground; root-leaves heart-shaped, hairy, petioled; among these arise the flower-stalks, which are channelled and hairy, nearly three feet high, putting out one or two smaller stalks from the side; these grow erect, and have one or two heart-shaped leaves closely embracing the stalk; this and each branch is terminated by one large yellow flower, which appears in May, and ripens seed in July.—Native of France, Switzerland, Germany, Austria, Carniola,

Hungary, and Savoy. This plant has been stigmatized as poisonous, without much occasion, although it derives its name from this imaginary noxious quality. The famous Conrad Gesner, however, took two drachms of the root without injury; and some say that it is an antidote to poison, which is still farther from the truth. It is not used in the present practice; and Dr. Stokes informs us, that two drachms occasioned a sense of inflation in the stomach, and also of general weakness, but that these symptoms were only of short duration; he adds, that it has been recommended in vertigo, epilepsy, and menstrual obstructions, but that these powers want the confirmation of a more accurate experiment.—It multiplies very fast by its spreading roots; and if the seeds be permitted to scatter, they will produce plants wherever they happen to fall, so that it becomes a weed where it is once established: it loves a moist soil and shady situation.

2. *Doronicum Plantagineum*; *Plantain-leaved Leopard's Bane*. Leaves ovate, acute, somewhat toothed; branches alternate. The stalks rise about two feet high; each is terminated by a large yellow flower, which has two or three alternate embracing leaves, not so hairy as those of the first species.—Native of Germany, France, Spain, and Portugal. This is equally hardy with the first, and multiplies abundantly.

3. *Doronicum Bellidiastrum*; *Daisy-leaved Leopard's Bane*. Stem naked, very simple, one-flowered. This, like the two preceding, has a perennial root; the leaves are like those of the common Daisy, but longer and not so broad; the flower grows on a naked stalk, nearly a foot long; and the root seldom sends out more than one stalk; the ray of the flower is white, very like that of the common Daisy; disk yellow. Haller found it in the Lower Alps with a deep red flower.—Native of the Swiss, Tyrolese, and Italian Alps, and of Austria, Carniola, and Silesia. This species is propagated by parting the roots, for the seeds do not ripen well in England; it must have a shady situation, and a moist soil. The flowers do not make a much better appearance than those of the common Daisy, only they stand on much taller stalks.

Dorstenia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: receptacle common one-leaved, flat, cornered, very large, covered by the receptacle, with very numerous floscules inhabiting the disk, very small; perianth proper four-cornered, concave, imbedded in the receptacle, and united with it. *Corolla*: none. *Stamina*: filamenta four, filiform, very short; antheræ roundish. *Pistil*; germen roundish; style simple; stigma obtuse. *Pericarp*: none; receptacle, common becoming fleshy. *Seeds*: solitary, roundish, acuminate. ESSENTIAL CHARACTER. *Receptacle*: common one-leaved, fleshy, in which solitary seeds nestle.—It will be difficult to obtain these plants, because the seeds are seldom to be found good, nor will they grow if they be kept long out of the ground; so that the only sure method to obtain them, is to have the roots taken up at the time when their leaves begin to decay, and planted pretty closely in boxes of earth, which may be brought very safely to England, provided they be preserved from salt water, and are not too often supplied with fresh during their passage. As soon as they arrive, each of them should be transplanted into a separate pot, filled with fresh earth, and plunged into the bark-stove, which should be kept of a moderate heat: they must be frequently refreshed with water during the summer season; but in winter, when their leaves are decayed, it should be more sparingly given. These directions will enable any one who conforms to them, not only to maintain, but increase the plants, by parting their

roots in the spring, before they put out their leaves.—The species are,

1. *Dorstenia Houstoni*. Scapes rooted; leaves heart-shaped, angled, acute; receptacles quadrangular. It sends out the leaves upon footstalks eight or nine inches in length, and very slender; the leaves are about three inches and a half long, and almost four broad at their base, the two ears having two or three angles, which are acute, and the middle of the leaves are extended, and end in acute points like a halbert; they are smooth, and of a lucid green; the footstalk which sustains the placenta is nine inches long, and about half an inch square, and the upper surface closely set with small flowers.—Native of Campeachy, in South America.

2. *Dorstenia Conrayerva*; *Conrayerva*. Scapes rooted; leaves pinnatifid-palmate, serrate; receptacles quadrangular. It sends out several leaves from the root, which are about four inches long, and as much in breadth; these are deeply lacinated into five or seven obtuse parts standing upon footstalks nearly four inches long; they are smooth, and of a deep green. The stalks arise from the root, and grow nearly four inches high, upon which the fleshy placenta is vertically placed; this is of an oval form, about one inch long, and three quarters broad: upon the upper surface of this the small flowers are closely situated, the fleshy part becoming an involucre to them; they are very small, and very indistinct at a distance, being of an herbaceous colour.—Native of New Spain, Peru, Tobago, and St. Vincent's. The roots and seeds of this plant are excellent aromatics, and alexipharmics or counter poisons, and cure the bites of serpents, and stings of scorpions, or black spiders. A decoction of the root in water, is also good in dropsies, and debilitations, or taken as a bitter in wine, with the addition of steel. The root, says Motherby, has a light aromatic smell, and a very pungent bitter taste; it promotes perspiration, resists putrefaction, and is an excellent medicine in malignant, low, and putrid fevers. Meyrick recommends it for strengthening the stomach and digestive faculties, dispersing wind, easing the colic, and is excellent in the decline of ardent fevers, and through the whole course of putrid ones. Hill remarks, that we use the roots; he adds, our druggists keep them, and they are the principal ingredients in that famous powder, called, from its being rolled up into balls, *lapis conrayerva*. It is an excellent cordial and sudorific, good in fevers, and in nervous cases, and against indigestions, colics, and weaknesses of the stomach: it may be taken in powder, or in tincture, but it is better to give it alone than with that mixture of crab's claws, and other useless ingredients, which are compounded in the conrayerva-stone. In fevers and in nervous disorders, it is best to give it in powder; in weaknesses of the stomach it is best in tincture, and is also an excellent ingredient in bitter tinctures, so that it is wonderful that the present practice has not put it to that use. All the old prescribers of recipes for these things have put some warm root into them, but none is so proper as this, although the galangale is the most commonly used; but that has a very disagreeable flavour in the tincture, while the conrayerva, with equal or superior virtues, is entirely free from that defect.

3. *Dorstenia Drakena*. Scapes rooted; leaves pinnatifid-palmate, quite entire; receptacle oval. This plant sends out leaves of different forms, some of the lower ones are heart-shaped, having a few indentures on their edges, and ending in acute points, but the larger leaves are deeply cut, like the fingers on a hand, into six or seven acute segments; these leaves are five inches long, and six broad in the middle; they are of a deep green, and stand upon long footstalks. The placenta is very thick and fleshy, an inch and a half long, and three-quarters broad, having four acute corners; these have

a number of small flowers placed on the upper surface, like the other species.—Native of Vera Cruz, and Tobago. Mr. Miller informs us, that the roots of all the three species are brought over, indifferently to be used in medicine and in dying; and that it was not known what the plant was, the roots of which were imported, and had been long used in medicine, until Dr. Houston informed us.

4. *Dorstenia Cauleseus*. Peduncles on a stem. This is a small plant, the leaves of which proceed irregularly from the stem, which is short. The leaves are ovate-acute, and pretty strongly dentated at the edges; the male flowers are collected into little heads, and the females into a kind of sharply lobed or irregular flattish heads; they stand upon remarkably long footstalks.—Native country unknown.

5. *Dorstenia Lucida*. Caulescent: leaves obliquely ovate, entire, even; peduncles in cymes, axillary. Native of the Society Islands.

6. *Dorstenia Pubescens*. Caulescent: leaves obliquely ovate, serrate, pubescent; peduncles axillary, bearing heads.—Native of the Society Islands.

7. *Dorstenia Cordifolia*. Scapes rooting; leaves cordate-ovate, toothletted; receptacles orbiculate; disk a little concave: male flowers in the disk, towards the ray; calices immersed in the receptacle, or four-toothed hole; filamenta two, three, or four, short, with twia antheræ; flowers in the middle of the disk, female; germen ovate; style bifid; stigmas reflex.—Native of Jamaica and St. Domingo.

8. *Dorstenia Chinensis*. Peduncles cauline; petioles three or five leaved. Root fusiform, three inches long, white within and without, fleshy, aromatic; stem perennial, suberect, round, simple, whitish; leaves ternate or quinate, lanceolate, quite entire, smooth, on a long common petiole; receptacle of the flowers lateral, fleshy, suboval, with many florets put forth at the top; the calix is funnel-form, and three-toothed. The root is aromatic, and used in medicine.—Native of China, in the northern provinces; and called there *pechi* and *bach-chi*.

Douglassia; a genus of the class Polyadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, turbinate, half six-cleft, permanent; segments ovate, acute, coloured. *Corolla*: none; nectaries six, ovate on the outside with two oblong pits, on the inside convex; anthera-bearing, terminated by two glands, convex without, concave within, ending at bottom in a capillary pedicel, shorter than the calix, inserted at the base of the segments, with a villose gland on each side at the insertion of it. *Stamina*: filamenta none; antheræ very many, minute, one-celled, with the valve opening at the base. *Pistil*: germen ovate, superior; style filiform, the length of the stamina; stigma six-cleft. *Pericarp*: berry ovate, acute, one-celled. *Seed*: single, with a brittle shell. ESSENTIAL CHARACTER. *Calix*: half six-cleft. *Corolla*: none. *Nectaries*: six. *Filamenta*: none. *Germen*: superior. *Stigma*: six-cleft. *Berry*: ovate, one-celled. *Seed*: one, with a brittle shell.—The only known species of this genus is,

1. *Douglassia Guianensis*. With alternate lanceolate leaves. This is a middling-sized shrub, growing in Guiana; it is about five feet high, and branching at top, its diameter five or six inches; the wood white and compact; the branches are subdivided into smaller ones; and the flowers grow at their extremities in a kind of straggling clusters, they are small and yellowish. The berry is black, with viscid pulp; the seeds oily and aromatic. It is called by the natives *aiouvé*.

Draba; a genus of the class Tetradynamia, order Siliculosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets ovate, concave, from erect spreading, deciduous.

Corolla: four-petalled, cruciform; petals oblong, somewhat spreading, with very small claws. *Stamina*: filamenta six, length of the calix; of these the four opposite ones somewhat longer, from erect spreading: antheræ simple. *Pistil*: germen ovate; style scarcely any; stigma headed, flat. *Pericarp*: silicle elliptic-oblong, compressed, entire, destitute of style, two-celled; dissepiment parallel with the valves; valves plano-concave. *Seeds*: several, small, roundish.

ESSENTIAL CHARACTER. *Silicle*: entire, oval-oblong; valves flattish, parallel to the dissepiment.—*Style*: none.—These plants are easily propagated by parting the heads in autumn, for they shoot up to flower very early in the spring; they will thrive, and flower annually, in a moist soil and shady situation, and require no other culture but to be kept clean from weeds. Some of them are peculiarly adapted to adorn rock-work, and they all prosper best in that situation.—The species are,

1. *Draba Aizoides*; *Hairy-leaved Alpine Willow Grass*. Scape naked, simple; leaves ensiform, keeled, ciliate. Root perennial; stem three inches high; petals entire; silicle hairy, rough, ovate, sharp at both ends, ending in a long style, four lines in length, the cells having six to eight seeds, which are round and flattened; flowers in a sort of corymb, which becomes a raceme when the fruit is ripe; petals yellow, usually entire. It is well adapted to rock-work, and is a pretty plant with a pleasant smell.—Native of the mountains of France, Switzerland, Savoy, Austria, Carniola, and Silesia.

2. *Draba Ciliaris*. Stem almost naked; leaves linear, ciliate about the edge and along the keel; petals entire; root perennial; root-leaves forming a close tuft, imbricate, crowded, even, keeled, distinctly ciliate; petals obovate, white; style longer than the stamina; peduncle naked, the length of the stem, filiform, few-flowered; flowers terminating, subsessile; leaflets of the calix erect, almost equal, lanceolate, obtuse, green on the outside, yellowish on the inside; germen ovate, longer than the stamina.—Native of Provence, in dry rocky places.

3. *Draba Alpina*. Scape naked, simple; leaves lanceolate, quite entire; petals emarginate. Perennial: all the root-leaves spreading, sprinkled with hairs on the upper surface, by no means imbricate, linear, ciliate or smooth on the upper surface; stem leafless, with a few hairs scattered about it, not one-leaved or smooth; petals slightly emarginate, not entire.—Native of the European Alps.

4. *Draba Verna*; *Common or Spring Willow Grass*. Scapes naked; leaves somewhat serrate, often very entire; petals divided. Root annual; stems about three inches high, one to five or more from the same root, in a rich soil, smooth after flowering, but hairy when young; peduncles alternate, bearing one flower only; leaflets of the calix obtuse and somewhat hairy; petals white, twice the length of the calix, two-parted; filamenta bending forward, the four longer ones the height of the pistil; seeds ovate, brown, fixed to the edge of the partition, from three to six in a cell, according to Scopoli, but sometimes as many as twenty-four: by these it propagates itself with such amazing rapidity, that it is a weed which it is hardly possible to eradicate wherever it has obtained admittance. Linnaeus observes, that it hangs down the flowers in the night and in wet weather; that in Smoland they sow Rye when this plant is in blossom; and that in dry soils whole fields are covered with the flowers early in the spring. In England it is common upon walls, dry banks, fields, and pastures, flowering in March and April, or earlier if the weather be mild. In some countries abundance of this little plant is supposed to prognosticate dearth of corn, which may have some foundation, as a wet season produces

a great crop of this little weed, which some say is much liked by sheep. Gerarde calls it *whiteblowe*, or *whitlowe-grasse*, or *naile-woort*. This small plant may serve as an index of the difference of climates; for in Sweden it flowers in the month of April; in Germany a month earlier; in England, Holland, and France, in February; while in the genial air of Sicily it flowers throughout the winter.

5. *Draba Pyrenaica*. Scape naked; leaves wedge-shaped, palmate, three-lobed. It is a perennial plant, seldom more than two inches high, with a shrubby stalk dividing into many small heads; leaves small, the lower ones have five short narrow lobes, the upper have but three; the flowers come out in clusters, sitting close to the leaves, they are of a pale purple colour, and appear early in the spring; root creeping, putting out erect branching shoots, which at the end bear thick, shining, stiffish, spreading leaves, half-three-lobed, narrowed at the base into a sort of half-embracing erect petiole, marked with three lines; the lobes spreading oblong, sharpish, ciliate at the tip, and interruptedly on the edge.—Native of the mountains of Switzerland in the canton of Appenzel, Provence, Carniola, Austria, and Piedmont; flowering in May. This decorates the loftiest mountains of Europe with its pale purple diminutive flowers, in the spring and early summer, and vies with the neighbouring *Androsaces* and *Arctiæ* in beauty.

6. *Draba Muralis*; *Wall Whitlow Grass*. Stem branched; leaves ovate, sessile, toothed. Root annual; root-leaves entire at the base, toothed upwards; stem-leaves rather heart-shaped; fruit-bearing peduncles horizontal, longer than the silicles; corollas pale yellow, or white, with the petals slightly emarginate; silicles exactly elliptic, ending in a short blunt knob; seeds reddish-brown. It rises with an upright branching stalk about ten inches high, terminated by loose spikes of white flowers, which appear in the beginning of May. The wood variety being sown with this in a garden, became so like it as not to be distinguished, the yellow flowers becoming white.—Native of Sweden, Switzerland, Germany, the south of France, and of Italy, in the fissures of rocks. Mr. Ray found it near Montpellier, and between Lucca and Pisa, in hedges. In England, it is met with in Derbyshire, Yorkshire, and Westmoreland; and is common about Malham.

7. *Draba Hirta*. Scape one-leaved; leaves subhirsute; silicles oblique, pedicelled. Petals white, emarginate, perennial; root-leaves elliptic, smooth, ciliate, tongue-shaped; stem-leaves sessile, ovate-acuminate, having only two teeth.—Native of Lapland, Denmark, Provence, Switzerland, Silesia, Austria, and Piedmont, in the fissures of the rocks; flowering in May.

8. *Draba Fladnizensis*. Scape two-leaved; leaves smooth, ciliate; silicles straight, pedicelled. Root fusiform, perennial; root-leaves forming roses, lanceolate, bluntish, quite entire, flat, shining, smooth, firm, ciliate, with distant hairs; stems from the centre of the roses, erect, undivided, slender, an inch high, naked; they have one or two sessile, lanceolate, smooth, entire leaves on them, villose, ciliate on the edge; raceme terminating, few-flowered; flowers from five to eight, pedicelled; calicine leaflets naked, half the length of the petals, green; petals snow-white, slightly emarginate; filamenta awl-shaped, white, with ovate yellow antheræ; silicle naked. It has no scent.—Native of Carinthia.

9. *Draba Incana*; *Hoary Whitlow Grass*. Stem-leaves numerous, hoary; silicles oblong, oblique, subsessile. Root biennial; root-leaves very numerous, spreading like the flower of a rose, lanceolate, tomentose, and somewhat hairy, entire, acute; stem a hand in height, straight, and stiff, hoary, clothed with many leaves, frequently more than thirty,

very like the root-leaves, but shorter, so that the uppermost are ovate, sessile, and have a few teeth, on the lower part of the stem they are more crowded; flowers in a small terminating corymb; petals white, obscurely emarginate; silicles in a raceme, erect, twisted in a direction contrary to the sun's diurnal motion, compressed, naked; peduncles hoary, three times shorter than the silicles, stiff, approaching to the stem.—Native of Lapland, Sweden, Denmark, Norway, and Britain; as in Westmoreland, Yorkshire about Settle, and near the summit of Ingleborough; in the Scottish islands of Isla and Skye; and in Carnarvonshire, North Wales. It flowers in May and June.

Dracæna; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong, somewhat upright, equal, cohering by the claws. *Stamina*: filamenta six, inserted into the claws, subulate, thicker in the middle, membranaceous at the base, length scarcely of the corolla; antheræ oblong, incumbent. *Pistil*: germen ovate, six-striated; style filiform, the length of the stamina; stigma three-cleft, obtuse. *Pericarp*: berry ovate, six-furrowed, three-celled. *Seeds*: solitary, ovate-oblong, incurved at the tip. ESSENTIAL CHARACTER. *Corolla*: six-parted, erect. *Filamenta*: somewhat thicker in the middle. *Berry*: three-celled, one-seeded. For propagation and culture, see *Phanix*.—The species are,

1. *Dracæna Draco*; *Dragon Tree*. Arboreous: leaves somewhat fleshy, with a thorny end. This rises with a thick trunk, nearly equal in size the whole length, the inner part very pithy, next to this a circle of strong fibres, and the outside soft; height twelve or fourteen feet; the trunk is marked with circular rings where the leaves are fallen off; and the top sustains a large head of leaves coming out singly all round it; they are shaped like those of the common Iris, but are much longer, being often four or five feet in length, and an inch and a half broad at their base, where they embrace the trunk; they lessen gradually, and terminate in a point: these leaves are also pliable, hanging down, entire, of a deep green, smooth on both surfaces. It is called Dragon Tree, because the inspissated juice becomes a red powder, very like the Eastern Dragon's-blood.—Native of the East Indies.

2. *Dracæna Ferrea*; *Purple Dracæna*. Arboreous: leaves lanceolate, acute. Stem shrubby, almost simple, eight feet high, erect, round, with close protuberant rings from the fallen leaves; these are quite entire, a foot and a half in length, erect, smooth, on stem-clasping petioles, and of a dusky red colour; flowers red-purple, subterminating; spathe diffused; spathe long, awl-shaped, permanent; corolla bell-shaped, six-parted, inferior; segments oblong, obtuse, spreading; antheræ sagittate, sharp, and bifid at the end; style awl-shaped, thick, trifid, equal to the stamina; stigmas simple; berry red.—Native of China. The Chinese call it *tat-sio*, or *tsiet-tsao*, and, as well as the Cochin-chinese, plant it in their gardens. It flowers in March and April.

3. *Dracæna Striata*. Frutescent, caulescent, erect: leaves lanceolate, obliquely sickle-form, striated; stem flexuose.—Native of the Cape of Good Hope.

4. *Dracæna Terminalis*. Herbaceous, caulescent: leaves lanceolate. Raceme terminating, composed of a few branches; pedicels alternate, solitary, shorter than the flower, surrounded at the base by an obtuse glume. It is a hardy tree.—Native of the East Indies, and the Society Isles. This plant was found by Captain Cook very useful in making a kind of beer. The juice of the root is sweet and mucilaginous.

5. *Dracæna Ensifolia*; *Sword-leaved Dracæna*. Herbaceous, subcaulescent; leaves ensiform. Root perennial, horizontal, creeping, somewhat woody, odoriferous, simple; root-

leaves heaped, thick, striated, shining, reflex, a foot long; scape three feet high, leafy at bottom, naked at top, round, slender, declining; flowers terminating, subumbelled; corolla bell-shaped, spreading; petals lanceolate, blue on the outside, white within, small; filamenta spreading, dilated at the base; berry roundish, blue, three-grooved, containing many minute seeds.—Native of the East Indies, and Cochinchina.

6. *Dracæna Undulata*. Herbaceous, caulescent, erect: leaves ovate, acute, many-nerved; flowers axillary, peduncled.—Native of the Cape of Good Hope.

7. *Dracæna Medecoloides*. Herbaceous, twining; leaves ovate, nerved.—Native of the Cape of Good Hope.

8. *Dracæna Erecta*. Herbaceous, caulescent, erect; leaves lanceolate, subulate, sessile.—Native of the Cape.

9. *Dracæna Volubilis*. Herbaceous, twining: leaves lanceolate.—Found at the Cape.

10. *Dracæna Graminifolia*. Herbaceous, stemless: leaves linear. Scape scarcely longer than the leaves; four or five flowers at each tooth of the raceme, on pedicels shorter than the flower itself, coming out from a kind of obscure glume.—Native of Asia.

11. *Dracæna Emarginata*. Shrubby: leaves tooth-spiny; racemes axillary; berries many-seeded.—Native of the Isle of Bourbon.

12. *Dracæna Borealis*. Herbaceous, subcaulescent; leaves elliptic. The whole herbage somewhat pubescent.—It flowers in June; and is a native of Hudson's Bay, and Newfoundland.

13. *Dracæna Indivisa*. Arboreous: leaves ensiform, acute; raceme compound. Trunk round, full of small chinks, undivided, leafy at top, from six to nine feet high; raceme apparently lateral, but perhaps this was owing to the next set of leaves destined for the ensuing year coming out; it is ovate, nodding, with the partial racemes digested into a cylindrical thyrsoid form; pedicels one-flowered, very short, horizontal; bracts at the base of the pedicel, two, very small, lanceolate, acute, concave; petals subreflex; germen superior; style short; berry globular, blue, marked above with three hollow dots, mucronate, with the permanent style, having about seven seeds in each cell, involved in an aril or membrane, so as to appear only one; they are black, smooth, semilunar, and three-sided. The berries of this species are eaten by the New Zealanders; they are ripe in May, that is, at the beginning of their winter. The young leaves, or rather the hybernacle concealed among them, is an excellent salad, which, together with the *Areca Oleracea* and *Sapida*, *Apium Graveolens*, or *Smallage*, *Tetragonia Halimifolia*, *Lepidium Oleraceum* and *Piscidium*, and *Sonchus Oleraceus* or *Sow-thistle*, was found to be of great service to our navigators in resisting the putrid scurvy.—Native of New Zealand.

14. *Dracæna Australis*. Arboreous: leaves ensiform, acute; raceme terminating, erect, superdecapound.—Native of New Zealand.

Dracocephalum; a genus of the class *Didynmia*, order *Gymnospermia*.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, permanent, very short. *Corolla*: one-petalled, ringent; tube length of the calix; throat very large, oblong, inflated, gaping, a little compressed at the back; lip superior, straight, arched, complicated, obtuse; lip inferior, three-cleft; lateral divisions upright, as it were the segments of the throat, the intermediate one hanging down, small, prominent, forwards at the base, roundish, emarginate. *Stamina*: filamenta four, subulate, hid beneath the upper lip of the corolla, of which two are a little shorter; antheræ somewhat cordate. *Pistil*: germen four-parted; style fili-

form, in the situation of the stamina; stigma two-cleft, sharp, slender, reflex. *Pericarp*: none; calix cherishing the seeds in its bosom. *Seeds*: four, ovate-oblong, three-sided. ESSENTIAL CHARACTER. *Corolla*: throat inflated; upper lip concave.—The species are,

* *In Spikes.*

1. *Dracocephalum Virginianum*; *Virginian Dragon's Head*. Flowers crowded; leaves linear-lanceolate, serrate. It rises with an upright stalk, nearly three feet high; leaves about three inches long; and half an inch broad, sessile; they are usually in pairs at each joint, but sometimes there are three together: the flowers are purple, in terminating spikes, and make a pretty variety among other hardy plants.—It is perennial, flowering from July to September; and a native of North America, in woods, and by the sides of rivers. It will live in the open air of our climate, but requires a moist soil, or should be duly watered in dry weather, otherwise the leaves will shrink, and the flowers make little appearance. It may be allowed a place in the shady borders of a garden, for it will not ramble nor take up much room, and may be propagated by parting its roots in autumn.

2. *Dracocephalum Denticulatum*; *Denticulated Dragon's Head*. Flowers remote; leaves obovate-lanceolate, denticulate above. It is allied to the first species, but is inferior in point of beauty; it spreads more on the ground; its flowering-stems are not altogether so upright, nor so tall; its leaves are broader; and the flowers in the spikes less numerous.—It flowers in August and September; and is a native of North America. Like the first, it is a hardy perennial, multiplying considerably by its roots, which creep in some degree: it requires a moist soil, and a shady situation.

3. *Dracocephalum Canariense*; *Canary Dragon's Head*, or *Balm of Gilead*. Leaves compound. This plant is perennial, rising with several stalks to the height of three feet or more, and becoming woody at the lower part; leaves at each joint, having three or five oblong, pointed, serrate leaflets: the flowers come out on short thick spikes at the top of the stalks, they are of a pale blue colour, and are produced from July to September; but the corolla is flesh-coloured, or pale purple with white lines.—Native of the Canary Islands, whence it was imported into Europe, under the name of *permento de Tana*: the old writers call it *Camphorosma* and *Cedronella*; and the moderns, *Balm of Gilead*, from its rich odour on being gently rubbed. It is usually kept in the green-house, but in mild winters the plants will live abroad in warm borders; and those which are kept in pots will thrive much better when sheltered under a frame, than in a green-house, where the plants are apt to draw up weak, for they require as much free air as possible in mild weather, and need only be sheltered from severe frost. This species may be propagated by seeds, which if sown in autumn will more certainly grow than those which are sown in the spring; but if these be sown in pots, they must be sheltered under a frame in winter, and if the plants do not come up in the same autumn, they will rise in the spring; but if the seeds are sown in the full ground, it should be in a warm border, and they should be defended from hard frosts, otherwise the young plants will be destroyed. They may also be propagated by cuttings, which, if planted in a shady border any time in summer, will very soon take root, and furnish plenty of rooted plants.

4. *Dracocephalum Pinnatum*. Leaves cordate, pinnately sinuate. Stems shrubby, decumbent; leaves transversely pinnatifid, obtuse, with remote lobes, on long petioles. The spike is like that of the *Mclampyrum Arvense*. The bracts are lanceolate, with bristly teeth, and are often red; corollas

small; styles twice as long as the flowers.—Native of Jerkatsch in Siberia.

5. *Dracocephalum Peregrinum*; *Prickly-leaved Dragon's Head*. Flowers somewhat spiked; stem-leaves ovate-oblong, gashed; bractes linear-lanceolate, denticulate, spiny. Root perennial; stems several, a long span in length, with the joints an inch asunder; leaves like those of the common Hyssop or Rosemary, moderately hoary underneath; from the axils of these come out branches with similar leaves, but smaller, and flowers at the end, with rigid calices, and corollas of a very elegant blue purple colour; seeds oblong, angular, blackish.—Native of Siberia.

6. *Dracocephalum Austriacum*; *Austrian Dragon's Head*. Leaves and bractes linear, parted, spiny. Root perennial; stalks hairy, a foot and a half high, sending out several side-branches; flowers terminating in short whorled spikes, with some very narrow leaves or bractes under each whorl. This, says Jacquin, is a beautiful plant, and grows in Austria, where it was first observed by Clusius. The stems, which vary in number according to the soil, are annual, squarish, and villose; the leaves opposite, hoary below, smooth and green above, and are deeply lobed, or cut in a pinnafid manner. The flowers are axillary on the upper part of the plant, commonly in pairs, sometimes in threes, large, and of a violet purple colour, paler without.—Native of Austria and Hungary. This, and the seventh and eighth species, will be best propagated by seed, which should be sown in the latter end of March, in a bed of fresh light earth, in an open exposure, and in about five or six weeks after, the plants will appear, when they should be carefully cleared from weeds; and, if the season should prove dry, they must be refreshed now and then with water, which will greatly promote their growth. When the plants are about two inches high, they should be carefully transplanted into a bed or border of fresh, light, undunged earth, observing to shade them from the sun until they have taken root, as also to refresh them with water until they are well established in this bed; after which time, they will require no farther care, but to keep them constantly clear from weeds till Michaelmas, when they are to be removed into the places where they are finally to remain. When they are first removed from the seed-bed into the nursery-bed, they should be planted six inches asunder every way, which will be sufficient room for them the first season; and this will admit of the hoe to come between the plants to destroy the weeds, which is safer than pulling them up by hand, as well as sooner performed: for as the hoe stirs the ground between the plants, it not only cuts down the weeds which were up and visible, but also destroys all those whose seeds were sprouted, and would soon after have appeared; so that one hoeing, if well performed, and in dry weather, will more effectually destroy the weeds, than two hand weedings would do, were they performed ever so carefully; besides, the stirring the ground is of great service to the plants. At Michaelmas, when they are transplanted for good, they should be carefully taken up with balls of earth to their roots, and planted in fresh light earth in the middle of the borders of the pleasure garden, where, when intermixed with other hardy plants of the same growth, they will make a pretty appearance when they are in flower, and will continue three or four years, and have been known to live six or seven years in stony soils, where, however, the spikes of flowers are neither so large nor so vigorous as those of younger plants. Hence, as these plants do not continue many years, it will be proper to raise a supply of young plants to succeed them; for the old plants will produce seed plentifully, which are ripe the latter end of August, or the beginning of September.

ber, when they should be gathered in dry weather, and kept in a warm dry room ready for use.

7. *Dracocephalum Ruyschiana*; *Hyssop-leaved Dragon's Head*. Leaves and bractes lanceolate, undivided, awnless. Root perennial; stems about two feet high, with two smooth linear leaves at each joint, about an inch long, and one-eighth of an inch broad, with a deep furrow along the middle; at each joint, at the other sides of the stem, come out two or three very narrow small leaves of the same shape. The calices are cut into five segments at top, of which, four are narrow and acute, and the fifth, which is on the upper side of the corolla longer than the calix, swelling, and large at the chaps; the upper lip broad, erect, and arched over the tube, the lower shorter, with two short, erect, side segments; but the middle segment is broad, rounded, indented at the point, and reflex. The flowers appear in June, and are of a fine blue colour.—Native of Norway, Sweden, Switzerland, and Siberia. See the sixth species.

** *In Whorls.*

8. *Dracocephalum Sibiricum*; *Siberian Dragon's Head*. Flowers subverticilled; peduncles bifid, pointing one way; leaves cordate, oblong, acuminate, naked. The stalks of this species do not grow erect, like the preceding, but spread nearer to an horizontal position; they divide into several branches, which have a pair of large leaves at each joint, and four smaller, two on each side; they are smooth, have sharp indentures on their edges, and stand erect. The flowers come out from the side of the stalks, at the base of the leaves, two or three together, on each side; calix purple, cut into five acute segments, three broad in the upper lip, two narrower in the lower; upper lip of the corolla broad, indented at the point, and erect, lower trifid, but the middle segment not so much reflexed as that of the preceding, and the whole of a paler blue. The chaps of the corolla are broad, and almost inflated; the upper lip is compressed and bifid, the lower toothletted, and villose in front; the two upper stamina are hirsute at the base. The smell of this plant is fetid, and not unaptly compared to that of rancid oil.—Native of Siberia. See the sixth species.

9. *Dracocephalum Moldavica*; *Moldavian Dragon's Head*, or *Balm*. Leaves dotted underneath; bractes lanceolate, the serratures capillaceous. This is an annual plant, rising with branching stalks, a foot and a half high, with oblong leaves, deeply serrate on their edges. The flowers come out in whorls round the stalks at every joint, are blue, appear in July, and continue to the middle of August. The seeds ripen in September. It has a strong balsamic odour, which is very agreeable to some persons.—Native of Moldavia. This, with the five following species, may be propagated by seeds, sown either in the spring or autumn, in small patches upon the borders where they are to remain. When the plants come up, they should be thinned where they grow too near together, and kept clear from weeds.

10. *Dracocephalum Canescens*; *Hoary Dragon's Head*. Bractes oblong, with spiny serratures; leaves subtomentose. The stalks are hoary, a foot and a half high, putting out two or three side-branches, with hoary leaves, nearly two inches long, and half an inch broad, a little indented on their edges; they are placed just under the whorls of flowers which sit close to the stalk; the corolla is large, of a fine blue colour, and makes a pretty appearance among the hoary leaves. It flowers and seeds about the same time as the foregoing sort, and is generally treated as an annual, although the roots will survive two or three years in a dry soil. There is a variety

with white flowers.—It was discovered by Tournefort in the Levant. See the ninth species.

11. *Dracocephalum Peltatum*; *Willow-leaved Dragon's Head*. Bractes orbiculate, serrate-ciliate. This is an annual plant, about a foot high, sending out two small branches from the lower part; leaves lanceolate, crenate, petioled; flowers small, purplish.—Native of the Levant. See the ninth species.

12. *Dracocephalum Grandiflorum*; *Great-flowered Dragon's Head*. Leaves crenate; root-leaves cordate; stem-leaves orbiculate, sessile; bractes acuminate, toothed. Root-leaves like those of *Betony*, petioled, obtuse, wrinkled, pubescent; stem-leaves almost wedge-shaped, rounded, very obtuse, crenate-toothed. The bractes and floral-leaves are somewhat of a violet colour. The whorls have the flowers by threes on each side; calices subpeduncled, five-cleft; the three upper teeth less divided. Corollas large, blue; the chaps much inflated, with a rising streak at the back on each side; upper lip bifid, lower trifid; the middle segment larger, dark blue, reflex, bearded at the end; antheræ oblong. An alpine species.—Native of Siberia. See the ninth species.

13. *Dracocephalum Nutans*; *Nodding Dragon's Head*. Bractes oblong, ovate, quite entire; corollas rather large, nodding. Annual; stalks weak, many, about nine inches high, having at the bottom ovate-lanceolate leaves, about two inches long, and an inch and a quarter broad, crenate, and on pretty long footstalks. The upper part of the stalk has smaller leaves, sitting close at the joints, and from these come out the flowers in whorls; they are of a deep blue colour, and hang down, appearing at the same time with the preceding. The seeds ripen in autumn.—Native of Siberia. See the ninth species.

14. *Dracocephalum Thymiflorum*; *Small-flowered Dragon's Head*. Bractes oblong, quite entire; corollas scarcely longer than the calix. Stalks a foot and a half high; lower leaves very like those of *Betony*, standing upon very long footstalks; the upper small, sitting close to the stalks. The flowers come out in whorls at every joint; they are of a pale purple or blue colour, and being small, make little appearance. Seeds small, ovate-oblong, slightly convex on one side, angular on the other, dark chesnut colour.—Native of Siberia. See the ninth species.

15. *Dracocephalum Cochinchinense*. Flowers in spikes; bractes roundish, acute; leaves ovate-lanceolate, quite entire. Stem herbaceous, ten inches high, erect, grooved, villose; leaves villose, few; flowers violet-coloured, in terminating spikes; bractes many-flowered; filamenta hairy.—Native of Cochinchina.

Dracontium; a genus of the class Gynandria, order Polyandria.—GENERIC CHARACTER. *Calix*: spathe boat-form, leathery, one-valved, very large. *Spadix*: extremely simple, cylindric, very short, coated on all sides with fructifications disposed into a head, of each of which the perianth proper none, unless you call the corolla so. *Corolla*: proper five-petalled, concave; petals ovate, obtuse, somewhat equal, coloured. *Stamina*: in each filamenta seven, linear, depressed, upright, equal, longer than the corolla; antheræ four-cornered, twin, oblong, obtuse, upright. *Pistil*: germen somewhat ovate; style columnar, straight, length of the stamina; stigma obscure, three-sided. *Pericarp*: in each a roundish berry. *Seeds*: very many. ESSENTIAL CHARACTER. *Spathe*: boat-form. *Spadix*: covered. *Calix*: none. *Petals*: five. *Berries*: many-seeded.—The species are,

1. *Dracontium Polyphyllum*; *Many-leaved Dragon*. Scape very short; petiole rooted, torn; leaflets three-parted; divisions pinnatifid. It has a large, knobbed, irregular root, covered with a rugged brown skin. The stalk

rises about a foot high, is smooth, and of a purple colour, full of sharp protuberances of different colours, shining like the skin of a serpent; it is naked to the top, where it has a tuft of leaves, which are divided into many parts. The flower-stalk rises immediately from the root, and is seldom more than three inches high, having an oblong swelling hood, or sheath, at top, which opens lengthwise, showing the short, thick, pointed style within, upon which the flowers are closely ranged. When the sheath opens, says Linneus, it exhales a smell like that of the most putrid carcase, capable of taking away any person's senses or understanding; but it is remarkable, that after a few days, when the antheræ begin to shed their pollen, this poisonous fetor in an hour's time absolutely ceases.—It grows naturally in several of the islands of America, also in Surinam and Japan, where they prepare a medicine from the acrid roots, which they call *konjakf*, and esteem as a great emmenagogue, which dissolutes women take to procure abortion. In the Society Islands, it is cultivated for the sake of the roots, which are eaten in a scarcity of the bread-fruit, notwithstanding their extreme acrimony.—This, and the second species, are tender, and require a warm stove to preserve them in England. The roots must be planted in pots filled with light kitchen garden earth, and plunged into the tan-bed in the stove, where they should constantly remain; in the winter, they must be watered very sparingly, but should be often refreshed in warm weather, when they are in vigour. With this management the plants will flower; but their roots do not increase in our climate.

2. *Dracontium Spinosum*; *Prickly Dragon*. leaves sagittate; peduncles and petioles prickly. The root is oblong, thick, and full of joints, from which arise several leaves, shaped like those of the common *Arum*; but their footstalks are covered with rough protuberances. The stalk which supports the flower is short, and set with similar protuberances; at the top is a spathe, about four inches long, as thick as a man's finger, which opens longitudinally, and exposes the spadix, which is set with flowers.—It grows naturally in the island of Ceylon, and in several parts of India.

3. *Dracontium Fœtidum*; *Fetid Dragon*, or *Scunk-weed*. Leaves roundish. The flowers of this plant appear first; after they arrive to a state of perfection, the leaves come out at a small distance, in a conic form, very closely rolled together: they are nearly ovate when expanded, and petioled. The plant has no stem. The globe of flowers is nearly the colour of the spathe, which is beautifully variegated with scarlet and yellow. The corolla has four erect, very thick, narrow, obtruncated petals. The stamina have four flatish filamenta, rising from the receptacle, longer than the corolla; style rather longer than the stamina; stigma bifid; seeds large, roundish, single, inclosed within the receptacle.—Native of North America; where it is found in swamps, and upon the borders of meadows, flowering in April and May. The vulgar names of *Scunk-cabbage* and *Scunk-weed*, are taken from its rank smell, nearly resembling that of a scunk or polecat. The roots, dried and powdered, are an excellent remedy in asthmatic cases. It may be given with safety to children, in doses of four, five, or six grains; and to adults, in doses of twenty grains and upwards. It appears to be antispasmodic, and bids fair to be useful in many disorders. In collecting the roots, particular care ought to be taken, that the *White Hellebore*, or *Poke-root*, which some call *Scunk-weed*, be not mistaken for this. There is this obvious difference; *White Hellebore* has a stalk, the real *Scunk-weed* has none. Cattle will not touch it during summer. The Swedes, settled in North America, call it *byorn-blad*, or *byorn-retter*, *bear's-leaf*, or *bear's-root*;) because the bears, when they

leave their winter quarters in the spring, are very fond of it.

4. *Dracontium Camschatcense*; *Kamtchatka Dragon*. Leaves lanceolate. The roots of this species resemble the common Arum, and the leaves come out each on a separate footstalk, immediately from the root, as in that plant. It has never flowered in England.—Native of Siberia; requiring a shady situation, and being fully able to bear the greatest cold in our climate.

5. *Dracontium Pertusum*; *Perforate-leaved Dragon*. Leaves perforated; stem climbing. This species has slender jointed stalks, which put out roots at every joint, that fasten to the trunks of trees, walls, or any support which is near them, and thereby rise to the height of twenty-five or thirty feet. The leaves are placed alternately, standing upon long footstalks; they are four or five inches long, and two and a half broad, having several holes in each; so that, on the first view, they appear as if eaten by insects. The flowers are produced at the top of the stalk, which always swell to a larger size in that part than in any other; these are covered with an oblong spathe, or hood, of a whitish green colour, which opens longitudinally on one side, and shews the spadix closely covered with flowers, of a pale yellow, inclining to white. When this plant begins to flower, it seldom advances farther in height, so that these seldom are more than seven or eight feet high; but the leaves are much larger on these, than those of the plants which ramble much farther.—Native of the West Indies, and of the isle of Tanna in the South Seas.—This plant is easily propagated by cuttings, which, if planted in pots filled with poor sandy earth, and plunged into a hot-bed, will soon put out roots, if they had none before; but there are few of the joints which have not roots. The plants being tender, will not endure the open air in England; and the pots should, on that account, be placed near the walls of the hot-house, against which the plants will climb, and fasten their roots into the wall, and thereby support the stalks. They should have but little water in the winter; but in warm weather, it must be given them three or four times a week; and in the summer, free air should be admitted to them in plenty. The plants have no particular season of flowering; for they sometimes flower in autumn, and sometimes in the spring, but never ripen their seed in our climate. The plants of this genus, are preserved in the gardens of the curious, both in England and Holland, more for variety than for beauty; but this species is an exception, and may be suffered to have a place against the wall of the stove, over which it will spread, and cover the nakedness of the wall; and the leaves, which are so remarkably perforated, remaining all the year, make a singular appearance.

Drilling. See *Hoing*, p. 696.

Dropwort. See *Spiræa*.

Dropwort, Water. See *Ænanthe*.

Drosera; a genus of the class Pentandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-cleft, sharp, upright, permanent. *Corolla*: funnel-form; petals five, somewhat ovate, obtuse, rather larger than the calix, and alternate with it. *Stamina*: filamenta five, subulate, length of the calix, and alternate with the petals; antheræ small, growing to the filamenta. *Pistil*: germen superior, roundish; styles five, simple, length of the stamina; stigmas simple. *Pericarp*: capsule surrounded with the calix, somewhat ovate, one-celled, three, four, or five-valved

at the tip. *Seeds*: very many, very small, somewhat ovate, scabrous, fixed to a branching loose receptacle in the centre at the bottom. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: five. *Capsule*: one-celled, five, or three-valved at the tip. *Seeds*: very many.—These plants are not easily preserved in gardens. They must be taken from their native bogs, with a sufficient quantity of bog-earth and water-moss, and planted in pots, set in pans, constantly supplied with water. They will also succeed better if defended from the sun, and well enveloped in moss kept constantly wet. The leaves, in most of the species, only next the root, furnished with glandulous hairs on the upper surface, and fringed with them round the edge: these hairs have each a small globule of a pellucid liquor likewet, continuing even in the hottest part of the day, and in the fullest exposure to the sun; from which remarkable circumstance, their English name of *Sundew* is derived.—The species are,

1. *Drosera Acaulis*; *Stemless Sundew*. Flower radical, without any scape, solitary; leaves oblong. This plant is singular for having a sessile flower in the bosom of the root-leaves.—This and the following are natives of the Cape.

2. *Drosera Cuneifolia*; *Wedge-leaved Sundew*. Scapes radicate; leaves wedge-form, rounded. It resembles the third species, but is larger, and has sessile leaves rounded at the summit, but gently attenuated towards the base.

3. *Drosera Rotundifolia*; *Round-leaved Sundew*. Scapes radicate; leaves orbiculate; styles six. Root perennial, black; root-leaves many, forming a tuft, two or three lines in length and breadth, set with red hairs about the edge and on the upper surface, the under surface smooth; the petioles red, and half an inch or eight lines in length, ciliate at the base; scape erect, round, slender, simple, three or four inches in height; flowers in a kind of racemed spike, bent in at the top before flowering-time, they point one way, are alternate, erect, and from six to eleven in number; the peduncles are half a line or a line in length; corolla white; calix smooth; stigmas obtuse, white; bractes none. The flowers open from nine to twelve. The young leaves before they expand are rolled inwards, and at the same time bent in to the very peduncle.—In England it flowers in July and August; and is found on Hampstead Heath; at Battle's well, near Harefield, and Iver heath; on Hinton and Teversham moors, and Gamlingay bogs, in Cambridgeshire; on Malvern chace; Birmingham heath; Selborne, in Hampshire; Ludgvan Lee, on the Barton and Moors, and Senan, in Torvorian commons, Cornwall; Halston, in Northamptonshire; near Mansfield and Oxtun in Nottinghamshire; and frequently in various parts of Scotland. The variety mentioned by Ray, was found by Mr. Willisel in Devonshire.—The whole of this plant is acrid, and sufficiently caustic to corrode the skin; some ladies, however, know how to mix the juice with milk, so as to make it an innocent and safe application to remove freckles and sun-burn. The unmixed juice will destroy warts and corns, if a little of it be frequently put upon them. These effects, however, show its internal use to be dangerous, although some authors very gravely tell us, that a water distilled from this plant is highly cordial and restorative! The leaves only, bruised and externally applied, will erode the skin, and bring on such inflammations as are not easily removed. This plant has the same effect upon milk as the *Pinguicula Vulgaris*; and, like that too, is supposed to occasion the rot in sheep. Is not, says Withering, the sour coagulated milk of the Syrians, called *labun*, or *leven*, at first prepared with some plant of this kind? In Great Britain this plant is called generally, *Sundew*, *Youthwort*; in the north parts, *Red-rot*.

4. *Drosera Longifolia*; *Long-leaved Sundew*. Scapes radicate; leaves ovate-oblong. Linneus is of opinion that this is scarcely specifically distinct from the preceding species, since they only differ in the form of their leaves. This seems not to be so common as the round-leaved sort, although Mr. Woodward informs us that it is frequent in Norfolk; and Mr. Lightfoot, that it is so also in Scotland. On Brigsteer moss, near Kendal, it grows thrice as large as any where about London: it is also found on Hinton Moor, near Cambridge; on Bagshot Heath, in Surry; and at Selborne, in Hants.—*Great Sundew*, which Mr. Hudson makes a distinct species, because it is larger, has eight styles, and four-valved capsules; it is common, as he informs us, in the northern counties, also in Devonshire, Hampshire, and Norfolk; three miles from Carlisle towards Scotland, where Mr. Dickson found it near Fort Augustus; near Ellesmere; and in Ireland. Another variety was found by Mr. Willisel, between Doncaster and Bautrey, in Yorkshire; and by Mr. J. Sherard on Westfield Down near Hastings. The three last species have the same property with *Dionæa Muscipula*, of entrapping small insects with their folded leaves; which was discovered by surgeon Whately, in August, 1780. On inspecting some of the contracted leaves, he observed a fly in close imprisonment; and on centrically pressing other leaves yet in their expanded form, with a pin, he observed a sudden elastic spring of them, so as to become inverted upwards, and as it were encircling the pin. The same account occurs in a German author, in July 1779: an ant was placed on the middle of a leaf, the insect endeavoured to escape, but was held fast by the clammy juice at the point of the hairs; in some minutes the short hairs on the disk of the leaf began to bend; then the long hairs, and laid themselves upon the ant; after a while the leaf began to bend; and in some hours the end of the leaf was so bent inwards as to touch the base: the ant died in fifteen minutes.

5. *Drosera Capensis*; *Cape Sundew*. Scapes radicate; leaves lanceolate, scabrous underneath. Root putting out spiral threads; flowers violet-coloured.—Native of the Cape.

6. *Drosera Lusitanica*; *Portuguese Sundew*. Scapes radicate; leaves subulate, convex underneath; flowers ten-stamined. The stem has a few leaves on it, and from two to four peduncled flowers at the end; capsule twice as long as the calix.—Found in Portugal by Tournefort.

7. *Drosera Cistiflora*; *Cistus-flowered Sundew*. Stem simple, leafy; leaves lanceolate. Stems a foot high, pubescent; leaves alternate, with glutinous hairs; flowers terminating, one to three, large, on peduncles; the bottom of the corolla dark; stamina black, the length of the calix; antheræ yellow, cordate; pistil black; germen ovate, and round the top, but not on the top of it; five black styles the length of the corolla; stigmas several times dichotomous, even into hairs.—Native of the Cape.

8. *Drosera Indica*. Stem branched, leafy; leaves linear; peduncles axillary, with two or three flowers.—Native of the East Indies. The Ceylonese call it *kandulaessa*, from *kandula*, a tear; the leaves being surrounded with drops, as in our European species; the stem is half a foot high, and very slender; the leaves extremely fine, and coming out alternately all over the stem and branches, bent upwards at the ends; the peduncles are the length of the leaves, or longer, and sustains three flowers or more, but the weaker only one.

9. *Drosera Umbellata*. Scapes rooted; leaves ovate; flower umbelled. Stem none; leaves next the ground, only on long petioles; scapes various, naked, five inches long, terminated by an umbellule of about five flowers, with corollas of five petals.—Native of China.

Besides the foregoing, there are two species, natives of New South Wales: the first, *Drosera Peltata*, whose stem bears triangular peltate leaves fringed with numerous glands, and several rose-coloured flowers; the second, *Drosera Dichotoma*, whose stalk is solitary, naked, corymbose, a foot or more high, bearing numerous, large, elegant white flowers. The leaves are all radical, stalked, once or twice forked, linear, narrow, acute, the upper side clothed with glandular hairs, the margins entire.

Dryandra; a genus of the class Diœcia, order Monadelphica.—**GENERIC CHARACTER.** *Male.* Calix: perianth, two-leaved; divisions ovate, acute, shorter than the corolla; *Corolla*: five-petalled, petals obovate-oblong, from reflex patulous, unguicular. *Stamina*: filamenta nine, united below into one body, unequal, shorter by half than the corolla. Antheræ minute. *Female.* *Pericarp*: tricocous, or tetracocous, three-grooved, or four-grooved, wrinkled, fleshy. *Seeds*: solitary, oblong. **ESSENTIAL CHARACTER.** *Calix*: two-leaved. *Corolla*: five-petalled; (or calix five-leaved, resembling a corolla, surrounded by a two or three-leaved calicle.) *Stamina*: nine. *Fruit*: three or four grained.—The only known species is,

1. *Dryandra Cordata*. Stem arboreous, a fathom or more in height; branches round, with a wrinkled bark, dotted, smooth; leaves at the ends of the twigs approximate, alternate, petioled, cordate, acute, entire, five-nerved, the nerves branching, smooth, paler underneath, spreading, a hand in length and breadth; petioles almost the length of the leaf, round; flowers terminating in a panicle, the branches of which are dichotomous, or trichotomous, and patulous; petals yellow. From the seeds they express an oil for lamps and the table.—Native of Japan, flowering in May and June.

Dryas; a genus of the class Icosandria, order Polygynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved; eight-parted; divisions spreading, linear, obtuse, equal, a little shorter than the corolla. *Corolla*: petals eight, oblong, emarginate, spreading, inserted into the calix. *Stamina*: filamenta numerous, capillary short, inserted into the calix. Antheræ small. *Pistil*: germina many, crowded, small; styles capillary, inserted into the side of the germen; stigmas simple. *Pericarp*: none. *Seeds*: numerous, roundish, compressed, furnished with extremely long woolly styles. **ESSENTIAL CHARACTER.** *Calix*: five to ten-cleft. *Petals*: five to eight. *Seeds*: tailed, hairy.—The species are,

1. *Dryas Anemonoides*. Five petalled: leaves pinnate, with all the pinnas distinct. This is a very small plant: the radical leaves are commonly ternate, compound, consisting of a middle leaflet longer than the rest, and two lateral ones: all the leaflets are deeply cut or divided, but vary much as to breadth and length, in different individual plants; sometimes the leaves have more than three divisions, they are of a bright green, and very smooth; the footstalk is round. The stalk is terminated by a single flower, which is large in proportion; the calix is outwardly green, and inwardly lanuginous, and of a silvery appearance; the corolla is pale yellow, the petals striated; the stamina are extremely numerous and short; the germina converge into a globe, and are coated with a thick white down.—Native of Siberia.

2. *Dryas Octopetala*. Eight-petalled: leaves simple. This delicate evergreen plant, with its snow-white blossoms, is a great ornament to alpine heights; the stalk and branches are woody and perennial, lying flat upon the ground, and spreading flat about the rock in tufts; leaves evergreen, ovate, turned back at the edge, ending very obtusely, and sometimes emarginate, deeply and bluntly serrate, or more properly cre-

nate, hard and stiff, of a dark green wrinkled surface on the upper side, and hoary underneath, having woolly footstalks, and a large halbert-shaped stipule to each, embracing the stem: peduncles naked, downy, scattered with purple hairy glands, each bearing one flower, an inch in diameter, consisting generally of eight petals, but sometimes often or six, seldom of five; seeds oblong, gibbous on one side, straightish on the other, somewhat villose, reddish, brown, narrowing at bottom, ending at top in a feathered flexile tail, eight times the length of the seed; the corolla is frequently double.—Native of high mountains in Lapland, Denmark, Switzerland, where it was observed by Ray, on Thuri, one of the highest points of mount Jura; the Grisons, Savoy, Austria, Carniola, Stiria, Carinthia, Germany, France, Italy, Siberia, Ireland, Scotland, and the north of England; as, between Gort and Galloway, where it was found by Mr. Heaton; and near Sligo in Ireland; Breadalbane, Isle of Skye; Ross-shire, Sutherland, and Argyshire, in Scotland; Arncliffe Clowder, in Kintendale, near Kilnsay; and near Settle, in Yorkshire. It flowers in June. No cattle will eat it. *Dryas Pentapetala*, mentioned by Sibbald as growing in the den of Bethaick, four miles from Perth, is not now to be found there; possibly the *Potentilla Argentea* was mistaken for it.

Drypis; a genus of the class Pentandria, order Tryginia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, half five-cleft, permanent. *Corolla*: petals five; claws length of the calix, narrow; border flat; plates two-parted; divisions linear, obtuse; throat crowned with the two toothlets of each petal. *Stamina*: filamenta five, length of the corolla; antheræ simple, oblong, incumbent. *Pistil*: germen obovate, compressed; styles three, simple, patulous; stigmas simple. *Pericarp*: capsule roundish, covered by the calix, one-celled, small, clipped round. *Seed*: single, kidney-form, glossy. ESSENTIAL CHARACTER. *Calix*: five-toothed. *Petals*: five. *Capsule*: clipped, round, one-seeded.—The species are,

1. *Drypis Spinosa*. The first steps are procumbent, four-cornered, brachiata; the last dichotomous, and flower-bearing. Fresh green branches push forth in the spring; from the dry ones of the former year, the extreme ones are dichotomous, and bear flowers; leaves subulate, somewhat three-cornered, mucronate, those at the subdivisions of the stem are lanceolate with three teeth on each side; peduncles shorter than the flower; calix erect; corolla crowned, purple or white; petals narrow, spreading; stamina erect: biennial.—Native of Barbary, Italy, Istria, &c. This plant in its adult state becomes shrubby. Johnson and Gerarde call it *Sperage Thistle*; the Italians have named it *erba ciuccia*, or ass's herb, because that animal feeds freely on it.

Duck's Foot. See *Podophyllum*.

Duck's Meat. See *Lemna*.

Duranta; a genus of the class Didynamia, order Angiosperma. GENERIC CHARACTER. *Calix*: one-leafed, tubular, somewhat truncated, five-cleft. *Corolla*: one-petalled; tube longer than the calix, somewhat curved; border patulous, five-parted, nearly equal, rounded. *Stamina*: filamenta four, the two longer ones within the tube; antheræ roundish. *Pistil*: germen inferior, roundish; style filiform, length of the stamina; stigma thickish. *Pericarp*: berry roundish, covered by the calix. *Seed*: kernels four, two-celled. ESSENTIAL CHARACTER. *Calix*: five-cleft, superior. *Berry*: four-seeded. *Seeds*: two-celled. (According to Gærtner, calix five-toothed; corolla funnel-shaped, five-cleft; berry one-celled, containing four two-celled stones.)—The plants of this genus being natives of warm countries, require a stove to preserve them in England; they are propagated by

seeds, which should be sown in small pots, and plunged into a hot-bed of tanner's bark; and when the plants are fit to remove, they must be planted each into a separate pot, filled with light earth, and plunged into the hot-bed, observing to shade them until they have taken new root, and afterwards treat them in the same manner as other plants from the same country. They may also be increased by cuttings, which put out roots very readily. They thrive best during winter in a temperate heat. In summer, place them in a warm sheltered situation in the open air.—The species are,

1. *Duranta Plumieri*; *Smooth Duranta*. Fruiting calices twisted. It grows fifteen feet high, with alternate branches, erect or reclining; spines awl-shaped, opposite, but very frequently wanting; leaves lanceolate, on short petioles, acute, bluntly and unequally serrate above the middle, smooth, opposite, two inches long; racemes loose, wide, reclining, both axillary and terminating; flowers slightly sweet-smelling, very many, blue, on very short peduncles; fruit yellow, the calix also then becoming yellow, and like a berry, the whole being changed, and different from its former shape.—Native of South America and the West Indies.

2. *Duranta Ellisia*. Fruiting calices erect. This shrub is a fathom in height or more, branched and even; branches long, reclining, quadrangular, subdivided, with axillary, opposite, ovate-lanceolate, acuminate, serrate, nerved leaves, smooth on both sides; racemes compound, terminating, brachiate, many-flowered; flowers on short peduncles, and blue. The specific character of this and the preceding, taken from the contortion of the calix above the fruit, is vague and insufficient, since the differences occur frequently in the same raceme; they are therefore in all probability not specifically distinct. Jacquin also remarks, that it is extremely like the first species, except that the fruiting calix is not twisted in the upper part, but continues convergent and erect. Notwithstanding this approximation, Dr. Patrick Browne made it a distinct genus, under the name *Ellisia*, from Mr. Ellis, the ingenious author of a treatise on Zoophytes, or plant-like marine productions of an animal nature: he says that this shrub rises frequently to the height of six or seven feet; that the leaves are very like those of green tea; and that the branches, though sometimes beset with thorns, are often otherwise.—Native of the West Indies; in Jamaica it is frequently found in hedges between Kingston and San Jago de la Vega.

3. *Duranta Mutisii*. Leaves elliptic, quite entire. This differs from the two preceding species merely in the leaves.—It is a native of South America, and was found there by Mutis.

Durio; a genus of the class Polyadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth one-leafed, pitcher-shaped, five-lobed; lobes rounded, deciduous. *Corolla*: petals five, added to the calix, and less than it, concave. *Stamina*: filamenta in five bodies, divided into seven, subulate, longer than the corolla; antheræ twisted; (or, according to Jussieu, filamenta five, flat at the base, seven or eight-cleft at the top; the divisions connate, subulate, bearing thirty-five to forty twisted antheræ.) *Pistil*: germen roundish, stipitate; style bristle-form, length of the stamina. *Pericarp*: pome roundish, on all parts mucicated with many-sided dagger-points, five-celled, gaping open in five directions: cells one to five seeded. *Seeds*: large, ovate, involved in a mucous pulp, in a membranaceous aril. ESSENTIAL CHARACTER. *Calix*: five-cleft, pitcher-shaped, inferior. *Corolla*: five-petalled, small. *Style*: one. *Stamina*: in five bodies. *Pome*: five-celled.—The only species is,

1. *Durio Zibethinus*. A lofty tree, with alternate flowers below the leaves; the leaves resemble those of the Cherry,

but are not dented at the edges, and on that account more resemble Nutmeg leaves; the flowers are borne in loose heads, they are large, and of a pale yellow white colour; the fruit is of the size of a man's head, and round or oblong, resembling in some degree a rolled up hedge-hog, with a hard bark or rind; the seeds are yellowish brown, their tunics white, of a soft, mucous, and very tender substance: these tunics constitute the eatable part of the fruit, which is esteemed one of the most delicious vegetable productions of India. Persons, however, not accustomed to eat it, are at first deterred from tasting it, from its unpleasant heavy smell, something resembling that of rotten onions; and the smell of the breath of those who eat it is infected also in a high degree; but when once a person has accustomed himself to eat this fruit, he generally considers it preferable to all others.—Native of Sumatra, Malacca, Java, Borneo, &c.

Duroia; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, cylindric, truncate, contracted, very short, superior. *Corolla*: monopetalous; tube cylindric; border length of the tube, six-parted; divisions ovate, spreading. *Stamina*: filamenta none; antheræ six, oblong, within the tube. *Pistil*: germen inferior; style filiform, the length of the tube; stigmas two. *Pericarp*: pome globular, umbilicate, covered with erect hairs. *Seeds*: very many, nestling, oval, flat, very smooth, incumbent, in a double row. ESSENTIAL CHARACTER. *Calix*: cylindric, truncate. *Corolla*: six-parted. *Filamenta*: none. *Pome*: hispid.—The only known species is,

1. *Duroia Eriopila*. A tree, with thick unequal branches, hirsute at the end; leaves terminating, opposite, approximating, many, subpetioled, a span in length, obovate, quite entire, rather obtuse, ribbed, pubescent above, netted underneath: petioles very short, hirsute; flowers at the ends of the branches, sessile, heaped, many, several of them abortive; corollas white. The flowers are frequently abortive, nay, there are some genuine male flowers without any germen; it should therefore be rather referred to the class Polygamia. Fruit somewhat larger than a turkey's egg, spherical, covered very thick with erect brown hairs, umbilicate with the hollow calix, and filled with numerous seeds lodged in the pulp, which is eatable, and compared by some to that of the European Medlar. It is well-flavoured, and much esteemed at Surinam; of which it is a native.

Dwale. See *Atropa*.

Dwarf Trees were formerly in much greater request than they are at present, for though they have many advantages to recommend them, yet the disadvantages attending them greatly overbalance; and since the introduction of espaliers into the English gardens, dwarf-trees have been little in esteem for the following reasons: 1. The figure of a dwarf-tree is very often so much studied, that in order to render the shape beautiful, little care is taken to procure fruit, which is the principal design in planting these trees. 2. The branches being spread horizontally near the surface of the ground, renders it very difficult to dig or clear the ground under them. 3. They take up too much room in a garden, especially when grown to a considerable size, so that nothing can be sown or planted between them. 4. They spread their branches close to the ground, and continually shade the surface of the earth, so that neither the sun nor air can pass freely round their roots, to dissipate noxious vapours, with which the circumambient air will become very replete, and these crude rancid vapours being drawn in by the leaves and fruit, will render the juices of the latter crude and unwholesome, as well as ill-tasted. It is also very difficult to get to

the middle of these dwarf-trees in the summer, when their leaves and fruit are on the branches, without heating off some of the fruit, and breaking the young shoots; whereas the trees on an espalier can at all times be approached on each side to tie up the new shoots, or remove all that are luxuriant, which would soon rob the trees of their nourishment if suffered to remain. Add to this, the fruit-buds of all sorts of pears and apples, and most sorts of plums and cherries, are first produced at the end of the former year's shoot, which must be shortened to keep the dwarfs to their proper figure, so that the fruit-buds are cut off, and a greater number of branches are obtained than can be permitted to stand, so that all those sorts of fruit-trees whose branches require to be trained up at their full length, are very improper to train up as dwarfs; and the peaches and nectarines which will bear amputation, are too tender to be trained so in this country. These evils being entirely remedied by training the tree to an espalier, has jointly gained them the preference; however, if any one still feel disposed to have dwarf-trees, notwithstanding what has here been said, we shall lay down a few rules for their management: If you design to have dwarf Pear-trees, bud or graft them on Quince stocks; but as many sorts of Pears will not thrive if they are immediately budded or grafted on Quince stocks, so some of these sorts which will take freely, should be first budded on the Quince stocks; and when these have shot, the sorts you intend to cultivate should be budded into these, for free stocks are apt to make them shoot so vigorously, as not to be kept within bounds; these grafts or buds should be put in four or six inches above the surface of the ground, that the heads of the trees may not be advanced too high; and when the bud or graft has put out four shoots, the ends of the shoots should be stopped, in order to force out lateral branches. Two years after budding, these trees will be fit to transplant where they are to remain; for though many people choose to plant trees of a greater age, yet they seldom succeed so well as young ones. The distance these trees should be planted is twenty-five or thirty feet asunder, for less will not do if the trees thrive well. The ground between them may be cultivated for kitchen-garden herbs while the trees are young, but they ought not to be sown or planted too near the roots of these trees. In order to train the trees regularly, drive stakes into the ground round each tree, to which the branches should be fastened down with list in an horizontal position; for if they are suffered to grow perpendicularly, while young, they cannot afterwards be reduced to any tolerable figure without great violence; the necessary directions to be afterwards followed, are, not to suffer any branches to cross each other, and always in shortening any shoots, to take care and leave the uppermost eye outwards, whereby the hollowness in the middle of the tree will be better preserved; and be careful also to cut off every perpendicular shoot in the middle of the tree as soon as it appears. The other necessary rules will be found under the article *Pruning*. The sorts of Pears which answer best as dwarfs, are summer and autumn fruits, for winter Pears are not worth planting in dwarfs; they seldom bear well, and are always ill-tasted, and generally stony, because they are commonly grafted on Quince stocks. Apples are also planted in dwarfs, most of which are now budded or grafted on paradise stocks; but as these are for the most part of a short duration, they are not profitable, and are fit only for small gardens, as a matter of curiosity, producing fruit sooner and in greater plenty, than when they are upon Crab or Apple stocks. The distance these trees should be planted, if on paradise stocks, should be six or eight feet; and upon Dutch stocks, eighteen or twenty; but if on Crab stocks, twenty-five

or thirty feet asunder each way; which are managed in the same way as Pears. Some persons also plant Apricots and Plums for dwarfs, but these seldom succeed well, as being of a tender constitution; and those which will produce fruit on dwarfs, are much more likely to do so when trained on an espalier, where they can be better managed.—After what has been here said concerning dwarf-trees, we can hardly sup-

pose that many persons will still continue to prefer them to espaliers; and we refer those with whom the objections here urged against the former have no weight, to the article *Grafting*, where they will find many corroborative proofs of the advantages arising from the latter, together with other useful hints upon the same subject.

Dyer's Weed. See *Genista* and *Resida*.

E C H

EARTH Nut. See *Arachis*, and *Bunium*.

Earth Pea. See *Lathyrus*.

Farwort. See *Hedysotis*.

Ebenus; a genus of the class Diadelphia, order Decandria.

—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, terminated by five filiform teeth, which are villose, and nearly equal. *Corolla*: papilionaceous, length of the calix; standard roundish, straight, entire; rudiments of wings obscure, crescent-shaped, gibbous, ascending at the tip. *Stamina*: filamenta diadelphous, all growing together into a sheaf, with tips distinct; antheræ roundish. *Pistil*: germen roundish, villose; style capillary; stigma terminal, acuminate. *Pericarp*: legume ovate. *Seed*: single, rough with hairs. ESSENTIAL CHARACTER. *Calix*: with teeth, the length of the corolla; wings scarcely any. *Seed*: one, rough with hairs.—These plants are propagated by seeds, which should be sown in the autumn, in pots, and placed under a frame in winter, where they may be protected from frost. In the spring the plants will come up; they should be kept clean from weeds, and now and then refreshed with water. When they have acquired strength enough to be removed, they should be each planted in a small pot filled with light earth, and plunged into a moderate hot-bed, just to promote their taking new root; then they should be gradually inured to bear the open air, into which they should be removed the latter end of May, placing them in a sheltered situation, where they may remain till autumn, when they must be removed into shelter, for these plants will not live in the open air through the winter, nor should they be too tenderly treated, lest they draw up weak. They succeed best when placed in an airy glass-case, without fire in the winter, where they will have more sun and air than in a green-house. During winter the plants must be sparingly watered, but they often require to be refreshed in the summer. Among other hardy exotic plants they make a fine variety.—The species are,

1. *Ebenus Cretica*; *Cretan Ebony*. Leaves ternate, quinate, or pinnate, with two pairs of leaflets; spikes terminating. It rises with a shrubby stalk three or four feet high, with several side-branches; leaves at each joint, hoary, composed of five narrow lanceolate leaflets, which join at their tails to the footstalk, and spread out like the fingers of a hand; the branches are terminated by thick spikes of large purple flowers; the spikes are from two to three inches long, and make a fine appearance. It flowers in June and July, and in warm seasons will sometimes perfect seeds in England.—It grows in Crete, and some islands of the Archipelago.

2. *Ebenus Pinnata*; *Pinnated Ebony*. Leaves pinnate, with four pair of leaflets; spikes axillary, on very long peduncles.—It flowers in July, is biennial, and a native of Barbary and the Levant.

Ebony. See *Amerinum*, and *Diospyros Ebenaster*.

Echinophora; a genus of the class Pentandria, order Dignia.—GENERIC CHARACTER. *Calix*: umbel universal, with very many rays, the intermediate ones shorter; partial

E C H

with very many sessile flowers, the central one sessile, receiving the germina between the pedicels; involucre universal, with some sharp rays; partial turbinate, one-leaved, six-cleft, acute, unequal; perianth proper, five-toothed, permanent, very small. *Corolla*: universal, difform, rayed; floscules male, abortive, the central one of the umbel female; proper five-petalled; petals unequal, patulous. *Stamina*: filamenta five, simple; antheræ roundish. *Pistil*: germen oblong, inferior, clothed with an involucre; styles two, simple; stigmas simple. *Pericarp*: none, in place of which is a hardened mucronate involucre. *Seed*: single, ovate-oblong. ESSENTIAL CHARACTER. Lateral flowers male, central hermaphrodite. *Seed*: one, immersed in an involucre.—These plants do not produce their seeds in our climate, but are increased by their creeping roots. Transplant them in the beginning of March, a little before they shoot. They require a warm situation, and a dry soil; or else you must cover them in winter, to prevent the frost from destroying them.—The species are,

1. *Echinophora Spinosa*; *Prickly Sea Parsnep*. Leaflets subulate-spiny, quite entire. Root perennial, creeping; stalks branching, five or six inches high, with short thick leaves, terminating in two or three sharp thorns, and opposite, in pairs; flowers in an umbel, on a naked peduncle, which arises from the side of the stalk; under the umbel an involucre composed of several leaves, terminating in sharp spines; corolla white.—It flowers in June; and is a native of the sea-coast of Europe, especially on the shores of the Mediterranean Sea. It was found by Mr. Ray on the sea-coast of Lancashire; and by Mr. Blackstone, between Feversham and Sea-salter in Kent.

2. *Echinophora Tenuifolia*; *Fine-leaved Sea Parsnep*. Leaflets gashed, unarmed. Root perennial; stalk nearly a foot and a half high; whence come out two opposite side-branches at every joint.—At the lower part of it are leaves finely divided, like those of the Carrot; and the flowers grow in small umbels at the extremities of the branches, having a short prickly involucre.—It flowers in July; and is a native of the sea-coast of Apulia.

3. *Echinophora Trichophylla*. Leaflets thread-shaped, elongated, undivided, scarcely spinous. The plant is smooth, and abounds with gum. The petals are whitish.—Native of the Levant.

Echinops; a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: common many-leaved, with scales, subulate, totally reflected, containing many flowers. *Perianth*: partial one-flowered, oblong, imbricate, cornered; leaflets subulate, loose above, upright, permanent. *Corolla*: one-petalled, length of the calix, tubular; border five-cleft, reflex, spreading. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular, five-toothed. *Pistil*: germen oblong; style filiform, length of the corolla; stigma double, somewhat depressed, rolled back. *Pericarp*: none. *Calix*: unchanged, larger. *Seeds*: single, ovate, oblong, narrower at the base, with obtuse tip; down

obscure. *Receptacle*: common globose, bristly. **ESSENTIAL CHARACTER.** *Calix*: one-flowered. *Corolla*: tubular, hermaphrodite. *Receptacle*: bristly. *Down*: obscure.—These plants are easily propagated by seeds, which, if permitted to scatter, the plants will come up in plenty, and a few of them may be transplanted to the places where they are designed to remain and flower; they require no other culture, but to keep them clean from weeds; the second year they will flower, and produce seeds, and the roots will continue two or three years after. But if the seeds scatter, the plants will become troublesome weeds; to prevent which, the heads should be cut off as soon as the seeds are ripe. They will grow almost in any soil or situation.—The species are,

1. *Echinops Sphærocephalus*; *Great Globe Thistle*. Heads globular; leaves sinuate, pubescent. Root perennial; stalks many, four or five feet high; leaves long and jagged, divided into many segments, the jags ending in spines; they are of a dark green on their upper side, but woolly on the under. There are several globular heads of flowers on each stalk. The florets are commonly blue, but sometimes white; they come out in July, and ripen seed in August.—Native of France, Spain, Italy, Austria, Carniola, Germany, &c.

2. *Echinops Spinosus*; *Thorny-headed Globe Thistle*. Heads interspersed with long spines. This plant is of the same stature with the preceding, but the stem and leaves are more tender. The heads are like those of the first species; but the florets are white, and larger, with the jags reflex-hooked. Among the florets, every where come out spines, formed of unexpanded calices, four times the length of the florets, which at length are cloven in two.—Perennial, and a native of Egypt and Arabia.

3. *Echinops Ritro*; *Small Globe Thistle*. Head globular; leaves pinnatifid, smooth above. This has a perennial creeping root, sending up several strong stalks, two feet high, and branching; leaves cut into many fine segments to the midrib; each branch is terminated by a globular head of flowers, smaller than those of the first species, and of a deeper blue, but sometimes white; they appear in July. The roots are bitter, diuretic, and nourishing: the heads are eat by the horse, goat, &c.—Native of the south of France, Italy, and Siberia.

4. *Echinops Strigosus*; *Annual Globe Thistle*. Heads in bundles, lateral; calices barren; leaves strigose above. It is an annual plant, with a stiff white stalk, two feet high; leaves divided, ending in many points, which have spines; their upper side green, covered with brown hairs, their under side white, and woolly; the stalk is terminated by one large head of pale blue flowers, appearing in July.—Native of Spain and Portugal.

5. *Echinops Græcus*. Stem one-headed; leaves spiny, all pinnatifid and villose. Root creeping, and perennial; stalks about a foot high; leaves shorter, and much finer divided than the preceding sorts; they are hoary, and armed on every side with sharp thorns; the stalks are terminated by one middle-sized globular head of blue or white flowers, appearing at the end of June.—Native of Greece.

Echites; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, sharp, small. *Corolla*: one-petalled, funnel-form; border five-cleft, flat, spreading very much; nectary of five glands, standing round the germen. *Stamina*: filamenta five, slender, erect; antheræ stiff, oblong, acuminate, converging. *Pistil*: germen two; style filiform, length of the stamina; stigma oblong-headed, two-lobed, attached by a gluten to the antheræ. *Pericarp*: follicles two, extremely long, one-celled, one-valved. *Seeds*: very many, imbricate, crowned

with long down. **ESSENTIAL CHARACTER.** *Corolla*: contorted, funnel-shaped, with the throat naked. *Follicles*: two, long, straight. *Seeds*: downy.—These plants have a singularity in their habit, by which they may be known at first sight. The leaves are opposite, petioled, quite entire, veined, and shining; the third species only having them frequently rugged; common peduncles seldom longer than the leaves, lateral, and alternate, except in the tenth species; flowers scentless. The nectareous glands and the downy seeds are in follicles, which is of great importance in determining the character; while the corolla, which varies much in the different species, is of no consequence in this respect. The stigma in all is glued to the inside of the wall of the cone, formed by the antheræ, and which separates at the explosion of the pollen, whilst the outer wall of the cone continues undissolved; the fecundation of the greater part being accomplished within the closed tube of the corolla, but in the rest within the cone, stretched beyond the tube. The plants abound with an acrid milky juice. They have not yet been introduced into European cultivation; and being mostly inhabitants of the West Indies, they will require the protection of the bark-stove, and should be propagated and managed in the same way as the tender sorts of *Apocynum*, which see.—The species are,

1. *Echites Biflora*. Peduncles two-flowered. This is a branched shrub, full of milky juice, supporting itself by stems, partly erect, partly twining upon trees, and mounting them to the height of twenty feet; from which circumstance, it frequently acquires the air of a tree; leaves oblong, growing narrower to the base, obtuse at the end, with a small point, three inches long; peduncles sometimes, but rarely, three-flowered; flowers handsome, very white, with a yellow throat.—Native of the Caribbee islands, in salt marshes.

2. *Echites Quinquangularis*. Peduncles racemed; leaves ovate, acute. Stem twining, shrubby, somewhat scabrous; leaves three inches long; racemes simple; flowers about sixteen, green, with a yellowish border; the edge of the tube white, and in the form of a pentagon. It is not milky, like the preceding: flowers in October, and is a native of Carthage in South America.

3. *Echites Suberecta*; *Savanna Flower*. Peduncles racemed; leaves subovate, obtuse, mucronate. This shrub differs much from all others of this genus. It abounds in milky juice, grows among other shrubs to the height of ten feet, but is only three feet, and sometimes scarcely a foot high, in savannas; stems scarcely twining, and climbing, the leaves more or less ovate, either smooth on both sides, or scabrous at the back. The peduncles support a few large, handsome, yellow flowers, hirsute on the outside, and in the tube. The follicles are slender, and brown. The flowers being of a bright yellow, and large, make a fine appearance.—It grows naturally in the savannas of the island of Jamaica, where it is chiefly known by the name of Savanna-flower. It is also very common in the island of St. Domingo, flowering from September to March. Browne declares all parts of it to be extremely poisonous; and an intelligent traveller has lately informed us, that it operates as a slow or quick poison, according to the dose; and that fatal accidents have happened from stopping breakers of rum with grass, in which this noxious weed has been concealed. The antidote for this poison, is expressed arrow-root juice: see *Maranta Arundinacea*.

4. *Echites Agglutinata*. Peduncles racemed; leaves ovate, emarginate, with an acumen; stems twining, shrubby; leaves four inches long; common peduncles the length of the leaves, often difform, sometimes bifid. The flowers are small, and white. When the follicles are separated, which is easily done,

a drop of watery glutinous liquor, such as the whole plant abounds with, flows out at the two points by which they had cohered.—It flowers in December, and is found on the mountains, near Cape François in St. Domingo.

5. *Echites Torulosa*; *Climbing Echites*. Peduncles sub-racemed; leaves lanceolate, acuminate, two inches long. This plant is so weakly, that it commonly sustains itself by the help of the neighbouring bushes, and frequently rises to a considerable height among them. The common peduncles support about six small yellow flowers, and the whole plant abounds in a milky gluten.—It flowers in March, and is often found at the foot of the mountains of Liguanea in the island of Jamaica.

6. *Echites Umbellata*; *Umbelled Echites*. Peduncles umbelled; leaves ovate, obtuse, mucronate; stem twining.—It climbs to the height of fifteen feet, by means of its shrubby, twining, pliant stems, which are woody and tuberous at the bottom, but round, green, and glossy above. The whole abounds in a clear glutinous juice. Leaves roundish, ovate, subcordate at the base, three or four inches long. The common peduncle has from four to seven flowers at the end, in a kind of umbel, with some stipules serving the purpose of an involucre. The flowers are large and handsome; the border white, and the tube green on the outside. Browne describes them to be of a pale yellow, with a longish slender tube. He remarks, that, like other plants of the same natural class, it is rather deleterious; and that there is a variety of it found in the drier savannas, which has pointed leaves, and very slender stalks.—It flowers from October to February, and is a native of Jamaica, Cuba, and St. Domingo.

7. *Echites Trifida*. Peduncles trifid, many-flowered; leaves ovate-oblong, acuminate; stems twining, shrubby; leaves three inches in length; common peduncles short, with difform pedicels; flowers large, pretty, the tube purple, and the border green. It climbs trees to the height of twelve feet, and the whole plant is milky.—It flowers in October, and is a native of South America, near Carthagen.

8. *Echites Repens*. Peduncles many-flowered, divided; leaves lanceolate, oblong. This is an elegant shrubby plant, not milky, with round, smooth, sarmentose stems; the older ones procumbent, and putting out roots; the younger sub-erect, and thickened at the joints into discoid knots. The common peduncles are usually bifid, bearing elegant, tender, red flowers, which appear from October till December.—Native of St. Domingo.

9. *Echites Corymbosa*. Racemes corymbed; stamina standing out; leaves lanceolate-ovate, smooth, shining above, pale underneath, two inches long. This climbs up trees with its twining shrubby stems, twenty feet in height, and the whole abounds with a white glutinous milk; racemes terminating, branched, spreading, red; flowers numerous, small, red or purple; teeth of the calix very minute, coloured; corolla cylindrical, very short; border reflex, with sharp segments; nectareous glands connate; filamenta from the bottom of the tube, longer than the corolla; germen twin, pubescent; style with a very slight longitudinal groove on each side, by which it may be easily split in two; stigma within the cone of the antheræ; follicles horizontal, reflex, roundish, obtuse, two-valved; seeds oblong, with a bristly down.—Native of the island of St. Domingo, where it flowers in November; and of the mountainous woods of Hispaniola, where it flowers in the spring. The French call it *gras de galle*.

10. *Echites Spicatum*. Spikes axillary, short; stamina standing out; leaves subovate. This plant abounds in a white milk, and climbs the trees to the height of sixty feet. Stems round, woody, pliant, twining, an inch in diameter,

with alternate branches a foot and a half long, at different distances, and leafy their whole length; leaves oblong, veined, smoothish, acuminate, distich, half a foot long; spikes opposite, close, an inch and a half long, solitary, spreading, sometimes, but rarely divided in two; flowers numerous, white, small, subsessile.—Native of Carthagen in New Spain, where it is found in thick lofty woods, flowering in July and August.

11. *Echites Caudata*. Corollas funnel-form, with very long linear tips. It is a tree, with lanceolate-elliptic, naked leaves. The flowers are axillary, peduncled, erect, the size of those of Nerium or Oleander, funnel-form; border erect, terminating in linear tips longer than the whole corolla, a circumstance in which it differs from all other known plants.—Native of the East Indies.

12. *Echites Scholaris*. Leaves subverticilled, oblong; follicles filiform, very long; umbels compound. The branches of this tree are leafy only at the joints, where there are five or seven oval-lanceolate leaves, which are coriaceous, and transversely streaked. A few peduncles are produced among the leaves, of the same length with them. The flowers are very small, and the follicles in pairs, a foot and a half long, and therefore longer than any others that are known.—Native of the East Indies.

13. *Echites Annularis*. Stem twining; corollas salverform, with an elevated ring on the tube; leaves a foot long; racemes bifid, peduncled, axillary; calcine leaflets oblong, erect, concave; tube of the corolla cylindrical, longer than the calix; segments of the border roundish, emarginate; antheræ connate, within the throat; stigma obtuse, surrounded by a sharp ring. The nectary covers the germen with five small ovate scales.—Native of Surinam.

14. *Echites Siphilitica*. Leaves ovate, subpetioled, very smooth, ribbed; panicles dichotomous; flowers in spikes.—This tree yields a milky juice. The leaves are on short petioles, a long span and upwards in length, and sharp; peduncles axillary, divided into two branches, and these again into two shorter spikes, closely covered with flowers, and erect; corolla large, white, with a large flat border; follicles in divaricating pairs.—Native of Surinam; where a decoction of it is often used as a remedy in the venereal disease.

15. *Echites Succulenta*. Prickles in pairs, extrafoliaceous; leaves linear, tomentose underneath; corollas funnel-form.—Native of the Cape of Good Hope.

16. *Echites Bispinosa*. Prickles in pairs, extrafoliaceous; leaves lanceolate, smooth; corollas salver-form. This very strongly resembles the preceding, and both are very singular shrubs, succulent, milky, and two-spined.—Native of the Cape of Good Hope.

17. *Echites Costata*. Peduncles in cymes; leaves elliptic-lanceolate, acuminate.—Native of the Society Isles.

18. *Echites Tomentosa*. Leaves cordate-oblong, acuminate, both they and the stem rough-haired; flowers in racemes, hairy; stem twining, round, as are also the petioles; the rib, nerves, and edges of the leaves, rough-haired; leaves three inches long, a little narrowed towards the base, broader at top, cordate at the base, the sinus being closed by the incumbent lobes; they are somewhat rugged, nerved, veined, having hairs pressed close, and scattered over both surfaces, but more copiously, and of a greater length, on the rib and nerves, especially underneath; peduncles axillary, shorter than the leaf, rough-haired; flowers approximating, alternate, on short pedicels; segments of the calix lanceolate, attenuated, smooth; corolla two inches in diameter, or a little more, with ash-coloured hairs scattered over the outside, but very thick in the tube, where the filamenta are inserted; style filiform, the length of the tube.—Found by Von Rohr in Cayenne.

19. *Echites Domingensis*. Peduncles racemed; leaves cordate-ovate, somewhat rigid, of a different colour underneath; stem twining.—Native of the West Indies.

20. *Echites Asperuginis*. Peduncles racemed; foliicles filiform; leaves oblong, acute, rough above; stem twining.—Native of the West Indies.

21. *Echites Circinalis*. Peduncles axillary, many-flowered, jointed; segments of the corolla waved; leaves elliptic; stem twining.—Native of the West Indies.

22. *Echites Floribunda*. Racemes corymbed; leaves ovate, acuminate; nerves parallel; branches almost erect.—Native of the West Indies.

23. *Echites Difformis*. Flowers small, greenish; calix angular at the base; corolla lined with a silky villus around the orifice; antheræ simple; style one, as long as the stamina; stigma annulate, two-lobed, viscid; germen surrounded at the base by a glandular five-toothed torus.—Native of South America.

Echium; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, upright, permanent; divisions subulate, upright. *Corolla*: one-petalled, bell-shaped; tube very short; border upright, gradually widened, five-cleft, obtuse; divisions generally unequal; the two superior ones longer; the inferior smaller, sharp, reflex; throat pervious. *Stamina*: filamenta five, subulate, length of the corolla, declined, unequal; antheræ oblong, incumbent. *Pistil*: germina four; style filiform, length of the stamina; stigma obtuse, two-cleft. *Pericarp*: none; the calix grown stiffer, guarding the seeds in its cavity. *Seeds*: four, roundish, obliquely acuminate. ESSENTIAL CHARACTER. *Corolla*: irregular, with the throat naked. *Stigma*: deeply cloven. *Seed*: four, naked.—Most of these plants are herbaceous; some, however, are suffrutescent. The flowers are in spikes, or spike-panicled; in the spikelets, the flowers all point one way.—The species are,

1. *Echium Fruticosum*; *Shrubby Viper's Bugloss*. Stem shrubby; leaves lanceolate, attenuated at the base, villose, strigose, without veins; calicine leaflets lanceolate-acute. It has a shrubby stalk, two or three feet high, dividing at top into several branches; leaves sessile, hairy, light green; stamina not longer than the corolla. The flowers are produced singly between the leaves, at the ends of the branches; they are of a purple colour, and in shape much like those of the Cretan sort. It flowers in May and June, but does not ripen seed in England.—Native of the Cape of Good Hope. This plant is propagated by seeds, when they can be obtained, which should be sown in pots, filled with light sandy earth, soon after they are received. These may be exposed to the open air till the beginning of October, when the pots should be placed under a frame, to guard them from frost; but in mild weather, they should have the free air, to prevent the seeds from vegetating till the winter is past; for if the plants come up at that season, their stems will be weak and full of juice, and very liable to rot with damps; therefore it is much better if the plants do not come up till toward March, which is the usual time of their appearing, when the seeds are not forced by warmth. When the plants are fit to remove, they should be each planted into a small pot filled with light earth, and placed under a frame, to forward their putting out new roots; then they should be gradually inured to bear the open air, and may be placed abroad in a sheltered situation at the latter end of May, where they may remain till the beginning of October, at which time they must be removed into an airy glass-case, where they may enjoy the sun, and have free air in mild weather. During the winter season, these plants must be sparingly watered; for as their

stems are succulent, too much moisture will cause them to rot. In the summer they should be set abroad in a sheltered situation, and treated in the same way as other plants from the same country.

2. *Echium Candicans*; *Hoary Tree Viper's Bugloss*. Stem shrubby; leaves lanceolate, nerved; they and the branches hirsute; calicine leaflets oblong, and lanceolate-acute; styles rough with hairs. This handsome shrub has woody stems, and branches which are somewhat tomentose, marked with linear transverse scars from fallen leaves; leaves a span long, approximating, lanceolate-subulate, attenuated at the base, to the insertion where it widens, marked with lines above, and veined underneath; veins very long, and simple; towards the panicle they are imbricate, and narrower at the base; flowers in a conical panicle, formed of many spikes at the ends of the branches; spikes pedicelled, simple, pointing one way, bending inwards; corollas small, subhirsute, blue. The whole plant is white, and as it were silvery, with a soft close shaginess covering the whole, hardly excepting the corolla.—Native of the high rocks of Madeira.

3. *Echium Giganteum*; *Gigantic Viper's Bugloss*. Stem shrubby; leaves lanceolate, attenuated at the base, hairy; hairs very short; bractes and calices strigose; stamina longer than the corolla. It is a very lofty shrub, with woody, round, hoary, smooth branches; leaves a span long, and the breadth of a finger, scabrous, veined; flowers pointing one way, and forming a very large, pyramidal, terminating thyrses, consisting of long-spiked peduncles; corollas obtuse, nearly equal, white.—Found by Masson on the rocks of Teneriffe.

4. *Echium Strictum*; *Upright Viper's Bugloss*. Stem shrubby, stiff, branching; leaves oblong-lanceolate, hairy; corollas somewhat bell-shaped; stamina longer than the corolla. It is distinguished, as its English name imports, by the uprightness and stiffness of the stem, by its petioled oblong leaves, and by the hairs of the stem being turned downwards; peduncles axillary at the top of the stem, solitary, naked, with three-parted spikelets, contracted into a head at the tip. The corolla is small and blue, with the stamina standing out.—It is biennial, and flowers most part of the year; and was found by Masson on the rocks of Teneriffe.

5. *Echium Spicatum*; *Spiked Viper's Bugloss*. Stems ascending, very simple; flowers in spikes; root-leaves very many, a hand in length, lanceolate-linear, very narrow; stems twice the length of the leaves, with a few smaller alternate hairy leaves; spike terminating, nearly a finger's length, compact; calices hoary; stamina longer than the corolla.—Native of the Cape of Good Hope.

6. *Echium Argenteum*; *Silvery Viper's Bugloss*. Leaves linear, hirsute, and whitish, patulous at the tip; stem branched determinately.—Native of the Cape of Good Hope.

7. *Echium Capitatum*; *Headed Viper's Bugloss*. Stem hairy; leaves hispid; flowers crowned closely into terminating heads; corollas regular, funnel-form; stamina twice as long as the corolla; and style double the length of the stamina.—Native of the Cape of Good Hope.

8. *Echium Plantagineum*; *Plantain-leaved Viper's Bugloss*. Root-leaves ovate, marked with lines, petioled; leaves above hairy, soft, hispid; root-leaves like those of Plantain, very entire, large; stem-leaves lanceolate, sessile; stems hairy, with soft, not strigose, hairs; brown dots under the hairs, as in the rest, but minute; corollas violet-coloured; bractes between the flowers, half cordate, the length of the calix, not subulate, not longer than the calix.—It flowers from July to October, is annual, and a native of Italy.

9. *Echium Lævigatum*; *Smooth-stalked Viper's Bugloss*. Stem even; leaves lanceolate, naked, scabrous about the edge and at the tip; corollas equal; the stems are also under-shrubby, and about a foot in height; leaves smooth, except that they are scabrous with mucronate callous dots about the edge, along the keel, and at the tip above; racemes from the axils of the upper leaves, pointing one way, and smooth; calix smooth; corolla but slightly irregular; stamina declined; seeds muricate.—Native of the Cape of Good Hope.

10. *Echium Italicum*; *Wall Viper's Bugloss*. Stem herbaceous, hairy; leaves linear-lanceolate, strigose, hirsute, the lower ones nerved; corollas nearly equal; stamina longer than the corolla; the stalk is upright and hairy; the flowers are produced in short spikes on the side of the branches; they are small, and scarcely appear above the calices; the calices are very hairy, and cut into acute segments. Some plants have white flowers, others purplish.

11. *Echium Rubrum*; *Red Viper's Bugloss*. Flowers in a long spike made up of little short racemes; corollas nearly equal; leaves hispid; stem erect, about a foot high, rough, and covered with red points; radical leaves long and lanceolate, hairy, deepish green above, paler below, and with a strong back-nerve; stem-leaves smaller and narrower; spike of flowers about a foot long, consisting, as in the Common *Echium*, of a great many separate spikelets, or smaller flowering spikes, proceeding from the axils of the small leaves, and at first coiled as usual, rather small than large, of a palish red, and with nearly equal and somewhat triangular segments; antheræ pale blue.—It grows plentifully in Hungary, where it is a native.

12. *Echium Vulgare*; *Common Viper's Bugloss*. Stem tuberled and hispid; stem-leaves sessile, four or five inches long, all lanceolate, quite entire, scabrous, and hairy on both sides; flowers in lateral spikes, numerous, those of each spike pointing one way, and closely wedged together. The whole plant is hispid; the stem often, and the leaves in some instances, beautifully spotted with red; the hairs on the stem rise from glossy purplish black tubercles; the root-leaves form a tuft, nearly two feet long, petioled. Corolla before it expands, of a fine red, afterwards of a bright blue, which varies to pale red and white; if the colour be blue, the stems are bluish, the stamina purple, and the bulbs from which the hairs spring are blood-red; but if the corolla be pale red, then the other parts of the flower are of the same colour, and the hair-bulbs are yellow; and if it be white, all the parts of the flower are of the same colour, and the hair-bulbs are green; the outside of the corolla is set with short hairs, and marked with five rising ribs, extending from the middle of each segment down to the base; the upper and lateral segments are rounded, the lowest somewhat pointed; the filaments are red, and longer than the corolla, sometimes much longer, and sometimes very little longer, or barely equal to the upper segment; antheræ gray; style very hairy; germina imbedded in a fleshy receptacle. It is a showy plant; and such is the absurdity of fashion, that if it were not common, it would assuredly obtain admittance in our gardens. It is biennial, and appears abundantly once in three years, in the corn-fields of Cambridgeshire, where it is known by the name of *Cat's Tail*. Bees are fond of the flowers; but, unfortunately for those useful and interesting insects, the strong hairs of the corolla and style often tear their wings.—Hill informs us, that the leaves, especially those growing near to the root, make a good cordial by infusion, which operates by perspiration, and alleviates fevers, headaches, and all nervous complaints.

13. *Echium Violaceum*; *Violet-flowered Viper's Bugloss*. Corollas equal to the stamina; tube shorter than the calix;

stem a foot high, branching at the top and bottom; the hairs are soft, and some of them rise from tubercles; these are hardly if at all discernible on the leaves, though they are on the stem, where they are intermixed with short hairs, not rising from tubercles; corolla deep blue, half as long again as the calix, at the bottom of the two upper segments, beset both within and without with hairs, which give it a whitish colour. Found near Norwich, in England.—Native of Austria and Germany. It flowers in July.

14. *Echium Creticum*; *Cretan Viper's Bugloss*. Stem procumbent; fruiting calices distant. It has trailing hairy stalks, about a foot long, putting out several side-branches; leaves lanceolate, hairy, about three inches long, and three-quarters of an inch broad, sessile; the flowers come out on slender spikes, upon long peduncles, from the axils; they are large, of a reddish purple, and turn to a fine blue when dried.—Native of the Levant. There is a variety with branching stalks, a foot and a half long, declining towards the ground, and covered with stinging hairs; leaves four inches long, and not more than half an inch broad, pretty much warted, and hairy: the flowers grow in loose spikes from the sides of the stalks, and also at the ends of the branches; they are of a reddish purple colour, but not so large as those of the preceding; and the stamina are longer than the corolla.—This plant is annual, and the most beautiful of the whole genus: to propagate it, the seeds must be sown every year where they are designed to remain, and the plants require no other culture but to keep them clear from weeds, and to thin them where they grow too close; they flower in July, and their seeds ripen in five or six weeks after. The seeds of the other sorts being sown in the spring, will, in the second summer after, produce flowers and seeds, after which they seldom continue. They delight in a rubbishy gravelly soil, and will grow upon the tops of old walls or buildings, where, when they have once established themselves, they will drop their seeds, and thereby maintain a succession of plants without any care; and on these places they will appear very beautiful.

15. *Echium Orientale*; *Oriental Viper's Bugloss*. Stem branched, about three feet high, an inch thick, pale green, hard, solid; stem-leaves ovate; flowers solitary, lateral; root above a foot long, and two inches thick, mucilaginous, and sweetish; the lower leaves are fifteen or sixteen inches long, and four or five inches wide, pointed, whitish-green, satin-like above, and cottony underneath, with a strong midrib; they diminish considerably along the stem, not being above half a foot in length; they are also less cottony than the former, and much more pointed: branches about half a foot long; both they and the top of the stem are rough with strong hairs, accompanied by leaves about an inch and a half in length. All these branches are subdivided into smaller ones, bending like a scorpion's tail, and loaded with flowers an inch and a half in length, of a pale blue colour, with two red bands on three of the segments, on a bright purple ground, scentless; calix almost as long as the corolla, rough with very large hairs; style almost as long as the corolla, slightly villose, and purple.—Found by Tournefort in the Levant.

16. *Echium Lusitanicum*; *Portugal Viper's Bugloss*. Corollas longer than the stamina; the lower leaves are more than a foot long, and two inches broad in the middle, gradually lessening to both ends, and covered with soft hairs; the stalks grow two feet high; the flowers are in short spikes from the sides of them.—Native of Spain and Portugal.

17. *Echium Sericeum*; *Silky Viper's Bugloss*. Leaves linear, awl-shaped; stem suffruticose, both hoary. Stems several, diffused, woody at the base, simple, a palm or more in height, soft at bottom, somewhat rugged at top, hoary, with

white hairs, pressed close, and placed on minute tubercles, the lower ones longer, the upper ones more dispersed. The lower leaves from two to three inches long, crowded, linear, ciliate below, gradually widening towards the top, dilated at the base, embracing, obtuse, hoary on both sides, with close short hairs placed on minute dots; the upper ones an inch long, and recurved. Spike terminating, pointing one way, hoary-haired; bractes ovate-lanceolate, obtuse; corolla villose on the outside; stamina longer than the corolla.—Native of Egypt.

18. *Echium Setosum*; *Hoary Viper's Bugloss*. Leaves linear-lanceolate; stem suffruticose, procumbent, both hispid and hoary; spike terminating, solitary; flowers at first crowded, but afterwards more remote; bractes ovate; corolla half an inch in diameter, hoary; stamina longer than the corolla; nuts small, ovate, acuminate, muricate.

19. *Echium Glabrum*; *Smooth Viper's Bugloss*. Leaves linear-lanceolate, smooth above, callous-dotted beneath on the outside; spikes alternate; branches scattered, a little compressed at top, purplish ash-coloured, with very slender appressed villose hairs; leaves sessile, firm, an inch long, even; spikes from the upper axils, erect, few-flowered, two inches long; bractes ovate-lanceolate, the length of the calix; calices hairy, with lanceolate segments, the same length with the tube of the corolla; stamina longer than the corolla.—Native of the Cape of Good Hope.

20. *Echium Rosmarinifolium*; *Rosemary Viper's Bugloss*. Leaves petioled, linear-lanceolate, reflex at the edge, hairy underneath, and hoary; branches round, scarred, hoary with the hairs; petiole very short; raceme terminating, short; leaflets of the calix linear, hairy; corolla almost regular, half as long again as the calix.—Native of the Cape of Good Hope.

21. *Echium Sphærocephalum*; *Round-headed Viper's Bugloss*. Leaves linear-lanceolate, strigose; heads solitary, terminating, globular, hairy, on short peduncles, with small flowers that are almost regular, and having stamina longer than the corolla; branches smooth.—Native of the Cape.

Eclipta; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common many-leaved; leaflets lanceolate, nearly equal, in a double series. *Corolla*: compound rayed; of the ray most plentiful, female; of the disk hermaphrodite: proper of the hermaphrodite tubular, four-cleft, upright, outwardly mealy; in the females very narrow, ligulate. *Stamina*: in the hermaphrodites; filamenta four, very short; antheræ cylindrical. *Pistil*: in the hermaphrodites; germen oblong; style mid-dling; stigma two-cleft, spreading. *Pericarp*: calix unchanged. *Seed*: in the hermaphrodites, oblong, compressed, notched, obtuse, unarmed; in the females, three-sided, oblong, notched, obtuse, unarmed. *Receptacle*: flattish, chaffy; chaffs very narrow. ESSENTIAL CHARACTER. *Receptacle*: chaffy. *Down*: none; corollets of the disk four-cleft.—These plants are all propagated by seeds, sown upon a hot-bed in the spring; when they are fit to remove, they should be transplanted into a fresh hot-bed to bring them forward; they must be shaded till they have taken new root, and then treated as other tender annuals, being careful not to draw them up too weak. In June they may be taken up with balls of earth, and being planted in pots, are to be set in a stove, where they must remain, and be shaded and watered, in order to flower well.—The species are,

1. *Eclipta Erecta*; *Upright Eclipta*. Stem erect; leaves deflected at the base, and sessile; peduncles alternate, usually in pairs, longer than the leaves, one-flowered; flowers white; calix of five or six leaves; scales broad-lanceolate, the two larger somewhat hispid; flowers discoid; of the disk

numerous, four-cleft, minute; of the ray very many, minute; seeds angular, thickish, naked, without any down; receptacle naked, not chaffy.—Native of the West Indies, and of the East Indies, Cochin-china, &c. Loureiro says, that in Cochin-china the leaves are not nerved, nor properly serrate, nor sessile; and that the flowers are not in pairs: he adds, that the juice is used for dyeing the hair both of men and quadrupeds, whence the natives call it *Ink-plant*. It flowers from July to September; and is an annual plant, although Linneus has marked it as biennial.

2. *Eclipta Punctata*; *Dotted-stalked Eclipta*. Stem erect, a foot and a half high, dotted; leaves flat; peduncles one-flowered, subterminating; flowers whitish, having no smell. The whole plant produces a green watery sap, which becoming black when exposed to the air, may be used as ink, and if it could be fixed would make a very fine dye. The negroes are said to increase the blackness of their skin by rubbing it with this juice. This resembles the first species; but the stem has white dots scattered over it.—It is annual, and a native of St. Domingo and Martinico.

3. *Eclipta Latifolia*; *Ovate-leaved Eclipta*. Stem erect, two feet high; leaves ovate, petioled; root annual; flowers terminating, solitary, on very short white peduncles; calix close, the length of the flower; ray of the corolla short, with subtrifid petals; in the disk four florets, which are five or six cleft; antheræ black; stigmas recurved; seeds oblong, sub-trigonal; receptacle the length of the seeds.—It flowers in September and October, and is a native of the East Indies.

4. *Eclipta Prostrata*; *Trailing Eclipta*. Stem prostrate; leaves somewhat waved and petioled. It is often found erect, like the first species, with subsessile flowers, or at least on very short peduncles; the flowers come out alternately in pairs; calix simple; antheræ brown; seeds awnless and muricate, in four rows. It is an annual plant.—Native of the East Indies, Japan, Cochin-china, and the isle of Tanna in the South Seas.

5. *Eclipta Sessilis*; *Sessile-leaved Eclipta*. Stem erect; leaves slightly embracing, ovate, toothed; flowers axillary, sessile, discoid.—This is an annual plant, and a native of Jamaica.

Edgings.—The best and most durable plant for edgings in a garden, is Box; which, if well planted and rightly managed, will continue in beauty for many years. The best season for planting it, is either in the autumn or very early in the spring, for if it be planted later, and the season happen to turn out hot and dry, it will be very subject to miscarry, unless great care be taken to supply it with water. The best sort for this purpose is the Dwarf Dutch. Box-edgings are only planted upon the sides of the borders next the walks, and not, as the fashion formerly was, to plant the edgings of flower-beds, or the edges of fruit borders, in the middle of gardens, unless they have gravel walks between them, which makes it necessary to keep the walks clean, by keeping the earth of the borders from washing down into the walks during heavy rains.—It was also the custom to plant edgings of divers sorts of aromatic herbs, such as Thyme, Savory, Hyssop, Lavender, Rue, &c. but as these very soon grow woody, and therefore cannot be kept in due compass, and are also often killed in whole patches by hard winters, whereby the edgings are rendered incomplete, they are now seldom used for this purpose. Some persons make edgings of Daisies, Thrift, Catch-fly, and other flowering plants; but these also require to be transplanted every year, in order to have them handsome, for they soon grow out of form, and are subject to decay in patches, so that there is not any plant which so completely answers the design as Dwarf Box.

Egg-plant. See *Solanum*.

Eglantine. See *Rosa*.

Ehretia; a genus of the class Pentandria, order Monogynia.

—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, bell-shaped, half five-cleft, obtuse, very small, permanent. *Corolla*: one-petalled; tube longer than the calix; border five-cleft; divisions somewhat ovate, flat. *Stamina*: filamenta five, subulate, patulous, length of the corolla; antheræ roundish, incumbent. *Pistil*: germen roundish; style filiform, thicker above, length of the stamina; stigma obtuse, emarginate. *Pericarp*: berry roundish, one-celled. *Seeds*: four, convex on one side, cornered on the other. **ESSENTIAL CHARACTER.** *Berry*: two-celled. *Seeds*: solitary, two-celled; stigma emarginate.—These plants are too tender to thrive abroad in England, where they require a moderately warm stove in the winter; but when they have acquired strength they may be placed in the open air during the heat of the summer, but it should be in a sheltered situation; and when the evenings grow cold in the autumn, they must be removed into shelter. They are propagated by seeds, when they can be obtained, which should be sown in small pots, and plunged into a hot-bed. They may also be increased by layers, but these are long before they put out roots.—The species are,

2. *Ehretia Tinifolia*; *Tinus-leaved Ehretia*. Leaves oblong-ovate, quite entire, smooth; flowers paniced. It is an upright tree, from twenty to thirty feet high, with an oblong thick head; branches unarmed, roundish, subdivided; leaves alternate, veined, blunt, about four inches long, on short petioles; panicles terminating, oblong, large; flowers numerous, white, small; calix five-parted, with minute ovate segments; corolla a little larger than the calix, with acute segments, finally rolled back; filamenta longer than the corolla; style scarcely shorter than the stamina, awl-shaped, bifid; stigmas simple; berry spherical, at first yellow, then black; seeds two, hemispherical, two-celled.—It flowers in January and February, and is a native of Cuba and Jamaica, where it is pretty common in the lower lands, being known by the name of *Bastard Cherry-tree*. It generally rises to the height of sixteen or twenty feet; and produces small berries, which seldom exceed the largest of our European currants in size, and serve to feed the poultry, and are even eaten by the poorer sort of people.

2. *Ehretia Spinosa*; *Thorny Ehretia*. Thorny. This tree has a trunk three or four inches in diameter, dividing almost close to the ground, usually in three parts, which run up twenty-five or thirty feet high; these having put out a few similar boughs in their progress, scarcely attain the length of ten feet before they are bowed back to the ground, and require support from the boughs of the neighbouring trees; they have many very short lateral branches, scatteringly disposed; their bark is ash-coloured and smooth; strong, woody, short, very thick, awl-shaped spines are scattered over the trunk, principal boughs, and secondary branches, the oldest of which frequently put forth from their middle a perpendicular leafy branchlet of the same length with themselves; flowers small, with yellowish corollas.—It flowers in August, bears fruit in October, and is a native of Carthage in New Spain, where it is known by the name of *Cacara-cacara*, but differs much in habit from the preceding description.

3. *Ehretia Bourreria*; *Oval-leaved Ehretia*. Leaves ovate, quite entire, smooth; flowers in a kind of corymb; calices smooth. This small inelephant tree has an adust habit, and is often found fifteen feet high in the island of Curaçoa, though in Martinico it seldom exceeds five; trunk unequal, with a chinky bark; branches very many, irregular; leaves

alternate, petioled, quite entire, various, obtuse, acute, or emarginate; on rocks smooth, elsewhere rugged; differing in size; racemes corymbed, terminating; flowers sweet; corollas white, with roundish segments; antheræ oblong; calix in the fruit cloven; berries shining, saffron or orange coloured, pulpy, sweet, succulent, more quadrangular as they are larger, eaten by children and the natives.—Native of the West Indies, growing from the crevices of rocks, where there is no soil. According to Dr. Browne, it grows in the savannas of Jamaica, where it is called *Poison Berries*, and by the French *Bois Cabril Batard*.

4. *Ehretia Exsucca*; *Dry-fruited Ehretia*. Leaves wedge-form, lanceolate, with the edge reflex. This small tree is fifteen feet in height, sometimes erect, and sometimes supporting itself on other trees; leaves ovate, acute, very smooth, alternate, petioled, two inches long; racemes branched, subcorymbed, subterminating; flowers having a slight degree of sweetness, much larger than in the preceding species; corollas white, with heart-shaped segments; antheræ ovate, and large; berries green, four-cornered, slightly four-grooved, ending in a blunt point, without any pulp, becoming finally of a reddish black colour, dividing into four parts, with the seeds sticking in them, and continuing a long time on the tree.—It is often found in the neighbourhood of Carthage in New Spain, in mountain woods, where it flowers from May to August, and ripens seed in October.

5. *Ehretia Virgata*. Leaves oblong, entire, rugged on the upper surface; branches filiform; flowers terminating, scattered; calices hirsute.—Native of Hispaniola.

Ehrharta; a genus of the class Hexandria, order Monogynia or Digynia.—**GENERIC CHARACTER.** *Calix*: glume one-flowered, two-valved, ovate, concave, shorter than the corolla, patulous; one valve a little larger than the other, and membranaceous. *Corolla*: double, longer than the calix, scarcely gaping; outer two-valved; valves oblong, complicate, keeled, retuse, transversely wrinkled, villose on the outside of the base; inner compressed, two-edged, of two valves, which are folded, membranous, keeled, unequal. Nectary two-leaved, very small; leaflets jagged and ciliate, involving the genitals. *Stamina*: filamenta six, capillary, very short; antheræ upright, linear, emarginate, shorter than the corolla. *Pistil*: germen ovate, minute, smooth; styles two, very short, erect, contiguous; stigmas long, approaching each other, at length divaricated, each consisting of two opposite feathery rows. *Pericarp*: none. *Seed*: single, ovate, smooth. **ESSENTIAL CHARACTER.** *Calix*: a two-valved one-flowered glume. *Corolla*: double, each two-valved; the outer corolla notched at the base.—The species are,

1. *Ehrharta Mnematea*. Beardless: outer corolla rugose; obtuse, beardless; panicle simple, lax; stem simple; margin of the leaves cartilaginous and crisped; flowers tinged with purple, on capillary drooping stalks.—Native of the Cape.

2. *Ehrharta Panicea*. Beardless: outer corolla smooth, somewhat rugged, obtuse; panicle slightly branched, drooping; stem subdivided. It has the habit and small green flowers of a Panicum or Poa.—Native of the Cape.

3. *Ehrharta Ramosa*. Beardless: outer corolla rough, abrupt; panicle close; stem much branched, rather shrubby. The calix is nearly as long as the corolla.—Native of the Cape.

4. *Ehrharta Melicoides*. Beardless: outer corolla very smooth and obtuse; panicle widely spreading; glumes of the corolla peculiarly bare and rounded.—Native of the Cape.

5. *Ehrharta Calycina*. Beardless: outer corolla somewhat hairy, obtuse, with a short point; panicle close, nearly simple; stem branched.—Native of the Cape.

6. *Ehrharta Geniculata*. Awned: outer corolla hairy; one valve awned; panicle close; stem decumbent, bent at the joints. This species is distinguished from the last by its crisp-ed leaves and pointed awned corolla.—Native of the Cape.

7. *Ehrharta Longiflora*. Awned: outer corolla rugged, hispid; both valves awned; panicle rather lax, branched. This is a large species, with the habit of an *Avena*. The length of the awns varies.—Native of the Cape.

8. *Ehrharta Gigantea*. Awned: outer corolla hairy; valves both awned; panicle close, somewhat whorled; stem remotely jointed; calix very membranous, half as long as the corolla. This is one of the largest species, being six feet high; the flowers also are more hairy and larger than any other.—Native of the Cape.

9. *Ehrharta Bulbosa*. Awned: outer corolla with obovate, emarginate, rugged, short-awned glumes; panicle lax. The root of this species is more bulbous than of some others. The number of stamina vary from three to four or more.—Native of the Cape.

Ekebergia; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, tomentose, four-parted; divisions ovate, obtuse. *Corolla*: petals four, oblong, obtuse, tomentose on the outside, a little longer than the calix; nectary a ring surrounding the base of the germen. *Stamina*: filamenta ten, very short, pubescent; antheræ ovate, acute, upright. *Pistil*: germen superior; style cylindric, very short; stigma capitate. *Pericarp*: a globular berry. *Seeds*: five, oblong. ESSENTIAL CHARACTER. *Calix*: four-parted. *Petals*: four. *Nectary*: like a garland, surrounding the germen. *Berry*: containing five oblong seeds.—The only known species is,

1. *Ekebergia Capensis*. A tree resembling the Ash, with abruptly or unequally pinnate leaves; the common petiole flattened; the flowers panicled and axillary, they are small and whitish. The wood of this tree is hard, and used for many utensils.—Native of the Cape.

Elæagnus; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, four-cleft, superior, straight, bell-form, outwardly scabrous, inwardly coloured, deciduous. *Corolla*: none. *Stamina*: filamenta four, very short, inserted into the calix below the divisions; antheræ oblong, incumbent. *Pistil*: germen roundish, inferior; style simple, a little shorter than the calix; stigma simple. *Pericarp*: drupe ovate, obtuse, smooth, with a dotted tip. *Seed*: nut oblong, obtuse. ESSENTIAL CHARACTER. *Corolla*: none. *Calix*: four-cleft, bell-form, superior; drupe below the calix.—The species are,

1. *Elæagnus Angustifolia*; *Narrow-leaved Oleaster*. Leaves lanceolate. A tree, branching from the bottom, growing sometimes to the height of three fathoms, with a trunk the thickness of a man's arm or thigh, elegant in its appearance, especially from the silvery brightness of the leaves; bark smooth, brown; wood pale, prettily veined with gray and brown, but not hard; branches and branchlets slender, frequent, alternate, smooth, unarmed, or having thorns, especially in young trees. The flowers come out at the middle leaves of the smaller branches, usually solitary, or two together, sometimes, but very seldom, three from each axil, in which case one or two are on shorter peduncles, and barren, having no germen, though they have a style and antheræ; drupe always solitary, oblong, hoary, white when young, thicker and yellowish when ripe, enclosing within a sweet pulp a woody, gray, furrowed nut. In the deserts near the Volga, the fruit is hardly bigger than the berries of the Bar-

berry, whereas in the more southern parts it is of the size of the Cornelian Cherry. Mr. Miller specifically distinguishes the Thorny from the Unarmed Narrow-leaved Oleaster. The latter, he says, is that which is most commonly preserved in the English gardens. The leaves are more than four inches long, and not half an inch broad; they are very soft, and have a shining appearance like satin. The flowers come out at the footstalks of the leaves singly, or two, and frequently three, at the same place; the outside of the calix is silvery and studded, the inside of a pale yellow; it has a very strong scent. The flowers appear in July, and are sometimes succeeded by fruit. Mr. Miller conceives the thorny *Oleagnus* to be the common sort, which grows naturally in Bohemia, and of which he saw some trees in the curious garden of the famous Boerhaave, near Leyden. The leaves of this are not more than two inches long, and about three-quarters of an inch broad in the middle; they are white, and have a soft cottony down on their surface; at the footstalk of every leaf comes out a pretty long sharp thorn; the leaves being alternate, the spines come out on each side of the branches. The flowers are small, and have a strong scent when fully open. Native of the Levant.—This species is extremely hardy, and sets the frost at defiance. It is not, however, of very long duration; young plants, therefore, should be raised, once in three or four years, by seeds or layers.

2. *Elæagnus Orientalis*; *Oriental Oleaster*. Leaves oblong, ovate, opaque. This has the appearance of the foregoing species, but the leaves are twice as broad, ovate-oblongish, soft to the touch on both sides, pale underneath, but neither surface shining or silvery. In its stature and manner of growth, this tree resembles a middle-sized Willow, as it does also in the hoariness of its leaves, and the division of its branches. This, and the *Spinosa* of Linneus, do not seem to differ, except as a garden-tree does from a wild one, or the thorny variety of the preceding species from the unarmed.—Native of the mountains of Persia, from Caucasus to Derbent; found in abundance on the shores of the Caspian sea, and also in the Levant. This plant requires the protection of a green-house.

3. *Elæagnus Latifolia*; *Broad-leaved Oleaster*. Leaves ovate. This rises with a woody stem to the height of eight or nine feet, dividing into many branches; leaves silvery, with several irregular dark-coloured spots; they are alternate, and continue all the year.—Native of the East Indies and China. This sort requires a warm stove to preserve it in this country; for it is too tender to live in the open air, except for a short time in the warmest part of summer. It may be raised from the seeds.

4. *Elæagnus Crispa*; *Curled-leaved Oleaster*. Leaves lanceolate-oblong, obtuse, wavy; flowers solitary. This is an upright tree; branches and branchlets alternate, round, divaricate, upright, ash-coloured, scabrous with dots; the last twigs angular, and whitish; leaves alternate, petioled, entire, above naked, brownish, dotted, with a middle longitudinal furrow, silvery underneath, from erect patulous, an inch and a half in length; petiole furrowed above, scarcely a line long; flowers not in the axils, but scattered over the last twigs, solitary, and peduncled; peduncle capillary, shorter than the flower.—Native of Japan.

5. *Elæagnus Multiflora*; *Many-flowered Oleaster*. Leaves obovate, obtuse; flowers axillary, aggregate; peduncles longer than the flower; stem shrubby, little branched; branches and branchlets alternate, few, round, ferruginous, brown, spreading, scabrous with dots; leaves from each bud, many, alternate, petioled, entire, upright, above half naked, with scaly silver dots, wholly covered with silvery

scales underneath, unequal, about an inch in length; petioles capillary, a line in length; flowers many, peduncled from a bud among the leaves; peduncles capillary, loose, silvery, an inch long; calix club-shaped, oblong.—Native of Japan.

6. *Elæagnus Umbellata*; *Umbelled Oleaster*. Leaves obovate, obtuse; flowers axillary, aggregate; peduncles shorter than the flower. Stem shrubby; branches and branchlets alternate, round, upright, ferruginous, brownish, scabrous with dots; leaves from alternate buds, many, petioled, patulous, rather naked above, with silvery dots, underneath silvered all over, half an inch in length; petioles capillary, scarcely a line long; flowers many, from a bud among the leaves, in a kind of umbel, peduncled, drooping; peduncles capillary, nodding, scarcely a line in length; calix ovate.—Native of Japan.

7. *Elæagnus Glabra*; *Smooth-leaved Oleaster*. Leaves ovate-oblong, acuminate; flowers axillary, subsolitary. Stem arborescent; branches roundish, almost naked, brown; branchlets angular, reddish, ash-coloured, scabrous with dots, alternate, from erect patulous; leaves alternate, petioled, entire, from spreading erect, above green, smooth, underneath reddish, scaly, with ferruginous dots interspersed, an inch and a half in length; petioles semicylindric, channelled above, half an inch long; flowers axillary, solitary, and in pairs, peduncled, upright; peduncles shorter than the flower, capillary.—Native of Japan.

8. *Elæagnus Macrophylla*; *Silver-leaved Oleaster*. Leaves rounded-ovate, silvery. This is an upright thornless tree; branches round, streaked, tubercled, with the deciduous branchlets ash-coloured, scabrous with dots, upright; branchlets angular, alternate, like the branches; leaves alternate, petioled, entire, from erect patulous, above smooth, green, beneath silvery, an inch in length; petioles semicylindric, above channelled, upright, half an inch long; flowers axillary, aggregate, peduncled, almost upright; peduncles four or more, the length of the flower.—Native of Japan.

9. *Elæagnus Pungens*; *Prickly Oleaster*. Branchlets becoming thorns; leaves oblong, waved; flowers axillary, in pairs. This is an upright tree a fathom in height, with a brown scabrous bark; branches round like the trunk, flexuose, leafless, spreading, branchlets alternate like the branches, leafy, stiff, spinescent at the end; leaves alternate, petioled, somewhat obtuse, entire, above smooth, green, beneath silvery, with scales interspersed with ferruginous dots, from reflex spreading, an inch long, stiff; petiole half an inch in length; flowers in the axils of the leaves, about two, distinct, upright; pedicels shorter than the flower.—Native of Japan.

10. *Elæagnus Argentea*. Unarmed; leaves undulated, oval-oblong, smooth on both sides, and covered with silvery scales; flowers aggregate, nodding; berry large, subglobose, covered with silvery scales. This shrub, 8 to 12 feet high, is found on the banks of the Missouri, and at Hudson's Bay.

Elæis; a genus of the class Diœcia, order Hexandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth six-leaved; leaflets concave, upright. *Corolla*: one-petalled, six-cleft, upright, sharp, length of the calix. *Stamina*: filamenta six, subulate, length of the corolla; antheræ oblong-sharp. *Female*. *Calix*: as in the male, (according to Gærtner, nine-leaved, with the inner leaflets longer.) *Corolla*: six-petalled. *Pistil*: germen ovate; style thickish; stigmas three, reflex. *Pericarp*: drupe fibrous, ovate, somewhat angulated, oily, (superior, berried, one-celled, according to Gærtner.) *Seed*: nut ovate, obscurely three-sided, with three holes, three-valved, one-celled. ESSENTIAL CHARACTER. *Male*. *Calix*: six-leaved. *Corolla*: six-cleft. *Stamina*: six. *Female*. *Calix*: six-leaved. *Corolla*: six-petalled.

Stigmas three. Drupe fibrous. Nut one to three valved.—The only species known and fully described is,

1. *Elæis Guineensis*. Leaflets long, narrow, and not so stiff as most of the Palms. The footstalks of the leaves are broad at their base, where they embrace the stem, diminish gradually upwards, and are armed with strong, blunt, yellowish thorns, which are largest at their base. The flowers come out among the leaves at the top of the stem; some bunches having only male flowers, others only female, the latter of which are succeeded by oval berries, bigger than the largest Spanish olives, but of the same shape; they grow in very large clusters, and are of a yellowish colour when ripe. From this fruit, the inhabitants of the West India islands draw an oil, in the same manner as if it were extracted from olives. They also obtain a liquor from the body of the tree, which, when fermented, has a vinous quality, and will inebriate. The leaves are wrought by negroes into mats, on which they repose. The West Indians call this tree the Oily Palm, and Negro's Oil; the fruit having been first imported from Africa by the negroes. It grows in great plenty on the coast of Guinea, and also in the Cape de Verd Islands, but was not found in any of our American colonies, till carried there by the negroes, who now propagate it in great plenty. The French call it *Palmier*. Gærtner mentions another *Elæis*, which he names *Melanococca*, from the blackness of the nuts, but thinks to be probably only a variety of the above. The shell, however, is much smaller, and not so much bellied, but rather oblong, and suddenly contracted at the tip into an oblique dagger-point, it is also thinner, and elegantly variegated on the outside with testaceous streaks irregularly confluent, and with alternate streaks like the others, but of a coal black; when broken, it appears of a sooty black colour, and the seed is ovate-oblong, and brown. Jacquin also describes another veiny thorny Palm, which has somewhat of the same habit as the *Elæis Guineensis*, and is called *Gigri* in the island of Martinico. The fruit is eatable, of an acid flavour, globular, slightly depressed, acuminate by means of the style, scarlet, and shining. The pulp is small, red, soft, and not fibrous, surrounded by a very thin pellicle. Nut brown, with three obscure holes, from which run lines in a stellate order, like veins, over the whole surface; kernel cartilaginous and hollow. A Palm occurs also about Carthagen in New Spain, which the natives call *Corozo*, and make both an oil and a butter of the fruit. The pericarp is shining, and yellow on the outside, supported by a three-leaved calix, and a three-petalled corolla, permanent, and shining. It is but little fibrous, not thick, and contains a pleasant oil. Its form is ovate, obscurely three-cornered. Nut black and shining, of the same form, with three obscure holes at the base; kernel roundish, cartilaginous, very hard, solid, with the fruit slightly cloven.—To propagate the species first described, it must be kept constantly in the bark-stove, otherwise it will make no progress. In about twenty years it will be too tall for most of our stoves. It is propagated by seeds; for the sowing and management of which, see *Cocos* and *Phoenix*.

Elæocarpus; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, spreading, permanent, five-parted; leaflets linear-lanceolate, concave, sharp. *Corolla*: petals five, with claws, multifid, lacinate, the extreme jags capillary, equal, scarcely longer than the calix, inserted at the base of the nectary. *Stamina*: filamenta twenty to thirty, capillary, very slender, short, inserted into the nectary; antheræ shorter than the corolla, upright, linear, scabrous, two-valved at the tip; valves spreading, with about five ciliate hairs, very slender, from reflex expanding, unequal. *Pistil*: germen somewhat

globular, villose, sitting on the nectary; style filiform, longer than the stamina; stigma sharp. *Pericarp*: drupe oblong, of a smooth even surface. *Seed*: nut oblong, grooved, and tubercled; shell subtrivalvular; kernel subtrigonal. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled, jagged; antheræ two-valved at the tip. *Drupe*: with a curled shell.—The species are,

1. *Elæocarpus Serratus*. Leaves alternate, lanceolate-elliptic, serrate; racemes axillary; branches round, warted, smooth; leaves petioled, three inches long, bluntly serrate, smooth, nerved, and veined; racemes axillary; flowers distant. Linneus observes, that they are simple, loose, solitary, the length of the leaves, which have a double gland at their base.—Native of several parts of the East Indies.

2. *Elæocarpus Dentatus*. Leaves alternate oblong, tooth-serrate at top; racemes axillary; flowers one-styled; branches round, dotted, smooth, with pubescent branchlets; leaves petioled, two inches long, sharp at the base, smooth on both sides, except on the midrib, nerved above, somewhat veined underneath; petioles villose.—Native of the islands of the South Seas.

3. *Elæocarpus Dicera*. Leaves opposite, ovate, doubly serrate; racemes compound; flowers four-styled. Branches round, a little compressed at top; leaves petioled, smooth, veined at top, two inches long; racemes three inches long, erect.—Native of the East Indies.

4. *Elæocarpus Copalliferus*. Leaves quite entire; panicle terminating. Leaves large, ovate, coriaceous, very entire, with transverse nerves; flowers in panicles: calix superior; the divisions linear-oblong, obtuse, tomentose on both sides; petals longer than the calix, ovate, entire; stamina forty or more; antheræ filiform at the tip; germen conic, streaked, tomentose; style angular; fruit a conic, fleshy, resinous, one-celled pome. The long linear antheræ, terminated by cirrhose threads, seem to furnish a better character than the torn petals. It yields the copal resin, of which there are nevertheless several sorts.—Native of the East Indies.

5. *Elæocarpus Integerrimus*. Leaves lanceolate; quite entire; flowers heaped, axillary. A middle-sized tree, with spreading branches; leaves smooth, petioled, alternate; flowers many, golden, sweet-smelling; calix five-leaved, with lax leaflets; petals lacerated, longer than the calix; germina ten, roundish, minute, placed round the base of the style; drupe small, black, subovate, subacute, ripening singly, the rest of the germina proving abortive.—Native of Cochin-china, where it is also cultivated for the sweetness and beauty of the flowers.

6. *Elæocarpus Oblongus*. *Drupe* berried, superior, ovate-oblong, or subcylindric, smooth, covered with a soft fleshy bark; shell stony, oblong, muricate, and curled, with irregular tubercles, having three spurious sutures, never opening, one-celled, testaceous; seed oblong, attenuated to both ends, obscurely three-cornered, ferruginous.—Native of the East Indies.

Elæodendrum; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets roundish, blunt, concave, spreading very much, small, permanent. *Corolla*: petals five, roundish, blunt, concave, spreading very much, twice as long as the calix. *Stamina*: filamenta five, subulate, bent back, arising from a gland beneath the germen; antheræ roundish, erect. *Pistil*: germen roundish, conical, placed on a gland; style conical; stigma obtuse, bifid. *Pericarp*: drupe ovate. *Seed*: nut ovate; shell thick and very hard, two-celled; kernels oblong, compressed. **ESSENTIAL CHARACTER.** *Corolla*: five-petalled. *Drupe* ovate, with a two-celled nut.—The species are,

1. *Elæodendrum Orientale*. This is a moderate-sized twiggly shrub or tree, a native of the Oriental regions; with the leaves ovate-lanceolate, smooth, sometimes slightly waved, and sometimes even a little inclined to a subserrated appearance on the upper parts of the shoots; flowers borne towards the ends of the branches, standing by twos and threes, of a pale green colour, sweet-smelling, supported on short pedicels, each of which springs from a somewhat longer common pedicel. The lower shoots, or those nearest the ground, appear to be somewhat procumbent, and have narrower and longer leaves in proportion than the upper ones; the nerves or midribs of these leaves are also of a reddish colour.

2. *Elæodendrum Argan*. Branches spiny; leaves ovate, obtuse. It is a middle-sized tree, with short thickish spines at the ends of the branches. Leaves solitary, and in bundles, an inch long, petioled, quite entire, coriaceous, others decrease towards the petiole, so as to be almost spatulate; flowers in the axils of the leaves and spines, heaped, sessile; calix inferior; leaflets a little unequal, hirsute, and brown on the outside, with the edges smooth and whitish; petals half ovate, entire, greenish with white edges; filamenta longer than the corolla, compressed, fastened to the base of the petals; antheræ ovate; drupe dry; nut very hard and smooth, pale brown, divided longitudinally by a white line, and having a single kernel in each cell; the calix and style abide after the petals are fallen, but are wanting in the fruit; one of the cells in the nut is generally abortive. It is called *Argan* by the Moors, who express an oil from the fruit, which the Europeans employ in a variety of manufactures, and the Moors for the table.—Native of the woods of Morocco.

Elate; a genus of the class Monœcia, order Triandria.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: spathe two-valved; spadix branching. *Corolla*: petals three, roundish. *Stamina*: filamenta three, simple; antheræ adœate. *Female Flowers*, in the same spadix with the males. *Calix*: spathe common with the males. *Corolla*: petals three, roundish, permanent. *Pistil*: germen roundish; style subulate; stigma sharp. *Pericarp*: drupe ovate, acuminate. *Seed*: nut ovate, grooved. **ESSENTIAL CHARACTER.** *Male.* *Calix*: three-toothed. *Corolla*: three-petalled; antheræ six, sessile. *Female.* *Calix*: one-leaved. *Corolla*: three-petalled. *Pistil*: one; stigmas three. *Drupe*: one-seeded.—The only known species is,

1. *Elate Sylvestris*; *Prickly-leaved Elate*. Fronds pinnate; leaflets opposite. This Palm grows to the height of about fourteen feet, the trunk being covered with an ash-coloured crust, closely united with a very hard whitish wood; pinnate leaves break out from the top of the trunk only, in a decussated order, the old ones dropping off as the young ones break forth; the midribs are green, smooth, and shining, flat within, convex without, with long stiff spines at bottom; leaflets opposite, on short petioles, numerous, oblong, rounded, acuminate, close, smooth, of a shining green, closed at the base towards the inside, finely streaked longitudinally; the flowers are concealed in stiff, green, coriaceous spathes, they are small, several on the same peduncle; petals whitish-green; stamina whitish, lanuginose; they have no smell, but a rough taste; the fruit is oblong-round, small, like a wild plum, with a hard woody point at top, covered with the calix at bottom, first green, then red, but when ripe of a reddish brown, or blackish and shining, covered with a thin rind that is easily broken, and having a whitish sweet farinaceous pulp within; the nut or stone is oblong, rufous, marked longitudinally with a deep furrow, and containing a whitish bitter kernel; the fruits grow on green smooth shining branches, near a yard long, and two fingers broad, flat, stiff, and woody, whence

a clear austere liquor flows when they are cut or wounded. The poorer sort of people chew the nut in the same manner with the Areca nut, with the leaf of the Betel and quick-lime. The elephant is very fond of the fruit-branches, which are very sweet; the leaves, fruit, &c. are very astringent, and are looked upon as powerful in stopping fluxes.—Native of the East Indies. For its propagation and culture, see *Coccus* and *Pennis*.

Elaterium; a genus of the class Monœcia, order Monandria.—GENERIC CHARACTER. *Male Flowers*. *Calix*: none. *Corolla*: one-petalled, salver-shaped; tube cylindrical; border five-cleft; divisions lanceolate, channelled on the back, the incisures furnished with a toothlet. *Stamina*: filamentum single, columnar; antheræ linear. *Female Flowers*. *Calix* and *Corolla*: as in the male. *Pistil*: germen inferior, echinate; style columnar, thickening; stigma capitate. *Pericarp*: capsule inferior, echinate, leathery, filled with pulp, uniform, one-celled, two-valved, elastic. *Seeds*: several. ESSENTIAL CHARACTER. *Male*. *Calix*: none. *Corolla*: salver-shaped. *Female*. *Calix*: none. *Corolla*: salver-shaped. *Capsule*: inferior, one-celled, two-valved.—The species are,

1. *Elaterium Carthaginense*. Leaves cordate, angular; stems round, smooth, herbaceous, diffused, scandent, with tendrils bifid and lateral. Leaves very finely serrate, smooth underneath, somewhat rugged above, petioled, alternate, numerous; peduncles of the male flowers axillary, solitary, many-flowered, spreading, almost the length of the leaves, racemed or subumbellic; female peduncle from the same axil, solitary, one-flowered, short; corolla white, without scent in the day, but smelling sweet at night; fruit green, an inch and a half long, having but little watery pulp, smelling like Cucumber; when ripe it opens elastically with a very gentle touch, and disperses its seeds; or when approaching to maturity, if it be held some time in the hand closed, it will do the same.—Native of Carthage in New Spain, covering entire shrubs with its stalks, and flowering in October and November.

2. *Elaterium Trifoliatum*. Leaves ternate, gashed; capsule kidney-shaped, rough with hairs, two-valved, opening with a spring, and therefore of this genus.—Native of Virginia.

Elatine; a genus of the class Octandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets roundish, flat, size of the corolla, permanent. *Corolla*: petals four, ovate, obtuse, sessile, spreading. *Stamina*: filamenta eight, length of the corolla; antheræ simple. *Pistil*: germen orbicular, globose-depressed, large; styles four, upright, parallel, length of the stamina; stigmas simple. *Pericarp*: capsule orbicular, globose-depressed, large, four-celled, four-valved, flattened. *Seeds*: several, mooned, upright, surrounding the receptacle in the manner of a wheel.—The species are,

1. *Elatine Hydropiper*; *Opposite-leaved Waterwort*. Leaves opposite. This is a very small annual aquatic plant, being hardly a span in length; stem very tender, creeping; the shoots erect and leafy; leaves ovate-lanceolate, quite entire, sessile at the joints; flowers solitary, much smaller than in the second species, alternate, on very short peduncles, at the axils of the leaves on the branches, and close to them on the stem; petals white, purplish, or rose-coloured; styles none; stigmas very small; antheræ globular; capsules smaller than in the second.—Native of Denmark, Sweden, Switzerland, Silesia, and France, where it is found in ditches and other wet places, flowering in summer.

2. *Elatine Alsinastrum*; *Whorl-leaved Waterwort*. Leaves in whorls; stem decumbent, creeping at bottom, then erect, pellucid, brittle, six or seven inches in length, branched, round, the thickness of a quill, at the lower joints thick set

with roots hanging in the water, having at the rest whorled, sessile, entire leaves, four to six in a whorl, at top only three, the emersed leaves ovate-lanceolate, the immersed ones linear, or even capillaceous, bright green, reflex; flowers axillary, two or three, sessile; calix very small, greenish; petals three or four, white, a little larger than the calix; stamina seven or eight, very short; capsule a little flattened, the partitions growing to the axils, and opposite to the sutures of the valves; seeds numerous, very small, somewhat cylindrical, marked with longitudinal streaks, and transverse ones much finer, in a beautiful kind of net-work, bent a little, and ash-coloured. It flowers in June and July.—Native of Abo, Leipsic, Silesia, Switzerland, near Paris, and Montpellier; in England, in ditches, and also on the bogs of the common by the road from Eltham to Chisselhurst.—See *Antirrhinum*.

Elder. See *Sambucus*.

Elder, Marsh, or Water. See *Viburnum*.

Elecampane. See *Inula*.

Elegia; a genus of the class Diœcia, order Triandria.—GENERIC CHARACTER. *Male*. *Calix*: spathes within spathes, remote, one-valved, coriaceous, lanceolate, deciduous; spatix filiform, jointed, with an ament at each joint; ament loose, with pedicelled florets, distinguished by a bracte; bracte bristle-shaped, membranaceous, flat, longer than the florets; perianth proper, of six bristle-shaped, chaffy, loose leaflets. *Corolla*: none. *Stamina*: filamenta three, very short; antheræ incumbent, oval, larger than the perianth. *Female, on a distinct individual*. *Calix*: spathe as in the male, but shorter. *Spatix*: as in the male; ament with a compound raceme; perianth proper six-leaved; valves, the three outer lanceolate, channelled, petaloid, equal. *Corolla*: none. *Pistil*: germen somewhat oblong; styles three, filiform, the length of the perianth; stigmas simple. *Pericarp*: (according to Thunberg) a capsule of three cells. *Seed*: several, oblong.—The only known species is,

1. *Elegia Juncea*.—This plant is a native of the Cape of Good Hope, and has the habit of a rush; the stems are several, about a foot high, round, smooth, filled as if it were a rush; hard, strong, very simple, scarcely so thick as a quill, with a simple joint; there are scarcely any leaves, but two or three leafy sheaths towards the root, imbricated over each other, and of a brown colour; there is also a rudiment of a similar sheath towards the middle of the stem; the spathe is terminal, and divided into other interior ones, which are also compound; the parts of fructification are not very easily made out, but are most clear in the female flowers.

Elephantopus; a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: involucre of three broad sharp leaflets, many-flowered, large, permanent, without an umbel; perianth partial, four-flowered, oblong, imbricate; scales lance-subulate, mucronate, upright, of which the four longer are equal. *Corolla*: compound, tubular; corollets hermaphrodite, five or four, equal, disposed in a single circle; proper one-petalled, tubular; border narrow, five-parted, nearly equal. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: germen ovate, crowned; style filiform, length of the stamina; stigmas two, slender, spreading. *Pericarp*: none. *Calix*: unchanged. *Seeds*: solitary, compressed; down bristle-form. *Receptacle*: naked. ESSENTIAL CHARACTER. *Calix*: four-flowered. *Corolla*: tubular, hermaphrodite. *Receptacle*: naked. *Down*: bristle-form.—These plants are propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are come up, they must be transplanted into pots filled with fresh light earth, and plunged into a hot-bed of tanners' bark, observing to water and shade them until they

have taken root, when they must have a large share of fresh air admitted to them in warm weather, besides requiring to be frequently refreshed with water.—The species are,

1. *Elephantopus Scaber*; *Rough-leaved Elephant's Foot*. Leaves oblong, scabrous. This from its perennial root sends out many oblong rough leaves, which spread near the ground; between these in the spring arises a branching stalk, little more than a foot high; the side-branches are short, and generally terminated by two heads of flowers, each on a short peduncle; the florets are of a pale purple colour.—According to Dr. Browne, in the East Indies it is accounted a good vulnerary, and is much used in consumptive cases; the leaves are frequently used instead of *Carduus Benedictus*, among the inhabitants of the French West India islands. If this plant be set in a pot, and sheltered in the winter from frosts, it may be preserved for several years, and will flower annually.—Native of the East Indies, in moist shady places.

2. *Elephantopus Tomentosus*; *Woolly-leaved Elephant's Tooth*. Leaves ovate, tomentose; root-leaves four inches long and three broad, having many transverse nerves; they spread flat on the ground, and from among them rises a stiff stalk about a foot high, dividing into several branches, and terminated by two flowers composed of several florets, enclosed in a four-leaved involucre, having two of the leaflets alternately larger than the two others; this involucre being longer than the florets, they do but just appear within the two larger leaves; and the flowers make little appearance.—Native of South Carolina.

3. *Elephantopus Spicatus*. Leaves ovate-lanceolate, serrate, scabrous; bundles of flowers sessile, lateral; stem branched. It generally rises to the height of fifteen or twenty inches, sometimes more; the common receptacles of the flowers rise singly from the axils of the upper leaves, and seem disposed in the form of a spike, but there are seldom more than four florets in each; the seeds are crowned with four little bristles.—Native of Jamaica, Hispaniola, and Guiana: biennial.

4. *Elephantopus Angustifolius*. Stem-leaves linear-lanceolate, entire, villose; flowers glomerate, in sessile and peduncled bundles. Stem simple; root large, oblong, whence rises a single, round, striated, hollow stalk, about two feet high, having sessile leaves set on it alternately, the lower part whereby they are joined to the stalk having a membrane enclosing it; they are about five inches long, and half an inch broad near the top where broadest, and round, are of a pale green colour, and wrinkled; towards the top the flowers come out in a spike, enclosed in an involucre of a few dry brown membranes; these are followed by small channelled seeds, having much pappus on them.—Native of Jamaica.

5. *Elephantopus Carolinianus*. Leaves oval, narrowed at the base, and with the branching stem pilose.—Native of Maryland and Virginia.

Ellisia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted; divisions sharp, gaping. *Corolla*: one-petalled, funnel-form, smaller than the calix; border five-cleft. *Stamina*: filamenta five, shorter than the tube; anthers roundish. *Pistil*: germen roundish; style filiform, short; stigma two-cleft, oblong. *Pericarp*: capsule bag-form, leathery, two-valved, two-celled: the calix then very large, flat, star-form. *Seeds*: in each cell two, globose, black, hollow-dotted, but one seed over the other, scarcely separated by a transverse partition. ESSENTIAL CHARACTER. *Corolla*: funnel-form, narrow; berry dry, two-celled, two-valved. *Seeds*: two, dotted, placed over each other.—The species are,

1. *Ellisia Nyctelea*; *Cut-leaved Ellisia*. Root annual;

stem herbaceous, brittle, dichotomous very much branched, diffused, prostrate, round; leaves alternate, petioled, pinnatifid, during foliation imbricate backwards; the divisions sharp, with a tooth on each side; peduncles opposite to the leaves, one-flowered, spreading, elongated, pubescent; flowers drooping; corolla white, with minute purple dots on the inside of the divisions; the position of the seeds is singular.—It flowers in July and August, and is a native of Virginia.

2. *Ellisia Ambigua*. Decumbent and branching; stem glabrous, somewhat glaucous; leaves hirsute, lyrate-pinnatifid, subsessile; segments sublanceolate, angularly toothed or lobed; racemes opposite the leaves, both lateral and terminal; flowers small, scarcely longer than the calix. Annual.—In alluvial soils on the banks of the Missouri.

Elm. See *Ulmus*.

Elymus; a genus of the class Triandria, order Digynia.—GENERIC CHARACTER. *Calix*: receptacle common, lengthened into a spike; glume four-leaved, two-ranked, two subulate leaflets being placed under each spikelet. *Corolla*: two-valved; valve exterior larger, acuminate, awned, interior flat; nectary two-leaved; leaflets oblong, sharp, ciliate. *Stamina*: filamenta three, hair-form, very short; anthers oblong, two-cleft at the base. *Pistil*: germen top-shaped; styles two, divaricated, hairy, inflected; stigmas simple. *Pericarp*: none; corolla involving the seed. *Seed*: single, linear, convex on one side, covered. ESSENTIAL CHARACTER. *Calix*: lateral, two-valved, aggregate, many-flowered.—For the propagation and culture of plants of this genus, see *Grass*.—The species are,

1. *Elymus Arenarius*; *Sea Lyme Grass*. Spike upright, close; calices tomentose, longer than the floret; leaves reedy, glaucous or whitish, involute and mucronate, channelled and rigid; stems two or three feet high and more, strengthened by three or four joints; spike tomentose, linear, eight or nine inches long, as large, but less compact than a full-sized wheat-ear; spikelets two, straight, two-flowered, awnless. Like *Arundo Arenaria*, it prevents the sea-sand from blowing about, by means of its matted roots. Dr. Withering conjectures, that it may possibly admit of being made into ropes, as the *Stipa Tenacissima* is in Spain.—It is perennial; flowers from June to August; and is found on the sea-coast in many parts of Europe.

2. *Elymus Sibiricus*; *Siberian Lyme Grass*. Spike pendulous, close; spikelets in pairs, longer than the calix; stems tall, round, and smooth; leaves inoderately broad, and commonly distinguished by a kind of glaucous powdery complexion on the under sides; the awns are moderately long, and slightly flexuose. Flowering in June and July.—Perennial, and a native of Siberia.

3. *Elymus Philadelphicus*; *Philadelphia Lyme Grass*. Spike pendulous, patulous; spikelets six-flowered, the lower ones ternate. This strongly resembles the following species: perennial.—Native of Philadelphia.

4. *Elymus Canadensis*; *Canadian Lyme Grass*. Spike nodding, patulous; lower spikelets ternate, upper binate. The leaves of this species are bluish, especially underneath; the awns also of the corolla, when the seed is ripening, from spreading become reflex, which in the other species is not common. It is perennial; flowers in July and August; and is a native of Canada and Virginia.

5. *Elymus Caninus*; *Bearded or Dog's Lyme Grass*, or *Wheat Grass*. Spike nodding, close; spikelets straight, without any involucre, the lowest double; leaves bare of hairs underneath; sheaths smooth. It is perennial, and flowers in June and July.—It is found in woods and hedges in the north of England, and between Greenwich and Woolwich;

near Croydon; Ripton woods, Huntingdonshire; and Stokenchurch woods, Oxfordshire.

6. *Elymus Tener*; *Phant Elymus*. Spike pendulous; florets double; culm two feet high, smooth and even, with red joints.—Native of Siberia.

7. *Elymus Virginicus*; *Virginian Lyme Grass*. Spike erect; spikelets three-flowered; involucre streaked. The spike is larger than that of a common ear of barley.—Perennial, and a native of Virginia.

8. *Elymus Europæus*; *Wood Lyme Grass*, or *Barley Grass*. Spike upright; spikelets two-flowered, equal to the involucre; culm upright, stout, two feet high and more, having four or five joints. The leaf at each of these is about a span in length, and a quarter of an inch or more in breadth, smooth to appearance, but roundish to the touch, especially round the edges; sheaths hairy.—Native of Germany and Switzerland; and found on calcareous soils in woods near Berkhamstead, in Hertfordshire; Marlow and Hambleton, in Buckinghamshire; Henley and Stokenchurch, in Oxfordshire; Ripton woods, in Huntingdonshire; on rocks opposite to Matlock Baths; and frequently in the north. It is a coarse Grass, like most of those which grow in woods, and is sometimes, like them, drawn up to a great height. Perennial, and flowering in June.

9. *Elymus Caput Medusæ*; *Portugal Lyme Grass*. Spikelets two-flowered; involucre bristle-form, spreading very much; culm narrow, a foot high; spike oblong; partial involucre four-leaved, spreading very much, or reflex, the length of the florets with their awns.—Annual; flowering in July; and a native of the coasts of Spain and Portugal.

10. *Elymus Hystrix*; *Rough Lyme Grass*. Spike upright; spikelets without involucre, spreading. Annual; flowering in England in July and August.—Native of the Levant.

11. *Elymus Giganteus*. Spike erect, close; spikelets in sixes, six-flowered, villose; calices awl-shaped, smooth, longer than the spikelets; culm the thickness of the middle finger; leaves involute, strict.—Native country unknown.

Embothrium; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals four, linear, oblique, with the tip broader, roundish, concave, staminiferous, after fecundation revolute. *Stamina*: filamenta four, very short, on each petal one or none; antheræ oblong, within the cavity of the petal, largish. *Pistil*: germen linear, ascending, inflex; style none; stigma roundish, plain in front, behind concave, large. *Pericarp*: follicle round, one-celled. *Seeds*: four or five, ovate, compressed, with a winged membrane on one edge. ESSENTIAL CHARACTER. *Corolla*: four-petalled. *Antheræ*: sessile, sitting on the tips of the petals. *Follicle*: round.—The species are,

1. *Embothrium Umbellatum*. Umbels axillary, very simple, peduncled; leaves oblong, veinless; antheræ sessile. This is a handsome shrub, with small red flowers in solitary umbels.—Native of New Caledonia.

2. *Embothrium Coccineum*. Thyrses terminating, sessile; antheræ pedicelled; leaves obovate, veined, or oblong-ovate, ending in a cusp.—The whole of this plant is smooth; stem shrubby; leaves scattered, having one nerve branching on both sides, on short petioles, dilated at the base, and reddish; buds red, with lanceolate reflex scales; flowers in spikes, terminating; corolla scarlet, tubular, incurved, with an anthera lying in the broad end of each of the four petals; seeds in the follicle imbricate, with a sharp wing.—Found in Terra del Fuego by Forster, and in the straits of Magellan by Comermerson, who named it *Izora*. The common name is *Catas*. Several other species have been observed in Peru and Chili.

3. *Embothrium Speciosissimum*. This magnificent shrub is a native of New Holland; it grows to the height of eight or ten feet, with several simple, wandlike, round branches, clothed with numerous, large, alternate, bright green leaves, from four to six inches long, obovate, and blunt, but tipped with a small point; they are more or less serrated on the sides. The flowers grow in a very dense simple head on the top of each branch, and the head is surrounded at the base with numerous lanceolate leaves, or rather bractes, constituting the involucre, which, like the flowers themselves, are of a rich sanguine red.

4. *Embothrium Silaifolium*. The stems, which are several, grow three or four feet high or more, are upright, and alternately branched, and have alternate leaves, which in shape resemble those of the *Peucedanum Silaus*; the upper and lower leaves are, however, more simple: the flowers stand in a long, loose, terminal spike, and are white, with the tips of the petals revolute.—Native of New Holland.

Empetrum; a genus of the class Diœcia, order Triandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth three-parted; divisions ovate, permanent. *Corolla*: petals three, ovate-oblong, narrower at the base, larger than the calix, withering. *Stamina*: filamenta three, capillary, very long, hanging forwards; antheræ upright, short, two-parted. *Female*. *Calix*: perianth as in the male. *Pistil*: germen superior, depressed; style scarcely any; stigmas nine, reflex, expanding. *Pericarp*: berry orbiculate, depressed, one-celled, larger than the calix. *Seeds*: nine, jointedly placed in a circle, on one side bulging, on the other cornered. ESSENTIAL CHARACTER. *Male*. *Calix*: three-parted. *Corolla*: three-petalled. *Stamina*: long. *Female*. *Calix*: three-parted. *Corolla*: three-petalled. *Styles*: three to nine. *Berry*: three to nine.—These little shrubs are seldom propagated in gardens, unless for variety sake; but they may be cultivated in shady places, and will thrive well in a stiff soil. These plants should be procured from places where they grow naturally, for the seeds remain a year in the ground before they vegetate, and are very slow in their growth. If they are planted on a moist boggy soil in autumn, they will get root in the winter, and will require no farther care than to clear them from the weeds; for these low shrubs commonly grow upon the tops of wild mountains, where the soil is peaty, and full of bogs.—The species are,

1. *Empetrum Album*; *White-berried Heath*. Erect; berry guarded at the base by the calix, fleshy, white, shining; seeds two or three, seldom more, bony, on one side convex and obscurely furrowed, on the other angular or flattish.—Native of Portugal.

2. *Empetrum Nigrum*; *Black-berried Heath*, *Crow* or *Crahc-berry*. This is a small decumbent shrub. The outer bark is deciduous, and of a brown colour, the inner yellow; branches rough with the remains of the petioles. The terminating bud consists of five membranaceous leaflets, hairy at the edge; this puts forth five little branches, of which four are in a whorl. The leaves are in fours, they are somewhat three-cornered, with a white linear keel, and petioled; flowers axillary, sessile, solitary, surrounded by a bracte resembling an outward three-parted calix; calix whitish; petals purple; filamenta very long, and purple, with brownish black antheræ. The female is like the male, but the stem is redder; the leaves deep green, in fives; pistil black; berries brownish-black when ripe.—Native of the northern parts of Europe; generally in elevated situations, both on dry, barren, and moorish or boggy soils. It is found in the moors, from the Baltic to the Eastern Ocean, in Kamtschatka, and the American isles. The mountains of Lapland, and the mines

of Fahlun in Sweden, also produce it; and here it has been known to survive, when every other plant had perished with cold. In Warwickshire, Staffordshire, Derbyshire, and the northern counties of England, it is common; and the Scottish Highlanders, with their children, eat the berries; but they are no desirable fruit, and, if taken in large quantities, are said to bring on a slight headache. The Russian peasants, however, eat them; and the Kamtschadales gather great quantities of them to boil with their fish, or to make a sort of pudding with the bulbs of their Lilies. They are esteemed antiscorbutic, and diuretic. Grouse and heath-cocks feed upon them, and they give their excrement a tinge of purple. When boiled in alum-water, they afford a dark purple dye, and are said to be used in dyeing otter and sable skins black, when boiled with fat. Cattle do not seem to browse on this shrub. Linneus says, it flowers in April with the Elm.

Empleurum; a genus of the class Monœcia, order Tetrandria.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth one-leafed, bell-shaped, four-toothed, permanent. *Corolla*: none. *Stamina*: filamenta four, awl-shaped, longer than the calix, patulous; antheræ oblong, subquadrangular, retuse. *Female Flowers* on the same plant. *Calix*: as in the male. *Corolla*: none. *Pistil*: germen superior, oblong, compressed, terminated by a leafy erect process; style none; stigma placed on the lateral toothlet of the germen, cylindrical, deciduous. *Pericarp*: capsule oblong, compressed, crowned by a leafy process, one-celled, opening along the straighter margin. *Seed*: solitary, oblong, covered with a subcoriaceous bivalve aril. ESSENTIAL CHARACTER. *Male*. *Calix*: four-cleft. *Corolla*: none. *Female*. *Calix*: four-cleft, inferior. *Corolla*: none; stigma cylindrical, placed on the lateral toothlet of the germen; capsule opening on the side. *Seed*: one, arilled.—The only known species is,

1. *Empleurum Serrulatum*; *Cape Empleurum*. This is a shrub with wandlike even branches; leaves like those of a willow, alternate, subpetioled, linear-lanceolate, even above, beneath longitudinally wrinkled, smooth, quite entire on the edge, but appearing to be serrate by pellucid dots; peduncles few-flowered, lateral, much shorter than the leaves; flowers small, reddish, most of them male; capsules usually solitary, incurved, with a beak of the same length.—Native of the Cape.

Enargea; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong-ovate, concave, acute; three outer and three inner all marked below the middle with two green spots. *Stamina*: filamenta six, half the length of the corolla. *Pistil*: germen roundish. *Style*: three-cornered, thick. *Pericarp*: berry subglobular, three-celled. *Seeds*: four or five, globular. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: six, oblong-ovate, concave, acute; three outer and three inner green-spotted. *Berry*: three-celled, with four or five globular seeds.—The species are,

1. *Enargea Marginata*. A handsome little plant, a span high, erect, branched, angular; leaves alternate, nearly sessile, an inch or more in length, elliptical, acute, entire, their edges rough with minute spines; flowers terminal, solitary; petals white, ribbed, the three outer elliptical, the three inner broader and obovate; berry the size of a pea.—Native of Terra del Fuego.

2. *Enargea Buxifolia*. A shrub two or three feet high, with the aspect of Box. Leaves with numerous transverse veins, an inch long, their edges rough, with minute teeth near the point; flowers terminal, large, and handsome; the three outer petals elliptic, flat, an inch long; the three inner obovate, thrice as long, all veined.—Found by Commerson in the straits of Magellan.

Enchanter's Nightshade. See *Circœa*.

Endive. See *Cichorium*.

English Mercury. See *Chenopodium*.

Epacris; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, equal, permanent; divisions lanceolate. *Corolla*: one-petalled, funnel-form; tube gradually widening into a five-cleft border; divisions ovate, acute, villose above; nectary five obovate emarginate scales, fastened to the germen, and pressed close. *Stamina*: filamenta five, very short in the throat of the corolla; antheræ incumbent. *Pistil*: germen roundish, five-streaked; style cylindric, short; stigma capitate. *Pericarp*: capsule globular-flatted, five-celled, five-valved, gaping. *Seeds*: numerous, very small. ESSENTIAL CHARACTER. *Corolla*: funnel-form, villose. *Nectary*: scales fastened to the germen. *Capsule*: five-celled, five-valved.—The species, all natives of New Zealand, are,

1. *Epacris Longifolia*. Arboreous: leaves subulate, sheathing; racemes upright; flowers opposite; capsule superior, subturbinate, rounded, five-cornered; partitions inserted in the middle of the valves, and corresponding with the depressed grooves on the outside of the capsule.

2. *Epacris Juniperina*. Arboreous: leaves scattered, linear, acute, spreading, sessile; racemes drooping; flowers alternate. The fruit of this plant is a small, superior, juiceless, spherical berry, terminated by a short awl-shaped style; the rind is coriaceous, thin, and black; the pulp fungous, rather solid, white, and five-celled.

3. *Epacris Pumila*. Herbaceous: leaves ovate-oblong, imbricate; flowers sessile, subsolitary.

4. *Epacris Rosmarinifolia*. Shrubby: leaves linear, obtuse, rigid, sheathing; flowers solitary, lateral.

Ephedra; a genus of the class Diœcia, order Monadelphia.—GENERIC CHARACTER. *Male*. *Calix*: ament compounded of one-flowered scales, few, roundish, concave, length of the perianth; perianth proper, one-leafed, half two-cleft, roundish, inflated, small, compressed; divisions obtuse. *Corolla*: none. *Stamina*: filamenta seven, coalescing into a subulate pillar, divided at the tip, longer than the calix; antheræ roundish, turned outwards, of which four are inferior, the other three superior. *Female*. *Calix*: perianth five-fold, one placed on another, with alternate divisions, in an ovate figure, each one-leafed, somewhat ovate, two-parted, the exterior ones smaller. *Corolla*: none. *Pistil*: germen two, ovate, size of the last perianth, on which they are placed; styles simple, filiform, short; stigmas simple. *Pericarp*: none; calicine scales all thickened, succulent, constituting a divided berry. *Seeds*: two, ovate, sharp, on one side convex, on the other flat, compressed by the calix converging them on every side. ESSENTIAL CHARACTER. *Male*. *Calix*: of the ament two-cleft. *Corolla*: none. *Stamina*: seven. *Antheræ*: four inferior, three superior. *Female*. *Calix*: two-parted, five-folded. *Corolla*: none. *Pistil*: two. *Seeds*: two, covered with a berried calix.—These plants may be propagated by offsets, which they send forth in great plenty; for the roots creep under ground, and send forth suckers, which may be taken off to transplant in the spring. They love a pretty moist strong soil, and will endure the cold of our ordinary winters very well in the open air.—The species are,

1. *Ephedra Distachya*; *Great Shrubby Horse-tail*, or *Sea Grape*. Peduncles opposite; aments in pairs. It is a shrub, says Pallas, varying wonderfully according to its situation, sometimes a foot or eighteen inches high, sometimes only a finger's height, or even lower, prostrate or ascending; trunk fibrous, woody, often thicker than a finger, with some

branches spreading on the ground, and others, which are short and woody, rising and subdivided copiously into rush-like branchlets. The male plant is usually taller, with the aments of the upper joints commonly in pairs, opposite, on a peduncle issuing from one of the scales. The male aments are ovate, composed of three pairs of scales, decussately imbricate, somewhat fleshy, concave, rounded, greenish; in the bosom of each scale is a two-valved corolla, somewhat membranaceous, putting forth a stamina, standing out beyond the scales, having seven or eight globular yellow antheræ in a kind of raceme. Female aments usually solitary, larger, ovate-acute, composed of four pairs of scales, the upper ones gradually smaller. These scales, in a flourishing plant, when ripe become turgid, succulent, and of a beautiful scarlet colour, having two ovate-acute brownish-gray seeds, between the upper and most swelling scales. In dry soils, the scales continue almost the same, juiceless, yellowish-gray when ripe, with immature fruits, which have usually one seed only, and that barren. It is found in most of the southern parts of the vast Russian dominions; is common from the Volga to the Lena, and southward to Persia and India. The berries ripen in July and August; they are sweetish, mucose, and leave a little heat in the throat. They are eaten by the Russian peasants, and by the wandering hordes of all Great Tartary; the Calmucs and other Tartars also use them medicinally, in catarrhs, rheumatisms, &c.—Native of Siberia.

2. *Ephedra Monostachia*; *Small Shrubby Horse-tail*. Peduncles several; aments solitary. It flowers from September to November, strongly resembles the preceding, and is a native of most parts of Europe.

Ephelis: a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, spreading; segments roundish, acute. *Corolla*: petals five, having claws, roundish, spreading, emarginate, with the point, the length of the calix; nectary of ten scales, a pair to each petal fastened to the base, roundish, villose, smaller than the petals. *Stamina*: filamenta eight, bristle-shaped, longer than the corolla, inserted into a gland; antheræ four-cornered, roundish. *Pistil*: germen ovate, surrounded by a gland; style none; stigma blunt. *Pericarp*: capsule oblong, compressed, grooved on both sides, one-celled, two-valved. *Seeds*: two, kidney-form, fastened to one of the valves in the middle, one above the other. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five, with claws. *Nectary*: ten scales, two to each petal. *Capsule*: oblong, one-celled, two-valved, two-seeded.—The only known species is,

1. *Ephelis Guianensis*. This tree is fifty or sixty feet high, very much branched at top; the middle branches, or those in the centre, being the highest, and standing perpendicularly; the lower ones are more inclining and horizontal, and spread out to a great distance; they divide into many branchlets, furnished with alternate leaves, each of which is pinnated; the pinnules opposite, from four to six in number, entire, oval, pointed, of a smooth surface, and of a bright green; these pinnules or leaflets are sometimes eight inches in length. The flowers grow from the bosoms of the leaves, on long pedicels, divided at their extremities into several smaller ones; they are very small, and white.—The tree is a native of the forests of Guiana, and flowers in the month of October.

Epibaterium; a genus of the class Monœcia, order Hexandria.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth double, deciduous; outer six-leaved, very small, flat; inner three-leaved, three times the size of the other, with ovate spreading leaflets. *Corolla*: petals six, less than the

inner calix, roundish; three outer interposed between the calicine leaflets, three inner. *Stamina*: filamenta six, capillary, bowed inwards, the length of the petals; antheræ roundish. *Female Flowers*, on the same plant. *Calix* and *Corolla*: as in the male. *Pistil*: germen three, subglobular; styles three, bowed inwards, very small; stigmas compressed, spreading. *Pericarp*: drupes three, subglobular, mucronate with the permanent styles. *Seed*: nut kidney-form, compressed, slightly grooved. ESSENTIAL CHARACTER. *Calix*: double; outer six-leaved, small; inner three-leaved, large. *Petals*: six, three outer, between the calicine leaflets, three inner. *Drupes*: three, subglobular, mucronate, with three permanent styles enclosing a kidney-form nut.—The only known species is,

1. *Epibaterium Pendulum*; native of St. Jago.

Epidendrum; a genus of the class Gynandria, order Diandria.—GENERIC CHARACTER. *Calix*: spathes vague; spadix simple; perianth none. *Corolla*: petals five, oblong, extremely long, very spreading; nectary tubular at the base, top-shaped, placed downwards within the petals, with an oblique two-cleft mouth; the superior lip very short, three-cleft, the inferior lengthened into a point. *Stamina*: filamenta two, very short, sitting on the pistil; antheræ covered by the upper lip of the nectary. *Pistil*: germen slender, long, twisted, inferior; style very short, fastened to the upper lip of the nectary; stigma obscure. *Pericarp*: silique extremely long, columnar, fleshy. *Seeds*: numerous, extremely small. ESSENTIAL CHARACTER. *Nectary*: turbinate, obliquely reflex. *Corolla*: spreading. *Spur*: none.—Of the propagation of this genus of plants, Mr. Miller remarked, that by any art yet known they cannot be cultivated in the ground; but if that were possible, many of them would produce very fine flowers of uncommon forms. He informs us, that he had three species sent him from America, which he carefully planted in pots, and placed in a stove, where they just displayed their flowers, and soon after perished. Since Mr. Miller's time, however, many species of this fine and very singular genus have been introduced into our gardens, and some of them cultivated with success, by the superior skill of modern practice, which despairs not of rearing and preserving any plants, where expense is not regarded. It, however, certainly requires great skill and attention, to overcome the united difficulties which attend the cultivation of plants, which are at the same time of the Orchis tribe, and parasitical. Dr. Smith says, We have scarcely seen any one species of this genus, except in a dry state, before the year 1787, when the twenty-fourth species flowered for the first time in the stove at Kew; nor was it till October 1788, that the sixty-third species exhibited its fragrant and elegant bloom in the same rich collection. They are all cultivated in the stove, with very great heat: being mostly parasitical, they flourish best with fragments of half-rotten bark at their roots. They may be increased by parting their roots, or what are commonly called offsets, of which they have in general an abundance.—The species are.

* *Climbing*.

1. *Epidendrum Vanilla*; *Vanilla*, or *Vanilloe*. Leaves ovate-oblong, nerved, sessile, cauline, tendrils spiral; stem trailing, somewhat like common ivy, but not so woody, fastening itself to whatever tree grows near it, by small fibres or roots, produced at every joint, by which it may receive nourishment, when cut or broken off from the root a considerable height above ground. The leaves are as large as those of the Common Laurel, but not quite so thick; they are placed alternately at the joints, which are six or seven inches asunder, and are of a lively green colour above, but paler underneath. The stems

shoot into many branches, which also fasten themselves to the boughs of trees, and thus rise to the height of eighteen feet or more, spreading quite over smaller trees. The flowers are of a greenish yellow colour, mixed with white, and are succeeded by fruit six or seven inches long. The pods grow in pairs, are generally the thickness of a child's finger, and about five or six inches in length; they are green at first, then yellowish, and turn of a brownish cast as they ripen. The stalk is moderately slender, and throws out a long winding tendril, opposite to each of the lower leaves, by which it sticks to the branches or bark of the tree; but after it gains the top, these become useless, and the place of each is supplied by a yellow leaf. The manner of growth and flowering, the size of the flowers, fruit, and lens-shaped dark shining seed, without any aril, distinguish this from the other species. When the fruit turns of a yellowish colour, and begins to open, they gather it, and lay it in small heaps to ferment two or three days, in the same manner as is practised for the cocoa or chocolate pods; then they spread them in the sun to dry, and flat them with their hands, when they are about half dried; and afterwards rub them over with the oil of Palma Christi, or of the Cocoa; then they expose them to the sun again to dry, and afterwards they rub them over with oil a second time; then they put them in small bundles, covering them with the leaves of the Indian Reed, to preserve them. These plants produce but one crop of fruit in a year, which is commonly ripe in May, fit for gathering, for they do not let them remain on the plants to be perfectly mature, because then they are not so fit for use; but when they are about half changed yellow, they esteem them better for keeping than when they are changed to a dark brown colour, at which time the fruit splits, and shews a great quantity of small seeds, which are enclosed within it. While the fruit is green, it affords no remarkable scent; but as it ripens, emits a most grateful aromatic odour. When the fruit begins to open, the birds attack it, and devour all the seeds very greedily, but do not eat any other part of the fruit. Those which are brought to Europe are of a dark brown colour, about six inches long, and scarcely an inch broad; they are wrinkled on the outside, and full of a vast number of black seeds, like grains of sand, of a pleasant smell, like balsam of Peru. In England the Vanilla fruit is only used as an ingredient in chocolate, to which it gives a pleasant flavour to some palates, but which to others is equally disagreeable. The Spanish-American physicians employ it in medicine, and esteem it grateful to the stomach and brain, for expelling wind, as a diuretic, an antidote against poison, or a cure for the bite of venomous animals. The Spaniards, French, and Italians, not only use the Vanilla to give chocolate a delicate smell and agreeable flavour, but also to perfume snuffs and other substances. It yields a great quantity of oil and volatile salt.—Mr. Miller has another species, which he calls *Vanilla Axillaris*, distinguished by its oblong, blunt, compressed, jointed leaves, and axillary flowers. It was sent him from Carthage in New Spain, where it naturally grows. It has a climbing stalk, sending out roots from the joints like the other, and mounting to a great height. The leaves, which come out singly at each joint, are oblong, smooth, and jointed. The flowers come out from the side of the branches; they are shaped like those of the great Bee Orchis, but are longer; the helmet is of a pale pink; and the lip is purple. There are two or three varieties of the Common Vanilla, differing in the colour of the flowers, and length of the pods.

2. *Epidendrum Flos Æris*. Stem columnar, somewhat branched; leaves lanceolate; petals linear, obtuse. This plant is parasitical. The flowers resemble a spider.—Native of Java.

** *Stem upright, leafy.*

3. *Epidendrum Tenuifolium*. Leaves on the stem subulate, channelled.—Native of Malabar in the East Indies.

4. *Epidendrum Spatulatum*. Leaves on the stem oblong, alternate, obtuse, veinless; lip of the nectary bifid and divaricate.—Native of the East Indies.

5. *Epidendrum Furvum*. Caulescent: leaves imbricate, lanceolate; racemes axillary.—Native of the East Indies.

6. *Epidendrum Coccineum*. Leaves on the stem ensiform, obtuse; peduncles one-flowered, axillary, crowded. This is an elegant parasitical plant; roots round, numerous, fibrous, ash-coloured; stems several, scarcely attaining to a foot in height; before these spring, the flowers come forth in the axils of the root-leaves; they also come out from the axils of the stem-leaves successively as the stems advance; flowers void of scent, the whole, with the germen, scarlet, agreeing in character with the eighth species, except that the petals are ovate, acuminate, and concave.—Native of Martinico, where it is found in moist woods, particularly by the side of torrents: also in Jamaica, where, however, it is not common.

7. *Epidendrum Secuudum*. Leaves on the stem oblong, emarginate; stem compressed; spike directed one way; tube of the nectary length of the corolla. Parasitical: roots fibrous, white; stem round at bottom, gradually compressed, leafy, pendulous; leaves sessile, sheathing, alternate, spreading in two rows; the outmost tip emarginate, veinless; peduncle scape-form, often two feet long; flowers terminating, in form of a corymb, nodding one way, pale red or brown. It varies with a rounder and more compressed stem; leaves broader, or more acuminate; flowers terminating, or breaking out on the side; and tube of the nectary shorter or longer than the petals.—Native of the mountainous woods of Martinico and Jamaica.

8. *Epidendrum Lineare*. Leaves on the stem distich, linear, obtuse, emarginate; stem simple, from one to two feet long, erect, filiform, leafy, compressed a little, smooth. Parasitical: roots filiform, creeping, strict, white; sheaths radical, withering, whence the stems appear to be jointed; leaves alternate, approximating, sessile, sheathing, slightly streaked, smooth on both sides; sheaths of the leaves compressed; spike scarcely the length of the leaves; flowers in a sort of spike, sessile, alternate, imbricate, from six to ten, small, and blood-red; spathes sheathing under the flowers, coloured; corolla three-cornered, gibbous at the back; the three outer and the two inner petals almost equal, oblong, concave, blunt; the two outer in front vaulted, compressed at the tip; nectary of the same shape with the inner petals, erect, embracing the column at the base, having two dark purple spots at the edge, concave, blunt at top, blood-red: seeds extremely minute, dusty, and bristly; and, according to Jacquin, irregularly shaped like saw-dust.—It flowers in spring, and is a native of the woods in Martinico, and other of the West India Islands.

9. *Epidendrum Punctatum*. Leaves lanceolate, nerved; sheaths imbricate; scape panicled, and corollas dotted. The sheaths of the leaves, the panicle, and the petals, are dotted; hence the name.—Native of America.

10. *Epidendrum Caudatum*. Leaves lanceolate, nerved; scape panicled; petals spotted, tailed, two very long.—Native of America.

11. *Epidendrum Ovatum*. Leaves on the stem ovate, acute, stem-clasping, nerved; scapes panicled.—Native of the East Indies.

12. *Epidendrum Ciliare*. Leaves oblong, veinless; lip of the nectary three-parted, ciliate, the middle segment linear; stem two-leaved. This elegant plant is a foot and a half

high, and grows parasitically on the trunks of vast trees, from which it hangs down towards the ground; roots thick, fibrous, numerous; stem simple, smooth; leaves two, obtuse, quite entire, shining, veinless, coriaceous, flat, alternate in two rows, half a foot in length, erect like a hare's ears, each arising from an oblong, thick, striated, spongy body, forming the base of the stem; spike loose, composed of about ten handsome white flowers, four inches in diameter, all pointing one way.—Native of Martinico.

13. *Epidendrum Nocturnum*. Leaves oblong, veinless; lip of the nectary three-parted, quite entire, the middle segment linear; roots round, thick, filiform, whitish; stem from one to two feet high, simple, erect, round, many-leaved, smooth; leaves sheathing, alternate, substich, from two to three inches long, oblong, entire, thickish, veinless, shining; flowers terminating, two or three, sessile, large, whitish yellow; spathes a few, ovate, compressed; petals almost equal, lanceolate linear, spreading, the two inner narrower and white; seeds resembling saw-dust.—It smells very sweet during the night; and is a native of the mountain woods in Martinico and Jamaica, but not very common in the latter.

14. *Epidendrum Cucullatum*. Leaves subulate; scape one-flowered; lip of the nectary ovate, ciliate, acuminate; petals elongated.—Native of America.

15. *Epidendrum Teres*. Stem sheathed with the rudiment of the leaves, decumbent; leaves columnar, alternate, fleshy, sharp, a finger's length; roots several, filiform, flexuose, creeping.—Native of Japan.

** *Scape naked; Leaves radical.*

16. *Epidendrum Nodosum*. Leaf single, subradical; spathe containing about four flowers; roots thick, numerous, filiform, strict, whitish, knee-jointed; stem one-leaved, thick, round, sheathed, a foot high, thickened towards the roots, knotted; sheaths closed, alternate, closely surrounding the stem, keeled, streaked, membranaceous, whitish; petals three outer, lanceolate linear, long, spreading, two inner linear; germen very long, round, filiform; stigma moistened in front under the cavity of the antheræ; capsules an inch long, oblong, pendulous, six-grooved, three-valved, many-seeded; seeds dusty, bristly.—It flowers in the spring, and is a native of the West Indies, where it is usually found near the sea-coast.

17. *Epidendrum Carinatum*. Leaves oblong, obtuse, compressed, jointed.—Native of this Philippine islands, growing upon trees.

18. *Epidendrum Aloifolium; Aloe-leaved Vanilla*. Leaves oblong, obtuse, broader at the end; root thick, fungous, crinite, knobbed, parasitical; leaves several from the knob of the root, from two to three feet long, and two fingers' broad, smooth, shining, brownish green, thick; flowering-stems several, undivided, round, green, shining; three of the petals are narrow, oblong, a fine red colour within, with white edges, on the outside white and green, in streaks, with a tinge of red; nectary yellow, with red lines. It grows on different trees.—Native of Malabar.

19. *Epidendrum Guttatum*. Leaves lanceolate, channelled; petals wedge-shaped, retuse. From a matted root this sends out several leaves three inches long, and not a quarter of an inch broad, almost triangular, and of a yellowish green colour; from the midst of these comes the flowering-stalk; each flower is made up of four little white petals, spotted with brown, and one large one with fewer spots, on which is a small yellow hood, and opposite to it one like it of a blue colour, on pedicels an inch long, round the top of the stalk.—Native of Jamaica, where it grows on the Ebony trees.

20. *Epidendrum Juncifolium*. Leaves subulate, furrowed;

scape and petals dotted; lips without dots, dilated.—Native of America.

21. *Epidendrum Scriptum*. Leaves ovate-oblong, three-nerved; flowers racemed, spotted.—Native of the East Indies.

22. *Epidendrum Retusum*. Leaves linear, retuse at the end, in two rows; flowers racemed, spotted. It is three feet in height; root white, woody, bent in, curled, fixing itself into the bark of trees by its capillary hairy fibres; stem rising between two rows of leaves, simple, shining, smooth, marked with rings; the leaves which come out from the top of the stem, and, when dry, constitute the stem itself, are oblong, narrow, equally thick and broad on every side, folded together, smooth, shining, without any visible veins or nerves; flowering-branches ten or twelve together, rising straight from among the leaves, green, rigid, accompanied at the base by abundance of very minute whitish buds, gradually enlarging, but not opening till they have acquired a considerable size; all the flowers opening together invert the stem, and resemble a fox's tail; they are on whitish peduncles, issuing from a small acute bracte, stiff, thick, oblong, irregular, whitish, spotted with red, blue, and lucid colours.—Native of Malabar, where it flowers in April and October, the flowers continuing two months; and a branch set in water will flower for a month.

23. *Epidendrum Amabile*. Leaves broad-lanceolate, veinless, like *Crinum* or *Squills*, fleshy, half a foot long; petals lateral, orbiculate; roots thick, like packthread; stem two feet high, naked, surrounded by a few acute very short scales; flowers snow-white, like those of *Orchis Susannæ*, the size of *Narcissus* flowers; the two side-petals are orbiculate, the three others arc ovate; cowl three-leaved, the two side ones long, the middle hastate, bifid, with two awl-shaped, bristled. Osbeck observed it in the East Indies. Rumphius also saw it growing on the branches of trees on the coast of Java. The flowers are large and odoriferous: when laid in a room, they do not wither for several days, and fill it with a most agreeable perfume. On the island of Ternate, none but princesses are allowed to wear this precious flower.

24. *Epidendrum Cochleatum*. Leaves oblong, double, smooth, streaked, growing on the bulb, involved in membranaceous sheaths; scape many-flowered; nectary cordate; roots filiform, strict, whitish; flowers terminating, four or five, large, subsessile; petals linear, acuminate, reflex, yellowish; nectary lip heart-shaped, blunt, concave, dark blood-red, streaked with white at the base, yellow at the tip.—It flowers here in January and February, and is a native of the mountainous parts of Jamaica. This is the first of the tribe that ever flowered in England. It is cultivated in a stove, in rotten bark, contrived so as to imitate its natural situation in the clefts of aged trees, with occasional supplies of water.

25. *Epidendrum Tuberosum*. Leaves broad-lanceolate, nerved, membranaceous, growing on the bulb; scape sheathed; nectary boat-form, bifid.—Native of America.

26. *Epidendrum Pusillum*. Leaves ensiform, somewhat fleshy, acute, all radical; scape few-flowered, between each of the leaves solitary, the length of the leaves, with three or four minute leaflets scattered over them; root fibrous; plants little more than an inch high; flowers terminating, one or two, from a three-valved glume, the three uppermost petals spreading, oblong, the uppermost very small, the two inner toothed; lip trifid, the side lobes subcordate, the middle larger, bifid; or, according to Allamand; petals ovate-oblong, acute; upper lip of the nectary ampullaceous, tubular, emarginate, lower very large, sinuate, with four lobes on each side, opposite, equal; capsule spherical, six-keeled.—Observed by Dhalberg in Surinam.

27. *Epidendrum Ensifolium*. Stem round, even; leaves ensiform; petals lanceolate; lip lanceolate, recurved, dotted; root perennial, consisting of a few thick fleshy fibres. Leaves radical, several, equitant, erect, clothed with some brown permanent scales at the base, rigid, rather sharp-pointed, with a rough margin towards the top, channelled, nerved, smooth on both sides, when dry becoming longitudinally striated; stalk growing on the outside of the leaves, and not quite so long, erect, simple, brown, bearing from four to six flowers, and furnished with three or four alternate, sheathing, acute, striated, brown scales, and compressed towards the top; flowers alternate, sessile, a little drooping; bractes solitary, resembling the scales on the stalk, but smaller. The flowers have a sweet lemon-like odour, pungent, but not strong, most powerfully perceived at night, or on entering the hot-house in a morning: on account of this perfume the plant is much cultivated in China.—Native of China and Japan.

28. *Epidendrum Monilliforme*. Stem round, jointed, streaked, necklace-form, naked, quite simple; leaves linear, acute.—This is a parasitical plant, with white flowers, observed at Misima in Japan, by Thunberg, during his travels through that country; who says it was tied up in bundles, and hung out before a house. It can live several years without water, or other nourishment, and yet grow and flower all the while.

29. *Epidendrum Ophioglossoides*. Stem one-leaved; flowers racemed, pointing one way.—Native of America.

30. *Epidendrum Ruscifolium*. Stem one-leaved; flowers from the sinus of the leaf, aggregate; roots numerous, filiform, rigid, whitish. Stems aggregate, often united at the base, filiform, a foot high, erect, sheathed, smooth; leaf terminating, ovate-lanceolate, half the length of the plant, acuminate, entire, keeled, channelled at the base, compressed, smooth, thick, veined; sheaths of the stem long, acuminate, streaked, withering; peduncles short, two-flowered.—Native of the high mountains of Jamaica, where it is found on the trunks of old trees; and in the thick woods of Martinico.

31. *Epidendrum Graminifolium*. Stem one-leaved; flowers from the sinus of the leaf in pairs.—Native of America.

32. *Epidendrum Capense*. Scape naked; leaves imbricate in two rows, linear, obtuse; flowers directed one way; horn very long; parasitical.—Native of the Cape of Good Hope.

33. *Epidendrum Fuscatum*; *Brown Epidendrum*. Stems simple; leaves oval; peduncle terminating, elongated, scaly; lip of the nectary five-lobed, the middle lobe minute. Flower-stalk erect, very long, simple, compressed, with many knotty joints, smooth, green, but entirely covered with brown, membranaceous, sheathing scales, which are alternate, sharpish, compressed, keeled, and ribbed; spike terminating, erect, forming a globose dense head of many small flowers; bractes solitary under each flower, lanceolate, concave, acute, purplish-green, one-third the length of the germen; flowers pale greenish purple, with a faint herbaceous smell.—Native of Jamaica.

34. *Epidendrum Tripterum*; *Triangular-fruited Epidendrum*. Leaves from a bulb and from the root sword-shaped; stalks radical, sheathed, many-flowered; germen three-winged; lip equal to the petals; roots of a few thick, fleshy, long, and nearly simple fibres, slightly downy; bulbs above ground, numerous, ovate, but little compressed, smooth, green, somewhat glaucous, an inch long; stalks thrice as high as the bulbs, erect, thickly covered at the base with smaller, concave, bluish, reddish scales, imbricated in a two-fold order, in the upper part roundish, ending in a cluster of many flowers; flowers on footstalks, spreading, white, and scentless.—Native of Jamaica.

35. *Epidendrum Barringtonæ*; *Large-flowered Epidendrum*. Leaves broad-lanceolate, nerved, arising from a bulb; peduncles radical, mostly single-flowered; lip fringed; column with a cover; root consisting of numerous branched fleshy fibres, brown, downy, and divaricating; bulbs several above the surface, large, ovate, slightly compressed, smooth, green, with an unequal and somewhat furrowed surface; flower-stalks three inches high, nearly erect, bearing one flower, rarely two, round, green, smooth, clothed with four or more sheathing alternate scales, which are ovate, concave, green, with a rusty-coloured powdery down; flowers from the uppermost scale, a little drooping, and inodorous; petals lanceolate, obtuse, somewhat succulent, slightly spreading, greenish, towards the tips of an olive brown, the two innermost rather the smallest, the two lowermost lengthened out at the base, and united into a short blunt pouch; lips of the nectary arising from the back part of the inside of this pouch, unconnected with every thing above, somewhat shorter than the petals, covered on its upper side with an oblong, yellowish, deeply-furrowed callosity, inversely heart-shaped in front; its margin is three-lobed, the lateral lobes small, acute, entire, erect, thin, and transparent; nectary very large, of a rusty brown, blunt, hollowed above, swelling below, pale, and beautifully fringed all round the margin; column of the fructification white, elongated at the base, connected by its back to the pouch of the corolla, and by its forepart at the bottom to the lip of the nectary, incurved, and blunt at the top, behind obtusely keeled, flat, and with two slight furrows before; cover pointed, obscurely three-celled within; stamina red, close together; antheræ red, two on each filamentum, obovate, yellow; stigma large, very much excavated; germen somewhat longer than the pouch of the flower, green, nearly cylindrical, with six furrows. This is the most distinguished of the species hitherto introduced among us, not only on account of its size, but its singularity.—Native of Jamaica.

36. *Epidendrum Claviculatum*. Stem climbing, round, branching; leaves sessile, half stem-clasping, acute, concave, recurved, rigid. This plant hangs down from the branches of trees, and creeps up others to the height of forty feet. *Observe*. The stem is jointed at the distance of five inches, and at every joint there are fibres three or four inches long, catching hold, by their broad viscid end, of any part of a tree they come near; it is about three-quarters of an inch in diameter, very smooth, round, and deep green, solid, juicy, and sometimes branched; here and there, opposite to the tendril, comes out a thin membranaceous leaf, from a broad beginning, ending in a point.—Native of Jamaica and Hispaniola.

37. *Epidendrum Ramosum*. Stem very branching, suffrutescent; leaves linear, emarginate; racemes terminating, compressed. This plant is a foot and a half high, leafy, parasitical; roots fibrous; branches compressed a little, smooth, ash-coloured; leaves oblong, obtuse, coriaceous, rigid, veinless, entire, shining, sheathing at the base, dirty green, alternate, an inch and a half long; spathes cordate-ovate, acute, converging; spikes loose, distich, an inch and a half long, generally four-flowered; flowers small, inelegant, greenish; petals somewhat rigid, equal in length, the three outer lanceolate, the two inner linear; lower lip of the nectary oblong-cordate, acuminate, concave, rigid, the length of the petals, of which it occupies the place of the third interior one; antheræ roundish.—Native of Martinico and Jamaica.

38. *Epidendrum Nutans*. Stem simple; leaves ovate-lanceolate, nerveless, stem-clasping; spike terminating, nod-

ding; lip of the nectary three-lobed, the middle lobe three-toothed.—Native of Jamaica.

39. *Epidendrum Umbellatum*. Stem simple; leaves ovate, emarginate, stem-clasping, veinless; flowers terminating, unilobed. Parasitical; smooth, seldom a foot in height: roots round, fibrous, ash-coloured, numerous; stems round, leafy, commonly horizontal, or pendulous; leaves oblong, coriaceous, pale green, sheathing, clothing the whole stem, alternate, an inch or an inch and a half in length, mostly difform; spadix very short, concealed within the sinus of the terminating leaf, with about five leaves; spathes very few; flowers somewhat fetid, greenish-white, rigid.—Common in the vast woods of Martinico, and in Jamaica.

40. *Epidendrum Aneeps*. Leaves cordate-lanceolate, stem-clasping, horizontal; raceme terminating, compressed, ancipital, subflexuose; flowers distich; inner petals capillary, with a three-lobed lip.—Native of Jamaica.

41. *Epidendrum Rigidum*. Leaves oblong, obtuse, sheathing; raceme terminating, compressed, ancipital; flowers distich, larger than the spathes; lip entire, cordate-ovate, acute. Parasitical; a foot high; roots fibrous, ash-coloured, round, numerous; stems simple, round, leafy, ending in a very loose distich spike, four-flowered.—Native of woods in Martinico and Jamaica.

42. *Epidendrum Diffusum*. Leaves oblong, stem-clasping; stem ancipital; panicle terminating, very much branched, diffused; lip entire, acuminate.—Native of Jamaica.

43. *Epidendrum Montanum*. Leaves lanceolate, flat, recurved, spreading, submembranaceous; raceme terminating, simple; flowers pointing one way; lip trifid.—Native of Jamaica.

44. *Epidendrum Serrulatum*. Stems aggregate, subdiphylous; leaves lanceolate, keeled, serrulate, raceme terminating; flowers distich.—Native of Jamaica.

45. *Epidendrum Teretifolium*. Leaves semicylindric, stem one-flowered; lip three-sided at the tip.—Native of Jamaica.

46. *Epidendrum Globosum*. Leaves cylindric; channelled; flowers terminating, subsolitary; lip ovate, acute; capsules globular. Roots fibrous, round, ash-coloured, numerous, parasitical; stem cespitose, quite simple, two or three inches high, round, smooth, leafy, ending in a spadix, bearing one flower, seldom two, very seldom three, whence there are very few spathes; leaves awl-shaped, acute, smooth, shining, somewhat rigid, sessile, alternate, an inch long; flowers small, scarcely coloured, erect.—Native of the woods of Martinico and Jamaica.

47. *Epidendrum Sertularioides*. Stem filiform, creeping, jointed; leaves lanceolate; peduncles one-flowered, from radical sheaths.—Native of Jamaica.

48. *Epidendrum Testæfolium*. Stem creeping; leaves incumbent, elliptic, concavo-convex, keeled; flowers sessile under the leaves.—Native of Jamaica.

49. *Epidendrum Undulatum*. Leaves elliptic, acute; scape sarmentose, very much branched; petals ovate, clawed, obtuse; lip dilated, emarginate, waved. This is parasitical, and the largest of the kind; roots large; stalk round, tough, brown, crooked, six feet high, with joints at every eight or nine inches' distance, where are branches standing straight out, with several flowers on peduncles an inch long; leaves many, smooth, dark green.—Native of Jamaica.

50. *Epidendrum Variegatum*. Leaves lanceolate, keeled, channelled, cartilaginous, serrate on the edge; sheaths imbricate; scapes sheathing, with a simple raceme; lip cruciate, two-lobed. This is an elegant parasitical plant: roots round, ash-coloured, fibrous; leaves radical, awl-shaped, acuminate, keeled, somewhat rigid, coriaceous, obtusely angular on the

back, with acute angular margins, pale green, sometimes rugged, with rust-coloured dots, sometimes without, and quite smooth, from an inch and a half to six inches in length; scape round, slender, from a foot to two feet in length; flowers sweet-smelling, elegantly variegated with purple, violet, yellow, and red; petals four.—Native of the woods in Jamaica and Hispaniola.

51. *Epidendrum Utricularioides*. Leaves lanceolate, marked with lines, flat; scape panicle; lip large, heart-shaped; horn very short.—Native of Jamaica and Hispaniola.

52. *Epidendrum Triquetrum*. Leaves three-sided, cultrate, compressed at the tip, lanceolate, acute; scape simple; lip heart-shaped, ovate; sides emarginate.—Native of Jamaica.

53. *Epidendrum Sessile*. Leaves compressed at the base, broader at the top, lanceolate-linear, obtuse, veinless; peduncles radical, very short, one-flowered.—Native of Jamaica.

54. *Epidendrum Flabelliforme*. Leaves compressed at the base, dilated at top, ovate-lanceolate, acute, flat, nerved; peduncles one-flowered, elongated.—Native of Jamaica.

55. *Epidendrum Subulatum*. Leaves awl-shaped, grooved; peduncles sheathed, radical, many-flowered.—Native of Jamaica.

56. *Epidendrum Satyrioides*. Leaves subulate, cylindric; scape few-flowered; corollas ventricose at the base in front.—Native of Hispaniola.

57. *Epidendrum Tribuloides*. Leaves pedicelled, lanceolate, obtuse, emarginate; peduncles very short; capsules globose, echinate.—Native of Jamaica.

58. *Epidendrum Corniculatum*. Leaves pedicelled, wedge-shaped, oblong; peduncles radical, one-flowered; corollas acuminate, curved.—Native of Jamaica.

59. *Epidendrum Lanceolatum*. Leaves pedicelled, lanceolate, acute; peduncles from radical sheaths, two-flowered.—Native of Jamaica.

60. *Epidendrum Angustifolium*. Leaf linear, growing upon the bulb; scape panicle.—Native of Jamaica.

61. *Epidendrum Palmifolium*. Leaves broad lanceolate, nerved, membranaceous, growing on the bulb; peduncles radical, sheathed, many-flowered; nectary boat-shaped, entire, reflex.—Native of Jamaica.

62. *Epidendrum Altissimum*. Leaves lanceolate, growing on the bulbs; scape very much branched, sarmentose; petals oblong, lanceolate, acute; lip obovate, shorter than the petals. This is an elegant parasitical plant: roots round, fibrous, ash-coloured, numerous; leaves acute, ensiform, oblong, veinless, shining, quite entire, thickish, an inch wide, and half a foot long, keeled at the base, in other parts flat, each springing from a joint, or an ovate-compressed smooth tuber, sometimes as big as a goose-egg, which is placed on the base of another root-leaf or two, like the others; between this and the joint arises a solitary, round, smooth scape, of a rust colour, slender, inclined, four feet high, racemed at top, clothed at the peduncles and joints with membranaceous, lanceolate, ash-coloured spathes; peduncles two or three flowered, alternate, in two rows; flowers without scent, yellow, with brown spots, numerous; petals oblong, distinct, acute at both ends, waved, nearly equal.—Native of the woods of Martinico.

63. *Epidendrum Fragrans*. Leaf broad-lanceolate, nerveless, growing on the bulb; scape many-flowered, abbreviated; lip heart-shaped; nectary pale, streaked with red. The flowers have a sweet smell.—It flowers in October, and is a native of Jamaica.

64. *Epidendrum Sanguineum*. Leaves in pairs, oblong, growing on the bulb; scape many-flowered, subflexuose; lip

roundish, waved, emarginate; horn adnate. It has many thick white fibres, like those of Leeks, or the tendrils of Ivy, taking firm hold of the bark of trees, and matted together; these send out one thick, greenish, roundish, compressed, bulbous, or tuberous leaf, of an inch diameter, covered with some brown withered filamenta; from the top of this come two smooth, striated, hollow, hard, pale green leaves, three inches long and one broad, between which springs out a naked, brown, jointed, round, smooth stalk, about a foot high, near the top of which stand several long, reddish, purple flowers.—Native of Jamaica, where it is found in the savanna woods, growing upon the Ebonies and other trees.

65. *Epidendrum Labiatum*. Leaves radical, oblong; middle bulb solitary, one-leaved; scapes few-flowered; lip oblong, with a fleshy corpuscle growing to it at top.—Native of Hispaniola.

66. *Epidendrum Polybulbon*. Stem creeping, bulb-bearing; bulbs two-leaved, one-flowered; flower peduncled; lip heart-shaped.—Native of Jamaica.

67. *Epidendrum Proliferum*. Caulescent: leaves distich, subimbricate, ovate; bulbs from the sheaths of the leaves two-leaved; flowers axillary, sessile.—Native of Jamaica.

68. *Epidendrum Vestitum*. Stem leafless, imbricate all round with sheaths, roundish, bulb-bearing; bulbs growing on the leaf; flowers crowded from the sheaths of the stem.—Native of Jamaica.

69. *Epidendrum Vomiforme*. Caulescent: leaves growing on the bulbs, ovate-acuminate, convex, channelled, three-sided beneath; scapes from the bosom of the leaves.—Native of Jamaica.

70. *Epidendrum Echinocarpon*. Stem compressed, decumbent, one-flowered; leaves imbricate all round, distich, ovate; capsules muricate. Roots small, branched, fibrous; stems pendent, simple; leaves alternate, numerous, small, reflex, quite entire, subtomentose, stem-clasping. From the axils of the leaves, flowers solitary, on very short peduncles; corolla of a coral red colour, the upper and the two lower petals of the same size and figure, the two lateral ones larger and wider; nectary small, three-lobed, the two upper lobes rounded and concave, the lower emarginate; capsule red, ovate, warted.—Native of Guiana, where it is found on the trunks of old trees, which are sometimes found quite covered with it.

71. *Epidendrum Trichocarpon*. Stem compressed, round, rooting; leaves imbricate all round, distich, linear; capsules tomentose.—Native of Jamaica.

72. *Epidendrum Glaucum*. Stem compressed, almost upright, many-flowered; leaves imbricate all round, distich, broad lanceolate, very smooth, glaucous beneath; capsules naked.—Native of Jamaica.

73. *Epidendrum Graminoides*. Stem erect, compressed, many-flowered; leaves imbricate all round, distich, remote, linear; peduncles longer.—Native of Jamaica.

74. *Epidendrum Micranthum*. Stem one-leaved; leaf broad lanceolate; raceme very long, filiform; flowers pointing one way, roundish, six-cornered.—Native of Jamaica.

75. *Epidendrum Trigoniflorum*. Stem one-leaved; leaf oblong-lanceolate; raceme the length of the leaves; flowers mostly pointing one way, three-cornered. This is a small parasitical plant, only about four inches high; roots fibrous, whitish, numerous; leaf cauline, acute, quite entire, coriaceous, rigid, veinless, flat, shining, two or three inches long; flowers small, directed all to the same side, without scent, on short peduncles, of a dirty yellow colour.—Native of the mountain woods in Jamaica and Martinico.

76. *Epidendrum Racemiflorum*. Stem one-leaved; leaf

ovate; raceme longer than the leaves; flowers pointing one way, inner petals ovate.—Native of Jamaica.

77. *Epidendrum Alpestre*. Stem one-leaved; leaf ovate-lanceolate; racemes loose; keels of the capsules muricate.—Native of Hispaniola.

78. *Epidendrum Laxum*. Stem one-leaved; leaf oblong; raceme the length of the leaves; inner petals awl-shaped; lip ovate; capsules naked.—Native of Jamaica.

79. *Epidendrum Ovalé*. Stem one-leaved; leaf ovate, acuminate; raceme pressed close, many-flowered; petals roundish, the inner ones remote in front at the base; capsules pedicelled.—Native of Jamaica.

80. *Epidendrum Pulchellum*. Stem one-leaved; leaf roundish, acute; raceme loose, few-flowered; petals acuminate, ciliate, the inner one crossed at the tip.—Native of Jamaica.

81. *Epidendrum Tridentatum*. Stem one-leaved; leaf ovate-acute, three-toothed at the tip; raceme many-flowered; flowers three-sided, acuminate; petals of the nectary erect, bowed inwards.—Native of Jamaica.

82. *Epidendrum Cochlearifolium*. Stem one-leaved; leaf orbiculate, concavo-convex; raceme few-flowered.—Native of Jamaica.

83. *Epidendrum Funale*. Leafless, filiform, rooting; peduncle two-flowered; lip two-lobed; horn very short, awl-shaped.—Native of Jamaica.

84. *Epidendrum Filiforme*. Leafless, filiform, rooting; peduncles subtriflorous; lip ovate; horn very short, headed at the tip.—Native of Hispaniola.

85. *Epidendrum Concretum*. Leaves radical, lanceolate-acute; nectary concrete with the petals. This plant is parasitical, and only a foot high; roots fibrous, whitish, thick, round, long; leaves radical, two, three, or four, lanceolate-acute, coriaceous, flat, stiffish, quite entire; scape simple, compressed, erect, ten-flowered, or thereabouts; common peduncles few, lateral, few-flowered; flowers small, sessile.—Native of Martinico.

86. *Epidendrum Cebolleta*. Leaf radical, single, awl-shaped, knot-rooted; raceme compound. It is a parasitical plant; roots round, fibrous, numerous.—Native of Carthage, especially in the woods on the coast. The leaf of this plant is smooth and fleshy, a finger in thickness at the bottom, and from one to two, or sometimes four feet in length, ending at the base in a knot or roundish tubercle, permanent after the leaf is decayed. The natives call it *Cebolletas*, (Cibouls,) or little bulbs, and make use of the tubercles, triturated with salt, in violent contusions, fractures, &c. It is entirely void of smell.

87. *Epidendrum Spathulatum*. Leaves bifarious, alternate, approximating, præmorse, with a double tip, coriaceous, scarcely a foot long; peduncles axillary, almost erect, sometimes pendulous, round, smooth, jointed, woody at the joints, bracted, undivided half way, a foot and a half long, within the raceme angular; pedicels spreading very much, scattered, bracted at the base, round, smooth, white, the length of the flowers; bractes oblong, pressed close, acute, rust-coloured; petals united at the base to the nectary, flat; two lateral spreading very much, ovate, broad, acute, larger; three inferior obovate, the middle one largest, all snow-white, with a large rose-coloured one at the end.—Native of the East Indies.

88. *Epidendrum Variegatum*. Leaves alternate, spreading, sheathing, ovate-acute, three-nerved, waved, smooth, variegated; stem none; scape erect, a palm high, solitary, seldom two, angular, striated, smooth, coloured, terminated by an oblong raceme; peduncles simple, subalternate, spreading very much, roundish, club-shaped, striated, coloured, scarcely the length of the flowers.—Native of the East Indies.

89. *Epidendrum Calceolariae*. Leaves bifarious, alternate, remote, spreading very much, awl-shaped, thick, smooth; roots capillaceous, numerous, flexuose, whitish; stems many, crowded, roundish, flexuose, jointed, perennial, scarcely a span high; racemes terminating, simple; flowers remote.—Native of the East Indies.

90. *Epidendrum Hexandrum*. Leaves bifarious, alternate, spreading, a little sessile, ending in sheaths, somewhat removed, lanceolate, emarginate, with a point, rigid; root capillaceous, flexuose, white, parasitical; stems several, round, naked a little way above the root, the rest covered with oblong, tubular, acute, striated, rigid, whitish scales. The whole plant is scarcely a foot high; the leaves are smooth, and the flowers white.—Native of the East Indies.

91. *Epidendrum Ophrydis*. Leaves alternate, sheathing, from erect spreading, ovate, acute, quite entire, nerved, smooth; a little bulbed on the surface, membranaceous, shorter than the scape, ending in tubular, keeled, smooth sheaths; roots fibrous, filiform, hirsute, white, fixed in the ground; scape erect, clothed with sheaths and leaves, round, grooved, acute, red, with recurved, linear, acute, smooth, green, long stipules, scattered over it, a foot high or more; spike erect, cylindrical, closely set with blood-red flowers, a palm and a half in length, the thickness of the middle finger.—Native of the East Indies.

92. *Epidendrum Supplex*. Leaves crowded, sword-shaped, sheathing, compressed, quite entire, acute, smooth, fleshy. This plant grows upon trees by capillaceous fibres, a little compressed; stem none; spikes terminating, naked at the base, filiform, longer than the leaves, scarlet.—Native of the East Indies.

93. *Epidendrum Orchideum*. Leaves bifarious, alternate, sessile, spreading, lanceolate, quite entire, acute, smooth, fleshy, rigid. This plant is parasitical by means of filiform, branched, smooth, green fibres; stems simple, pendulous, jointed, leafy, flexuose, sheathed, thicker than the roots, two feet long, and a little more slender at the base; flowers above the leaves usually solitary; spathes heart-shaped, small, somewhat fleshy, yellow, caducous; petals lanceolate, yellow, with large darker spots; the two upper ones ascending, the middle one spreading from the lower petals; the two lateral ones larger, more reflexed towards the back, narrower, all concavo-convex.—Native of the East Indies.

94. *Epidendrum Pusillum*. Shoots in bundles, appressed, a span long; racemes solitary, simple, upright, compressed, naked at bottom, toothletted towards the tip, smooth; roots capillaceous, few, white; parasitical; shoots in bundles, pressed close to the bark, little branched, sometimes jointed, unequal, a span long, hoary, green; racemes half an inch long, green rust-colour; flowers alternate, spreading; petals fastened to the nectary, erect, linear-lanceolate, acute, a little longer than the nectary, equal, yellow; nectary truncated at the base.—Native of the East Indies.

95. *Epidendrum Complanatum*. Leaves alternate, sessile, spreading, linear, moon-shaped, retuse, smooth; upper surface concave; lower keeled, fleshy; roots filiform, very long, whitish-green, parasitical; stem, with the long roots, commonly pendulous, roundish, sheathed with leaves, simple, short; leaves scarcely a span in length; petals linear, acute, pendulous, smooth, narrow, yellow.—Native of the East Indies.

96. *Epidendrum Clavatum*. Leaves alternate, sessile, spreading, a little linear, club-shaped, with two unequal teeth at the end, smooth, flat, having a large nerve, depressed above, permanent beneath; roots filiform, white, parasitical; stems at the threads of the roots pendulous, round, sheathed

with leaves, short; leaves bright green; spikes short, opposite to the leaves, spreading very much, peduncled, club-shaped; peduncles roundish, smooth, with a few coloured dots, woody, scarcely the length of the leaves; bracts solitary, pressed close, heart-shaped, smooth, rigid towards the middle of it; corolla six-petalled, or more properly one-petalled, five segments spreading, linear-lanceolate, nearly equal, yellow, long.—Native of the East Indies.

97. *Epidendrum Subulatum*. Leaves alternate, erect, sessile, awl-shaped, cylindrical, smooth, acute; sheaths obtuse, margined, smooth, with minute dark purple dots, short; roots filiform, smooth, white, parasitical; stems simple, erect, round, smooth, sheathed, short; leaves a span long; nectary in the disk of the flower, surrounded by the lower petals, semicylindric, obtuse, smooth, snow-white, with the edge of the blunt apex of a most elegant carmine colour; antheræ two, sessile on the truncated concave body, enclosed in the scalelet, yellow; silique filiform, smooth, roundish.—Native of the East Indies.

98. *Epidendrum Nudum*. Stem none; peduncles simple, one-flowered, with two or three smooth membranaceous tubular sheaths, investing the younger peduncles with an oblique mouth, caducous; roots filiform, branched, smooth, green, parasitical; peduncles several, round, woody, sheathed, jointed; corolla monopetalous, irregular; tube erect, capillaceous, with hairs scattered over it, snow-white, long; border double, lower four-parted.—Native of the East Indies.

99. *Epidendrum Tomentosum*. Leaves from the bulbs usually four, seldom two or three, alternate, almost erect, bifarious at the base, half sheathing the bulb, oblong, quite entire, acute, concave, recurved at the tip, smooth, eight-nerved, fleshy; roots parasitical, filiform, round, clothed with scales, flexuose from one bulb to another, the thickness of a goose-quill, putting out bristle-shaped thickish fibres, especially below the bulbs, of a chestnut colour; bulbs above the root almost erect, sessile, obovate, compressed, wrinkled, terminated by leaves, scarcely the size of a hen's egg; flowers racemed, distich, subalternate, peduncled; peduncles spreading, round, covered with a chestnut nap, shorter than the spathes; corolla irregular, consisting of double petals; the outer monopetalous, navicular, ascending.—Native of the East Indies.

100. *Epidendrum Bidentatum*. Leaves sheathing each other, three or four, seldom five, sword-shaped, bifarious, sessile, quite entire, with two sharp toothlets at the tip, smooth on both sides, keeled at the back; roots filiform, slightly complicated, a little flexuose, smooth, whitish-green, very long; stem scarcely any; corolla six-petalled, fastened to the germen below the nectary; the two lateral ones are obliquely ovate, erect, smooth, yellow; the three surrounding the back of the nectary, erect, of these the two more lateral ones are lanceolate, the third outer one is broader and ovate; filamentum single, fastened to the truncated body, flat, membranaceous, white, short; silique oblong, angular.—Native of the East Indies.

101. *Epidendrum Lycopodioides*. Stems crowded at the roots, pendulous, simple, compressed; leaves alternate, bifarious, sheathing one another at the base, pressed close above the sheaths, lanceolate, acute, a little margined, smooth, fleshy; roots simple, filiform, slender, flexuose, scariose, hoary, green, fastened to the bark of the Mangostan-tree; stems three or more, sometimes, but seldom, above a foot long; spikes terminating, solitary, peduncled, cylindrical, acute, resembling spikes of Wolf's Claw Moss, (*Lycopodium*,) but not so thick, and two inches long; flowers sessile, closely approximating, covered with heart-shaped, ciliate, appressed,

membranaceous, pale green, caducous spathes; corolla six-petalled, unequal, fastened to a coloured germen, the uppermost petal spreading very much, pressed close to the spike, ovate, sometimes obcordate, concave; the two upper lateral ones reflex towards the back of the upper one, ovate, smaller, the two lower lateral ones more spreading, incumbent on the lower, ovate, acute, very small, a little thicker, and more coloured; the lower petal flat, heart-shaped, a little less than the uppermost; the whole corolla orange-coloured; filamenta none; germen club-shaped; silique ovate.—Observed by Kœnig at Malacca, growing upon the Tamarind.

102. *Epidendrum Longiflorum*. Leaves growing to the bulbs, solitary, subpetioled, erect, lanceolate, retuse; margin quite entire, recurved, smooth, fleshy, rigid, brittle; roots in bundles, filiform, flexuose, parasitical; stems creeping, filiform, unequal, with a whitish bark; leaves more than a palm in length, and two-thirds of an inch in breadth; bulbs sessile, incumbent, straightish, solitary, ovate, grooved, wrinkled, scarcely more than half an inch in length, yellowish green; scapes solitary by the side of the bulbs, simple, erect, round, smooth, jointed, scaly, shorter than the leaves; petals unequal; the two upper ones approximating, linear, oblong, curved at the base, and spreading, a little concave, ciliate at the edge, nerved, having very small hairs scattered over them; the two side ones upright, oblong, flat, membranaceous, small, scarcely longer than the truncated nectary. In the morning the flowers are spread out, and hence two petals are long, straight, and upright; in the afternoon they are pendulous.—Native of the East Indies.

103. *Epidendrum Flabellum*. Leaves solitary, one from each bulb, erect, petioled, lanceolate, oblong, quite entire, emarginate, a little recurved, obscurely nerved, smooth, fleshy, rigid; roots filiform, flexuose, simple, parasitical; stem none; bulbs above the roots closely crowded, ovate, quadrangular, wrinkled, the size of sparrows' eggs; leaves a palm long, and two-thirds of an inch broad; petioles semicylindric, channelled, a little twisted, short; peduncle at the base of the bulb pressed close by a sheath, and another sheath above the base, the rest naked, ending in an umbel in an erect flat semicircle, with from six to nine flowers in a row; pedicels erect, but spreading towards the end, a little curved to one side, round, smooth, coloured; corolla four-petalled, unequal; the upper petal erect, linear-lanceolate, with two teeth at the tip, and a large ovate hole at the base, where it appears to be tubular on account of the edges being bent back; it is white, with a purple base, and more than an inch long; the two side-petals are erect, obliquely lanceolate, a little incurved at the tips, the edges yellow, recurved, and ciliate, with golden hairs; they are longer than the nectary, and of a blood-red colour; the lower petal spreading, ovate, acute, inflated, striated, ciliate, membranaceous, scarcely so long as the side ones, of a yellow-red colour; antheræ double, subglobular, yellow, small.—Native of the East Indies.

104. *Epidendrum Saaronicum*. Leaves alternate, subbifarious, sessile, spreading, lanceolate, flattish above, even, streaked slightly, and having five more evident nerves, beneath smooth, with a small groove along the mid-rib, but no streaks, emarginate, fleshy, rigid; roots filiform in bundles below the bulbs on the stems, parasitical, flexuose, smooth, woody, whitish green, shining; stems subscandent, variously branched, compressed a little, smooth, jointed, sometimes sheathed, ferruginous, green, long; bulbs at the base of the branches; racemes terminating, simple, sometimes, though rarely, a foot and a half in length; flowers nodding; sheaths solitary, sessile, with scalelets between; corolla boat-shaped,

five-petalled, snow-white. It flowers in the morning, shutting after noon, during several days.—Native of the East Indies.

105. *Epidendrum Plantaginifolium*. Leaves bifarious, sheathing each other, erect, linear, three-sided, slightly channelled, sharpish, smooth, fleshy, narrow at the base, next the sheaths; roots fibrous, flexuose, parasitical; stem none; sheaths membranaceous, striated, margined, smooth, the breadth of the leaves, short; spike axillary, simple, peduncled, bifarious, erect, longer than the leaves; peduncle erect, smooth, compressed, a little jointed in the middle, having a large, oblong, acute, membranaceous, caducous bracte; the upper one has two or three alternate smaller bractes; flowers on very short alternate pedicels, having involucre at the base, which are lanceolate-ovate, acute, solitary, appressed, membranaceous, whitish, much longer than the pedicels; corolla six-petalled, three outer larger, all spreading a little, concave, membranaceous, whitish; nectary a truncate body, very small, covered by an inflated, semiglobular membrane; antheræ two, twin, fastened to a single filamentum, oblique, ovate-oblong, obscurely angular, smooth; seeds very numerous, white, thrown out to a considerable distance by very slender elastic threads or hairs.—Observed by Kœnig in a wood near Malacca, upon the upper boughs of very lofty trees.

106. *Epidendrum Sessile*. Leaves scattered from sessile bulbs, spreading, subpetioled, retuse above, smooth, a little channelled, beneath convex, fleshy; stems scandent, branched, round, filiform, scaly; flowers among the scales in pairs, seldom solitary, approximating to the stem, small. Instead of a calix, an ovate, acute, keeled, scalelet, fastened to the germen, inflated, membranaceous, white, short; corolla six-petalled; three outer almost erect, ovate at the base, with lengthened tips, slightly awned, equal, whitish, stiffish; two inner lateral, fastened to the side of the nectary, erect, ovate, oblong, quite entire, rounded at the tip, flat, membranaceous, white, subtransparent, much shorter than the outer ones; the sixth or third inner petal is fastened to the upper tip of the nectary, ascending, lanceolate, recurved, a little channelled, longer than the two other interior ones, callous, yellowish; style none.—Native of the East Indies.

107. *Epidendrum Liliifolium*. Leaves from the bulbs subpetioled, erect at the base, more spreading at the tip, linear-lanceolate, sharpish, smooth, keeled at the back, membranaceous, scarcely rigid; roots filiform, flexuose, white, parasitical; bulbs crowded, ovate, angular, grooved, pale green, terminated by two, or seldom three leaves, the size of a lark's egg; leaves dark green, scarcely a palm and a half long, and four lines wide; flowers from eighteen to thirty, pedicelled, remote, the lower ones more so, alternate; petals, the four outer spreading very much, the lower and upper linear, acute, a little incurved at the tip, concave, the side ones broader, rounded at the tips, concave, more coloured, purple, all equal in length, somewhat fleshy, purple at the tips, the rest white.—Native of the East Indies.

108. *Epidendrum Calceolarie Terrestris*. Leaves spreading, bifarious, sessile, ending in sheaths, oblong, lanceolate, quite entire, slightly and obliquely emarginate, above even, shining, beneath smooth, with from nine to fourteen nerves, rigid; the lower ones short, broader; the upper longer, and scarcely an inch broad; roots creeping in the ground; stem simple, erect, round, sheathed, compressed, a little smooth, jointed; the interstices shorter than half the length of the leaf, from three to four feet long, and half the size of a goose-quill; sheaths at the joints closely involving the stem, membranaceous, striated, two-keeled, blunt at the mouth, having one toothlet opposite to the leaf, a little shorter than the

internodes; sheaths radical, and below the middle of the stem, semioval at the mouth, keeled on the back; flowers terminating on two or three alternate compressed spathes, toothed in two rows on the edge, flexuose, naked; germen cylindrical, less than half the length of the flowers, which are larger than those of the White Narcissus.—Found in the swampy parts of thick woods near Malacca.

109. *Epidendrum Flos æris*. Leaves from bulbs, ovate-oblong, acute, flat, fleshy. This climbs variously on trees; flowers subspliked, solitary, alternate, somewhat remote, sessile on the germen, spathaceous, boat-shaped. This is suspected to be the same as the second species; and is therefore named after it.—Native of the East Indies.

110. *Epidendrum Triste*. Leaves cylindrical, empty; sheaths fistulose; peduncles opposite to the leaves, corymbed, perforating the sheath; lip of the nectary entire, spatulate, heart-shaped.—Native of New Caledonia.

111. *Epidendrum Crispatum*. Leaves cauline, round, filiform, subincurved, empty, sessile; raceme quite simple; lip of the nectary with the middle segment revolute, waved, crenate.—Native of the Society Islands in the South Seas.

112. *Epidendrum Equitans*. Leaves equitant, ensiform, compressed, keeled, acuminate; scape naked; raceme spiked, nodding, filiform.—Native of the Society Isles.

113. *Epidendrum Myosurus*. Leaves sheathing at the base, obliquely divaricate, linear, obtuse, channelled; scape naked; raceme spiked, nodding, filiform.—Native of the Society Islands.

114. *Epidendrum Biflorum*. Leaves distich, linear-lanceolate, acute; peduncles two-flowered, solitary, perforating the sheaths of the leaves; lip of the nectary trifid, acuminate.—Native of the Society Islands.

115. *Epidendrum Autumnale*. Leaves cauline, lanceolate, nerved, crowded, sheathing; peduncles terminating, scaly, panicled; lip of the nectary erect, retuse.—Native of New Zealand.

116. *Epidendrum Fasciola*. Leaves rooting, parasitical, bundled, linear, waved; scapes several, racemed; lip of the nectary slipper-shaped, with a spur.—Native of the Society Islands.

117. *Epidendrum Umbellatum*. Runners creeping; leaves oval, fleshy, petioled; petioles fixed into ovate, angular-keeled apophyses; scape rooted; umbel simple, one-sided, lowest petals elongated.—Native of the Society Islands.

118. *Epidendrum Resupinatum*. Leaves cauline, petioled, ovate, acuminate, quite entire, plaited, keeled, five-nerved; raceme simple, spiked; flowers inverted; lower lip of the nectary toothed.—Native of the Society Islands.

119. *Epidendrum Clypeolum*. Leaf radical, roundish, cordate, cowlled at the base, reflex and sharp at the tip; scape almost erect, racemed; lower lip of the nectary orbiculate, emarginate, very large.—Native of the Society Islands.

120. *Epidendrum Nervosum*. Scape angular; leaves ovate, nerved; lip entire, reflex; flowers at the top of the scape in spikes, alternate, drooping, purple; spike sharp, angled, erect, smooth, about a span long. A very short, ovate, purple bract under each flower; upper petal ovate, reflex in the middle, grooved, emarginate, forming a helmet twice as broad as the others.—Native of Japan, where it is found between Osacca and Jedo, flowering in May and June.

121. *Epidendrum Striatum*. Scape angular, smooth; leaves sword-shaped, nerved; petals lanceolate; lip oblong, flat; flowers on the top of the scape in racemes, several, drooping; bractes like the leaves, gradually diminishing. The two upper petals equal, ovate, the length of the calix, yellow, with a purple line, concave.—It flowers in June; and is a native of Japan.

122. *Epidendrum Tesselatum*. Roots simple or branched, thick, smooth, long, contorted; fibres issuing from the lower naked part of the stem, and from among the lower leaves, adhering firmly to the bark of the tree; stem perennial, simple, one or two feet long, as thick as the little finger, crooked, the upper part covered with leaves, the lower naked, withering away at the lower extremity; flowers on axillary racemes, from five to ten in number, remote, facing two ways, beautifully waved, and striated, with various shades of a greenish yellow; petals oval, spreading, equal, scolloped; nectary length of the petals. This plant is a very beautiful parasite, found flowering during the wet season upon trees among the Circar mountains.

123. *Epidendrum Præmorsum*. Leaves remote, alternate, facing two ways, linear, channelled, smooth, very firm, and bitten, jointed just above their sheath-like base, about six inches long, and one inch broad; spike before the leaf, or leaf opposed, short, straight, thick, many-flowered; flowers surround every part of the spike, small, variegated with red and yellow.—Native of the East Indies.

124. *Epidendrum Pendulum*. The root consists of many fleshy fibres like the two last, but issuing from one head; stem none; leaves radical, three to five, alternate, facing two ways, from one and a half to three feet long, three or four inches at bottom involved in chaffy sheaths, the rest forming the raceme, pendulous, many-flowered; petals lanceolate, spreading, equal, striated with rose-colour and yellow; nectary red, lower lip three-parted.—Native of the East Indies.

125. *Epidendrum Vanda*. This handsome plant attaches itself chiefly to the highest Amras and Bilsa (the *Mangifera* and *Cratæva* of Linneus). Its leaves are excavated upwards, to catch and retain dew. It is an air plant, and will live (says Sir W. Jones) in a pot without earth or water.

126. *Epidendrum Magnoliæ*. Roots succulently fibrous, creeping, clasping round the smoother forked trees; stems caespitose, simple, two-leaved, four or five inches high; leaves striated, rigid, and coriaceous; scapes many-flowered; flowers yellow; petals spreading, linear, and obtuse, the inner ones much narrower; lip orbiculate, spreading, obtusely three-lobed, scarcely the length of the tube.—Mostly on the trunks of *Magnolia Grandiflora*, from South Carolina to Florida.

Epigæa; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth double, approximating, permanent. *Exterior Perianth*: three-leaved; leaflets ovate, lanceolate, acuminate, the exterior large. *Interior Perianth*: five-parted, upright, a little longer than the exterior; leaflets lanceolate, acuminate. *Corolla*: one petalled, salver-form; tube cylindrical, as long as the calix or longer, hirsute within; border spreading, five-parted; lobes ovate-oblong. *Stamina*: filamenta ten, filiform, length of the tube, affixed to the base of the corolla; antheræ oblong, sharp. *Pistil*: germen globose, villose; style filiform, length of the stamina; stigma obtuse, subquincifid. *Pericarp*: capsule subglobose, depressed, five-cornered, five-celled, five-valved. *Seeds*: very many, roundish, receptacle large, five-parted. ESSENTIAL CHARACTER. *Calix*: outer three-leaved, inner five-parted. *Corolla*: salver-form; capsule five-celled.—The species are,

1. *Epigæa Repens*; *Creeping Epigæa*, or *Trailing Arbutus*. Leaves cordate-ovate, entire, flat, sharp; corollas cylindrical. This is a low plant, with a trailing shrubby stalk, which puts out roots at the joints, and, when in a proper soil and situation, multiplies very fast. The stalks are garnished with oblong rough leaves, which are waved on their edges. The flowers are produced at the end of these branches, in loose bunches; they are white, and divided at the top into

five acute segments, which spread open in the form of a star. It flowers in July, but does not produce fruit in England.—Native of Virginia and Canada. This plant is easily propagated by its trailing stalks, which put out roots at the joints, and may be cut off from the old plant, and placed in a shady situation and a moist soil: the best time for this is in autumn, that the plants may be well rooted before the spring. If the winter should prove very severe, it would be proper to lay a few dried leaves, or some light covering, over them, which will defend them from the injuries of the frost; and after they are well rooted, they will require no farther care but to keep them clean from weeds.

2. *Epigæa Cordifolia*; *Heart-leaved Epigæa*. Leaves heart-shaped, roundish, serrate, convex, hispid, rigid; corolla ovate.—Native of Guadeloupe.

Epilobium; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, four-parted, superior; divisions oblong, acuminate, coloured, deciduous. *Corolla*: petals four, roundish, outwardly wider, emarginate, expanding, inserted into the divisions of the calix. *Stamina*: filamenta eight, subulate, the alternate ones shorter; antheræ oval, compressed, obtuse. *Pistil*: germen cylindric, extremely long, inferior; style filiform; stigma four-cleft, thick, obtuse, rolled back. *Pericarp*: capsule extremely long, cylindric, streaked, four-celled, four-valved. *Seeds*: numerous, oblong, crowned with down; receptacle extremely long, four-cornered, free, flexile, coloured. *Observe*. In some the stamina and pistil are upright, in others bent downwards to the lower side. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Petals*: four. *Capsule*: oblong, inferior. *Seeds*: downy.—This genus consists of hardy perennials, which, though not destitute of beauty, are in general only considered as weeds, and, excepting the first species, seldom find admission into gardens. They propagate spontaneously both by seeds and runners, and require to be restrained, rather than increased by the hand of art, but may be advantageously admitted to fill up remote shady corners, or decorate rock-work.—The species are,

* *Stamina bent down*.

1. *Epilobium Angustifolium*; *Narrow-leaved* or *Rosebay Willow-herb*. Leaves scattered, linear-lanceolate, quite entire, veined; flowers unequal; root creeping; stem upright, from three to six feet high, branched at top, round, and pubescent; branches and leaves alternate; flowers purple, showy, growing in a kind of long spike on purple peduncles, the length of the germen, bending down before the flowers open, but afterwards erect, seldom more than four or five blown together on the same spike; the two lowermost petals somewhat remote from each other. From the similitude of the leaves of this species to those of the Willow, this plant obtained the name of *Willow-herb*, or *French Willow*. It was formerly much planted in gardens; but as it overruns all the neighbouring plants by means of its creeping roots, it has generally been cast out; however, in low moist places, or in great shade, this plant will make a good appearance while it is in flower, which will continue nearly a month, unless the season be very hot. It is a native of most parts of Europe, from Lapland to Italy, but is not common in Great Britain, though it may be found on Maizehill beyond Greenwich, and in other places near London. Mr. Miller found it wild in great plenty near Alton in Hampshire, in Charlton forest, and several other woods in Sussex: it is also found about Birkhampstead in Hertfordshire, in several parts of Yorkshire, and many places in Scotland. Gerard informs us, that he had plants of this species from Yorkshire, and that they grew in his garden, and were very goodly to behold, for

the decking up of houses and gardens.—The young shoots are said to be eatable, although an infusion of the plant produces a stupefying effect. The pith, when dried, is boiled, and becoming sweet, is by a proper process made into ale, and this into vinegar, by the Kamtschadales; it is also added to the Cow-Parasit, to enrich the spirit that is prepared from that plant. As fodder, goats are said to be extremely fond of it, and cows and sheep to eat it. The down of the seeds, mixed with cotton or fur, has been manufactured into stockings, &c.

2. *Epilobium Angustissimum*; *Linear-leaved Willow-herb*. Leaves scattered, linear, obscurely toothleted, veinless: petals equal, quite entire. This has been confounded with the preceding species. It differs, however, in its woody stem, its very narrow leaves with salient glands on their edges, the much more lively colour of the flower, shorter siliques, and has an entirely different air. Haller says, that the stem is only a foot or eighteen inches high, with a branch from almost every axil; the flowers almost the same with the foregoing, but the leaves totally different. Villars informs us, that the flowers do not come in a spike, like those of the preceding, but terminate the stem, and are fewer in number. It is an Alpine plant, but is common low down in the beds of the Alpine torrents, as in the Veveys and the Grande Eau, near Aigle; it is also found in Provence; flowering in July and August.

3. *Epilobium Latifolium*; *Broad-leaved Willow-herb*. Leaves alternate, lanceolate-ovate; flowers unequal. This differs from the first species, in having flowers twice the size; the leaves broader, regularly alternate, not scattered, very smoothly tomentose on both sides. The stem is round, erect, and from eighteen inches to two feet in height.—Native of Denmark, Silesia, and Siberia.

** *Stamina upright, regular; Petals bifid*.

4. *Epilobium Hirsutum*; *Large-flowered Willow-herb*. Leaves ovate-lanceolate, half stem-clasping, hirsute; stem branching very much, from three to six feet high; root creeping, sending out from the upper part runners of a considerable thickness, which spread widely; and propagate the plant; flowers large, showy, purple or flesh-coloured, somewhat bell-shaped, and hanging down a little, on peduncles, solitary, alternate.—Native of most parts of Europe, by the sides of ditches, ponds, lakes, and rivers, flowering in July and August. The leaves, and particularly the top-shoots, when slightly bruised, have a delicate cool fragrance, resembling scalded codlings, whence its name of *Codlings and Cream*; but this fragrance is very soon lost after the plant is gathered. It is also called *Great Hairy-codded Loosestrife*. Horses, sheep, and goats eat it; and, if it were found to be an acceptable fodder, it might be advantageously cultivated in wet situations.—It varies with white flowers, and also with variegated leaves, in which state it is sometimes sold by the gardeners; but having a creeping root, it is very liable to increase too much.

5. *Epilobium Villosum*; *Hoary Willow-herb*. Leaves oblong, lanceolate, toothed, pubescent; stem columnar, villose. This species invariably differs from the foregoing in its corolla, root, and pubescence. The corolla is in general not more than one-third of the size; the root does not creep; and both stem and leaves are covered with numerous soft hairs, which give the whole plant a hoary appearance. It is also smaller, and less branched, than the preceding species, but grows in the same places, and flowers at the same time.

6. *Epilobium Montanum*; *Mountain or Wood Willow-herb*. The root has, on its upper part, little buds of a bright red colour; stem from one to three feet high, upright, red, cylindric; down scarcely perceptible; sometimes branched at

top, but often single; leaves opposite, except the uppermost, on very short petioles uniting at the base, sharp at the end, finely serrate, with unequal teeth, somewhat hooked, smooth on the upper side, on the under paler, and very slightly hairy; the downiness is just perceptible on both surfaces, according to Withering, but most underneath. The bottom leaves are often of a bright red colour; calicine leaflets four, lanceolate, with a conspicuous midrib, slightly hairy on the outside, and at the edges; petals obovate, deeply emarginate, pale purple, veined with deeper purple lines.—It flowers from June to August, is a native of Europe, found in woods and hedges, sometimes in moist meadows, but oftener in dry gravelly soils, in courts, neglected walks, upon walls, and also upon old trees, particularly Willows.

7. *Epilobium Tetragonum*; *Square-stalked Willow Herb*. Leaves lanceolate, toothletted, the bottom ones opposite; stem four-cornered; flowers small, purple. One of the most striking characters of this is the apparent squareness of the stalk, which arises from projecting lines running from the leaves down to it; to this we may add the narrowness of its leaves, the uncommon length of its pods, and its undivided stigma, which was first noticed by Kay. It flowers in July and August.—Native of Europe, the East Indies, China, and Cochinchina. It is not uncommon in Great Britain, being generally found in marshes, and by the sides of rivulets and ditches, as in the lane from Newington to Hornsey-wood; near Bungay, in Suffolk; and at Alconbury, in Huntingdonshire.

8. *Epilobium Palustre*; *Marsh Willow-herb*. Leaves opposite, lanceolate, quite entire; petals emarginate; stem erect, six inches high; calix a little hairy on the outside; petals reddish, or pale purple, emarginate, not cloven in the middle; the antheræ, when they are shedding their pollen, adhere firmly to the stigma; stigma thick, club-shaped, yellowish white, slightly cloven at top into four parts; siliques peduncled.—Native of Europe, on marshes, bogs, and by the side of lakes.

9. *Epilobium Alpinum*; *Alpine Willow-herb*. Leaves opposite, ovate-lanceolate, quite entire; siliques sessile; stem creeping. This plant is hardly a span high, decumbent at bottom, then upright, and bears one or two flowers at the top.—Native of the mountains of Lapland, Denmark, Switzerland, Silesia, Savoy, Dauphiny; and in Britain, on Cheviot-hills, near Settle; about Buckbarrow-well; and many parts of Scotland; by the sides of rivulets, and in sandy places.

10. *Epilobium Fruticosum*. Stem shrubby, very much branched, six feet high; leaves quite entire, alternate, hirsute; peduncles one-flowered; flowers superior, yellow; capsule columnar, eight-cornered, crowned with the permanent calix; seeds not pappous.—Native of Cochinchina.

11. *Epilobium Glabellum*. Leaves oblong, toothed, obtuse, the bottom ones opposite; stem roundish, erect.—Native of New Zealand.

12. *Epilobium Rotundifolium*. Leaves opposite, roundish, toothletted.—Native of New Zealand.

13. *Epilobium Parviflorum*. Leaves opposite, lanceolate-serrate, sessile, both they and the stem villose.—Native of Germany.

14. *Epilobium Alsinefolium*. Stem creeping; leaves ovate, acute, toothed; siliques the length of the stem.—This is very nearly allied to the ninth species in its size, habit, disposition of the leaves, flowers, and siliques: the flowers are bright red, a little emarginate, and middle-sized; the siliques are few and small. Both this and the ninth species grow upon the summits of the highest mountains, near the snow, and have their siliques often as long as their stems.

Epimedium; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-

leaved; leaflets ovate, obtuse, concave, expanding, small, placed directly below the petals, caducous, according to Jussieu, with a single bracte at the base of them. *Corolla*: petals four, ovate, obtuse, concave, expanding; nectaries four, cup-form, with obtuse bottoms, of the size of the petals, and leaning on them, affixed by the edge of the mouth to the receptacle. *Stamina*: filamenta four, subulate, pressing on the style. *Antheræ* oblong, erect, two-celled, two-valved, gaping from the base towards the tip, with a free dissepiment. *Pistil*: germen oblong; style shorter than the germen, length of the stamina; stigma simple. *Pericarp*: silique oblong, acuminate, one-celled, two-valved. *Seeds*: very many, oblong. **ESSENTIAL CHARACTER.** *Nectaries*: four, cup-form, leaning on the petals. *Corolla*: four-petalled. *Calix*: very caducous; fruit a silique.—The only known species is,

1. *Epimedium Alpinum*; *Alpine Barrenwort*. It has a creeping perennial root; from which arise many stiff smooth stalks about nine inches high, cylindrical, simple, near the root surrounded with scales, at top trichotomous; leaves once and twice ternate, pendulous, heart-shaped, ending in a point, serrate, the serratures ending in a hair, pale green on the upper side, gray on the under; flowers drooping with dark red petals, and yellow pellucid nectaries.—Native of the Alps and Apennines, also of Japan. It flowers in April and May, and even later in shady places: it is common in English gardens. The inhabitants of the northern parts of Europe give a decoction of the herb, in milk, to the females of domestic animals when going after the male; and they say that it effectually quenches those desires which nature excites at that season. Hill says, that a strong decoction of the roots, given to women of robust habits, have been often known to succeed, even in cases which have baffled all the efforts of regular practice. It may be increased by the roots, and succeeds best in the shade, where it must every year be reduced, otherwise it will spread its roots so as to interfere with the neighbouring plants. Although it is by no means showy, it deserves to be admitted into gardens on account of its beauty and singularity.

Equisetum; a genus of the class Cryptogamia, order Filices.—GENERIC CHARACTER. Fructifications disposed into a long ovate-oblong spike; each orbiculate, gaping at the base, with several valves, connected by a flat shield-shaped top.—Though the genus of the Horse-tails be inhabitants of the water, or at least flourish best where they can lodge their perennial creeping roots in a wet soil, or strong clay which holds the wet, yet they will grow in a garden, especially near water, under a north wall, or in the shade; they only require to be kept within bounds, as they run much at the root: hence it is better to plant them in pots plunged into the earth than in the open ground. It is very difficult to extirpate them from cultivated lands. Haller says, that he tried in vain to accomplish it by ploughing, dunging, and other methods; and that any one who published the secret of destroying those unpropitious weeds, so injurious to cattle, would merit a considerable reward. Draining the lands infested with it, seems most likely to remove the evil.—The species are,

1. *Equisetum Sylvaticum*; *Wood Horse-Tail*. Stems spiked; fronds compound. It grows to the height of a foot or eighteen inches, and sometimes reaches to three or four feet; stem slender, scabrous, angular; the angles edged with short spinules, scarcely visible without a microscope; the whorls are hardly an inch asunder; there are twelve or more branchlets, or leaves as some call them, in a whorl, these are very slender, about five inches long, quadrangular, and beset with several other secondary whorls, having five to seven

branchlets on each, so that the whole resembles a pine-tree in miniature; the flowering-spike is at the end of the frond.—Native of most parts of Europe, in woods and shady places, flowering in April and May. Linneus informs us, that it is a principal food for horses in some parts of Sweden. Scopoli affirms, that it is noxious to cows, making them shed their teeth, and bringing on them a diarrhœa. A strong decoction of it is an excellent medicine in immoderate discharges of the menses, and in fluxes of the belly attended with griping pains and bloody stools. Externally applied, it stops the bleeding of wounds, and quickly heals them. It is a very cooling astringent herb, and, taken either in powder, decoction, or juice, is of considerable efficacy, in spitting of blood, bloody urine, and for ulcers in the urinary passages. The whole plant may be usefully employed, either fresh or dry, though it is most efficacious when fresh gathered.

2. *Equisetum Arvense*; *Corn Horse-Tail*. Fruit-bearing scape naked, barren, leafy; the naked flowering-stems appear early in the spring, and soon decay, they are the thickness of a large wheat straw, a hand's-breadth or more in height, upright, yellowish, with from two to five joints, covered with membranaceous ribbed sheaths, divided at top into numerous segments or teeth; spike terminating, oblong, swelling, about an inch in length, throwing out a greenish powder when ripe, which moves as if it were alive, especially if it be breathed upon; every particle has three or four, rarely five, fine pellucid threads, club-shaped at the end, which occasion the motion, by extending and curling themselves up. It is a troublesome weed, and difficult to extirpate; is reputed to be noxious to cattle, especially cows, which it afflicts with a diarrhœa, but they are not very ready to meddle with it. The country people call it *Horse-pipe* and *Snake-pipe*. It is supposed to indicate subterraneous flowing waters or springs.—It flowers in March, April, and May, is found in corn-fields and wet meadows, and is a native of most parts of Europe, the Levant, Japan, and North America.

3. *Equisetum Palustre*; *Marsh Horse-Tail*. Stem angular; fronds simple. The stem is a foot or eighteen inches high, nearly smooth, channelled with five or six deep furrows; the sheaths are divided into seven or eight acute black dents with white edges, from these, at flowering-time, come out sixteen furrowed, smooth, simple, short branchlets, becoming afterwards longer; spike terminating, and turning black before it disperses the seed, which is very lively when fresh from the spike.—Found in marshes and ditches, flowering in June. There is a variety of it with smaller fronds, almost all the branchlets having a spike at the end, but that at the end of the stem twice as large as the rest. Haller declares, that this is also injurious to cattle. In Scotland they call it *Paddock-pipe*.

4. *Equisetum Fluviale*; *River Horse-tail*. Stem streaked; fronds almost simple. This is the largest of all the European species; the stem is three or four feet high, the thickness of a finger, and sometimes nearly an inch in diameter, streaked, not furrowed, smooth, soft, of a pale or whitish colour at first, but blackish in decay; joints numerous; sheaths streaked; branchlets or leaves quadrangular. The spikes grow distinct from the fronds on scapes, but from the same root; these come out earlier, are a foot or eighteen inches in height, and the spikes are replete with a bluish powder. Haller tells us, that this species was eaten by the common people among the Romans; and Linneus says, that the rein-deer, who refuse hay, will however eat this; that it is cut as fodder for cows, with a view to increase their milk; but that it is not acceptable to horses.—Native of Europe, flowering in May and June, and found upon the banks of rivers, lakes, ponds, and ditches.

5. *Equisetum Limosum*; *Smooth Horse-Tail*. Stem almost naked. It grows three or four feet high, and is often quite destitute of leaves, but sometimes produces a few straggling ones. The stem is smooth, channelled with twelve or more furrows, and terminated with a black oval spike; the dents of the sheath are acute and black, and of the same number with the furrows.—It flowers in May and June; and is found in watery places, lakes, ponds, and ditches.

6. *Equisetum Hyemale*; *Rough Horse-Tail*. Stem naked, scabrous, subracemed at the base; the sheaths are black at the base and edge, and obscurely indented with as many short obscure teeth as the stem has furrows; the flowering spike terminates the stem; and the sheath, which immediately subtends it, is pale at the base, but black at the edge, distinctly and acutely toothed. This is the best species for polishing wood and metal, being the hardest and roughest; hence our old writers called it *Shave-grass*. It is much used by the whitesmiths and cabinet-makers, under the name of *Dutch rushes*. The Northumberland dairy-maids scour their milk-pails with it. Gerarde says, that the women scour their pewter and wooden things of the kitchen therewith, and thence call it *Pewterwort*; and that the fletchers and comb-makers rubbed and polished their work with it. Professor Davy has detected a large proportion of flinty earth in the cuticle, to which its hardness and asperity are owing. Linneus informs us, that it is salutary for horses, but noxious to cows, who lose their teeth by feeding on it; and that sheep avoid it.—It flowers in July and August; and is a native of Europe and of Japan, growing in wet marshy places in woods.

7. *Equisetum Giganteum*; *Giant Horse-Tail*. Stem streaked, arborescent; fronds simple, strict, spike-bearing.—Native of South America; not yet described.

Eranthemum; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Culix*: perianth five-cleft, tubular, very narrow, upright, short, acuminate, permanent. *Corolla*: one-petalled, funnel-form; tube filiform, extremely long; border five-parted, flat; divisions obovate. *Stamina*: filamenta two, very short, in the mouth of the corolla. *Antheræ* subovate, compressed, beyond the tube. *Pistil*: germen ovate, very small; style filiform, length of the stamina; stigma simple. *Pericarp* and *Seeds* not described; recommended to the attention of the intelligent botanist. ESSENTIAL CHARACTER. *Corolla*: five-cleft, with a filiform tube; antheræ beyond the tube; stigma simple; fruit also undescribed.—The species are,

1. *Eranthemum Capense*. Leaves lanceolate-ovate, petioled; stems long, terminated by one or three spikes, from lanceolate, green, imbricate bractes, within each of which is a long purple flower.—Native of the Cape of Good Hope.

2. *Eranthemum Angustifolium*. Leaves linear, remote, patulous; stem erect, branched; racemes simple, very long, erect; tube of the corolla very long, with a small obtuse border; antheræ incumbent, linear.—Native of the Cape of Good Hope.

3. *Eranthemum Parvifolium*. Leaves ovate-linear, imbricate; bractes ovate.—Native of the Cape of Good Hope.

4. *Eranthemum Salsoloides*. Leaves fleshy, nearly columnar, linear, very smooth; racemes axillary, they and the calices pubescent; tube bent back. This shrub resembles *Salsola*, but with axillary pubescent racemes at the ends of the branches; pedicels reflex, and at the origin of each three subulate bractes; calix five-parted, with subulate pubescent divisions; tube of the corolla longer than the calix, bent back in the middle; divisions of the border ovate-acuminate.—Native of the Cape of Good Hope.

5. *Eranthemum Spinosum*. Leaves ovate, opposite; stipules

spiny; flower solitary. Stem suffruticose, a foot high, cespitose, erect, with short rising branches, spiny stipules and bractes; flower pale violet, solitary, lateral, peduncled; calix two-leaved, with acuminate erect leaflets; tube of the corolla curved at the base.—Native of Africa, in the suburbs of Mosambique.

Erica; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved; leaflets ovate-oblong, permanent. *Corolla*: one-petalled, bell-form, four-cleft, often bellied. *Stamina*: filamenta eight, capillary, inserted into the receptacle; antheræ two-cleft at the tip. *Pistil*: germen roundish, superior; style filiform, upright, longer than the stamina; stigma crowned, four-cornered, four-cleft. *Pericarp*: capsule roundish, smaller than the calix, covered, four-celled, four-valved; partitions meeting with the sutures, or, according to Gärtner, opposite to the sutures. *Seeds*: numerous, very small. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: four-cleft. *Filamenta*: inserted into the receptacle. *Antheræ*: cloven. *Capsule*: four-celled.—It is difficult to guess at the number of the real species of *Erica*: Willdenow has 137, but some of these are duplicates. Our gardeners reckon about 300, many of which are merely varieties. And yet it is probable not a few remain to be discovered in the wilds of Southern Africa. None are found in America, in New Holland, nor scarcely in the Torrid Zone. The habit of the whole genus is shrubby, very rarely arborescent. Their leaves are very small, linear, lanceolate or ovate, imbricate or remote, entire, ciliate or serrate, in some opposite, in most whorled, in others again scattered; bractes usually three, two opposite. The flowers are either axillary or terminating, and variously disposed, partaking of all the most exquisite tints of red, purple, yellow, or orange, occasionally variegated with green or white; and some are entirely white. Antheræ oblong or linear; germen generally smooth. In some of the species the antheræ are awned, in others they are crested, and in others awnless; in some they are included within the corolla, in others they are projected, or stand out beyond the corolla. Hence this unwieldy genus is commodiously divided into four sections, and these sections are again subdivided into subordinate sections, according to the disposition of the leaves. The inclusion or projection of the style also affords another division of the species. The calix in some is double; and, lastly, the form of the corolla assists us much in distinguishing the numerous species. The campanulate and ovate forms, with their several modifications, are the predominating ones. All this may be best understood by the following table, which is of great use to exhibit these material differences at one view:

Antheræ awned, from species No. 1 to 29.

—— crested, 30 to 43.

—— awnless, 44 to 83, 85.

—— included, 1 to 69, 85.

—— standing out, 71 to 81.

Leaves in pairs, opposite, 1, 2, 44, 45.

—— in threes, 3 to 19; 30 to 38; 46 to 55; 71 to 76; 84.

—— in fours, 20 to 28; 39 to 43; 56, 57; 77 to 79; 82 to 85.

—— more than four, 29, 68, 69, 80, 81, 83.

Style included, 2 to 7; 9 to 14; 20 to 21; 23 to 25; 29 to 35; 39; 44; 56 to 58; 60 to 66; 84.

—— standing out, 1; 15 to 19; 22; 26 to 28; 36 to 38; 45; 47 to 52; 55, 59, 70, 72; 74 to 83, 85.

—— middling, 42, 43.

Corolla bell-shaped, 1; 9 to 18; 21, 22, 37, 45, 47, 55, 62, 64; 75 to 78; 81

Corolla bell salver-shaped, 49.—pitcher bell-shaped, 43.

—— globular bell-shaped, 30, 31.

—— globular, 20, 48, 64.—subglobular, 6, 50.

—— ovate, 2 to 4; 23, 24, 27; 32 to 36; 39 to 41, 46, 54, 82.—ovate bell-shaped, 51.

—— ovate-conical, 7, 8.—ovate-oblong, 42, 66.

—— ovate funnel-shaped, 63.—funnel-shaped, 85.

—— oblong, 5, 28, 79.—roundish, 53.

—— cylindric fig-shaped, 69.

—— cylindric, 19, 38, 59, 68, 71, 72, 73, 80, 83.

—— fig-shaped, 25, 26, 29.—salver-shaped, 61.

—— club fig-shaped, 56, 57, 58, 60.

—— tubular, 67.—four-cornered, 84.

This genus has, within the compass of a few years, risen from neglect to splendour. Mr. Pope marks it with contempt, at the same time that he celebrates the colour of the flowers:

“E'en the wild Heath displays its purple dyes.”

The plants of this genus which are natives of the Cape of Good Hope, or the more interior parts of Africa leading to that famous promontory, must be preserved in the dry-stove, green-house, or glass-case. These may be increased either from cuttings or from layers; there are few but what may be increased, by cuttings, provided good young shoots can be procured, especially if they be put under bell-glasses, and the pots are set where they can be shaded, and have a moderate heat. When the plants have become perfectly rooted, they should be removed into other pots, filled with the undermentioned composition, being then put into the dry-stove or green-house, where some of them require to be constantly placed. These plants should have a light and rather poor soil to grow in; a composition of bog earth and light loam will suit them well. The third, twenty-ninth, thirty-fourth, fortieth, forty-second, fifty-fourth, sixty-ninth, and a few other species, have not yet been struck from cuttings, and must therefore be propagated from layers, which, however, will not always strike the first year.—The species we shall now describe, are 85 in number, viz.

* *Antheræ* awned; *Leaves* opposite.

1. *Erica Vulgaris*; *Common Heath*. Corollas bell-shaped, almost equal; calices double, the inner longer than the corolla; leaves sagittate, imbricate in four rows. *Common Heath* is a foot or two in height, or more; the stems brown and woody, very much branched; the branches in opposite pairs, mostly upright, round, downy, and reddish; the branchlets square; flowers solitary, on peduncles the length of the leaves, from the sides of the branches, slightly nudging, opposite, but generally pointing one way, giving the branches the appearance of long bunches, but leafy shoots will be always found at the end. The inner or proper calix consists also of four oval-oblong concave leaflets, slightly adhering at the base, alternating with the segments of the corolla, of the same colour, and nearly of the same texture with them, five times as long as the outer calix, open, but after flowering approaching with the points bent in. We may here observe a curious instance of the gradual transition from the green herbaceous leaves of the stem, to the more delicate texture of the corolla, which is of a pale purple rose-colour, whitish towards the base, divided two-thirds of the way down into four, sometimes five, ovate, blunt, equal, open segments; filamenta awl-shaped, double, to and fro towards the point, white, or tinged with purple, springing from small glands at the base of the germen. There is a variety with white flowers, and with hoary leaves; which has been considered by some as a distinct species, and by others confounded with the 52d species: it is common on Bagshot-Heath, Enville-Common

in Staffordshire, Birmingham-Heath, and, as Ray says, not only about Windsor, where Clusius observed it, but all over England.—This plant, which is little regarded in warmer climates, is made to serve a great variety of purposes in the bleak and barren Highlands of Scotland, and other northern countries. The poorer inhabitants cover their cabins with it instead of thatch, or else twist it into ropes, with which they bind down the thatch in a kind of lattice-work. They also form walls with alternate layers of Heath, and a sort of cement made of black earth and straw; and these hardy people have even been known to make their beds of it. In most of the Western Isles they dye their yarn of a yellow colour, by boiling it in water with the green tops and flowers of this plant; and woollen cloth boiled in alum-water, and afterwards in a strong decoction of the tops, comes out a fine orange colour; and in some of those islands they tan their leather with a strong decoction of it. Formerly the young tops are said to have been used alone to brew a kind of ale; and Boethius relates that this liquor was much used by the Picts; and in several of the isles it is said that they still brew ale with one part malt, and two parts of the young tops of Heath, sometimes adding hops. In many parts of Great Britain, besoms are made of it, and the turf, with Heath growing upon it, is cut up, and dried for the fuel of the cottager, heating ovens, covering under-ground drains, &c. Sheep and goats will sometimes eat the tender shoots, but are not fond of them. Cattle not accustomed to browse on Heath give bloody milk, but are soon cured by drinking plentifully of water. The branches of Heath afford shelter, and the seeds a principal part of the food of many birds, especially those of the grouse kind; and for this purpose, the seed-vessel is formed and defended in such a manner, that the seeds are protected a whole year, or even longer. Bees collect largely from the flowers; and honey made from them was anciently supposed to be of a bad quality, but in fact it is only of a darker colour. The foliage affords nourishment to the phalæna quercus, or great egger moth. Dodder frequently entwines itself about this plant, and gives it a singular appearance. Meyrick says, that a water distilled from the flowers is a good application to inflamed eyes; and an oil made from them is reported to be of great efficacy in curing the shingles, and other cutaneous eruptions.—Almost every part of Europe abounds with Heath, especially the northern countries; it is also common in all the temperate parts of the vast Russian dominions. It is called *Ling* in some parts of England; *Grig*, in Shropshire; and *Hather* in Scotland. It is remarkable that Shakspeare enumerates Heath and *Ling* as quite distinct plants; the former of these names is derived from the German *Heide*, and the latter from the Danish *Ljng*. The Swedes call it *Ljung*; the Italians, *Erica*; the Spaniards, *Brezco*; the Portuguese, *Urze*, *Erica*, *Torga*, or *Estorga*; and the Russians, *Weresh*. Common Heath, which overruns immense tracts, especially in the elevated parts of northern countries, can only be effectually extirpated by paring and burning. In some lands, deep and cross ploughings, getting up roots with heavy harrows, burning the whole, and spreading the ashes, may be sufficient. Dr. Anderson affirms, that wherever Heath abounds, there is generated, by the rotting of the plant, a peculiar black earth, that is not only sterile of itself, but has a powerful tendency to make any other soil unproductive, so that in improving heathy grounds, the top soil should be buried by trenching or deep ploughing.—*Propagation*. Notwithstanding the commonness of our British Heaths, they deserve a place in small quarters of humble flowering shrubs, where, by the beauty and long continuance of their flowers, together with the diversity of their leaves, they make an agreeable

variety. This, and the 23d, 36th, and 81st species, may be taken up with a ball of earth growing to their roots, from the natural places of their growth, in autumn; the soil should not be dunged; and the less the ground is dug, the better they will thrive, for they commonly shoot their roots near the surface. They may also be propagated by seeds; but this is a tedious method.

2. *Erica Lutea*; *Yellow Heath*. Corollas ovate-acuminate; flowers heaped; leaves linear. The whole is smooth, with a rufescent upright stem, two feet high; branches scattered, from erect spreading, wand-like; branchlets also scattered, filiform, very frequent, wand-like, short; leaves opposite, blunt, grooved underneath, a line in length; flowers on the extreme branchlets, one, two, or three together, upright; bractes linear, obtuse, concave, pale; calicine leaflets ovate-acuminate, keeled below the tip, it varies with the corolla, calix, and bractes, yellow or white. The whole plant being covered with its shining golden or silvery flowers, is very beautiful.—Native of the Cape of Good Hope.

Leaves in threes.

3. *Erica Halicacaba*; *Purple-stalked Heath*. Corollas ovate, inflated; style included; flowers solitary. Stem smooth, rugged, brown, flexuose, decumbent, strict, lofty; branches alternate, divaricate, purplish; leaves crowded, lanceolate-acute, smooth, flat above, convex beneath, and rugged about the edge; peduncles tomentose, reflex; bractes ovate, acute, approximating, many times smaller than the calix; calicine leaflets ovate, acute, keeled, entire, pressed close, smooth, pale, two lines in length; corolla purplish, smooth, distinct from all others in its flowers being the size of an acorn. It flowers in May and June, and is the largest plant of the genus.—Native of the Cape.

4. *Erica Regerminans*; *Self-sowing Heath*. Corollas ovate; style included; calices acute; flowers racemed. Stem shrubby, determinately branched; branches rushy; leaves linear, subulate, acuminate, even, patulous; racemes pointing one way, nodding, on peduncles the length of the flower, flesh-coloured; bractes remote, minute, coloured; calix red, lanceolate, very small; corolla ovate-globular, red, with a blunt mouth; antheræ a little shorter than the corolla; style included, the length of the corolla; stigma subcapitate.—Native of the Cape.

5. *Erica Monsoniana*; *Bladder-flowered Heath*. Flowers at the ends of obtuse branchlets; calices caliced; corolla oblong, inflated; style included. The stem is erect, pubescent, leafless, two feet high; branches scattered, frequent, spreading, covered with leaves, very short, simple; leaves in threes, ovate, obtuse, convex beneath, with a longitudinal groove, flat above, entire, imbricate, smooth, scarcely a line in length; flowers solitary, nodding, on pubescent reflex peduncles; bractes ovate, keeled, acute, white, a little shorter than the calix, on the middle of the peduncle; calicine leaflets ovate-acute, concave, keeled, white, smooth, almost three times shorter than the corolla, which is almost an inch long, divided at the mouth into four very short blunt segments. It resembles the third species, but has ovate leaves; smaller, less inflated, and deeply divided corollas; the flowers more copious, and the stem erect. This plant is one of the most beautiful of this beautiful genus, and has large white flowers.—Thunberg found it in the interior of Africa.

6. *Erica Mucosa*; *Mucous Heath*. Corollas subglobular, mucous; style included. Stem frutescent, determinately branched, with white awl-shaped decurrent lines under the scars of the leaves, which are linear, even, pressed close, scarcely longer than the interstices; flowers terminating, subumbelled, on peduncles the length of the flowers; bractes

linear, minute, remote; calix scarious, mucous, a little shorter than the corolla, ovate, acute; corolla blunt; antheræ ovate, short; style short, cylindric; stigma naked.—Native of the Cape.

7. *Erica Urceolaris*; *Hairy-flowered Heath*. Flowers umbelled; calices lanceolate; corollas ovate-conical, villose; style included. Stem flexuose, erect, ash-coloured, two feet high; branches opposite, or in threes, cinereous-villose, wandlike; branchlets filiform, scattered, frequent, wandlike; leaves in threes, linear-lanceolate, beneath grooved from the revolute margins, tomentose, whitish, from erect spreading, curved a little; peduncle, calix, and corolla, hirsute; calix shorter by half than the corolla, which is flesh-coloured, oblong, subcampanulate, and a line in length; it varies with flowers very hirsute and hairy, red and whitish flesh-colour. It flowers in May and June.—Native of the Cape.

8. *Erica Marifolia*; *Marum-leaved Heath*. Leaves ovate, pubescent, whitish underneath; corollas ovate-conical; style of a middling length. It flowers in May and June.—Native of the Cape.

9. *Erica Bergiana*; *Bergius's Heath*. Calices reflex; corollas bell-shaped; style included. This shrub is about two feet high, and pubescent; leaves linear, subciliate, erect; flowers at the ends of the branchlets, subsolitary, on very short peduncles; calix lanceolate, acute, one-third of the corolla, spreading, or reflex; corolla shaped like that of the Lily-of-the-valley, purple, blunt; stamina shorter than the corolla; pistil the length of the corolla; stigma subcapitate. It is covered with beautiful flowers.—Found by Bergius at the Cape.

10. *Erica Depressa*; *Flat-stemmed Heath*. Stem depressed; flowers few; corollas bell-shaped; style included. Stems procumbent, copious, a palm in length; leaves lanceolate, bluish, even, keeled; flowers scattered, solitary; calix scarious, lanceolate, acute, shorter by half than the corolla, which is obtuse, red, and even; antheræ very short; stigma blunt.—Native of the Cape.

11. *Erica Pilulifera*; *Rounded Heath*. Flowers umbelled; corollas bell-shaped; style included. The whole shrub is smooth, purple, erect, a foot high or more; branches and branchlets trichotomous, from erect spreading, subfastigiate; leaves in fours, obliquely whorled, three equal in situation, the fourth lower, linear, obtuse, flat above, beneath convex, with a deep longitudinal groove; the lower smooth, the uppermost very finely ciliate, attenuated into paler petioles, imbricate; flowers terminating, four to ten, drooping; peduncles blood-red, longer than the leaves; calicine leaflets boat-shaped, acute, pale, blood-red, smooth, ciliate at the tip, pressed close, a little shorter than the corolla, which is blood-red and smooth. The above is Thunberg's description.—Native of the Cape.

12. *Erica Viridi-Purpurea*; *Green-blue Heath*. Flowers scattered; corollas bell-shaped; style included. Leaves lanceolate, smooth; flowers in racemes, directed all the same way; corolla purple. It varies with the leaves in fours.—Native of Portugal. This, and the 16th, 17th, 38th, 52d, 76th, 77th, 78th, 79th, 80th, and 82d species, which are natives of the southern countries of Europe, will bear the open air in England, when placed in a dry soil and a warm situation. They may be increased and treated in the same manner as our British Heaths, (see the first species;) and may also be increased by layers and cuttings.

13. *Erica Pentaphylla*; *Five-leaved Heath*. Flowers pubescent; corollas bell-shaped; style included.—Native of the Cape.

14. *Erica Nigrita*; *Black Heath*. Calices imbricate,

three-flowered, sessile; corollas bell-shaped; style included. Stem brown, upright, a foot high and more; branches and branchlets scattered, and whorled, flexuose, erect, wandlike, ash-coloured, tomentose; leaves linear, ovate, obtuse, very finely rugged about the edge, flat above, convex beneath, with a slender longitudinal groove, shining, pressed close at the base, spreading, and recurved from the middle, a line in length; flowers terminating in threes, peduncled, erect; bractes oblong, acute, keeled, white, approximating to the calix, imbricate, shaped like the calicine leaflets, which are ovate, acute, keeled, very finely rugged about the edge, white, smooth, nearly equal to the corolla. This plant has its trivial name from its conspicuous dark anthers, elegantly contrasted with the white corolla and calix.—Native of the Cape.

15. *Erica Planifolia*; *Smooth-leaved Heath*. Leaves spreading very much; corollas bell-shaped; style standing out. Branches filiform, creeping; flowers violet-coloured; leaves ovate, acute, ciliate.—Native of the Cape.

16. *Erica Scoparia*; *Small Green-flowered or Brush Heath*. Corollas bell-shaped; stigma standing out, peltate. This is a shrub, growing to the height of several feet. The leaves soon fall off; and the branches are made into besoms, from which circumstance it has derived its trivial name.—It flowers in April and May, and is common in the south of Europe. See the twelfth species.

17. *Erica Arborea*; *Tree Heath*. Branchlets hoary; corollas bell-shaped; style standing out. This is an upright shrub, growing to the height of six feet, with upright branches, covered with a white nap; leaves very abundant, upright, smooth, almost awl-shaped, covering the branches, wrinkled when dry; flowers very numerous on the middle of the branches, so that the latter leaves are above them; they are on branching peduncles, forming a panicle; calix single, short, with lanceolate leaflets; corolla white, short, broad, four-cleft two-thirds of the way. It flowers from February to May.—Native of the south of Europe, and the island of Madeira. See the twelfth species.

18. *Erica Vespertina*; *Evening Heath*. Corollas bell-shaped; style standing out. This is an upright shrub, with the branches growing by threes; leaves triquetrous, even, pressed close; flowers in a panicle, nodding, alternate, white, on white pubescent peduncles, with ovate, alternate, white bractes; leaflets of the calix ovate, keeled, sharpish, the length of the tube; corolla double the length of the calix, broad, sharp; antheræ black, two-parted, above the throat; style purpurascant, rather longer than the corolla; stigma blunt.—Found by Thunberg at the Cape.

19. *Erica Cruenta*; *Bloody-flowered Heath*. Leaves smooth; bractes remote; calices awl-shaped, dilated at the base; corollas cylindrical, incurved; style standing out. Branches round, smooth; branchlets pubescent; leaves linear, awl-shaped, grooved, spreading, half an inch long, on appressed petioles, scarcely half a line in length; flowers axillary; peduncles hardly half an inch long, sometimes bifid or trifid; bractes three, awl-shaped, three-sided; leaflets of the calix keeled, smooth, two lines in length; flowers axillary; corolla deep crimson, an inch long, a little bent in, smooth, subpellucid, a little swelling at top, with a four-cleft mouth; segments sharpish, broad, suberect; filamenta whitish; antheræ included, oblong, brown, bifid; awns subulate, capillary, the length of the antheræ; style a little longer than the corolla, red; stigma standing out, incrassated, very dark purple. It flowers at various seasons.—Native of the Cape.

Leaves in fours.

20. *Erica Ramentacea*; *Slender-branched Heath*. Leaves

bristle-shaped; corollas globular; style included; stigma doubled. Branches filiform, ramentaceous, long, ferruginous; leaves very narrow, upright, pressed close; flowers umbelled; calix shorter than the corolla, green; corolla purple; antheræ with two ciliate horns, inwardly mucronate, opening in an ovate form on the sides; style purple; stigma double, the upper roundish, the lower quadrifid. It flowers in July.—Native of the Cape.

21. *Erica Persoluta*; *Blush-flowered Heath*. Calices ciliate; corollas bell-shaped; style included. Stem shrubby, smoothish, with pubescent branches; leaves linear, obtuse, erect, channelled underneath, the length of the joints, hispid, or subscabrous; flowers umbelled, dispersed on the upper twigs.—It flowers from February to May, and is a native of the Cape.

22. *Erica Strigosa*; *Dwarf Downy Heath*. Leaves pubescent, ciliate; corollas bell-shaped, smooth; style standing out. Branches somewhat villose; leaves linear-acute, spreading, somewhat villose, ciliate, with a few long hairs, glandulous at the tip, three lines long, on petioles half a line in length; flowers axillary on the extreme twigs, on peduncles a line and a half long; corolla pale red, almost twice as long as the calix. It flowers in March and April.—Native of the Cape.

23. *Erica Tetralix*; *Cross-leaved Heath*. Leaves ciliate; flowers in heads; corollas ovate; style included. Stems shrubby, from nine to twelve inches high, branched, brown, somewhat rugged from the remains of the leaves which have fallen off. Branches woolly. Leaves commonly in fours, but sometimes in fives, ovate-linear, spreading, near the flowers, pressed close to the stem, the edges turned in, and ciliated, each hair terminating in a small round gland; the upper surface is flat, the lower concave and white. Flowers hanging down one over another all one way, forming a little head; peduncles downy, about the length of the flowers; bractes three at the base of each flower on the upper side, of the same shape as the leaves of the calix, the lowermost the largest, inserted about a line below the calix, the two others, one on each side, rising from the base of the calix; calcine leaflets from four to six, linear, three times shorter than the corolla, woolly, fringed with long hairs tipt with brownish red globules; corolla pale purple or flesh colour, varying to white, divided into four very shallow segments, which turn back; antheræ sagittate, purple, with two white horns at the base, and two little apertures for the discharge of the pollen; germen woolly, glandular at the base; capsule villose, truncate. It flowers twice in the year, though some say only in July and August, and is a native of the northern parts of Europe, on moist heaths, and moorish grounds.—This species is not inferior to many of the foreign Heaths in the delicacy and beauty of its flowers. It is distinguished from the other British Heaths, not only by the flowers growing in a pendulous cluster on the tops of the stalks, but by the leaves growing in fours, and forming a sort of cross; whence the trivial and English names. Our old writers call it *Low-Dutch Heath*, or *Besom Heath*. See the first species.

24. *Erica Pubescens*; *Hairy Heath*. Leaves rugged; flowers sessile, lateral; corollas ovate; style included. Stem ash-coloured, hispid, flexuose, erect, two feet high and more; branches scattered, seldom in whorls like the stem; branchlets filiform and capillary, short, wandlike; leaves in threes or fours, frequently four on the branches, and three on the branchlets, seldom all in fours, linear, obtuse, rugged, villose, incurved, grooved beneath, spreading, a line in length; flowers at the end of the branchlets, umbelled, two, three, or more together, abundant, blood-red, hirsute. According to Thun-

berg, this varies much in the branches, leaves, and flowers. It has its name from the pubescence of the flowers. The principal varieties are, 1. Hairy: with leaves in threes, and the corollas very finely hairy. 2. Hispid: with leaves in threes, and hispid. 3. Villose: with leaves in fours, rugged, and the branches in whorls. 4. Small-flowered: with the leaves on the branches in fours, on the branchlets in threes, hispid; corollas minute.—Native of the Cape.

25. *Erica Abietina*; *Fir Heath*. Flowers sessile; corollas fig-shaped; style included. Stem ash-coloured, rugged, erect, a foot high and more; branches and branchlets in a sort of whorl; from erect spreading; leaves in fours, lanceolate, subulate, grooved underneath, smooth, imbricate; flowers at the ends of the branches in racemes, nodding; peduncles blood-red, villose, the length of the leaves; bractes below the middle of the peduncle ovate, acute, ciliate, keeled, pale. This is remarkable for its thickset leaves and crowded golden blossoms, as well as its pulpy seed-vessels. It flowers in June and July.—Native of the Cape.

26. *Erica Mammosa*; *Breasted Heath*. Corollas fig-shaped; style standing out. Stem somewhat rigid, with white awl-shaped decurrent lines from the scars left by the fallen leaves; leaves awl-shaped, crowded, somewhat rugged on the edge; flowers in a sort of head, on very short purple peduncles, with very small remote bractes; calix blood-red, ovate, very short; corolla ovate, cylindric, blood-red, very long, with a blunt mouth. There is a scarlet variety, a beautiful plant, and which is common with us.—Native of the Cape.

27. *Erica Caffra*; *Caffre Heath*. Leaves pubescent; flowers heaped; corollas ovate; style standing out. This is the size of Juniper.—Native of the Cape.

28. *Erica Sessiliflora*; *Sessile-flowered Heath*. Flowers in a spike, sessile, bent down, oblong; corollas club-shaped; styles standing out. This a brown rugged shrub, determinately branched, somewhat rigid, having the appearance of a small *Pinus Sylvestris*. Leaves crowded very much together, linear, acute, deep green; spike terminating, surrounded by sessile, imbricate, broadish flowers.—Native of the Cape.

Leaves scattered.

29. *Erica Fascicularis*; *Bundled Heath*. Leaves several, linear, truncated; flowers in bundles; corollas fig-shaped; style included. Stem shrubby, upright, compound, two feet high; leaves crowded, scattered, almost filiform, an inch long, even, capillary at the base, from erect spreading a little, glandular near the tip; flowers tipped with green, terminating, fastigiate.—Native of the Cape.

** *Antheræ crested; Leaves in threes.*

30. *Erica Triflora*; *Three-flowered Heath*. Flowers terminating; corollas globular, bell-shaped; style included. Stem brown, smooth below, hispid at top, erect, a foot high; branches dichotomous, brown at bottom, and smooth above, ash-coloured, hirsute, erect, fastigiate; branchlets scattered all over the branches, filiform, frequent, hairy, rough, wandlike; leaves linear, subulate, entire, smooth, flat above, convex beneath, with a very slender groove, incurved, from erect spreading; flowers solitary, or two or three together, on very short drooping peduncles, ash-coloured, tomentose.—Native of the Cape.

31. *Erica Baccans*; *Arbutus-flowered Heath*. Leaves imbricate; corollas globular, bell-shaped, covered; style included. Stem erect, branched; flowers terminating in threes or thereabouts, nodding; the size of a pea, on purple peduncles, with alternate, remote, flesh-coloured bractes; calix flesh-coloured, lanceolate, the length of the corolla, keeled, bent in; corolla obtuse, red; antheræ awnless, very short, yellowish. It flowers in April and May.—Native of the Cape.

32. *Erica Gnaphaloides*; *Soft-leaved Heath*. Corollas ovate, covered; style included; stigma four-parted. It is a small smooth shrub, of a cinereous brown colour, erect, a span high; branches and branchlets dichotomous and trichotomous, filiform, from erect spreading, fastigiate; leaves ovate, entire, smooth, flat above, convex beneath, with a longitudinal groove, pressed close, the length of the internodes forming as it were jointed branchlets, a line and a half in length; flowers terminating, about three together, purple.—Native of the Cape.

33. *Erica Corifolia*; *Slender-twigg'd Heath*. Flowers umbelled; calices turbinate; corollas ovate; style included. Stem shrubby, compound; calix spreading, with ovate, purple leaflets; corollas purple; stigma headed.—It flowers in August, and is a native of the Cape.

34. *Erica Articularis*; *Jointed Heath*. Corollas ovate, acuminate; style included, longer than the calix. Flowers racemed, peduncled; corolla bell-shaped, white; style dark purple.—Native of the Cape.

35. *Erica Calicina*; *Calicined Heath*. Calices spreading very much, wheel-shaped; corollas ovate; style included. Calix and bracte white; corolla yellow; leaves three-sided; bractes alternate.—Native of the Cape.

36. *Erica Cinerea*; *Fine-leaved Heath*. Corollas ovate; style a little standing out; stigma capitate. Root perennial, woody; stems shrubby, about a foot high, with opposite branches; the bark ash-coloured; leaves linear, fleshy, spreading above, smooth and shining, transversely wrinkled, towards the end beset with a few scattered hairlike points; beneath having a longitudinal furrow, which is white from a woolliness apparent to the magnifier; the edge somewhat membranaceous, and when viewed with the microscope, appearing serrulate; the leaves when young have three flat sides, but when full-grown are nearly flat. Flowers in long; clustered, whorled, terminating spikes, sonorous when struck; they come out from the sides of the young shoots; those from the end-shoots are near each other, but scattered and bare; those from the small lateral branches generally in pairs; peduncles shorter than the flowers, purplish-brown, somewhat downy, the lower nodding, the upper upright, with a bracte about the middle; corolla three times as long as the calix, bluish-purple, shrivelling, and turning of a fawn colour, the clefts very shallow.—It flowers from June to August, and is a native of all parts of Europe, except the extreme southern and northern regions; and is also found in the Levant. It may be applied to the same purposes as the Common Heath; and the flowers are much more showy. For its propagation and culture, see the first species.

37. *Erica Paniculata*; *Panicled Heath*. Flowers minute; corollas bell-shaped; style standing out. This is a shrub, with linear upright leaves, almost even; flowers purple, very small, as are also the calices and peduncles; and are so abundant as to cover the whole plant. It flowers from February to April.—Native of the Cape.

38. *Erica Australis*; *Spanish Heath*. Leaves spreading; corollas cylindrical; style standing out. This is an upright rigid shrub, with an ash-coloured bark; leaves in threes or fours, linear, obtuse, somewhat rugged on the edge; flowers terminating, two or three subsessile; calix rude, acute, keeled, imbricate with similar bractes; corolla scarcely club-shaped, obtuse, three times as long as the calix; the segments becoming hoary. It flowers in April and May.—Native of Spain and Portugal. See the twelfth species.

Leaves in fours.

39. *Erica Physodes*; *Expanded Heath*. Flowers solitary; corollas ovate, inflated; style included. Leaves patulous, broad-linear, keeled; calix ovate, smooth, colour-

ed, one-third of the length of the corolla, which is the size of a pea, and viscid. The flowers are at the ends of the branches in a sort of umbel.—Native of the Cape.

40. *Erica Enopetrisfolia*; *Crowberry-leaved Heath*. Flowers sessile, lateral; corollas ovate. Stem brown, rugged, a foot high; branches in whorls like the stem, flexuose, erect; branchlets trichotomous and dichotomous like the branches; leaves in sixes, oblong, obtuse, incurved, above three-cornered, flat, beneath grooved, rugged, especially underneath, very finely ciliate, imbricate, a line in length; flowers aggregate, in whorls in the middle and at the ends of the branchlets; calicine leaflets lanceolate, ciliate, blood-red; corolla ovate, bell-shaped, hairy, rough at bottom, blood-red; style purple, curved, twice as long as the corolla, with the headed stigma standing out. It flowers in April and May.—Native of the Cape.

41. *Erica Cernua*; *Drooping Heath*. Flowers ovate, capitate; calices ciliate; antheræ included. The whole plant is smooth, brown, erect, a foot in height; branches scattered in threes, filiform, flexuose, erect; leaves ovate, obtuse, ciliate, flat above, convex beneath, grooved, imbricate; flowers terminating, drooping.—Native of the Cape.

42. *Erica Retorta*; *Crook-leaved Heath*. Leaves recurved; corollas ovate-oblong; style of a middling length. Stem frutescent, somewhat rugged, determinately branched; leaves ovate-oblong, terminated by a little bristle, convex above, smooth, shining; flowers terminating, corymbed, subsessile; calix red, lanceolate, with an awn at the end; corolla long, inflated, viscid, with a globular throat, and a four-parted acuminate short border; filamenta linear, membranaceous.—Native of the Cape.

43. *Erica Margaritacea*; *Pearl-flowered Heath*. Corolla pitcher-bell-shaped; style of a middling length. Flowers terminating, four or eight from the uppermost axils; peduncles filiform, shorter than the leaves; bractes linear, three in number; corolla white; tube pitcher-shaped, a little longer than the calix; segments of the border obtuse, patulous; filamenta white, shorter than the tube, bent in at the tip; antheræ ovate, compressed, brown, two-parted; germen red, having eight little knobs at top; style the length of the corolla, whitish; stigma headed, flat beneath, convex above, commonly four-lobed. This is a very pretty plant when laden with its pearly blossoms, which appear in May and June.—Native of the Cape.

*** *Antheræ awnless, included; Leaves opposite.*

44. *Erica Tenuifolia*; *Small-leaved Heath*. Corolla and calix blood-red. The whole stem is smooth, erect, a span high; branches and branchlets filiform and capillary, erect; leaves opposite, lanceolate, smooth, convex beneath, with a slender groove, pressed close; flowers terminating, umbelled, in threes; calicine leaflets equalling the corolla, keeled; flowers blood-red; style included.—Native of the Cape.

45. *Erica Passerina*. *Passerine Heath*. Corollas bell-shaped; style standing out, (according to Thunberg, included.) Flowers solitary, terminating, peduncled; peduncles white, tomentose, generally longer than the flowers; calix bell-shaped, bluntish, four-parted, with ovate leaflets; filamenta the shortest of any; germen white, tomentose; stigma subcapitate. This has the herb of *Passerina Ericoides*, not to be distinguished from it; inasmuch that *Passerina Ericoides* has entirely the herb of an *Erica*, with the flowers of *Passerina*. This is an instance of the intermixture of genera, which is not uncommon in the Cape plants.—Native of the Cape.

Leaves in threes.

46. *Erica Albens*; *White Heath*. Racemes pointing one way; corollas ovate-oblong, acute. Stem frutescent, with

determinate wandlike branches; leaves linear, three-sided, erect, even, longer than the internodes, sharpish: flowers in a sort of spike, white, with lanceolate white bractes on the peduncle; calix scarious, white, ovate, acuminate, half the length of the corolla, which is white, with the belly hyaline, and the border four-parted, narrowed, acute, funnel-form; antheræ bifid, obtuse, short; style shorter than the corolla.—Native of the Cape.

47. *Erica Spumosa*; *Six-angled Heath*. Corollas in threes, covered by a common calix; style standing out. A small shrub, with narrow branchlets; leaves ovate-oblong, three-sided, channelled; flowers terminating, nodding, sessile; calices globular, imbricate with roundish scales, keeled, and bent in at the tip, blood-red.—Native of the Cape.

48. *Erica Capitata*; *Woolly Heath*. Flowers sessile; corollas covered with a woolly calix; antheræ middling. Stem seldom erect, commonly decumbent, smooth, flexuose, filiform; branches filiform, flexuose, villose; branchlets capillary, frequent, tomentose; leaves ovate, spreading, rough with long hairs; flowers at the ends of the extreme branchlets, peduncled, one, two, or three together. This species is known by its globular flowers, covered with a greenish-yellow lanugo. It flowers in April, and continues till July.—Native of the Cape.

49. *Erica Melanthera*; *Black-anthered Heath*. Corollas bell-shaped, longer than the coloured calix; antheræ middling; style standing out. Stem shrubby, flexile; leaves linear, obtuse, even, patulous; flowers terminating, subumbelled, scattered in close parcels, nodding a little; peduncles the length of the corolla, purplish; bractes lanceolate, alternate, coloured; calix blood-red, obovate, more in breadth than length, keeled, with a dagger-point at the tip; corolla bell-salver-shaped, blood-red; tube the length of the calix; border spreading, generally longer than the tube; the segments roundish, ovate; anthers dark-coloured, bifid, the length of the border.—Native of the Cape.

50. *Erica Thunbergii*; *Thunberg's Heath*. Corollas flat, with a globular tube; antheræ middling; style standing out. Stem rufescent, round, seldom branched; leaves linear, even, sessile, acute, generally pressed close; flowers terminating, peduncled; bractes two, alternate, scarious, lanceolate. This is a beautiful species, conspicuous for its globose white tube and large deep-orange limb.—Native of the Cape.

51. *Erica Absynthoides*; *Wormwood Heath*. Corollas ovate, bell-shaped; style standing out; stigma funnel-shaped. This shrub is panicled, and grows to the same height as Wormwood; stem rufous; branches in threes; leaves linear, gibbous on the outside, subhirsute; flowers at the ends of the branchlets; corollas pale; antheræ very dark purple, bifid, within the mouth of the corolla; stigma purple, four-cleft. Thunberg informs us, that this species has four varieties, viz. 1. With a wandlike stem, and branches and leaves very hirsute and rugged. 2. With a wandlike hirsute stem and branches, and wrinkled villose patulous leaves. 3. With a panicled stem, very short branchlets, and the leaves a little rugged and hirsute. 4. With a panicled stem, longer fastigiate branchlets, and the leaves a little rugged and smooth.—Native of the Cape.

52. *Erica Ciliaris*; *Ciliated Heath*. Racemes pointed one way; corollas ovate, fig-shaped; style standing out. This plant is suffruticose, two feet high; leaves spreading very much, sessile, ovate, acute, reflex, and ciliate on the edge; raceme terminating, whorled by threes; style almost twice as long as the corolla. It flowers from July to September.—Native of Spain and Portugal. See the twelfth species.

53. *Erica Hispidula*; *Hispid Heath*. Stem hispid; leaves about three, ovate, acute, ciliate; corollas roundish. Stems

decumbent, half a foot high, strigose or hairy; leaves subsessile, horizontal, patulous, even; flowers small, bell-shaped, bent towards the ground, scattered thinly; style longer than the corolla.—Native of the Cape.

54. *Erica Petiolata*; *Rosemary-leaved Heath*. Leaves oblong, petioled; corollas in threes, ovate, the length of the calix; antheræ standing out a little; style standing out. Stem round, flexuose, decumbent, rigid, smooth; branches scattered, opposite, or by threes, almost erect, bent in, flexuose, tomentose at top; flowers terminating, umbelled, on very short tomentose peduncles. It flowers from March to June.—Native of the Cape.

55. *Erica Leucanthera*; *White-anthered Heath*. Flowers in threes; calix white; corolla bell-shaped; antheræ and style standing out. Stem erect, smooth, a foot high and more; branches commonly in threes, pubescent, erect, wandlike; branchlets scattered, very frequent, filiform and capillary, pubescent, erect, leafy; leaves three-cornered, obtuse, pressed close, smooth, with a very slender groove underneath; flowers on very short peduncles, erect. This is distinguished by its white corolla, and awnless, projected, white anthers.—Native of the Cape.

Leaves in fours, or more.

56. *Erica Tubiflora*; *Tube-flowered Heath*. Leaves subciliate; corollas club-fig-shaped; antheræ and style included. Leaves linear, even, the upper ones ciliate; flowers terminating, solitary, sessile; corollas purple, acuminate, pubescent, several times longer than the calix; the segments lanceolate; style scarcely projected.—Native of the Cape.

57. *Erica Curviflora*; *Curve-flowered Heath*. Leaves smooth; corollas club-fig-shaped; antheræ and style included.—Native of the Cape.

58. *Erica Coccinea*; *Scarlet Heath*. Calices hirsute; corollas club-fig-shaped; anthers subincluded; style included; flowers copious; corollas pubescent.—Native of the Cape.

59. *Erica Conspicua*; *Long-tubed Yellow Heath*. Leaves smooth; corollas cylindric, curved, very long, hairy, with a revolute border; anthers subincluded; style standing out. It flowers from May to August.—Native of the Cape.

60. *Erica Cerinthoides*; *Honeywort-flowered Heath*. Corollas club-fig-shaped; stigma included, cruciate. Branches compound; leaves oblong, convex, even, grooved underneath, ciliate with spinules; flowers large, heaped on the side into a sort of head, sessile, pubescent; calix rough with white hairs, as it were doubled; corolla bright blood-red, rough also with white hairs, having the mouth obscurely four-cleft. It flowers most part of the year.—Native of the Cape.

61. *Erica Fastigiata*; *Pointed Heath*. Corollas salver-shaped, in bundles; style included. This is a small shrub with even branches, streaked in four rows; leaves linear, acuminate, three-sided, even, rugged about the edge, erect, the length of the internodes, but the upper ones longer; flowers erect, fastigiate, terminating; calix similar to the leaves; corolla with a cylindric patulous tube, a little longer than the leaves; border flat, red above, white underneath, the four segments subcordate; stamina shorter than the corolla; anthers scarcely emarginate.—Native of the Cape.

62. *Erica Cubica*; *Square Heath*. Calices four-cornered; corollas bell-shaped, acute; style included. Stem shrubby, determinately branched; leaves spreading, linear, acute, longer than the internodes, slightly incurved, on white petioles; flowers terminating, corymbd, on submentose peduncles, having bristle-shaped bractes in the middle; calix scarious, with the leaflets obcordate, keeled, and bent in; corolla half four-cleft, purple, with a pale base, twice as long as the calix; stigma obtuse.—Native of the Cape

63. *Erica Denticulata*; *Toothed Heath*. Calices toothed; corollas ovate, funnel-shaped; style included. Stems distorted, as in Common Heath; leaves crowded together, spreading a little, subcylindric, even; flowers in terminating bundles; calix doubled; tube of the corolla long, ovate, the segments ovate, obtuse, spreading; anthers not longer than the corolla; stigma obtuse.—Native of the Cape.

64. *Erica Viscaria*; *Clammy-flowered Heath*. Flowers in racemes; corollas bell-shaped, glutinous; style included. Stem determinately branched; leaves linear, erect, acute, longer than the internodes, rugged at the edge; bractes calicine, rude, approximating; calix rude, awl-shaped, half the length of the corolla, which is purplish, with the segments erect and acute; antheræ bifid, with a cavity on the outside, and very short; style shorter than the corolla, but twice as long as the stamens, purple; stigma headed, four-lobed. It flowers in March.—Native of the Cape.

65. *Erica Granulata*; *Granulated Heath*. Calices subimbricate; corollas globular; style included; leaves linear, erect; flowers terminating, few, peduncled; calix scarious, very short; colour of the corollas red; anthers rugged, bifid at the tip, as it were two-horned; stigma headed. This resembles the 20th species.—Native of the Cape.

66. *Erica Comosa*; *Tufted-flowered Heath*. Flowers heaped; corollas ovate-oblong; style included. Branches heaped above the flowers; leaves linear, bluntish, erect; flowers heaped, lateral, below the top of the stalk; stigma headed.—Native of the Cape.

67. *Erica Sparmanni*; *Sparmann's Heath*. Leaves imbricate, ciliate; heads four-flowered; corollas tubular, strigose-hispid; anthers subincluded. This species is remarkable for having the flowering heads divided into four flowers; before these are elongated, the head appears globular and echinate, as in *Achyranthes*, from the very spreading yellow bristles of the leaves of the involucre and calix. Corollas extremely hirsute, with a four-cleft mouth, the segments very short.—Observed by Sparmann far inland from the Cape.

68. *Erica Concinna*; *Flesh-coloured Heath*. Leaves in sixes or thereabouts, smooth; flowers terminating, umbelled; corollas cylindric, attenuated at the base. Branches smooth; leaves on the branches in sixes, on the branchlets in fours, petioled, erect, acerose, four lines in length; petioles smooth, scarcely half a line long; flowers from three to six in an umbel; peduncles filiform, somewhat hairy, two lines in length; corolla flesh-coloured, somewhat villose on the outside, scarcely an inch long, the thickness of a fowl's quill; filaments smooth, a little shorter than the tube of the corolla; anthers oblong, acuminate at the base, two-parted at top, as far as the middle, where they are fixed to the filaments, they are awnless, and of a brown colour; germen turbinate, concave above, crenulate on the edge; style red, the length of the stamina; stigma subcapitate, very dark red. It flowers in September and October.—Native of the Cape.

69. *Erica Massoni*; *Tall Downy Heath*. Leaves in eight rows, imbricate, pubescent; flowers capitate; corollas cylindric, fig-shaped. Stems shrubby, filiform, covered all round with leaves; leaves in fours, imbricate in eight rows, very short, elliptic, crowded, obtuse, ciliate, so that they appear villose; flowers in a terminating sessile head, tipped with green.—Native of the Cape.

70. *Erica Rosaria*; *Rose-scented Heath*. Leaves in four rows, obtuse, recurved, toothed; antheræ simple, included, with long pores; corollas ovate, viscid. The leaves resemble those of the 39th species, but are more distant and recurved. Flowers about the ends of the branches, on mostly axillary, long, viscid stalks, with two or three oblong, pellucid, concave

bractes towards their middle; the flowers droop a little, and are remarkable for their fragrant scent, resembling that of roses. The calix-leaves are like the bractes, and about one-third as long as the corolla, which is of a pale straw-colour, ovate, inflated, viscid, its segments obtuse, crenate, but little spreading; stamina about the length of the calix, their filamenta purple at the summit, without any crust or appendages; antheræ brown, oblong, with pores two-thirds of their length; germen turbinate, furrowed, smooth; style twice as long as the stamina; stigma capitate, dark-coloured.—Imported lately from the Cape.

**** *Antheræ awnless, standing out; Leaves in threes.*

71. *Erica Plunkenetii*; *Smooth-twigged Pencil-flowered Heath*. Calices simple; corollas cylindric; anthers very long; style standing out. Leaves linear, crowded; flowers peduncled, nodding; calix shorter by half than the corolla, awl-shaped, keeled; corolla long, with the mouth obscurely four-cleft; stamens almost membranaceous, linear, obtuse, twice as long as the corolla. This resembles the following species; but the calix in this is simple, in that cartilaginous and imbricate.—Native of the Cape.

72. *Erica Petiveri*; *Downy-twigged Pencil-flowered Heath*. Calices imbricate; corollas acute; anthers very long; style standing out. This is a brown shrub; branches covered with branchlets in threes, crowded, very short, pubescent, clothed with squarrose leaves, which are also crowded, awl-shaped, subtrigonal, somewhat rugged at the edge, patulous, or standing out at the tip; flowers solitary at the end of the branchlets, drooping, on a short pubescent peduncle; calix subcartilaginous, angular, imbricate, with similar but shorter bractes, in threes; corolla cylindric, three times as long as the leaves, with a four-cleft, acute, yellow mouth. It flowers from January to March.—Native of the Cape.

73. *Erica Nudiflora*; *Naked-flowered Heath*. Branches tomentose; corollas cylindric, scattered. Stem shrubby, determinately branched, round, twisted; bark covered with a white nap, chinky, deciduous; branchlets very many, erect, leafy, many-flowered, very closely tomentose; flowers numerous, axillary, peduncled, nodding a little; peduncles the length of the leaves, capillary, pubescent; bractes none; corolla bell-cylindric, half the length of the peduncles, almost four times as long as the calix, smooth, four-cleft at the edge; segments small, blunt, upright; filaments erect, parallel, capillary, smooth; stigma headed, blunt.—Native of the Cape.

74. *Erica Bruniades*. Flowers scattered; corollas covered by a woolly calix; style standing out. Leaves linear, remote, patulous, with a few hairs scattered over them; the calices, clothed with a white wool, cover the whole subtruncate corolla. Thunberg makes this to be the same with the 48th species.—Native of the Cape.

75. *Erica Imbricata*; *Imbricate Heath*. Corollas bell-shaped, covered with the imbricate calix; style standing out. Flowers lateral, white; corolla covered with the white calix.—Native of the Cape.

76. *Erica Umbellata*; *Umbelled Heath*. Leaves acerose; corollas bell-shaped; style standing out. This little shrub has the habit of common Heath. Leaves short, smooth, with a white line underneath; umbellets naked, without an involucre; calix compound; corolla pale blue, angular; anthers gibbous, tailed at the base.—Native of Portugal. See the 12th species.

Leaves in fours, or more.

77. *Erica Purpurascens*; *Purple Heath*. Flowers scattered; corollas bell-shaped; style standing out. Leaves in threes or fours, but on the upper branchlets in fives, according to Seguier; calix awl-shaped; corollas cylindric.—Native of the south of Europe. See the twelfth species.

78. *Erica Vagans*; *Wandering Heath*. Flowers solitary; corollas bell-shaped; style standing out. Stem like that of *Empetrum*, shrubby, somewhat rugged; the extreme branches whitish and divaricating; leaves in fours, seldom in fives, linear, bluntish, sometimes smoothish, sometimes a little rugged, beneath convex and channelled, shortish, crowded; flowers on the sides of the branchlets, scattered, peduncled; calix coloured, erect, concave, very short; corolla blunt; anthers without any tail, two-parted; stigma simple. This and the 81st species are supposed to be the same.—Native of Africa. See the twelfth species.

79. *Erica Herbacea*; *Early-flowering Dwarf Heath*. Flowers directed all one way; corollas oblong; style standing out. This is a small shrub, from a foot to eighteen inches in height, decumbent at bottom, then upright, branched, flexible. Leaves almost covering the whole stem, deciduous, resembling those of the Fir, thickish, having a prominent nerve, narrow, very sharp, smooth; flowers at the tops of the branchlets, on short peduncles, alternate, among the leaves; they come out in autumn, continue closed in winter, and are then green; in May, the year following, the flowers are unfolded, the anthers which were enclosed are protruded, the calix and corolla opening are both changed into a pale purple or flesh-colour.—Native of Austria, Switzerland, and Silesia. See the twelfth species.

80. *Erica Multiflora*; *Many-flowered Heath*. Leaves in fives; flowers scattered; corollas cylindrical; style standing out. Stem the height of a man; leaves in fours or fives, spreading, obtuse, gibbous at the base; flowers purplish. It flowers from June to November.—Native of the south of Europe. See the 12th species.

81. *Erica Didyma*; *Double-anthered Heath*. Leaves in fives; peduncles scattered, longer than the flower; corollas bell-shaped; anthers twin; style standing out. Stems twisted, trailing; branches between scored and angular, light reddish brown, the more slender shoots ash-coloured, all lateral, to seven or more rising from the same point in the manner of an umbel; leaves linear, somewhat like those of Fir, bowed sideways, smooth, but not glossy; flowers roundish, on long slender peduncles from the sides of the branches, beginning from below the middle, and extending to the ends, continuing on, at least in the cultivated plants, till the next season; corolla truly bell-shaped, pointed at the base, cloven near half way down; segments broad, soon coming to a bluntish point, spreading, generally of a pale flesh-colour, approaching to white, but sometimes with a deep tinge of purple; filaments capillary; somewhat flattened, white, as long as the corolla; seeds reddish brown.—Found on heaths; as on Goonhilly-downs, going from Helston to the Lizard Point, in Cornwall. It flowers from June to August. See the first species.

82. *Erica Mediterranea*; *Mediterranean Heath*. Leaves spreading; flowers scattered; corollas ovate; style standing out. Branches whitish, angular; leaves in fours, seldom in fives, even; flowers lateral; calix simple, coloured, lanceolate-acute, shorter by half than the corolla; style twice as long as the corolla. It flowers from March till May.—Native of the south of Europe. See the 12th species.

83. *Erica Grandiflora*; *Great-flowered Heath*. Leaves in sixes or thereabouts, acrose, smooth; flowers axillary, peduncled; corollas cylindrical, subincurved, smooth; style elongated. It flowers from May to July.—Native of the Cape.

84. *Erica Tetragona*; *Four-sided Heath*. Leaves in threes; flowers in racemes, pointing all the same way; calix linear; corolla four-cornered, oblong; style included. Flowers yellow.—Native of the Cape.

85. *Erica Pyramidalis*; *Pyramidal Heath*. Antheræ awnless, included; corollas funnel-shaped, in fours; style a little protruded; leaves in fours, pubescent.—Native of the Cape of Good Hope.

Erigeron; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common oblong, cylindrical, imbricate; scales subulate, upright, gradually longer, nearly equal. *Corolla*: compound, rayed; corollas hermaphrodite, tubular in the disk; females ligulate in the ray; proper of the hermaphrodite funnel-form; border five-cleft; of the female ligulate, linear, subulate, upright, commonly quite entire. *Stamina*: in the hermaphrodites; filaments five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: in the hermaphrodites; germen very small, crowned with a down longer than its corollet; style filiform, length of the down; stigmas two, very slender. *Pericarp*: none; the calix converging. *Seeds*: in the hermaphrodites oblong, small; down long, hairy; of the females, extremely like the hermaphrodites. *Receptacle*: naked, flat. *Observe*. The inmost or intermediate florets of the disk are commonly males: one species has female florets. ESSENTIAL CHARACTER. *Receptacle*: naked. *Down*: hairy. *Florets* of the ray linear, numerous, and very narrow.—The species are,

1. *Erigeron Viscosum*; *Clammy Erigeron*. Peduncles one-flowered, lateral; leaves lanceolate, toothletted in the middle, reflex at the base; calices squarrose; corollas radiate. Stem upright, stiff, striated, hairy, viscid, branched from the very bottom, near three feet high; leaves stem-clasping, thick, rough with hairs, having glands between them, exuding a clammy juice; strong-scented, rounded; on the branches linear, entire; flowers single, on pretty long foot-stalks, some from the side, others from the end of the stalk; they are yellow, have an agreeable odour, and appear in July.—Native of the south of France, Italy, Sicily, Portugal, and Spain, by way-sides, and on the borders of vineyards. It is used to drive away fleas and gnats, the strong scent, as some suppose, being disagreeable to those insects; but it is probable they are caught by the clammy juice of the leaves and stalks. The old name of this plant is *Great Sweet Fleabane*, or *Great Fleawort*.—It is propagated by seeds, which, if sown in autumn, will more certainly succeed than those which are sown in the spring. When the plants come up, they should be thinned, if they are too close, and kept clean from weeds till autumn, when they should be transplanted where they are to remain. They delight in a dry soil and sunny exposure. The second year the plants will flower and perfect their seeds, but the roots will continue several years, and annually produce their flowers and seeds.

2. *Erigeron Graveolens*; *Strong-smelling Erigeron*. Leaves sublinear, quite entire; branches lateral, many-flowered. Root annual; stems upright, purplish, hairy, and viscid, from eight or ten to eighteen inches in height, striated, branched the whole length; branches patulous, at bottom longer, alternate, simple, crowded, all flowering; leaves sessile, narrow, lanceolate, quite entire, a little scabrous, with very small hairs, viscid at the end, scattered over them, strong-smelling, of a russet dusky colour; corolla yellow, small, with a minute upright ray of five or six florets, purplish underneath. In gardens the stalks are stiff, and about three feet high; the flowers are produced in close bunches, from the side of the stalk towards the top; they appear in July, and in warm seasons the seeds ripen in England. It was formerly called *Small True Fleabane*.—It is a native of the south of France and Italy, and very common near Madrid.

3. *Erigeron Glutinosum*; *Glutinous Erigeron*. Leaves lanceolate-linear, hairy, viscid; peduncles one-flowered. Root

perennial; stems a long span in height, slender; leaves quite entire, narrow and sharp, villose and glutinous; peduncles alternate, one-flowered, few in number; semiflorets twenty and more in a flower, purple.—Native of the south of France and Spain, on mountains near the sea-coast. It flowers in August.

4. *Erigeron Siculum*; *Red-stalked Erigeron*. Lower calicine scales loose, longer than the flower; peduncles leafy; stems red; flowers without any ray, small; peduncles covered with linear, recurved, minute leaves. Annual.—Found in Sicily, and about Montpellier, in marshes. It flowers in August and September.

5. *Erigeron Carolinianum*; *Carolina Erigeron*. Stem panicled; flowers subsolitary, terminating; leaves linear, quite entire. Stems three feet high and more, straight, round, streaked, the thickness of the little finger at bottom, where they are red, growing gradually more slender upwards; the leaves from top to bottom are frequent, very narrow, and somewhat hairy: towards the top the stem puts forth branches, forming in the whole a sort of pyramid; these are covered with leaves, like those of the stem, only shorter and narrower; each of these bears one small flower, sometimes more; the root-leaves are like those on the stem, only shorter and blunter. Perennial.—It is a native of North America, and hardy enough to flower in the open ground, in July and August.

6. *Erigeron Canadense*; *Canadian Erigeron*. Flowers in panicles, hairy, rough; leaves lanceolate, ciliate; root annual; stem firm, hairy, sometimes three or four feet high, frequently crooked, much branched towards the top, and even from the middle; the branches gradually shorter, and forming a long cone; flowering-heads numerous, or simple; on branched slender peduncles; florets very small.—It came originally from North America, but now has the appearance of being indigenous in many parts of Europe; it is not uncommon about London, and in Glamorganshire, on cultivated grounds, and on rubbish. It flowers in August. Petivers calls it *White Golden Rod*. This, with the seventh, thirteenth, and fourteenth species, are preserved in botanic gardens for the sake of variety, but are seldom admitted into gardens for pleasure.

7. *Erigeron Bonariense*; *Buck's-horn Erigeron*. Leaves rolled back at the base. Root annual; stem angular, firm, hirsute, branched at top; leaves alternate, lanceolate, hirsute, and soft, sessile, the lower ones tooth-gashed, the upper entire, narrower, and almost linear, towards the base waved, the midrib more prominent and hirsute; flowers on the top of the stem, and at the extremities of the branches.—It flowers in July and August, and is a native of Buenos Ayres, in South America. It is an annual plant, and, like the thirteenth species, when once admitted into a garden, and suffered to scatter its seed, will become a very troublesome weed, although it is very serviceable to cover rubbish or rock-work.

8. *Erigeron Jamaicense*; *Jamaica Erigeron*. Stem few-flowered, subvillose; leaves wedge-form, lanceolate, with two serratures on each side. Root almost single, but sometimes subdivided, descending; stems erect, or ascending, often a span high, filiform, pubescent, almost single; flowers subsolitary, terminating, peduncled, whitish; those on the top of the stem resemble Groundsel flowers, composed of many small yellow florets set close together, encircled by many whitish, long, narrow semiflorets.—Native of Jamaica.

9. *Erigeron Philadelphicum*; *Spreading Erigeron*. Stem many-flowered; leaves lanceolate, subserrate, those on the stem half stem-clasping; floscules of the ray capillaceous, the length of the disk: perennial.—It flowers from June to August, and is a native of North America, where it was observed, as well as in Canada, by Kalm.

10. *Erigeron Purpureum*; *Purple Erigeron*. Stem many-flowered, hairy; leaves oblong, somewhat toothed, stem-clasping; corollas of the ray capillaceous, longer than the disk. Root perennial; stem herbaceous, branched, a foot or more in height; flowers panicled; corollas of the ray very numerous, purple, of the disk yellow.—It flowers in July and August, and is a native of Hudson's Bay.

11. *Erigeron Ægyptiacum*; *Egyptian Erigeron*. Leaves half stem-clasping, spatulate, toothed; flowers globular. Root annual; stem simple, upright, a foot and half high, somewhat streaked, ash-coloured, pubescent, and somewhat viscid; flowers panicled, terminating, four or five, peduncled, roundish, on purplish peduncles; corolla florets minute, those in the ray naked and abundant; style cloven, yellow, capillary, quickly disappearing.—Native of Sicily and Egypt.

12. *Erigeron Gouani*; *Cluster-flowered Erigeron*. Flowers heaped; calices scarious; leaves lanceolate, somewhat toothed, scabrous about the edge. Root annual, bitter; stem upright, round, a foot high, simple, with a few upright hairs; flowers panicled; corollas whitish, with white down; calix roundish, imbricate; scales lanceolate, naked, convex, close, scarious about the edge, bluntish, not patulous, with a subulate tip. It flowers in July and August.—Native of the Canary Islands.

13. *Erigeron Acre*; *Blue Erigeron*. Peduncles alternate, one-flowered; root perennial, or, according to some, biennial, fibrous, acrid; stems from six to eighteen inches high, upright, somewhat angular, hairy, often purple, in some scarce branched at all, in other plants very much so. The upper part of the stem is divided into alternate branches, each bearing a single flower, which never expands, and is externally purple, but internally yellow, with a cavity in the middle.—It is often found in dry lofty pastures, especially in sandy and calcareous soils, and upon old walls. It has been found growing at the Block-house at Gravesend, and near Charlton wood, but is not often seen near London. It flowers from July to September. Cows and goats refuse to eat it. The Germans take a decoction of it to attenuate viscid phlegm. English botanists have named it *Blue-flowered* or *Purple Fleabane*, which name is also applied to several other of this genus, and tends very much to confound it with the genus *Conyza*, to which the intelligent reader is referred.

14. *Erigeron Alpinum*; *Alpine Erigeron*. This so strongly resembles the preceding species, that Haller suspects it to be only a variety. It has frequently a higher stem, but the height varies much in both; the flowers are larger, the semiflorets more numerous, the leaves longer, the feather dense and whitish.—Native of Alpine pastures. Found on Ben Lawers, and other high mountains in Scotland. Perennial; flowering in July and August. It may be propagated by seeds, in a shady situation and moist soil. See the first species.

15. *Erigeron Uniflorum*; *Dwarf Erigeron*. Stem one-flowered; calix hairy. Root perennial; stems a finger's length; leaves few, lanceolate, almost smooth on the upper surface, but with spreading hairs scattered over the lower; the stem-leaves often sublinear, the root-leaves oblong. The flower is as large as in the foregoing species, thick; the scales covered with a white nap, lanceolate, broader; all the semiflorets ligulate, with no imperfect ones, sometimes purple. All the varieties with one and many flowers, with a smooth and hairy calix, with blue and white flowers, make but one species.—It flowers in August and September; and is a native of the European mountains, from Lapland to Italy.

16. *Erigeron Gramineum*; *Grass-leaved Erigeron*. Stem one-flowered; leaves linear, ciliate, scabrous. This is a small perennial plant, guarded with fading dry leaves.—Native of Siberia.

17. *Erigeron Camphoratum*; *Virginian Erigeron*. Leaves lanceolate-ovate, villose; serratures cartilaginous at the tip.—This plant is annual, and a native of Virginia.

18. *Erigeron Japonicum*; *Japan Erigeron*. Leaves sessile, obovate, serrate, villose; flowers panicled. Annual: stem simple, filiform, hairy, upright, a foot high; leaves attenuated to the petioles, half stem-clasping, obtuse, upright, an inch in length; flowers terminating; feather simple, ferruginous.—Native of Japan, where it flowers in June.

19. *Erigeron Scandens*; *Climbing Erigeron*. Leaves ovate, serrate, villose; flowers axillary; stem climbing, filiform, branched, purplish, smooth. Leaves from each bud three or four, subsessile, sharp, with setaceous teeth, villose on both sides, half an inch in length; flowers among the leaves, axillary, solitary.—Native of the Cape of Good Hope.

20. *Erigeron Tuberosum*; *Tuberous-rooted Erigeron*. Leaves linear; branches one-flowered; stem suffruticose. Root perennial, bitten; stem short, woody; branches simple, one-flowered; flowers yellow, terminating, sessile; feather gray.—Native of the south of France, and Syria.

21. *Erigeron Fœtidum*; *Stinking Erigeron*. Leaves lanceolate-linear, retuse; flowers corymbed; root perennial, thick, fibrous, from which arise several upright hairy stalks, near four feet high, putting out several side-branches. The stem is terminated by several large corymbs of golden-coloured flowers, which appear late in the autumn, continue in beauty during great part of the winter, fade in the spring, and are sometimes succeeded by oval seeds, which ripen in England; the stems generally decay the second year, and are then supplied by new ones from the same root; the old ones, with their green hairy leaves, remaining in vigour until the young ones are grown to a considerable height. It has been long cultivated in the gardens of curious Europeans. It is too tender to thrive in the open air in this country, so the plants should be kept in pots; and if in the winter they are placed in a common frame, where they may have a large share of free air in mild weather, and screened from hard frosts, they will thrive better than with tender treatment. It is easily propagated by cuttings, which, if planted in May, will readily put out roots, and the young plants will flower the autumn following.

22. *Erigeron Obliquum*; *Oblique-leaved Erigeron*. Very much branched; leaves ovate, oblique. Annual: stem herbaceous, a hand high, round, erect, hairy, branching very much; branches from all the axils, the lower ones gradually longer, diffused at top, dichotomous, opposite; flowers solitary, the length of the peduncle, one-flowered, copious; calix cylindrical, pubescent, with numerous, equal, subulate, approximating leaflets; corollas yellow; stigmas of the disk erect, of the ray patulous.—Native of the East Indies.

23. *Erigeron Tricuneatum*; *Wedge-leaved Erigeron*. Somewhat shrubby; leaves wedged, three-lobed. A small shrub, very much branched or panicled, leafy; flowers terminating, sessile, several, heaped together, the length of the leaf; calix the size of a Lentil-seed.—Native of Mexico.

24. *Erigeron Pinnatum*. Leaves pinnatifid, toothed; stem herbaceous, upright, a foot high, somewhat hispid, simple; flowers terminating, subglomerate, yellow; feather white.—Native of the Cape of Good Hope.

25. *Erigeron Sumatrense*. Tomentose; flowers raceme-panicled; leaves lanceolate, subserrate; stem three feet high and more, round, streaked, tomentose, red; peduncles long, raceme-panicled, with one or two narrow lanceolate leaves on them, generally entire.—Native of Sumatra.

26. *Erigeron Scriceum*; *Silky-leaved Erigeron*. Flowers panicled; leaves ovate-lanceolate, tomentose, silky, entire,

and serrate, appendicled at the base; stem upright, simple; tomentose; panicle diffused.—Native of Java.

27. *Erigeron Hirsutum*. Stem hispid; leaves linear-lanceolate, subserrate, very hairy on both sides. Stem herbaceous, two feet high, erect, round; flowers few, in a terminating erect panicle; florets in the disk yellow, in the ray stiff, quite entire, blue, many.—Native of China, near Canton.

28. *Erigeron Rivulare*. Leaves wedge-shaped, acute, rough with hairs, toothed on both sides at the tip, ciliate on the edge, those on the stem sessile; stem almost simple, erect, few-flowered.—Annual: native of Jamaica and Hispaniola.

29. *Erigeron Decurrens*. Leaves decurrent, linear, tomentose; flowers panicled; stem erect, striated, pubescent, tomentose at top; branches woody, pedicels capillary, with a pair of minute leaflets towards the tip; calices villose; scales bristle-shaped, shorter than the down; corollas of the ray naked.—Native of Arabia.

30. *Erigeron Incanum*. Leaves linear, tomentose, toothed a little; flowers corymbed. This is a shrub with tomentose branches; corymbs terminating, many-flowered; calix subvillose, with linear leaflets; corollas of the ray naked; down ferruginous, longer than the calix.—Native of Arabia Felix.

Eringo. See *Eryngium*.

Erinus, a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaves lanceolate, upright, nearly equal, permanent. *Corolla*: one-petalled, unequal; tube ovate-cylindric, length of the calix, bent back; border flat, five-parted; divisions equal, obcordate. *Stamina*: filamenta four, very short, within the tube of the corolla, of which the two opposite ones are a little longer. *Antheræ* small. *Pistil*: germen somewhat ovate; style very short; stigma headed. *Pericarp*: capsule ovate, rolled up in the calix, two-celled, gaping two ways. *Seeds*: numerous, small. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: border five-cleft, equal, with the lobes emarginate; upper lip very short, reflex. *Capsule*: two-celled.—The species are,

1. *Erinus Alpinus*; *Alpine Erinus*. Flowers racemed; leaves spatulate; root perennial. The root-leaves form a thick tuft close to the ground; they are all linear-spatulate, pubescent, with a few serratures at the end on both sides; stems many, very simple, a hand high, round, pubescent, upright, the side ones barren and decumbent; flowers alternate, separated by leaves like those on the stem, but smaller, and forming an upright simple raceme; corolla funnel-shaped. The leaves are about half an inch long, and one-eighth of an inch broad, of a dark green, on the stem alternate; the flower-stalk is scarcely two inches high; the flowers are in a loose raceme, and purple; they appear in May, or earlier, and sometimes are succeeded by ripe seeds in July. This is a desirable little plant for the decoration of rock-work, growing in close tufts, and producing its numerous lively purple flowers during most of the summer months.—Native of Germany, of the Swiss Alps, of the Pyrenees, and the south of France. This is propagated by parting the roots in autumn; requires a shady situation, and a loamy soil without dung.

2. *Erinus Africanus*. Flowers lateral, sessile; leaves lanceolate, somewhat toothed; stem herbaceous, branched, a span long, declined; flowers solitary, in the axils of the leaves, purple, slender.—Native of Africa.

3. *Erinus Capensis*. Flowers spiked; leaves linear, toothed; perennial. Stem erect, round, pubescent, two feet high; spike terminating, oblong, imbricate, with broader, ovate-lanceolate, toothed bractes; corolla yellow, smelling very sweet; tube filiform, three times as long as the calix; style filiform, the length of the tube.—Native of the Cape.

4. *Erinus Fragens*. Leaves lanceolate, oblong, toothed; divisions of the border entire; stem simple; corollas tomentose on the outside, of a dark colour, fragrant at night.—Native of the Cape of Good Hope.

5. *Erinus Peruvianus*. Leaves lanceolate-ovate, serrate.—Native of Peru; said also to be found at the Cape.

6. *Erinus Maritimus*. Leaves lanceolate, quite entire, smooth; divisions of the border cloven half way.—Native of the Cape of Good Hope.

7. *Erinus Tristis*. Leaves oblong, gashed, toothed; divisions of the border emarginate. The flowers are sweet, but of a dull colour.—Native of the Cape of Good Hope. This, and the five preceding species, require the protection of the dry-stove, and may be increased by cuttings.

8. *Erinus Laciniatus*. Leaves laciniate. See *Buchnera Americana*, and *Verbena Aubletia*.—This, together with the ninth, tenth, eleventh, twelfth, and thirteenth species, must be placed in the bark-stove. The eleventh, being a shrubby plant, will continue several years, but the others are annual. They are propagated by seeds sown in pots filled with light earth, and plunged into a moderate hot-bed, where sometimes they will come up in five or six weeks; but they frequently do not vegetate till the following spring, especially when the seeds have been kept long. When the plants are fit to remove, they should be each planted in a separate small pot filled with light earth, not too rich with dung, and then plunged into the bark-pit. When they have taken new root, treat them as other plants from the same countries, by admitting proper air when the weather is warm, and frequently refreshing them with water; with this management, the annual sorts will flower in July and August, and often ripen their seeds in autumn, if brought forward early in the spring. The shrubby sort must also frequently be refreshed with water in winter, but not in large quantities, nor in very cold weather: the plants will flower and perfect their seeds in the second year.

9. *Erinus Tomentosus*. Tomentose: stems procumbent; flowers sessile, axillary. Stems trailing, about six inches long. At the joints, just above the leaves, come out the flowers, sitting very close to the stems; they are white, and are succeeded by round capsules. At a distance, this plant bears a great resemblance to *Sea Cudweed*.—Native of Vera Cruz.

10. *Erinus Americanus*. Stem erect; leaves lanceolate, opposite; flowers loosely spiked, terminating. Stem upright, two feet high; towards the top, two smaller branches opposite and erect; these and the middle stalk are terminated by loose spikes of purple flowers, succeeded by oval capsules.—Native of Vera Cruz.

11. *Erinus Frutescens*. Stem upright, shrubby; leaves ovate-lanceolate, serrate, alternate; flowers axillary, single, or two and three at a joint, sessile, white, succeeded by round capsules.

12. *Erinus Verticillatus*. Stem branching, trailing; leaves ovate, serrate, smooth, opposite; flowers in whorls, sessile, white, making but little appearance, and succeeded by round capsules.—Native of Vera Cruz.

13. *Erinus Procumbens*. Stems procumbent; leaves ovate, smooth; flowers solitary, axillary; peduncles longer; they are bright yellow, on long slender peduncles, succeeded by oval capsules.—Native of Hispaniola.

Eriocaulon; a genus of the class Triandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth common, globose-depressed, imbricate; scales lanceolate, equal, permanent. *Corolla*: universal uniform, convex; proper three-petalled; petals equal, lanceolate, obtuse, villose at the tip, attenuated at the base, and connected into a style-shaped

pedicel, which is hairy. *Stamina*: filamenta three, capillary, sitting on the germen; antheræ oblong, versatile. *Pistil*: germen slender, superior, under the stamina; styles three, capillary, short; stigmas simple. *Pericarp*: none; calix unchanged. *Seeds*: solitary, crowned with the corolla. *Receptacle*: chaffs of the size and figure of the calcine scales, one-flowered, very many. ESSENTIAL CHARACTER. *Calix*: common, an imbricate head. *Petals*: three, equal. *Stamina*: upon the germen.—The species are,

1. *Eriocaulon Triangulare*. Culm triangular; leaves ensiform; heads ovate.—Native of Brazil.

2. *Eriocaulon Quinquangulare*. Culm quinquangular; leaves ensiform.—Native of the East Indies.

3. *Eriocaulon Sexangulare*. Culm hexangular; leaves ensiform. The leaflets surrounding the head, instead of an universal calix.—Native of the East Indies.

4. *Eriocaulon Setaceum*. Culm hexangular; leaves setaceous. This is a small annual herb, tufted, and bent back in a ring; heads terminating, small, oblong, subacute; flowers aggregate, male and female in the same common, globular, chaffy receptacle; calix none. The male flowers have three petals to the corolla, somewhat hirsute on the outside, and six stamina; the females have six petals, and resemble the males; they have a roundish three-cornered germen, and three styles. The roots are dispersed in the water.—Native of the East Indies, and of Cochinchina.

5. *Eriocaulon Decangulare*. Culm decangular; leaves ensiform; flowers in a head; males in the disk, and females in the circumference.—Native of the swamps of North America.

6. *Eriocaulon Quadrangulare*. Culm quadrangular; leaves ensiform; head of flowers globular, truncate at the base. This is an annual herb, with an upright, naked, four-cornered culm, eight inches high; leaves short, smooth, few; head of flowers whitish, flattish at the base, with roundish scales, attenuated at bottom, one-flowered, closed; petals two, sub-concave, blunt at the tip, toothed; seeds three, ovate.—Common in every part of Cochinchina.

7. *Eriocaulon Septangulare*. Stalk a span high, seven-angled, solitary, upright, simple, naked, twisted; leaves two inches long, sharp-pointed, with an internal net-work of cells; head of flowers terminal, solitary, variegated with dark purple and white; male flowers four-stamined.—Found in lakes in the isle of Skye, and in Galway in Ireland.

Eriocephalus; a genus of the class Syngenesia, order Polygamia Necessaria.—GENERIC CHARACTER. *Calix*: common upright; scales ten, ovate, equal, converging, of which the five exterior are keeled, the interior flat. *Corolla*: compound, rayed; corollules hermaphrodite, twice as many in the disk; females five in the ray; proper of the hermaphrodite funnel-form; border five-cleft, patulous; of the ray ligulate, obcordate, with three-lobed equal tips. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: in the hermaphrodites; germen very small, naked; style simple; stigma two-cleft, sharp. In the females, germen ovate, naked; style simple; stigma acuminate, inflex. *Pericarp*: none; calix scarcely changed. *Seed*: to the hermaphrodites, none; females solitary, obovate, naked. *Receptacle*: naked, flat, or else a down of the calix in a double row is interspersed both between the hermaphrodite and female floscules. *Observe*. A compressed corpuscle adheres to the base of each calcine scale. *ESSEN. CHAR. Receptacle*: subvillose. *Down*: none. *Calix*: ten-leaved, equal. In the ray five floscules.—The species are,
1. *Eriocephalus Africanus*; *Cluster-leaved Eriocephalus*. Leaves entire and divided; flowers corymbed. This plant has a shrubby stalk, from four to six feet high, putting out

many side-branches the whole length. The leaves are woolly, coming out in clusters, some taper and entire, others divided into three or five parts, which spread open like a hand; when bruised, they emit a strong smell, approaching to that of Lavender Cotton, but not quite so rank. The flowers are produced in small clusters at the ends of the branches, and stand erect. They appear in autumn, but do not produce seeds in this country. It flowers from January to March, and is a native of the Cape of Good Hope.—This plant is propagated by cuttings, which may be planted any time from May to the middle of August; for if they be planted later in the season, there will not be sufficient time for them to get good root before the winter: these cuttings should be planted in small pots filled with light earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun till they have taken root; they must also be refreshed with water twice or thrice a week, but they should not have too much at a time, for much moisture is very hurtful to these plants. As soon as the cuttings have taken root, they should be gradually inured to the open air, to prevent their shoots from being drawn up weak; afterwards they should be removed into the open air, and placed in a sheltered situation, where they may remain till October, when they must be placed in an airy glass-case, that they may have as much sun as possible, and enjoy the free air in mild weather, but be at the same time secured from frost and damp air, either of which will soon destroy them. During the winter, they must be sparingly watered, for the reason before given; but in the summer, when the plants are placed in the open air, they will require frequent refreshment with water in hot weather. Both this and the next species retain their leaves all the year, and are therefore a valuable addition to the variety of exotics in the winter season.

2. *Eriocephalus Racemosus*; *Silvery-leaved Eriocephalus*. Leaves linear, undivided; flowers racemed. It has the stature and appearance of the preceding species, but all the leaves are undivided; flowers on pedicels shorter than the calix; outer scales of the calix four, ovate, subtomentose, with a very soft wool from the bosom of them.—Native of the Cape of Good Hope.

Eriophorum; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: spike on all sides imbricate; scales ovate-oblong, flat-inflected, membranaceous, loose, sharp-pointed, separating the flowers. *Corolla*: none. *Stamina*: filamenta three, capillary; antheræ upright, oblong. *Pistil*: germen very small; style filiform, length of the calicine scales; stigmas three, longer than the style, bent backwards. *Pericarp*: none. *Seed*: three-sided, acuminate, furnished with villose hairs longer than the spike. *Observe*. Some species are polygamous. ESSENTIAL CHARACTER. Glumes chaffy, imbricate every way. *Corolla*: none. *Seed*: one, surrounded with a very long wool.—This genus consists of bog plants, and are seldom preserved in gardens. They may, however, be planted in pots filled with bog earth, set in pans wherein water is constantly kept; or by the side of ponds or other waters.—The species are,

1. *Eriophorum Vaginatium*; *Mountain or Single-spiked Cotton Grass*. Culms sheathed round; spike scariose; root-leaves obscurely three-cornered, sharp, streaked on two sides; convex on one side, flat on two sides. Scape twice as long as the leaves, flattish on one side, streaked; stem-leaves awnless, sheathing, (sheath swelling a little,) the uppermost purple at the base. Ray calls this plant *Hare's-tail Rush*, and in Westmorland it is named *Moss-Crops*; which is also applied to the third species, as they do not distinguish between them. Sheep are very fond of both, from which they derive this common name.—Native of bogs in cold barren situations, in

various parts of Europe. It is not very general in England; but is found on Shirley common, near Croydon; near Lynn; on Birmingham heath; and is often met with in all the northern counties; upon Elsemere meers in Shropshire; and on Pillin moss in Lancashire.

2. *Eriophorum Polystachion*; *Many-spiked Cotton Grass*. Culms columnar; leaves flat; spikes peduncled.—Native of the Cape of Good Hope.

3. *Eriophorum Angustifolium*; *Narrow-leaved Cotton Grass*. Culms columnar; leaves channelled, three-sided; spikes peduncled. Stem from nine inches to a foot or more in height, upright, smooth, with two joints projecting a little, covered throughout its whole length with the sheaths of the leaves. Those next the root are of a chestnut colour, short, lanceolate, streaked, marked with transverse lines, which give them a reticulated appearance; floral leaves three or four, of unequal lengths, forming sheaths at bottom, terminate the stalk, from the axils of which the spikelets proceed. In Germany, and the more northern parts of Europe, the down of this plant has been manufactured into various articles of dress, paper, and wicks for candles. In some parts of Sweden, the peasants stuff their pillows with it, whence it is called *poorman's pillow*. It becomes brittle when quite dry. Early in the spring, cattle crop the leaves before the grasses are sufficiently grown.—Common on moors and boggy ground; insomuch that they are often white all over with it, in June and July, when it is in seed. It flowers in April and May.

4. *Eriophorum Virginicum*. Culms leafy, columnar; leaves flat; spikes upright, compact, leafy, large, brown, or gold-coloured.—Native of Virginia.

5. *Eriophorum Cyperinum*. Culms columnar, leafy; panicle superdecumbent, proliferous; spikelets mostly in threes.—Native of North America.

6. *Eriophorum Alpinum*. Culms naked, three-cornered; spike shorter than the down. Thick tufts of culms and leaves rise from the root; spikelets erect, having no sheaths: the least of all the species, swelling only one or two lines in length, pale, yellowish brown, with white hairs much longer than the spikelet, which is made up of lanceolate, acuminate, imbricate glumes, the lowest longer and broader than the rest, divided by a nerve that stands out, and is extended into a point; seed very small, yellowish.—Native of the mountains of Lapland, Sweden, Denmark, Silesia, Carniola, Switzerland. It flowers in June and July.—It was found in a moss, about three miles east of Forfar, Angusshire, Scotland.

Erithalis; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, superior, pitcher-form, five-toothed, permanent. *Corolla*: one-petalled, five-parted; tube very short; divisions lance-shaped, long, bent back. *Stamina*: filamenta five, subulate, patulous, scarcely the length of the corolla; antheræ oblong, linear, erect. *Pistil*: germen inferior, roundish; style filiform, compressed above, length of the stamina; stigma sharp. *Pericarp*: berry globose, crowned, ten-celled. *Seeds*: small. ESSENTIAL CHARACTER. *Corolla*: five-parted, with the divisions bent back. *Calix*: pitcher-shaped. *Berry*: ten-celled, inferior.—The species are,

1. *Erithalis Fruticosa*. Leaves opposite; corymbs compound. This is an upright elegant branching tree, fifteen feet in height; racemes compound, corymbed, axillary, opposite; flowers numerous, caducous, with white petals, mostly six-stamined, with a six-cleft calix and corolla, smelling exactly like the common Syringa.—Native of Jamaica and Martinico. Jacquin describes another plant, which is a native of Curaçao, and probably only a variety of this species, arising from its growing in the clefts of rocks, where there is

no earth. It is a shrub two feet high, with procumbent dif- fused branches; the leaves are thicker, and numerous; the berry and flowers smaller; the former entirely void of scent, the latter whitish, or very seldom purple.

2. *Erithalis Polygama*. Leaves obovate; flowers axillary; males cymed; hermaphrodites solitary.—Native of the So- ciety Isles. It has a variety with narrower leaves.

Ernodea; a genus of the class Tetrandria, order Monogy- nia.—GENERIC CHARACTER. *Calix*: perianth four-parted, small, superior; segments erect, acute, equal, permanent. *Corolla*: one-petalled, salver-shaped; tube four-cornered, elongated; border four-parted; segments lanceolate, revol- ute. *Stamina*: filamenta four, inserted in the middle of the tube, awl-shaped, longer than the corolla; antheræ erect, acuminate. *Pistil*: germen four-cornered, inferior; style filiform, longer than the stamina; stigma obtuse, emarginate. *Pericarp*: berry roundish, crowned by the calix, two- grooved, two-celled. *Seeds*: solitary, hemispherical, striated. ESSENTIAL CHARACTER. *Calix*: four-parted. *Corolla*: one-petalled, salver-shaped; berry two-celled. *Seeds*: soli- tary.—The only species hitherto discovered is,

1. *Ernodea Littoralis*. Root perennial; stem square, smooth; leaves nearly sessile, acute, with a spinous point. Leaves on the branchlets, opposite, sessile, an inch and a half long, lanceolate, attenuated to both ends, veinless, obscurely three-nerved or five-nerved, very smooth on both sides, shin- ing, quite entire, mucronate, cusped, stipuled, surrounding the branch, truncate, ciliate; flowers axillary, opposite, ses- sile, yellowish. It varies with broader and narrower leaves. Browne has named this plant *Knoxia*, probably from Knox, who resided many years in the island of Ceylon, and published an account of it.—Native of Jamaica, frequently found near the shore in the parish of St. George, running three or four feet or more along the ground, throwing out a few spreading branches as it creeps along.

Erodium; a genus of the class Monadelphia, order Pentan- dria.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, acute, concave, permanent. *Corolla*: petals five, obcordate or ovate, spreading, large; nectary, five scales alternate with the filamenta, and milliferous glands placed at the base of the stamina. *Stamina*: filamenta five, awl-shaped, connected at the base with the scales into the shape of a pitcher, but spreading at top, shorter than the corolla; antheræ oblong, versatile. *Pistil*: germen five-cornered, beaked; style awl-shaped, longer than the stamina, perman- ent; stigmas five, reflex. *Pericarp*: capsule five-grained, beaked, the cells opening inwards, each having a long tail fixed to it, which becomes spiral, and is hairy or bearded on the inside. *Seeds*: solitary, (seldom two together,) ovate-oblong. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-petalled. *Nectary*: five scales, alternate with the filamenta, and glands at the base of the stamina. *Fruit*: five-grained, with a spiral beak, bearded on the inside.—For the propagation and culture of this genus, see *Geranium*.— The species are,

* *Leaves compound, or pinnatifid.*

1. *Erodium Absynthoides*; *Wormwood-leaved Crane's-bill*. Caulescent; peduncles four-flowered, or thereabouts; leaves interruptedly bipinnate-laciniate; segments linear.—Found in Armenia by Tournefort, and on Mount Olympus by Dr. John Sibthorp.

2. *Erodium Chrysanthum*; *Golden-flowered Crane's-bill*. Almost stemless; peduncles four-flowered; leaves decom- poundedly pinnate, laciniate, silky. This species is very distinguishable by its yellow flowers.—Found on Mount Parnassus, by Sibthorp.

3. *Erodium Trichomanifolium*; *Maidenhair-leaved Crane's- bill*. Stemless; scapes leafless, four-flowered; leaves bipin- natifid, hirsute. This differs from the preceding species, in having the flowers flesh-coloured, marked with lines; the leaves smaller, and less cut; the scapes leafless and radical.— It was discovered by Billardiere on Mount Libanus.

4. *Erodium Pulverulentum*; *Hoary-leaved Crane's-bill*. Caulescent; peduncles many-flowered; leaves decom- posedly laciniate, mealy, hoary. The whole of this plant is covered with frequent, short, villose hairs, whence it has the appearance of being dusty.—Found in the kingdom of Tunis in Africa.

5. *Erodium Crassifolium*; *Upright Crane's-bill*. Umbels many-flowered; leaves pinnatifid, laciniate, thick; segments linear.—Native of the island of Cyprus. It flowers in April and May.

6. *Erodium Fœtidum*; *Stinking Crane's-bill*. Almost stemless; scapes radical, many-flowered; leaves interruptedly bipinnatifid; petals roundish. All the leaves are heaped about the root; they are hoary with hairs, the whole forming a triangle; calices large, striated, very hirsute; leaflets blunt, membranaceous at the edge, ending in a short awn; corolla large, blue, purple, or red. Lobel reports this plant to be insufferably fetid; others say, it is singular in having a very strong nauseous smell; and Gouan asserts, that its smell is strong, but neither nauseous nor musky.—Native of the country about Montpellier.

7. *Erodium Macrademum*; *Spanish Crane's-bill*. Subcau- lescent; scapes radical, many-flowered; leaves interruptedly bipinnatifid; petals ovate. The herb of this plant exactly corresponds with that of the preceding species.—Native of Spain.

8. *Erodium Supracanum*; *Silky-leaved Crane's-bill*. Almost stemless; scapes radical, two-flowered or thereabouts; leaves interruptedly bipinnatifid, thickish, silk-hoary on the upper surface.—Found in Montserrat in Catalonia.

9. *Erodium Petroselinum*; *Parsley-leaved Crane's-bill*. Peduncles two-flowered; leaves pinnate; leaflets pinnatifid; segments linear.—It is found upon the sandy coasts of Barbary.

10. *Erodium Alpinum*; *Alpine Crane's-bill*. Peduncles many-flowered; leaves interruptedly pinnatifid, laciniate; root perennial, running very deep into the ground; lower leaves smooth, and on very long footstalks; stems a foot and a half high, with leaves of the same form, but smaller, and opposite; flowers purple, many together, on very long pe- duncles.—Native of Italy. It flowers with us in June, but will not ripen its seed in England.

11. *Erodium Romanum*; *Roman Crane's-bill*. Stemless; scapes radical, many-flowered; leaves pinnate, leaflets pin- natifid. It has a rather thick tuberous root; stems irregular, branching, diffused, somewhat woody, and having swelling joints; at each of these is one leaf, opposite to which comes out the peduncle; the peduncles on the lower part of the stem are very long and naked, but those which terminate the branches are shorter, and have one or two small leaves at the base; the flowers are in small bunches, and continue in suc- cession most parts of the summer.—Native of Italy, where it is found about Rome; also of the Pyrenees, and of Provence.

12. *Erodium Cicutarium*; *Hemlock-leaved Crane's-bill*. Peduncles many-flowered; leaves pinnate; leaflets sessile, pinnatifid. Root annual; stems several, thickish, round, hir- sute, procumbent, and branched; pinnae of the leaves slightly hairy; pinnales sharply indented; flowers in an umbel, from three to six, of a rose-colour. This species varies ex- tremely, from nearly smooth to very hairy, and from very large and branched, with a many-flowered umbel, to small

and nearly simple, with few flowers. Dillenius mentions another remarkable variety, in which the petals are irregular, the two upper shorter, rounder, and marked with a greenish spot at the base. The common sort is found all over Europe, in Africa, Asia, North America, and the island of Madeira.—The last has been found in England, near Hackney, and in several parts of Suffolk.

13. *Erodium Moschatum*; *Musk Crane's-bill*. Peduncles many-flowered; leaves pinnate; leaflets subpetioled, unequally gashed. This strongly resembles the preceding, but has an ambrosial or musky scent: the whole plant is covered with hairs, which are glutinous, particularly those of the calix. All the parts are larger; the stem is swollen and crooked at the joints; corolla red or purple. Annual.—Native of France, Switzerland, the Cape of Good Hope, Syria, Barbary, Peru, and Great Britain, where it is found about Battersea, Streatham, &c. near London, near Bristol, Stourbridge, and in Westmoreland and Yorkshire.

14. *Erodium Tordylioides*; *Algiers Crane's-bill*. Peduncles many-flowered; leaves bipinnatifid, unequally serrate, the outmost lobes confluent.—Found on rocks near Algiers.

15. *Erodium Gruinum*; *Broad-leaved Annual Crane's-bill*. Peduncles many-flowered; leaves ternate, crenate-toothed, the outmost pinnatifid-lobed. This is an annual plant, with very broad leaves, cut on their sides regularly and crenate; flowers on long axillary peduncles; petals entire, and blue; beaks of the fruit remarkably large.—Native of Spain, Sicily, Candia, Cyprus, and Syria.

16. *Erodium Ciconium*; *Long-beaked Crane's-bill*. This is also an annual plant, which has several prostrate stems, nearly a foot long; peduncles axillary, three inches long; flowers pale blue; beaks of the fruit very long, but by no means so long as those of the preceding.—Native of the south of Europe, Barbary, Syria, Cyprus, and Madeira. There is a variety, the whole plant of which is rough with hairs. It is a native of the sandy coasts of Spain, Portugal, and Italy.

17. *Erodium Lacerum*; *Torn Crane's-bill*. Peduncles many-flowered; leaves doubly pinnatifid; segments very remote, linear, quite entire; stem grooved, branched, more than a foot high; leaves opposite, longer than the petioles, divided almost to the petiole into three pinnated segments; the pinules linear, with a point; corolla very pale blue colour, with equal petals.—Native of Portugal.

18. *Erodium Diphylum*; *Two-leaved Crane's-bill*. Peduncles many-flowered; involucre two-leaved, roundish; lower leaves three-lobed, upper pinnatifid, lacinate, gashed. The involucre is composed of two opposite, membranaceous, largish bractes, that are very conspicuous, and give it the significant trivial name. It is annual, and a native of Portugal, Gibraltar, Algiers, Tunis, Candia, and Cyprus.

19. *Erodium Muticum*; *Beardless Crane's-bill*. Peduncles many-flowered; leaves ternatifid, gashed, toothed; calices awnless.—Found in the kingdom of Tunis in Africa.

20. *Erodium Hymenodes*; *Barbary Erodium*. Peduncles many-flowered, leaves ternate, or ternatifid; segments roundish, lobed. The stem is scaly at the base, with membranaceous stipules, larger than in any other species.—Found by Desfontaines on the rocks of Barbary.

21. *Erodium Incarnatum*; *Flesh-coloured Crane's-bill*. Peduncles few-flowered; leaves three-parted, or ternate, trifid, rugged; stem somewhat shrubby, slender, smooth, and hard. The leaves are on very long petioles, heart-shaped, roundish, undivided, small; stipules lanceolate, very sharp; flowers red, flesh-coloured, or scarlet, with a paler disk.—Native of the Cape of Good Hope.

** *Leaves lobed, or undivided.*

22. *Erodium Malacoides*; *Mallow-leaved Crane's-bill*. Peduncles many-flowered; leaves heart-shaped, three-lobed; lobes lobed, obtuse, obsolete toothed. This is an annual plant, with the branches inclining to the ground, and spreading a foot and a half each way. The peduncles are placed on the side of these, and sustain many bright-red flowers. The fruits have long beaks.—Native of the south of Europe, Madeira, Barbary, Syria, the islands of the Archipelago, and of Peru.—There is a variety of this species, called the *Various-leaved Crane's-bill*, which is a native of the isle of Chio in the Mediterranean.

23. *Erodium Populifolium*; *Poplar-leaved Crane's-bill*. Peduncles many-flowered; leaves heart-shaped, sublobed, obtuse-toothed; stamina hirsute.—Found in Barbary.

24. *Erodium Nervulosum*; *Nerved Erodium*. Peduncles many-flowered; leaves heart-shaped, almost undivided, toothed, thick, nerved.—Native of Sicily.

25. *Erodium Glaucophyllum*; *Glaucous Crane's-bill*. Peduncles many-flowered; leaves oblong, obsolete crenate, glaucous; beaks feathered. Annual. Stem extremely simple, very short; peduncles from three to five flowered; corolla purple or pale blue, with a dark trifid line at the base. It is easily known by the gray or glaucous colour of the leaves, and the very long feathered beaks to the fruit.—Native of Egypt.

26. *Erodium Guttatum*; *Spotted Crane's-bill*. Peduncles three-flowered; leaves heart-shaped, obsolete lobed, tooth-serrate, ash-coloured, the centre of a different colour. The flowers are violet-coloured, with a very dark violet disk, and are extremely sweet-scented.—Found by Shaw and Desfontaines in Barbary.

27. *Erodium Maritimum*; *Sea Crane's-bill*. Peduncles three-flowered, or thereabouts; leaves heart-shaped, gashed, crenate, rugged; stems depressed, branched, lying close to the ground; root-leaves on long petioles, spreading in a circle on the ground, hairy, variously cut and jagged, sometimes nearly lobed; stem-leaves similar; peduncles shorter than the leaves; flowers one to three, pale red, small; beaks of the fruit very small, not exceeding half an inch in length.—Native of the English and Dutch coasts. Found in Norfolk and Cornwall, and also on the sandy commons in Worcestershire.

28. *Erodium Chamædryoides*; *Dwarf Crane's-bill*. Almost stemless; peduncles one-flowered; leaves heart-shaped, obtuse, crenate; leaves radical, on very long petioles, numerous, orbiculate, heart-shaped, shining, much shorter than the petioles; scapes a little longer than the petioles, with opposite bractes; petals white, quite entire, oblong, with villose claws, between which are green fleshy orbiculate glands.—Native of the islands of Minorca and Corsica.

Eroteum; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, concave, incumbent, permanent. *Corolla*: petals five, ovate, roundish, concave, entire, spreading. *Stamina*: filamenta numerous, (thirty,) shorter than the petals, erect, filiform, placed on the receptacle; antheræ roundish, minute. *Pistil*: germen ovate, pubescent, superior; style erect, generally longer than the stamina, awl-shaped, trifid at the tip, permanent; stigmas obtuse, simple, reflex. *Pericarp*: berry roundish, juiceless, acuminate, with the permanent style, smooth, three-celled. *Seeds*: in threes or fours, oblong, compressed a little. *Observe*. It has the inflorescence, flower, and habit of *Thea*, but the fruit is of a different kind. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-petalled. *Style*: trifid. *Berry*: juiceless, three-celled, many-seeded.—The species are,

1. *Eroteum Thæoides*. Leaves ovate-lanceolate, serrate-toothed; flowers axillary, solitary.—Native of Jamaica.

2. *Eroteum Undulatum*. Leaves elliptic-lanceolate, acuminate, serrate; flowers crowded, axillary. Branches flexuose at top, hairy, tomentose, especially towards the tip; leaves alternate, two or three inches long, coriaceous, broad lanceolate, acute at both ends, smooth, paler underneath, thicker at the edge; the younger ones nerved, and hairy underneath; petioles very short; peduncles four or five, but sometimes solitary, one-flowered, the same length with the petioles; calicine leaflets ovate, very finely ciliate, obtuse. It varies with smooth branches.—Native of Jamaica, St. Kitt's, Montserrat, and Guadaloupe.

Ervum; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth five-parted, length of the corolla; divisions linear, acuminate, nearly equal. *Corolla*: papilionaceous; standard flat, slightly reflex, roundish, larger; wings obtuse, shorter by half than the standard; keel shorter than the wings, acuminate. *Stamina*: filamenta diadelphous, (simple, and nine-cleft,) rising; antheræ simple. *Pistil*: germen oblong. *Style*: simple, rising. *Stigma*: obtuse, beardless. *Pericarp*: legume oblong, obtuse, columnar, knotty with the protuberant seeds. *Seeds*: two to four, usually roundish, somewhat compressed. *Observe*. This genus differs from *Vicia* in the stigma alone. ESSENTIAL CHARACTER. *Calix*: five-parted, the length of the corolla.—The species are,

1. *Ervum Lens*; *Flat-seeded Tare*, or *Common Lentil*. About two flowers on a peduncle: seeds compressed, convex. It is an annual plant, and the least of the pulse kind that is cultivated. It rises with weak stalks, a foot and a half high, having pinnate leaves at each joint, composed of several pairs of narrow leaflets, terminated by a tendril, which supports it by fastening about some other plant. The flowers come out on short peduncles from the sides of the branches; they are small, of a pale purple colour, and three or four together; legumes short and flat, containing two or three flat round seeds, a little convex in the middle. The flowers appear in May, and the seeds ripen in July.—It grows spontaneously in the corn-fields of France and Germany, the pastures of Carniola, and the vineyards of the Valais. The Lentil has not been long cultivated in England, and is now propagated, either as food for cattle, or for the seeds, which are used in soups. They are commonly eaten by the poorer inhabitants of some islands of the Archipelago, and other warm countries, although they are held in little estimation. Hill says, that when ground into powder, they make poultices for swellings, but are not much regarded.—The seeds of Lentils are commonly sown in March, where the land is dry, but April is the best time in moist ground. The usual quantity of seed allowed to an acre is, from a bushel and a half to two bushels. If these be sown in drills in the same manner as Peas, they will succeed better than when they are sown broadcast: the drills should be a foot and a half asunder, to allow room for the hoe to clean the ground between them; for if weeds be permitted to grow, they will overtop and starve the Lentils. The seeds will ripen in July, when the plants should be cut and dried, and the seeds afterwards threshed out for use.—There is another sort, or rather variety, which is cultivated by the name of French Lentil. It is the *Lens Major* of Caspar Bauhin, and is much more worthy of cultivation than the common sort, which is preferred before it. This pulse is frequently called *Tills* in some parts of England.

2. *Ervum Tetraspermum*; *Smooth Tare*. About two flowers on a peduncle: seeds globular, four in a legume; root annual; stems, in open places, slender, weak, and much

branched, but among corn supporting themselves by tendrils to a foot or more in height, two-edged, and inclining to four-cornered; stipules in pairs, the lower semisagittate, the upper entirely or nearly so; flowers on slender capillary peduncles, as often single as in pairs; calix somewhat hairy, the lower segments longest; corolla violet, often blood-coloured. This is easily distinguished from the third species, for in that the pods are hairy, and contain only two seeds; in this they are smooth, and contain four; in that the flowers grow in a kind of cluster, in this seldom more than two grow together. It is exceedingly fertile, one plant, casually pulled up, having two hundred and twenty pods on it. It is found in most corn-fields, clinging to the corn, and, if the season favours its growth, sometimes quite overcoming it. Both this and the next species are small annual Tares, which flourish among Wheat and Rye in many parts of England, and are not admitted into gardens. They may be easily destroyed in fields, if only cut up when they begin to flower.

3. *Ervum Hirsutum*; *Hairy Tare*. Peduncles many-flowered; seeds globular, two in a legume. Annual. Stems weak, much branched, climbing, quadrangular, streaked, from one to two feet high; lower stipules with two, three, or four awl-shaped teeth; the upper ones awl-shaped or entire; leaflets mostly linear, sometimes lanceolate, eight to twelve pairs, somewhat alternate, terminated by a branched tendril. It is easily distinguished from the foregoing; the leaves not being pointed, as in that, but truncate; the stipules divided into many more segments; the flowers, and consequently the legumes, growing in a kind of cluster, being rough, and containing two seeds. It grows among corn, and is more destructive to it, being stronger and more prolific than the other species. In wet seasons whole crops are overpowered by this plant. All sorts of cattle eat it.—These two are called *Tine Tare*, that with smooth pods, and this with rough pods. They are common in Japan and Cochinchina. See the preceding species.

4. *Ervum Soloniense*; *Spring Tare*. About two flowers on a peduncle, awned; petioles acuminate; leaflets obtuse; flowers small, reddish; legumes slender, an inch in length, with three or four minute hexadral seeds in each. It is distinguished by its earliness, the tenuity of its parts, and the shape of its seeds. It appears at the close of winter, in neglected pastures, in France; and flowers in April and May. See the first species.

5. *Ervum Monanthos*; *One-flowered Tare*, or *Lentil*. Peduncles one-flowered, larger than the common Lentil, climbing by means of bifid and trifid tendrils; petioles horizontal; leaflets sixteen to eighteen, linear, retuse, with a point; stipules two, alternately larger, different in form; peduncle one-flowered; calix three times shorter than the corolla, with the toothlets nearly equal; standard compressed, whitish, with violet veins; legume large, somewhat nodding, containing two or three seeds, the size of peas, compressed, with an obtuse margin. Annual: flowering from May to July.—Native of Russia; found also among Lentils at Herborn in Germany, and in the county of Nice. See the first species.

5. *Ervum Ervilia*; *Officinal Tare*. Germina naked and plaited; leaves unequally pinnate. This is an annual plant, rising with angular weak stalks a foot and a half high, having at each joint one pinnate leaf, composed of fourteen or fifteen pairs of leaflets, like those of the Vetch, but narrower. The flowers come out from the sides of the stalk, on peduncles an inch long, each sustaining two pale-coloured flowers, which are succeeded by short pods a little compressed, each containing three or four round seeds: the pods swell at the place where each seed is lodged. The seeds ground to flour are

sometimes used in medicine abroad; and the green herb for feeding cattle in some countries, but the plant is not worth cultivating for that purpose in England.

Eryngium; a genus of the class Pentandria, order Digynia. —**GENERIC CHARACTER.** *Calix*: receptacle common, conic; chaffs separating the sessile floscules. *Involucre* of the receptacle many-leaved, flat, exceeding the floscules; perianth proper, five-leaved, upright, sharp, shorter than the corolla, seated on the germen. *Corolla*: universal, uniform, roundish; floscules all fertile; proper five-petalled; petals oblong, the tips bent inwards to the base, straitened longitudinally by a line. *Stamina*: filamenta five, capillary, straight, exceeding the floscules. *Antheræ* oblong. *Pistil*: germen hispid, inferior; styles two, filiform, straight, length of the stamina; stigmas simple. *Pericarp*: fruit ovate, divisible in two directions. *Seeds*: oblong, columnar. *Observe*: In some species the seeds are deposited from the crust of the pericarp, in others they remain included in it. **ESSENTIAL CHARACTER.** *Flowers*: in a head; receptacle chaffy.—These plants have somewhat the appearance of thistles; the leaves are often spinous, as are also the involucre; the umbellets in some are enclosed in an involucre, which is often irregular and branched, in others they are dispersed.—The species are,

1. *Eryngium Fœtidum*; *Stinking Eringo*. Root-leaves lanceolate-serrate; floral leaves multifid; stem dichotomous. Root annual, or biennial; root-leaves bluntish, the serratures terminating in harmless spines; stem a foot high or more, green, somewhat angular, spreading, with the extreme branches flexuose. The whole plant has a penetrating, strong, though not very unsavoury, smell; the flowers are produced in small sessile heads, coming out at every division of the stalks, and at the ends of the branches; they are of a dull white colour, and make little appearance: they appear in June and July, and the seeds ripen in autumn.—It is a native of the West Indies, Mexico, Surinam, and Virginia. All parts of this plant are reckoned very powerful anti-hysterics, and much used by the negroes and poorer whites, on all occasions of that nature, from whence they name it *Fit-weed*; it is chiefly administered in decoctions or infusions.—As this plant is a native of hot countries, it will not thrive in England but in a warm stove. It is propagated by seeds, which, if sown in pots, and plunged into a moderate hot-bed, will come up much sooner than those which are sown in a hot-bed; and when the plants are fit to remove, they should be each planted in a small pot, and plunged into the bark-bed, and afterwards treated like other tender plants from the same country: the second year they will produce flowers and seeds; soon after which they commonly decay.

2. *Eryngium Aquaticum*; *Marsh Eringo*. Leaves gladiate-serrate, spiny; floral-leaves undivided. This plant has a perennial root, from which rise several long leaves, disposed round the root, like those of the *Aloe* or *Yucca*; they are of a gray colour, a foot long or more, and one inch and a half broad, stiff, and ending in spines; the stem is strong, two feet high, and divides at top into several peduncles, each terminated by an oval head of flowers, which are white, with a little cast of pale blue. They come out in July, but unless the season be very warm, the seeds will not ripen in England.—It grows naturally in Virginia and Carolina, where it is called *Rattlesnake Weed*, from its use in curing the bite of that venomous creature. This sort is propagated by seeds, which, if sown in pots, and plunged into a moderate hot-bed, will come up much sooner than those which are sown in the full ground, whereby they will be much stronger before the winter. When the plants are fit to remove, they should be

each planted in a separate small pot filled with light earth; and if they are plunged into a moderate hot-bed, it will forward their taking root; then they must be gradually inured to bear the open air, into which they may be removed at the latter end of May, and placed among other hardy exotic plants. When the plants have filled these pots with their roots, some of them may be shaken out, and placed in a warm border; the others may be put into larger pots, and in the autumn placed under a common frame, where they may be exposed to free air in mild weather, but sheltered from severe frost; the following spring these may be turned out of the pots, and planted in a warm situation, where they will endure the cold of our ordinary winters very well; and if in severe frost they be covered with straw, pease-haulm, or any similar light covering, it will secure them from injury.

3. *Eryngium Planum*; *Flat-leaved Eringo*. Root-leaves oval-flat, crenate; heads peduncled; root perennial; stem upright, round, furrowed or streaked, whitish, about a foot and half in height, bluish at top, where it divides into three parts, each of which is terminated by a peduncled axillary flower; flowers in terminating heads, fenced with a six-leaved involucre, spreading, and reflex; the leaflets long-lanceolate, mucronate, as long as the flowers. It makes a pretty appearance when in flower, which is in July, especially that with blue stalks and flowers, for there is a variety in which they are white, with the leaves of a lighter green. As it does not spread at the root, it ought to be allowed a place in the pleasure ground.—Native of Austria, Silesia, Poland, and Russia. It is propagated by seeds, which if sown in the autumn, will more certainly succeed than when sown in the spring, for the latter commonly remain in the ground a year before they vegetate; and if the seeds are sown where the plants are to remain, they will flower stronger than those which are transplanted; for as they have long downright roots, so they are commonly broken in taking out of the ground, which greatly weakens them. The culture they require is, to thin them where they are too near, keep them clean from weeds, and dig the ground about them every spring before they shoot.

4. *Eryngium Pusillum*; *Dwarf Eringo*. Root-leaves oblong, gashed; stem dichotomous; heads sessile. This plant puts out oblong plane leaves from the root, which are cut on their edges; the stalks rise about a foot high, and branch out into many forked divisions, which are regular, and have a small head of flowers in each, sitting very close between the branches. It flowers from June to August.—Native of Spain and the Levant.

5. *Eryngium Trienspidatum*; *Trifid Eringo*. Root-leaves cordate; stem-leaves palmate, with ears bent back; chaffs three-cusped; root biennial, tuberous, approaching to the shape of the Radish; stem a foot high, with spiny heads at the top, and in the axils, with purple florets in them; involucre of long, narrow, hard, prickly leaflets, much longer than in the common sort.—Native of Spain, Sicily, and the Levant.

6. *Eryngium Maritimum*; *Sea Eringo*, or *Sea Holly*. Root-leaves roundish, plaited, spiny; heads peduncled; chaffs three-cusped; root creeping, and running deep into the ground; leaves roundish, stiff, gray, set with sharp spines on the edges; stems a foot high, branched, smooth, having at each joint leaves of the same form with the lower ones, but smaller. The flowers come out at the ends of the branches in roundish prickly heads, and are of a whitish blue colour; under each head is a range of narrow, stiff, prickly leaves, spreading like the rays of a star. The flowers appear in July. The young flowering-shoots, eaten like Asparagus, are very grateful and nourishing; the leaves are sweetish, with a

E. Diwn. &c.

slight aromatic warmth and pungency; the roots are supposed to have the same aphrodisiac virtues as the Orchis tribe: they are kept in the shops candied, and are still regarded by the Arabs as an excellent restorative. Boerhaave says, a decoction of the roots drank freely, increases the urinary discharge, and is serviceable in scorbutic complaints. Blackwell also informs us, that the roots are good in obstructions of the liver, and in the jaundice; they operate as a diuretic, and are a good restorative in those consumptions that are brought on by venereal excesses. The candied root, according to Hill, is a good medicine in coughs, and other disorders of the breast and lungs. A decoction of it while fresh forms a good diuretic, which is serviceable in the jaundice, and other disorders which arise from obstructions of the viscera: when resorted to for these complaints, the frest root should be preferred. Old English writers call this plant *Sea-Holly*, *Sea-Holme*, and *Sea-Hulver*. It grows in great abundance on the sandy and gravelly shores of many parts of Great Britain, and other countries of Europe. This species will grow in a garden, if the roots be planted in a gravelly soil, and produce flowers annually; but the roots will not grow near so large or fleshy as those which are found upon the seashore, where they are overflowed with salt water. The best time to transplant the roots is in autumn, when the leaves decay; the young roots are much better to remove than the old, because being furnished with fibres, they will readily take root, and when fixed in the ground should remain unremoved, and require no farther culture except to be kept clean from weeds.

7. *Eryngium Campestre*; *Field Eringo*. Root-leaves stem-clasping, pinnate-lanceolate; root perennial and strong. The whole plant is very stiff, and of a pale green colour; corolla blue, sometimes white or yellowish; appearing in July and August.—Native of most parts of Europe. In Great Britain not very common, but is found upon the coast near the ferry from Plymouth into Cornwall; near Newcastle-upon-Tyne; below Melling, in Yorkshire; also far inland, and opposite Brook-hall, near Daventry, in Northamptonshire. Gerard cultivated this species in his garden. It is a very troublesome weed, for the roots run deep into the ground, and are not easily destroyed by the plough; they spread and multiply greatly in the ground, to the prejudice of whatever is sown or planted on the land, and are therefore not admitted into gardens.

8. *Eryngium Amethystinum*; *Amethystine Eringo*. Root-leaves trifid, subpinnate at the base; the lower leaves are divided, like the fingers of a hand, into five or six segments, which are very much cut at their extremities into many parts, and have small spines; stem about two feet high, with smaller and more divided leaves; the upper part of the stem, and also the heads of flowers, are of the finest amethystine colour, so that they make a most beautiful appearance. There is a variety, which is smaller, and the involucre has trifid folioles. It flowers in July, and when the autumn proves dry, the seeds will ripen in England. It may be propagated in the same way as the third species, to which the reader is referred.—Native of the mountains of Stiria.

9. *Eryngium Triquetrum*. Root-leaves trifid; stem very much branched; peduncles three-sided; involucre three-leaved, keeled. Stem erect, rigid, a span or a foot in height, round, smooth, amethystine, as are also the branches and flowers; branches alternate, divaricate, subdichotomous, three-sided; stem-leaves three-parted, half stem-clasping; segments lanceolate, rigid, spiny, with a spiny tooth on each side at the base.—Native of dry plains in Tunis in Africa.

10. *Eryngium Alpinum*; *Alpine Eringo*. Root-leaves heart-shaped; stem-leaves ternate, gashed; involucre spiny, pin-

nate, ciliate; root perennial. The leaves are cordate, and toothed, the lower on long petioles, the upper stem-clasping; the lower leaves resemble those of *Cacalia*, but are more acute, and the teeth end in a soft spine; amethystine leaves surround the oblong head of flowers, some of them bristle-form and reflex, others pinnatifid and lanceolate; corolla white; antheræ green. It is a plant, says Villars, curious to see, on account of the beauty of the involucre, which are of a vinous azure blue, mixed with green and white, scarcely prickly; the heads of flowers are much elongated, cylindrical in the lower, and suddenly rounded in the upper part.—Native of the mountains of Switzerland, Dauphiny, and Italy. It is cultivated in the same way as the third species.

11. *Eryngium Bourgati*; *Cut-leaved Eringo*. Root and stem-leaves alternate and three-parted, twice trifid; involucre awl-shaped, many-leaved, somewhat spiny. Height from eight inches to a foot; stems thick, white, strong, and branched from the bottom. Mr. Miller, who cultivated this plant, says, that the stalks rise about two feet high; that the flowers are of a light blue colour, in very large heads, appearing in June and July, and ripening seed in autumn.—Native of the south of France.

Erysimum; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets ovate-oblong, parallel, converging, coloured, deciduous. *Corolla*: four-petalled, cruciform; petals oblong, flat, extremely obtuse at the tip; claws length of the calix, upright; gland nectariferous, double, within the shorter filamentum. *Stamina*: filamenta six, length of the calix, those of the two opposite shorter. Antheræ simple. *Pistil*: germen linear, four-cornered, length of the stamina; style very short; stigma headed, permanent, small. *Pericarp*: silique long, linear, strict, exactly four-cornered, two-valved, two-celled. *Seeds*: very many, small, roundish. ESSENTIAL CHARACTER. Silique columnar, with four equal sides. *Calix*: closed.—These plants are seldom introduced, except into botanic gardens; most of them perish soon after they have ripened their seeds, but the fifth sort will abide several years in a dry lean soil, or on a wall; in a rich land it soon decays. They may all be propagated by sowing their seeds in the autumn, where they are to remain, and afterwards require no farther culture, except thinning and weeding.—The species are,

1. *Erysimum Officinale*; *Common-Hedge Mustard*. Siliques pressed close to the spike, leaves runcinate; root annual; stem from one to two feet high, upright, round, finely grooved, beset with numerous short rough hairs, branched, and for the most part purplish, particularly at the angles of the branches, which spread very much; racemes of flowers terminating, roundish; of fruits filiform, elongated, naked, pubescent; seeds of a dull yellow, obliquely truncate at both ends, immersed in the partition, and eight in each cell. Viewed as it comes into blossom, and when its flowering-branches shoot out horizontally to a great length, it scarcely seems to be the same plant.—It is common on dry banks, under walls, pales, and in waste places, from May or June to September. Linneus informs us, that it is excellent in asthma, hoarseness, and other complaints of the breast. Rondeletius cured a hoarseness, brought on by loud speaking, in a few days with this herb; the juice of which is the most excellent of all remedies for diseases of the throat, especially in ulcerated sore throats, which it has been found to cure when all the advice of physicians and surgeons proved ineffectual. The above assertion is grounded on a manuscript note, found by the late celebrated Dr. Withering, in a copy of Parkinson's Herbal, which formerly belonged to Mr. Saun-

ders, surgeon, of Stourbridge. Hill informs us, that the whole plant is used, but that an infusion of it when fresh is to be preferred. A strong infusion is a good attenuater and dissolver of tough phlegm, and is excellent in asthmas, hoarseness, and other complaints of the breast: this simple infusion, made into a syrup with honey, also answers the same purpose, and keeps all the year round.—This, and some others of the class, are apt to spring up among the ashes where charcoal has been made, or where there has been any considerable fire. Besides its common name of Hedge Mustard, it has those of Bank Cresses, and Scrambling Rocket: Turner calls it Winter Cresses. The Germans name it *der hederich, wegesenf, wilder senf, falscher wassersenf, das gelbe eisenkraut, das weibchen des eisenkrauts, kreuzkraut*; the Danes, *wild senep, veysenep*; the Swedes, *vaggrassa*; the French, *le velar, la tortelle, l'herbe au chantre*; the Italians, *erisimo*; the Spaniards, *jaramago, hierba de San Alberto, irion*; the Portuguese, *erisimo*; and the Russians, *gorczyca polna* and *pszonak ziele*.—It is warm and acrid to the taste, and, when cultivated, is used as a spring potherb. Birds are fond of the seeds; sheep and goats eat it; cows, horses, and swine, refuse it.

2. *Erysimum Barbarea*; *Winter Hedge Mustard*, or *Cress*. Leaves lyrate, the outmost lobe roundish; root perennial; stem a foot or eighteen inches high, smooth, round, deeply furrowed, much branched; flowers in racemes, or thick spikes, at the ends of the stem and branches; peduncles compressed, quadrangular; calix green, caducous; two of the leaflets larger, with a helmet-shaped hollow at the top; petals yellow, much longer than the calix. There are several varieties of Winter Cress; one, mentioned by Linneus and Tournefort, is distinguished by Ray as having smaller leaves, more frequently sinuated, the pods thicker, and the seeds larger, pale brown, inclining to white. Petiver figures it under the name of Early Winter Cress, and says, that it flowers in April. A variety with double flowers is common in the gardens, under the name of Yellow Rocket. The common people in Sweden use the leaves in salads early in the spring, and late in the autumn; they also boil them as Kale. Some persons in England also cultivate it for spring salad, under the name of *French* or *American Cress*; but it has to most people a bitter unpleasant taste. It is found on the banks of ditches and streams, in watery places; sometimes in cultivated fields, and even on walls; flowering from May to July. It is called Winter Rocket as well as Winter Cress, and Herb St. Barbara. The Germans name it *die winterkresse, barbenkraut, barbelkraut, rapunzel, senskraut, schnodesens, habichtskraut, gelber beyfuss, falsche bumon*; the Danes call it *vinterkars*; the Swedes, *vinterkrasse*; the French, *la Barbarée, l'herbe Sainte Barbe, l'herbe aux charpentiers, la Julienne jaune, roquette*; the Italians, *Barbarea, erba di Santa Barbara, ruchetta*; the Spaniards, *hierba de Santa Barbara, raqueta*; the Portuguese, *herva de Santa Barbara*.

3. *Erysimum Alliaria*; *Stinking* or *Garlic Hedge Mustard*. Leaves cordate; root biennial; stem upright, from two to three feet high, round, smooth, somewhat striated, at bottom purple and slightly hairy, at top branched; the branches are few, alternate, and upright; flowers in a corymb, terminating, upright, on peduncles the length of the flowers; leaflets of the calix pale green, obtuse, deciduous, hollow at the tip; corolla white; petals obovate; border spreading; marked with a few veins.—The leaves are recommended to be taken internally, as sudorifics and deobstruents, of the nature of Garlic, but much milder; externally, as antiseptic, in gangrenes and cancerous ulcers. According to Linneus's observation, horses,

sheep, and swine, refuse it, but cows and goats eat it; if eaten by cows, it gives a very strong disagreeable taste to the milk. When it grows in poultry yards, the fowls eat it, and it gives an intolerably rank taste to their flesh. The whole plant has a strong smell and taste of Garlic, and is therefore used by the country people in sauces, with bread and butter, salted meat, and with lettuce in salads; from which it has acquired another name, that of *Sauce Alone*. The fresh leaves, plentifully eaten, says Meyrick, or the juice of them, taken either by itself or boiled into a syrup with honey, operate powerfully by urine, and are found serviceable in dropsies. The syrup is likewise good to cut and attenuate tough viscid phlegm, and for coughs and hoarsenesses. The seeds souffed up the nose excite sneezing, and a discharge of watery humours from the head; and the herb, when eaten as a salad, warms the stomach, and strengthens the digestive faculties.—It is commonly found by hedge-sides, on banks, and in shady places, and thence derived another vulgar name, that of *Jack-by-the-hedge*. It flowers in April and May. The Germans call it *das knoblauchkraut, der knoblauchhederich, lauchel, waldknoblauch, ramfen, rampen, ramschelwurzel, gersnel, salsekraut, saskraut*; the Danes name it *hvid logfurt, gaste-kaal*; the Swedes, *hvit ö sort*; the French, *l'alliare, l'herbe des eaux, l'herbe aux aillots*; the Italians, Spaniards, and Portuguese, *alliaria*.

4. *Erysimum Repandum*; *Small-flowered Hedge Mustard*. Leaves lanceolate, toothed; racemes opposite to the leaves; siliques racemed, subsessile; corollas minute; stem upright, angular; flowers small, pale; stigmas very slightly emarginate.—Annual: flowering in May and June, and a native of Spain, Bohemia, Silesia, Austria, and Italy.

5. *Erysimum Cheiranthoides*; *Treacle Hedge Mustard*, or *Wormseed*. Leaves lanceolate, quite entire, sometimes toothed; siliques patulous, an inch long. Root annual; stem from one to two cubits in height, upright, stiff, streaked, rough, usually simple, sometimes branched a little, others say very much branched; corollas small, yellow; rhomb quadrangular, obscurely knobbed where the seeds lie; partition membranaceous; valves keeled on the outside, at an acute angle; receptacle between the valves, filiform, ending in the very short style, with a blunt stigma. Seeds about eighteen in each cell, ovate, a little turgid, beaked, of a yellowish brown colour. They are as intensely bitter as Wormseed or Coloquintida, but are, according to the united testimony of Withering and Meyrick, undoubtedly excellent for destroying worms in the stomach and intestines, for which purpose they are much used by the inhabitants of the places where the plant is found, who therefore call it Wormseed, or Treacle Wormseed. The seeds are also given in obstructions of the viscera, and in the rheumatism and jaundice, with success: they operate moderately by urine, when taken in small doses; in larger, they purge briskly; and in still greater quantities, occasion vomiting—they should on this account be given with caution, and then they will answer all the purposes of mercurial worm medicines, (which are frequently attended with danger, especially amongst those who have not skill to manage such medicines properly.) All kinds of cattle will eat it.—It flowers from May to August, and is a native of most parts of Europe, though not very common in England: it is found, however, on the Osier-holts near Ely, and on the banks of the river between the bridge and that city; also in the corn-fields about Eldon; among Turnips, near Bungay in Suffolk; and near Ashburne in Derbyshire.

6. *Erysimum Hieracifolium*; *Hawkweed Hedge Mustard*. Leaves lanceolate-serrate; root biennial; stems upright, stiff, sometimes branched, many-angled, smooth; flowers in ra-

comes, yellow, smelling faintly; calix greenish yellow, brown at the end; petals almost linear, truncate; a small gland at the shorter stamina.—Native of Sweden, Denmark, France, Germany, Austria, and Italy.

7. *Erysimum Perfoliatum*. Leaves cordate, stem-clasping, smooth.—Native of Germany, and of the Levant. Linneus has not this plant, which he seems to have confounded with *Brassica Campestris*, from which it differs, in having a more diffused habit, a white flower, a longer silique, entirely quadrangular; whereas that has the silique cylindric, loose, dry, wrinkled, and veined, ending in a soft fistular horn. Annual: See *Brassica Orientalis*.

8. *Erysimum Bicornis*; *Horned Hedge Mustard*. Leaves lanceolate, hairy; siliques two-horned at the tip. Annual. Flowers small and yellow, appearing in August and September.—Native of the Canary Islands. It requires the protection of a green-house.

Erythrina; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, entire, tubular; mouth emarginate above, beneath furnished with a melliferous pore. *Calix*: papilionaceous, five-petalled; standard lanceolate, with sides bent back, ascending, very long; wings somewhat ovate, scarce longer than the calix, scarcely projecting beyond the tube of the standard, very small; keel straight, length of the wings, two-petalled; emarginate. *Stamina*: filamenta ten, conjoined at the lower part, but little bent in, the length of half the standard, unequal. *Antheræ* ten, sagittate. *Pistil*: germen pedicelled, subulate, attenuated into a subulate style, the length of the stamina; stigma terminal, simple. *Pericarp*: legume extremely long, protuberating at the seeds, terminated by a point, one-celled. *Seeds*: kidney-form. *ESSEN. CHAR.* *Calix*: two-lobed. *Corolla*: standard very long, lanceolate.—This genus of plants is best propagated by seeds procured from the countries where they naturally grow, for they do not produce any here: sow them in small pots, and plunge them into a moderate hot-bed, where, if the seeds be good, the plants will come up in a month or five weeks. When they are two inches high, shake them carefully out of the pots, and replant each in a separate small pot, filled with light earth, plunging them into a moderate hot-bed of tanners' bark, shading them from the sun until they have taken new root, and admitting a large share of air to them when the weather is warm, to prevent their being drawn up weak, giving them a larger portion of air as they increase in strength; water them moderately, for too much moisture will rot the fibres of their roots. Remove them into the stove in autumn, where for the two or three first winters they will need a greater degree of heat than will be necessary when they are grown stronger. They should be watered twice or thrice a week when the leaves are in vigour; but when the leaves are fallen, moisture is very injurious. They may also be increased by cuttings, planted in pots during the summer months, and plunged into a hot-bed; but seedling plants are best.—The species are,

1. *Erythrina Herbacea*; *Herbaceous Coral Tree*. Leaves ternate; stems entirely simple, shrubby: annual. It has a large woody root, producing fresh shoots every spring, and growing to the height of about two feet; they seldom throw out branches, and are sometimes perennial. The petioles are usually prickly underneath; there is sometimes a prickle or two scattered about the stem; leaflets hastate, deep green. The upper part of the stalks are terminated by a long bunch or spike of scarlet flowers.—This species flowers in September, but never produces seeds in England.—It is a native of South Carolina. It may survive the winter when placed in a warm green-house, but rarely flowers in that situation.

2. *Erythrina Carneæ*; *Flesh-coloured Coral Tree*. Leaves ternate, smooth; stem arboreous, prickly; calices campanulate, truncate. The seeds are of a bright scarlet colour, only half the size of the next species. The branches are very closely armed with crooked greenish spines, as are also the ribs and footstalks of the leaves. The flowers grow in very long close spikes, and are of a beautiful scarlet colour.—Native of the Cape of Good Hope. It is frequently planted in the gardens near Lisbon, where it flowers annually, and ripens seed; but neither this, nor any other species of the genus, will often flower in England, with any treatment we can give them.

3. *Erythrina Corallodendron*; *Smooth-leaved Coral Tree*. Leaves ternate, unarmed; stem arboreous, prickly; calices truncate, five-toothed. It has a thick woody stem, which rises about ten or twelve feet high in this country, but grows to twice that height where it is a native, sending out many strong irregular branches, which are covered with a brown bark. The flowers come out at the ends of the branches, in short, thick, close spikes; they are of a deep scarlet colour, and make a fine appearance, being commonly in beauty in May and June; but are not succeeded by pods here. In America, they produce thick, swelling, crooked pods, containing large seeds of a reddish purple colour. The leaves fall off in spring, and in autumn new leaves put forth, which continue green all the winter. The flowers do not appear till the leaves drop. Dr. Browne thinks it is not a native of Jamaica, but that it was introduced by the Spaniards, who planted it among their Cacao trees, where the walks were most exposed to the weather, in order to break the force of winds; whence it acquired the appellation of *mader di cocco*, among them. In Jamaica it is called the *Coral* or *Red Bean-tree*. There is some difference between the Western and Eastern plant; the prickles in the latter are blackish; but the difference seems scarcely sufficient to constitute them distinct species. The leaves sleep about noon, by conniving or clapping together.—It is a native of the Society Isles, and of the southern part of China and Cochin-china.

4. *Erythrina Picta*; *Prickly-leaved Coral Tree*. Leaves ternate, prickly; stem arboreous, prickly. This plant has shrubby branched stalks, seldom above eight or nine feet high, armed in every part with strong, crooked, black spines. The leaves are smaller than those of the preceding, and have a nearer resemblance to the first; the footstalks are armed with the same sort of spines, and the midrib has also some which are smaller, and not so black; the flowers are of a paler scarlet, and grow in looser spikes. The seeds are as large as those of the third sort, but of a dark purple colour.—This tree is generally planted in the East Indies, for a support to the pepper plants.

5. *Erythrina Crista Galli*; *Cock's-comb Coral Tree*. Leaves ternate; petioles somewhat prickly, glandular; stem arboreous, unarmed. This is a very lofty tree, without any prickles on the trunk. The branches are stiff; the leaflets ovate, oblong, and quite entire. The petioles elongated, having frequently one or two recurved prickles underneath; on this petiole, at the base of the pedicels on each side, is a gland, and there are also two glands on the middle of the intermediate pedicel: flowers two or three, axillary, purple, on separate peduncles, resupinate; calix bell-shaped, two-lipped; the lower lip dagger-pointed; germen oblong, villose; style subulate; stigma with a minute dot.—Native of Brazil.

6. *Erythrina Planisiliqua*; *Flat Coral Tree*. Leaves simple, oblong.—Native of South America.

7. *Erythrina Fusca*; *Brown Coral Tree*. Leaves ternate, unarmed, lanceolate; banner of the corolla convolute; stem arboreous, eight feet high, with a brown bark like that of

hemp, and many short scattered prickles. The branches are diffused; leaves scattered, petioled; leaflets quite entire, smooth; flowers of a brown red colour, in a terminating raceme; seeds oblong.—Native of Cochinchina, where it is found on the banks of rivers. Mr. Bruce affirms, that the seeds of one species of *Erythrina* are called *carats*, and are used in weighing gold and precious stones. Mr. Miller mentions several other sorts or varieties of this fine genus. One he names *Erythrina Inermis*, the pods of which are longer, and not more than half so thick as those of the third species; and the seeds of a bright scarlet, longer and slenderer than those of the other sorts; the leaves small and acute-pointed; the stalks smooth, and without spines. It does not grow very large, but shoots out into branches at a little distance from the ground; and these grow erect, so as to form a bushy shrub. The flowers come out at the ends of the branches in short spikes. The wings of the corolla are longer than in the other sorts, and the whole flower is more closed. It is a native of the West India islands. A second sort, Mr. Miller raised from small seeds of a bright scarlet colour, which were sent him from the Cape of Good Hope. The plants had no spines; the leaves were much larger than the other sorts; their stems were strong, and they had the appearance of growing to large trees. He raised a variety of the second sort, with paler flowers and seeds, and the plants less thorny. Also a variety of the third sort, which he received from the island of Barbuda, with the flowers and pods very short; the stamina much longer than the petals; the pods very short and crooked, but rather thicker than those of the third species; the leaves, stems, and branches, armed with spines.

Erythronium; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong-lanceolate, acuminate, alternately incumbent towards the base, gradually more spreading, from the middle bent backwards. *Nectaries*: tubercles two, obtuse, callous, growing to each alternate and interior petal near the base. *Stamina*: filaments six, subulate, very short; antheræ oblong. *Pistil*: germen turbinate; style simple, shorter than the corolla, straight; stigma triple, spreading, obtuse. *Pericarp*: capsule somewhat globose, narrower at the base, three-celled, three-valved. *Seeds*: very many, ovate, acuminate. ESSENTIAL CHARACTER. *Corolla*: six-petalled, bell-shaped. *Nectary*: tubercles two, fastened to the base of the alternate petals.

1. *Erythronium Dens Canis*; *Dog-tooth Violet*. Mr. Miller makes two distinct species. The first, with two ovate leaves joined at their base, three inches long, and one inch and a half broad in the middle, gradually lessening towards the ends: these at first embrace each other, enclosing the flower, but afterwards they spread flat upon the ground; they are spotted with purple and white all over their surface. Between them rises a single, smooth, purple, naked stalk, about four inches high, sustaining one flower which hangs down; the petals are reflex, and spread open to their base; their colour is commonly purple, but sometimes white; stamina purple, standing close about the style, which is longer than them. The roots are white, oblong, and fleshy, shaped like a tooth, whence this plant has the name of *Dog's Tooth* in English. The same idea has governed the name in all the European languages. The Germans call it *hundszaum*; the Swedes and Danes, *hundetand*; the French, *le dent de chien*; the Italians, *dente di cane*; the Spaniards, *diente de perro*; the Portuguese, *dente de cão*; and the Russians, *kandik*.—The second species differs in the shape of the leaves, which are longer and narrower; and the flowers are a little larger, but not so well coloured. There is also a variety, in which the

leaves are of a darker green, and the flower of a pale yellow colour. Ray observed the first, with a purple flower, near Turin, in the way to Asti, in April; and with a white flower, between Novi and Genoa. Clusius found the variety near Grätz in Stiria; and John Bauhin, at La Bâtie near Geneva, flowering in March. They grow naturally in the south of France, Italy, Savoy, Switzerland, Austria, Friuli, and Siberia.—It is increased by offsets from the roots, which they do not send out very plentifully. It is not therefore so common in gardens as most other flowers of the spring season. It may be transplanted any time after the beginning of June, when the leaves decay, till the middle of September; but the roots should not be often removed, nor kept out of the ground very long, which will cause them to shrink, and frequently to rot. They should not be planted scatteringly in the borders of the flower-garden, but in patches; and thus disposed, they will make a good appearance. It loves a shady situation, in a light loamy soil.

Erythroxyton; a genus of the class Decandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, turbinate; divisions ovate, sharp, very small, withering. *Corolla*: petals five, ovate, concave, expanding; nectary of five scales, emarginate, upright, coloured, inserted into the base of the petals. *Stamina*: filaments ten, length of the corolla, at the base connected by a truncated membrane; antheræ heart-shaped. *Pistil*: germen ovate; styles three, filiform, distant, length of the stamina; stigmas obtuse, thickish. *Pericarp*: drupe ovate, one-celled. *Seed*: nut oblong, obtusely quadrangular. ESSENTIAL CHARACTER. *Calix*: turbinate. *Corolla*: petals five, having a small emarginate nectareous scale at their base. *Stamina*: connected at the base; drupe one-celled.—The species are,

1. *Erythroxyton Areolatum*; *Dry Redwood*. Leaves obovate, mucronate; branchlets short, floriferous, scaly. Browne describes it as a small beautiful tree; the leaves of an oval form, and marked with two slender longitudinal lines upon the back, which were the utmost limits of that part of the leaf which was exposed, while it lay in a folded state. The flowers grow in little clusters, white, and fragrant, and are very thick upon the branches. The inward bark is of a flesh colour, and the wood of a reddish brown. It is reckoned an excellent timber wood, for the size of the tree, which seldom exceeds sixteen or eighteen feet in height, and five or six inches in diameter.—Native of dry coppices in the West Indies. Dr. Browne has another species, which he calls *Small Round-leaved Erythroxyton*, or *Redwood*, with very slender branches. This tree, he says, differs much from the foregoing, both in shape and manner of growth. It grows in the low-lands of Jamaica, like the other, and rises commonly to the height of eighteen or twenty feet; the leaves are roundish and smaller, and the branches very slender.

2. *Erythroxyton Havanense*. Leaves elliptic; flowers axillary. This is a shrub, three feet in height, having altogether the habit of the preceding, but the leaves ovate, obtuse, quite entire, without any lines underneath; fruit orange-coloured.—Native of the Havannah, on rocks near the coast.

3. *Erythroxyton Hypericifolium*. Leaves obovate, emarginate; branches floriferous; peduncles axillary, solitary. The branches are covered with a brownish wrinkled dotted bark, compressed at top, and toothletted from the fallen leaves. Scales on the branchlets awl-shaped, and deciduous; leaves petioled, glaucous underneath; peduncles capillary, nearly the same length with the leaves.—Native of the West Indies.

4. *Erythroxyton Squamatum*. Leaves elliptic-lanceolate, acuminate, obtuse; branchlets scaly, floriferous; branches

smooth, covered with ash-coloured bark; round below, but compressed at top; among the leaves at top having ovate, half-embracing, short, acute, keeled scales, with a longitudinal groove on the back, at the base of which is inserted an awn, the length of the scale.—Native of the West Indies. Observed by Rohr in Cayenne.

5. *Erythroxylo* *Macrophyllum*; *Small-leaved Redwood*. Leaves elliptic, acute; flowers axillary and lateral, aggregate; branches round at bottom, compressed at top, smooth; covered with a gray bark, at bottom, among the leaves, having approximating scales of an ovate-lanceolate form, half-embracing, keeled, striated, purplish, acute; near the base on the outside, is a broad awl-shaped awn, the length of the scale, concealed within the dorsal groove of the scales.—It was observed in Cayenne by Rohr.

Escallonia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: one-leafed, five-cleft, superior, permanent; divisions spreading, keeled, sharp. *Corolla*: petals five, tongue-shaped, distant, longer than the calix. *Stamina*: filamenta five, smooth, opposite to the divisions of the calix, alternate with the petals, and shorter than them; antheræ incumbent, fastened by the back to the filamenta, emarginate, two-celled. *Pistil*: germen half inferior, an oblate spheroid; style upright; stigma capitate. *Pericarp*: berry roundish, surrounded with the calix, terminated by the permanent style, two-celled. *Seeds*: numerous, small, nestling. ESSENTIAL CHARACTER. *Calix*: surrounding the fruit; stigma capitate. *Berry*: two-celled, containing many seeds.—The species are,

1. *Escallonia Myrtilloides*. Leaves serrulate, ending in a small dagger-point, veiny underneath. This is a branching leafy shrub; branches wandlike, obscurely angular, covered with a smooth, chinky, deciduous bark; branchlets alternate, spreading, angular, closely leaved, one-flowered; flowers terminating, solitary, peduncled, upright; berry the size of a pea, covered with a lid.—Native of New Granada.

2. *Escallonia Serrata*. Leaves serrate, subretuse, veinless underneath. This is a low shrub, very much branched, leafy, smooth; branches alternate, angular, somewhat flexuose, with a smooth pale bark; branchlets alternate, straightish, leafy, one-flowered, green; flowers terminating, solitary, peduncled, upright, very handsome, milk-white, with a violet-coloured germen; peduncles short, round, thickening at the tip, bent in, smooth; divisions of the calix spreading, deltoid, somewhat fleshy, smooth, pale underneath, coloured; petals spreading, obtuse, three times the length of the calix; filamenta broader at the base.—It was found in the straits of Magellan, and in Terra del Fuego.

Eschalot, or *Eschalotte*, so named from Ascalon in Palestine, about which place it grows wild; whence it has also derived the names of *Cepa Ascalonica*, or *Ascalon Onion*, and *Ascalonitides*. The old English name was *Barren Onions*, because it seldom puts up any flowering-stem. See *Allium*.

Espaliers are either rows of trees planted to enclose a whole garden or plantation, or in hedges, so as to enclose quarters or separate parts of a garden; they are trained up flat in a close hedge, for the defence of tender plants against the violence and injury of wind and weather. The most commonly received notion of espaliers are hedges of fruit-trees, which are trained up regularly to a lattice of wood-work, formed either of ash-poles, or square long timbers, cut out of fir; and it is of this sort of espalier that we intend to treat in this place. Espaliers of fruit-trees are commonly planted to surround the quarters of a kitchen-garden, for which purpose they are extremely useful, as well as highly ornamental; for by laying out the walks of this garden regu-

larly, which are bounded on each side by these hedges, when they are handsomely managed, they have a wonderful effect in sheltering the kitchen plants in their quarters, and also screening them from the sight of those who frequent the walks; so that a kitchen-garden laid out in this manner, and properly managed, will be equal to the finest regular parterre for beauty. The trees chiefly planted for espaliers, are apples, pears, and some plums, but the two former are mostly used. Some plant espaliers of apples grafted upon paradise stocks; but these being of humble growth, and a short duration, are not so proper for the purpose, except for very small gardens. We should rather advise the having them upon crab stocks, or, if in smaller gardens, where the trees cannot be allowed to grow so high, upon what the gardeners call the Dutch stock; which will cause them to bear sooner, and prevent their growing too luxuriantly, besides securing their vigour for many years. In choosing the trees for an espalier, endeavour as much as possible to plant the several sorts which are nearly of the same growth in one line, that the espalier may be more ready, and of an even height, which greatly adds to their beauty; for if you plant trees which shoot very unequally in the same line, it will be impossible to make the espalier regular: besides, the distance of the trees must be in proportion to their growth; for instance, some trees of a larger growth should be planted thirty or thirty-five feet asunder, whereas the smaller ones need not be placed at above twenty-five feet from each other. The width of the walks and borders between these espaliers should (in a large garden) be at least fourteen or sixteen feet, and, if it be intended to carry the trees up pretty high, the distance should be greater, that each side may receive the advantage of the sun and air, which is absolutely necessary, if you would have the fruit well-tasted. And if your ground be so situated as to leave you at full liberty which way to make the espaliers, Mr. Miller advises the placing the lines from the east, a little inclining to the south, and towards the west, a little inclining to the north, that the sun may shine between the rows in the morning and evening, when it is low; for in the middle of the day, when the sun is advanced far above the horizon, it will shine over the tops of the espaliers, and reach the surface of the earth about their roots, which is a matter of more consequence than many people are aware of. The sorts of apples proper for espaliers, are the golden pippin, nonpareil, rennette, grise, aromatic pippin, French pippin, Wheeler's russet, and Pile's russet, with some others. The season for planting, and the method of pruning and training these trees, will be found under the articles *Pruning* and *Pyrus*. The sorts of pears proper for an espalier, are chiefly the summer and autumn fruits; for some of the winter pears seldom succeed well in an espalier. These trees, if designed for a strong moist soil, should be upon quince stocks; but if for a dry soil, upon free stocks. The distance of planting must also be regulated by the growth of the trees, which is more unequal in pears than apples, and should therefore be more carefully examined before they are planted. As for the pears upon free stocks, the distance should never be less than thirty feet for moderate-growing trees; but for those that shoot vigorously, the space of forty feet is not too much, especially if the soil be strong, in which case they should be planted at a greater distance. The particular sorts of pear, which Mr. Miller recommends for an espalier, are the jargonelle, blanquette, poiresans, pean, summer boncretien, Hamden's bergamot, autumn bergamot, L'ambrette, Gros Ronssset, Chaumontelle, Beurru du Roy, le Marquis Cressane, with some others of less note; always remembering, that those pears which are of the melting kind,

will do better in espalier than the breaking pears, which seldom ripen well on an espalier; as also that many sorts of pears will ripen well on an espalier in a warm soil and situation, which require a wall in other places; you should also be careful of the stocks these are grafted on, for if the breaking pears are grafted upon quince stocks, the fruit will be stony, but the melting pears will be improved by them. For the method of planting them, the reader is again referred to the genus *Pyrus*; and for the pruning and management, to the article *Pruning*. In order to form the espalier to which the trees are to be trained, Mr. Miller gives the following directions.—The espalier should not be made until the third year after the trees are planted; for while they are young, it will be sufficient to drive a few short stakes into the ground on each side of the trees, in a straight line, to which the branches should be fastened in an horizontal position, as they are produced, in order to train them properly for the espalier, which stakes may be placed nearer, or at a farther distance, according as the shoots produced may require, and these will be sufficient for the three first years; for should you frame the espalier the first year the trees are planted, many of the stakes would rot before the espalier is covered. The cheapest method of making espaliers, is with ash-poles, of which two sorts should be provided; one of the largest size, which contains thirteen poles in a bundle, and the other size, those of half a hundred. The first, or largest-sized poles, should be cut about seven feet and a half long, which are intended for upright stakes, and must be sharpened at the largest end, that they may with more ease be driven into the ground; and if their bottoms are burred or rubbed over with a proper composition, they may be preserved a long time sound: these should be placed at a foot distance from each other in a direct line, and of an equal height, about six feet above ground; then you should nail a row of straight slender poles along upon the tops of the upright stakes, which will keep them exactly even, and continue to cross the stakes with the smaller poles, and also with the tops which were cut off from the larger stakes, at about nine inches' distance row from row, from the top to the bottom of the stakes. These rows of poles should be fastened with wire to the stakes, which, if made of fir, and painted over, will last a long time; and the largest end of the poles should be cut flat, and nailed to the upright stakes, which will secure the espalier almost as long as the poles will endure; whereas, if your fastening is not strong, the poles will be continually displaced with every strong wind. When the espalier is thus framed, the branches of the trees must be fastened thereto, either with small osier twigs, rope-yarn, or some such binding, observing to train them in an horizontal position, and at equal distances, being careful not to cross any of the branches, nor to lay them in too thick. The distance which should be allowed for the branches of pears and apples, must be proportioned according to the size of their fruit: those which produce large fruit, as the summer boncretien, Monsieur John, and Beurre du Roy pears, and the Rennet Grise, Holland pippin, French pippin, and other large apples, should have their branches six or eight inches' distance at least; and for those of lesser growth, four or five inches will be sufficient. But for farther directions, see the article *Pruning*, where these particulars are sufficiently explained. Besides this sort of espalier, made with ash-poles, there is another sort, that is by many people preferred, which is framed with square timbers, cut to a proper size, according to the strength thereof, or the expense the owner is willing to go to. These, though more sightly, when well fixed and painted, are not more lasting than the former sort, provided it be well made, and have upright poles of

sufficient strength; nor will they answer the purpose better, though they are much more expensive. The greatest beauty of an espalier consists in disposing the branches of the trees, which, especially in summer, when the leaves abound, entirely hide the frame. All expense, therefore, farther than what is necessary to secure the branches in regular order, is needless. Fruit-trees thus planted, and well managed, are much preferable to those trained up in any other figure; first, because they take up very little room in a garden, and are not injurious to the crops in the quarters; secondly, because the fruit is better tasted, the sun and air having free access to every part of the tree, and all dampness is quickly dissipated; thirdly, because the trees being kept low, and the branches fastened to the espalier, the fruit will not be so exposed, and likely to be blown down by high winds.

Ethulia; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Culix*: common, many-leaved, rounded, simple; leaflets linear, nearly equal, spreading. *Corolla*: compound, tubular; corollets hermaphrodite, uniform, distant by a space; proper funnel-form; border five-cleft, upright. *Stamina*: filamenta five, very short, capillary; antheræ cylindric, tubular. *Pistil*: germen prismatic; style filiform, length of the stamina; stigmas two, recurved. *Pericarp*: none; calix unchanged. *Seeds*: solitary, truncated, turbinate, five-cornered, five-furrowed; down none, but a little projecting margin. *Receptacle*: naked, convex, excavated with points. ESSENTIAL CHARACTER. *Receptacle*: naked. *Down*: none.—Most of the plants of this genus being annual, must be propagated by seeds; and coming from the East Indies, must be kept in the stove.—The species are,

1. *Ethulia Conyzoides*; *Panicled Ethulia*. Flowers panicled; root annual; stem herbaceous, the thickness of a finger, four feet in height, upright, round, but angular at top, pubescent, hollow; branches alternate, axillary, short, somewhat erect; flowers small, containing above twenty florets, of a pale blue colour. It is a large plant, remarkable for the slender and distant tubes of the florets, and in putting forth roots from the base of the stem, which is seldom the case in annual plants. The leaves smell very sweet. It flowers in July and August.—Native of the East Indies.

2. *Ethulia Sparganophora*. Flowers sessile, lateral; calix subglobular, imbricate, with unequal scales, recurved, and patulous at the tip; receptacle flat, with raised dots on it; seeds small, uniform, ovate, narrower at bottom; rhomb compressed, with angles at the sides, and one on the back; the rib white, but the interstices and the ventral plane of a pale testaceous colour.—Native of the East Indies.

3. *Ethulia Divaricata*. Leaves linear, toothed, decurrent; peduncles opposite to the leaves, one-flowered; stem divaricate. This is an annual plant, a hand in height; the stem upright, corymbed, smooth at bottom, pubescent at top, and branched; the primary branches shorter, sharply quadrangular; calix subglobular, subscurrose; scales oblong, patulous, or recurved at the tip; florets difform; those of the disk funnel-shaped, five-cleft, and rognoun, barren, fewer; in the ray awl-shaped, without teeth; female fertile, very numerous; receptacle flat, large, hollow, dotted.—Observed by Kœnig in the fields of Malabar.

4. *Ethulia Tomentosa*. Undershrubby; leaves linear, quite entire, tomentose; stems streaked, branched. The leaves are alternate, sessile, lanceolate-linear, hoary, or very finely tomentose, like those of Lavender; calices terminating, sessile, loose, somewhat leafy.—Native of China.

5. *Ethulia Bidentis*. Racemules directed one way; calices containing about five flowers; leaves lanceolate, opposite.

Stem herbaceous, upright, hexagonal, brachiately; leaves three-nerved, subpetioled, serrate, smooth; racemes two or four at the ends of the stem and branches, brachiately, on the upper side of which are sessile, narrow, yellow flowers, about five together, alternate, and supported by a subulate bract; seeds oblong, even, with a few streaks.—Native of Chili, and the East Indies.

6. *Ethulia Struchium*. Flowers axillary, sessile, all trifid. This plant generally rises to the height of two feet and a half or more; the leaves alternate, oblong, entire; the flower-bunches interspersed with a few smaller ones, that rise between the common cups, as they stand compact together at the axils of the leaves: corollets nearly equal, the marginal trifid, the central four-parted; germen oblong, angular, crowned with its proper calix, which has about four little notches; style longer than the corolla; stigmas oblong, revolute.—Native of Jamaica.

Eucalyptus; a genus of the class Icosandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth superior, permanent, truncate, covered with an hemispherical deciduous lid before flowering-time. *Corolla*: none. *Stamina*: filaments thread-shaped, numerous, inserted into the calix; antheræ roundish, two-lobed, small. *Pistil*: germen inferior, turbinate; style single. *Pericarp*: capsule four-celled, gaping only at the tip. *Seeds*: very many, angular, small. ESSENTIAL CHARACTER. *Calix*: superior, permanent, truncate, before flowering-time covered with an hemispherical deciduous lid. *Corolla*: none. *Capsule*: three or four celled, opening at the top, enclosing many seeds.—The species are,

1. *Eucalyptus Obliqua*; *Oblique-leaved Eucalyptus*. This is a very tall tree, growing to the height of more than a hundred feet, and above thirty in circumference; the bark is smooth like that of the Poplar, and the young branches are long and slender, angulated near the top, but as they grow older the angles disappear. The leaves are alternate, lanceolate, pointed, very entire, smooth on both sides, and remarkably unequal or oblique at their base; the veins are alternate, and not very conspicuous. The whole surface of both sides of the leaves is marked with numerous minute resinous spots, in which an essential oil resides. The footstalks are about half an inch in length, round on the under side, angular above, quite smooth. The flowers have not been fully examined, but the capsules are supposed to grow in clusters, from six to eight each, sessile, and conglomerated; each is about the size of a hawthorn berry, globular, but as it were cut off at the top, and of a dark brown colour; the seeds numerous, small, and angular.—Native of Botany Bay.

2. *Eucalyptus Resinifera*; *Red Gum Tree*. This tree is much larger than the English Oak; the wood is brittle, and contains a large quantity of resinous gum; the flowers grow in little clusters, or rather umbels, about ten in each, and every flower has its proper partial footstalk, about a quarter of an inch in length, besides the general one; the general footstalk is remarkably compressed, and the partial ones in some degree; the flowers are yellowish, and of a singular structure; the calix is hemispherical, perfectly entire on the margin, and afterwards becomes the capsule: on the top of the calix, rather within the margin, stands a conical pointed calyptra, which is of the same colour as the calix, and about as long as that and the calix taken together: this calyptra constitutes the essential mark of the genus. The antheræ are small and red, and in the centre is a single style, terminated by a blunt stigma; the stamina are very resinous and aromatic. The germen appears, when cut across, to be divided into three cells, each containing the rudiments of one or

more seeds. On making incisions into the trunk of this tree, large quantities of red resinous juice are obtained, sometimes more than sixty gallons from a single tree. When dried, this juice becomes a powerful astringent gum-resin, much resembling that known in the shops by the name of kino, and full as efficacious for all medical purposes. Mr. White, the chief surgeon to our settlement at Botany Bay, administered it to a great number of patients in the dysentery, and found it eminently serviceable, never failing in a single instance. This gum-resin dissolves almost entirely in spirit of wine, to which it gives a blood-red tincture; water dissolves about a sixth part only, and the watery solution is of a bright red; and both solutions are powerfully astringent.

Euclea; a genus of the class Diocia, order Dodecandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, many times shorter than the corolla, subangular, smooth, five-toothed; teeth very short, upright. *Corolla*: one-petalled, five-parted; segments ovate, obtuse, concave, patulous. *Stamina*: filaments thirteen, very short, eight in the circumference, five in the centre. Antheræ four-cornered, subulate, grooved, erect, perforated at the tip on both sides. *Female*. *Calix*: perianth one-leaved, four-toothed, (more seldom five-toothed,) permanent; segments erect, three times shorter than the corolla. *Corolla*: one-petalled, four-cleft; segments ovate, obtuse, concave, erect. *Pistil*: germen ovate, subvillose, superior; styles two, thickish, the length of the corolla; stigmas emarginate, bifid, obtuse. *Pericarp*: berry globular, umbilicate with a dot, smooth, fleshy, (according to L'Heritier, a berried capsule, three-horned, three-celled, three-valved; Linneus says two-celled.) *Seeds*: single, globular, smooth; (according to L'Heritier, roundish, arilled, one or two abortive.) ESSENTIAL CHARACTER. *Male*. *Calix*: four or five toothed. *Corolla*: four or five parted. *Stamina*: twelve or fifteen. *Female*. *Calix* and *Corolla*: as in the male. *Germen*: superior; styles two. *Berry*: two-celled.—The species are,

1. *Euclea Racemosa*; *Round-leaved Euclea*. This is a smooth branching shrub: leaves alternate, subpetioled, obovate, quite entire, obtuse, smooth; racemes of flowers from the axils of the upper leaves, simple, nodding, hardly the length of the leaves; petals snow-white; fruit red, the size of a pea.—It flowers in November and December, and is a native of the Cape of Good Hope.

2. *Euclea Undulata*. Leaves ovate, undulated. This resembles the preceding. Its red fruit is eaten by the Hottentots, who call the plant *Guarri-bosches*.—Native of the Cape.

Eucomis; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: inferior, six-parted, permanent, spreading. *Stamina*: filaments subulate, dilated at the base, and united there into a concave nectary, fastened to the bottom of the corolla. *Pistil*: germen superior; stigma simple. *Pericarp*: capsule three-celled. *Seeds*: many. ESSENTIAL CHARACTER. *Corolla*: inferior, six-parted, permanent, spreading. *Filaments*: united at the base into a nectary growing into the corolla.—The species are,

1. *Eucomis Nana*; *Dwarf Eucomis*. Scape club-shaped; leaves broad-lanceolate, acute.—It flowers in May, and is a native of the Cape of Good Hope.

2. *Eucomis Regia*; *Tongue-leaved Eucomis*, or *Fritillaria*. Scape cylindrical; leaves tongue-shaped, obtuse, close to the ground; root tuberous, from which arise in the autumn six or eight obtuse leaves, nearly five inches long, and two broad towards the top, growing narrower at their base, crenated on their borders, lying flat on the ground, and continuing all the

winter. In the spring arises the flower-stalk, in the centre of the leaves, about six inches high, naked at the bottom, but the upper part is surrounded by bell-shaped flowers of a greenish colour, appearing in April: the leaves decay in June. There is a variety of this species, with leaves more than a foot long, broad at the base, but narrow at the top, where they end in acute points; the flower-stalks rise higher; and the flowers are of the same shape and colour, but seldom appear till August.—They are both natives of the Cape.

3. *Eucomis Undulata*; *Wave-leaved Eucomis*, or *Fritillaria*. Scape cylindrical; leaves ovate-oblong, waved, spreading; the leaves of the coma almost as long as the raceme.—It flowers from March to May, and is a native of the Cape.

4. *Eucomis Punctata*; *Spotted Eucomis*. Scape cylindrical, leaves oblong-lanceolate, channelled, spreading; leaves of the coma short; racemes very long. This is the largest species.—Native of the Cape, flowering in July.

Evergreen Thorn. See *Mespilus Pyracantha*.

Everlasting Pea. See *Lathyrus*.

Eugenia; a genus of the class *ICOSANDRIA*, order *MONOGYNIA*.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, superior, elevated in the middle into a subvillose little ball, four-parted; divisions oblong, obtuse, concave, permanent. *Corolla*: petals four, twice as large as the calix, oblong, obtuse, concave. *Stamina*: filamenta very many, inserted into the bell of the calix, length of the corolla; antheræ small, roundish. *Pistil*: germen turbinate, inferior; style simple, length of the stamina; stigma simple. *Pericarp*: drupe four-cornered, crowned, one-celled. *Seed*: nut roundish, smooth. [Swartz observes, that this genus is not easily distinguished from that of *Myrtus*, except in the habit.] **ESSEN. CHAR.** *Calix*: four-parted, superior. *Petals*: four: drupe one-seeded, four-cornered.—To propagate this genus, set the stones fresh from their places of natural growth, in small pots filled with light earth; plunge them into a hot-bed, observing to keep the earth moist, but not wet. In about six weeks the plants will appear; when about four inches high, separate them carefully, plant each in a small pot, plunge them into a hot-bed again, and carefully shade them till they have taken new root. Treat them in the same way as other tender plants from the same countries, keeping them plunged in the tan-bed, and watering them sparingly in winter.—The species are,

1. *Eugenia Malaccensis*; *Broad-leaved Eugenia*. Leaves quite entire; peduncles branched, lateral. It rises with a tree-like stem from twenty to thirty feet high, covered with a brown bark, and sending out many branches; leaves oblong, ending in acute points, opposite; when young of a bright purple colour, but as they grow older becoming of a light green; the flowers are produced on the sides of the branches; every peduncle branching into three or four others, each of which supports one flower: fruit succulent, irregularly shaped, and enclosing a single nut. Loureiro calls it a berry: it is of a roundish form, commonly obtusely quadrangular, sometimes it is ovate, in size it is an inch and a half in diameter, fleshy, very sweet, smelling like the rose, not very juicy, covered with a thin, shining, yellowish skin, and containing commonly one seed, which is large, roundish, softish, not bony or horny; the fruit is very agreeable to the taste, smell, and sight, and is esteemed wholesome. Forster describes it as whitish, tinged with rose-colour, pear-shaped, and sometimes as big as the fist, but usually much smaller.—It is very common in most of the islands in the South Sea, and is cultivated almost every where between the tropics.

2. *Eugenia Jambos*; *Narrow-leaved Eugenia*. Leaves quite entire; peduncles branched, terminating. This rises to

the same height as the preceding species, but the leaves are longer and narrower; flowers mostly terminating, but some come out from the sides; fruit smaller, rounder, and not so much esteemed.—It flowers from May to July, and is a native of the East Indies, and Cochin-china.

3. *Eugenia Pseudo-Psidium*; *Bastard Eugenia*. Leaves quite entire; peduncles one-flowered, several lateral and terminating. This resembles a pear-tree, is upright, and about twenty feet in height; leaves lanceolate-ovate, acuminate, and sickle-shaped at the end, bright green, shining, from three to four inches long, opposite, on short petioles; calix deeply four-parted; petals white; fruit globular, at first green, then passing through the different shades of yellow as it ripens, till at length it becomes scarlet; it is scarcely half an inch in diameter, the skin thin, and the pulp soft, sweet, and red; the seed is large and globular.—Native of Martinico, where it is called *Goyavier Batard*. It flowers in October, and bears fruit in December and January.

4. *Eugenia Uniflora*. Leaves quite entire, cordate-lanceolate, peduncles one-flowered, lateral, solitary; flowers white; fruit bright red, soft, slightly grooved, with a sweet smell.—Native of Goa in the East Indies.

5. *Eugenia Cotinifolia*. Leaves ovate, obtuse, quite entire; peduncles one-flowered. The fruit is globular and succulent, enclosing a single shining membranaceous nut, having one seed in it.—Native of Cayenne, where the French call it *Cerisier de Cayenne*.

6. *Eugenia Acutangula*. Leaves crenate; peduncles terminating; fruits oblong acute-angled pomes; raceme simple, very long; flowers small, with longish stamina and pistils. Loureiro describes it as a large tree with spreading branches.—Native of the East Indies, and of Cochin-china.

7. *Eugenia Racemosa*. Leaves crenate; racemes very long; pomes ovate, quadrangular; peduncles simple, longer than the leaves, pendulous.—Native not only of India, but of New Caledonia, in the South Seas.

8. *Eugenia Sessiflora*. Flowers lateral, sessile; leaves oblong, quite entire, shining, dotted underneath; branches round, smooth, covered with an ash-coloured bark, leafy at top, warted below; fruit the size of a plum, globular, dotted.—Observed by West in the island of Santa Cruz.

9. *Eugenia Punctata*. Leaves oblong, dotted on both sides; peduncles opposite, three-flowered, the length of the leaves; branches round, alternate, ash-coloured at bottom, purplish at top, having raised dots scattered over them; the two lateral flowers pedicelled, the middle one sessile; there are two bristle-shaped bractes at the base of the lateral ones; segments of the calix five, round, dotted; petals, when magnified, appearing to be very finely ciliate.—Native of Santa Cruz.

10. *Eugenia Nervosa*. Leaves quite entire; flowers heaped, terminating; berries globular, nerved. This is a large tree with spreading branches; calix large; petals roundish, small, quickly deciduous; filamenta linear, more than a hundred, three times as long as the petals, spreading out wide into a globular head, with small nodding antheræ.—Native of the woods of Cochin-china.

11. *Eugenia Corticosa*. Leaves ovate acuminate, racemed, corymbed; filamenta very short. This also is a large tree with spreading branches, covered with a thick cloven bark, having something of an aromatic flavour; flowers reddish-white, small, numerous, subterminating; calix goblet-shaped, subtruncate; petals small, roundish, closed; filamenta twenty, awl-shaped, shorter than the corolla, and placed near the edge of the calix; antheræ roundish, very small; berry only a quarter of an inch in diameter, subturbinate, smooth, blackish,

enclosing one roundish softish seed.—Native of the woods of Cochiu-china.

Evolvulus; a genus of the class Pentandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets lanceolate, sharp, permanent. *Corolla*: one-petalled, rotate, five-cleft. *Stamina*: filamenta five, capillary, spreading, almost the length of the corolla; antheræ a little oblong. *Pistil*: germen somewhat globose; styles four, capillary, diverging, length of the stamina; stigmas simple. *Pericarp*: capsule somewhat globose, four-celled, four-valved. *Seeds*: solitary, roundish, cornered at one side. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-cleft, rotate. *Capsule*: three-celled. *Seeds*: solitary.—This genus entirely consists of stove-plants, to be cultivated and treated as the tender sorts of *Convolvulus* from the same countries.—The species are,

1. *Evolvulus Nummularius*. Leaves roundish; stem creeping; flowers subsessile. From a small, stringy, fibrous, annual root, spring long trailing stalks, taking root here and there where they touch the ground, and putting forth alternately, at small unequal distances, leaves almost round, three-quarters of an inch long, and an inch broad, having a small notch at the end, and on petioles a quarter of an inch in length, and of a brown colour; flowers axillary, on short peduncles, of a light blue colour.—Native of Jamaica and Barbadoes; common also in the dry plains of the other islands.

2. *Evolvulus Gangeticus*. Leaves cordate, obtuse, mucronate, villose, petioled; stem diffuse; peduncles one-flowered.—Native of the East Indies.

3. *Evolvulus Alsinoides*; *Chickweed-leaved Evolvulus*. Leaves obcordate, obtuse, hairy, petioled; stem diffuse; peduncles three-flowered. It is a little annual plant, with a creeping root; the stems, leaves, petioles, and peduncles, are covered with rufous hairs; leaves alternate, roundish, on a short petiole; flowers axillary, on long peduncles; corolla blue, large in proportion to the plant. The Ceylonese call it *Wisnugarandi*, from the Malabar idol *Wisnu*, and *Garandi*, which signifies the dysentery, for which disorder it is reputed to be a sovereign remedy. It flowers in June and July.—Native of the East Indies.

4. *Evolvulus Emarginatus*. Leaves kidney-form, repand. Annual; stems filiform, creeping; flowers axillary, solitary, small; peduncles the length of the petioles, mucronate underneath.—Native of the East Indies.

5. *Evolvulus Linifolius*; *Flax-leaved Evolvulus*. Leaves lanceolate, villose, sessile; stem upright, peduncled, three-flowered, long. The whole of this plant has the appearance of a very fine sort of flax. It seldom rises above ten or fourteen inches high; the stalk is generally simple, or but very little divided, slender, and upright; the leaves are narrow and few, they each throw out a long and delicate peduncle from their axils, furnished with a very small exterior two-leaved cup about the middle; the styles are two, and bifid; the capsules are divided into two or four cells, and contain many seeds.—In the low-lands of Jamaica it is frequently met with: annual, flowering in August and September.

6. *Evolvulus Tridentatus*. Leaves linear, wedge-form, three-cusped, dilated at the base, and toothed; peduncles one-flowered; stem twining.—Native of the East Indies.

7. *Evolvulus Sericeus*. Leaves lanceolate, sessile, silky underneath; peduncles short, one-flowered; the flower-stalks are very short; the cups single, and every flower furnished with four styles.—Native of the low lands of Jamaica.

Euonymus; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, flat; divisions roundish, concave. *Corolla*: petals

five, ovate, flat, spreading, longer than the calix. *Stamina*: filamenta five, subulate, upright, shorter than the corolla, placed on the germen as it were on a receptacle; antheræ twin. *Pistil*: germen acuminate; style short, simple; stigma acute. *Pericarp*: capsule succulent, coloured, five-sided, five-cornered, five-celled, five-valved. *Seeds*: solitary, ovate; involved in a berried aril. *Observe*. The fructification in some individuals or species takes away a fifth part of the number. In some there are no filamenta, except the points of the receptacle. ESSENTIAL CHARACTER. *Corolla*: five-petalled. *Capsule*: five-sided, five-celled, five-valved, coloured. *Seeds*: calyptred, or veiled.—The species are,

1. *Euonymus Europæus*; *Common Spindle Tree*. Flowers mostly four-stamined; peduncles compressed, many-flowered; stigmas awl-shaped; leaves smooth, bluntly serrate; angles of the capsules blunt. The common Spindle-tree, when growing in hedges, is seldom seen of any considerable size, but is a shrub; if planted single, however, and properly trained, it will have a strong woody stem, and rise more than twenty feet high, dividing into many branches; leaves lanceolate, about three inches long, and an inch and a quarter broad in the middle, opposite, entire, of a deep green colour. The flowers come out at the end of May, or in the beginning of June, in small bunches from the side of the stalks, on slender peduncles; the petals are whitish, and spread in the form of a cross; the seeds are pale flesh or rose coloured; the fruit ripens in October, at which time the seed-vessels spread open and expose the seeds, which being of a beautiful red colour, these shrubs then make a good appearance. The wood is said to be used by the musical instrument makers, and for skewers and toothpicks; the branches should be cut when the shrub is in blossom, for it is then tough, and not easily broken; in that state it is also used by watchmakers for cleaning watches. No animal but the goat browses upon it: the berries are said to be fatal to sheep; they vomit and purge violently; when powdered and sprinkled upon the hair, they destroy lice. From its use for skewers it has the name of *Prickwood*; *Gerarde* calls it *Prick-timber*; it is also called *House-berry*, *Dogwood*, and *Gatteridge-tree*, by which latter names it is confounded with *Cornus Sanguinea*: the Germans call it *Spindelbaum*; the Swedes, *Alster*; the Danes, *Beenved*; the Italians, *Fusaggine*; the Spaniards, *Bonetero*, *Bonete de Clerigo*; the Portuguese, *Barrete de Clerigo*; and the Russians, *Mereskletiana*, *Kislian-ka*, *Swida*, *Sedlini Beresdren*.—This, with the second, third, and fourth species, may be propagated either by seeds or layers; if by seeds, they should be sown in autumn soon after they are ripe, then the plants will come up in the spring following; but if the seeds are not sown till spring, the plants will not appear till the spring following, whereby a whole year is lost. The seeds should be sown upon a shady border, where they will succeed better than when they are more exposed to the sun; and when the plants appear, they will only require to be weeded till the following autumn, when, as soon as the leaves decay, the plants should be taken up, and transplanted into a nursery, in rows two feet distant, and the plants one foot asunder in the rows; in this place they may remain two years, and then they may be removed to the places where they are to remain. When they are propagated by layers, the young shoots should be laid down in autumn, and if the joint which is laid deepest in the ground be slit, as is practised for Carnations, it will cause them to put out roots much sooner than they otherwise would do; these layers will be sufficiently rooted in one year to bear transplanting, when they should be taken from the old plants, and treated in the same way as the seedlings. The cuttings of these sorts, planted in a shady border, will take root, but they should be planted

in autumn, as soon as their leaves begin to fall; they should be the shoots of the same year, with a knot of the former year at bottom.

2. *Euonymus Latifolius*; *Broad-leaved Spindle Tree*. Most of the flowers five-stamined; bark smooth; peduncles filiform, cylindric, many-flowered; leaves sharply serrate; angles of the capsules sharp. This species rises with a stronger stem than the first species, and grows to a larger size; the leaves are ovate-lanceolate, about four inches long, and two broad in the middle, opposite, entire, light green, on short footstalks; the flowers come out from the side of the branches upon very slender peduncles, two inches and a half long, branching out into a loose bunch, and the flowers on separate pedicels; petals five, at first white, but changing to purple; the same number predominates in the other parts of the fructification; the fruit is much larger than that of the common sort, and the peduncles being weak, it always hangs down. This plant was seldom seen in England, until Mr. Miller procured it from France, and is now become very common in the nurseries.—Native of Austria, Hungary, and most of the southern parts of Europe. See the first species.

3. *Euonymus Verrucosus*; *Warted Spindle Tree*. Flowers four-stamined; bark warted; peduncles filiform, cylindric, with about three flowers. This species differs from the two first, in having the stem and branches warted, the upper surface of the petals covered with a pile consisting of very small teats; the anthers rounded, and placed upon their pyramidal filamenta, like the cap of a mushroom. It flowers in May and June.—Native of Austria and Carniola. See the first species.

4. *Euonymus Atro-purpureus*; *Purple-flowered Spindle Tree*. Flowers four-stamined; peduncles compressed, many-flowered; stigmas four-sided, truncate. This shrub is about six feet high, with an ash-coloured bark, smooth, and free from tubercles; the branches are round, and a little compressed at their extremities: the leaves are oblong-lanceolate, smooth on both sides, veiny on the back, stand opposite, and are finely serrated on their edges, where they are of a purple tinge, as are also the footstalks; the common peduncles are biflorous, slender, and branchy, the proper ones red.—Native of the northern parts of Asia. See the first species.

5. *Euonymus Americanus*; *Evergreen Spindle Tree*. All the flowers five-cleft; leaves sessile. It rises with a shrubby stalk to the height of eight or ten feet, dividing into many branches, which come out opposite from the joints of the stem. Leaves lanceolate, two inches long, and about three-quarters of an inch broad in the middle, ending in acute points, they are opposite, and continue green all the year; the flowers are produced at the ends of the branches, and also from the sides, in small clusters, and are succeeded by round capsules, which are closely armed with rough protuberances. It flowers in July, but seldom produces ripe fruit in England. There is a variety in the nurseries with variegated leaves. As they are evergreen shrubs, they deserve a place in every curious garden, and particularly in all plantations.—It is a native of North America, and is so hardy, that it rarely suffers by the cold of our winters, provided it be not very much exposed. It may be propagated by laying down the young branches in the autumn, observing to tongue them in the same manner as is practised in laying of Carnations; these will have made good roots in one year, when they may be cut from the old plants, and planted for two years in a nursery, in order to acquire strength; after which they should be planted where they are designed to remain.

6. *Euonymus Tobira*. Flowers five-cleft; leaves oblong,

retuse, entire; stem shrubby, upright, leafless, branched, scarce a fathom in height; branches alternate, round, upright, leafless; branchlets alternate, upright, green, smooth, leafy; flowers at the ends of the branchlets aggregate, in a kind of umbel, upright; petals five, seldom six, white, smelling like Orange flowers, oblong-ovate, blunt, entire, patulous; stamina seldom six: the whole plant is rather milky.—Native of Japan, flowering in May.

7. *Euonymus Japonicus*. Flowers four-cleft; leaves ovate, obtuse, serrate; stem shrubby, strict, ash-coloured, naked, a fathom in height; branches opposite, from upright spreading, green, but little leafy; branchlets decussate, leafy, short, green; flowers axillary, panicled; panicle trichotomous, decomposed, divaricate, subfastigate; peduncle and pedicels angular, smooth, compressed; corolla four-petalled, white, patulous; petals rounded, concave, entire, a line in length; stamina four. It varies with leaves spotted with white; the flowers appear in June and July, and the fruit ripens in November and December.—Native of Japan.

8. *Euonymus Chinensis*. Stem scandent; leaves three-lobed; peduncles many-flowered. Stem herbaceous, long, climbing by tendrils; flowers white; calix five-cleft, spreading; petals five, oblong-ovate, spreading, longer than the calix.—Native of China, where it is found near the suburbs of Canton.

Euparca; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets lanceolate, acute. *Corolla*: petals five or twelve, oblong, narrow, spreading, longer than the calix. *Stamina*: filamenta five; anthers not described. *Pistil*: germen roundish, superior; style bristle-shaped, long; stigma simple. *Pericarp*: berry juiceless, globular, crowned with the permanent style, one-celled. *Seeds*: very many, roundish, small, adhering to a globular fungous free receptacle, in the middle of the berry. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five to twelve-petalled. *Berry*: superior, one-celled. *Seeds*: very many, adhering to a free receptacle.—The only species hitherto known is,

1. *Euparca Amœna*; which is a procumbent plant, having the appearance of *Lysimachia Nummularia*, but being only one-fourth of the size; the flowers have the colour of those of *Anagallis Phœnicea*, or *Pimpernel*, but are many-petalled; the fruit, which Gærtner in one place calls a capsule, and in another a juiceless berry, however it be pressed, will not open with regular valves, and is therefore nearly allied to *Trientalis*: the seeds have a navel in the belly opposite to the embryo.—Native of New Holland, and Terra del Fuego.

Eupatorium; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common oblong, imbricate; scales linear-lanceolate, upright, unequal. *Corolla*: compound uniform, tubular; corollets hermaphrodite, equal; proper funnel-form; border five-cleft, spreading. *Stamina*: filamenta five, capillary, very short; anthers cylindric, tubular. *Pistil*: germen very small; style filiform, very long, two-cleft almost to the germina, straight; stigmas slender. *Pericarp*: none; culix unchanged. *Seeds*: solitary, oblong, angular; down plumose, long, (according to Gærtner, pilose, only toothletted or ciliate.) *Receptacle*: naked. ESSEN. CHAR. *Calix*: imbricate, oblong; style cloven half way, long. *Down*: plumose. *Receptacle*: naked.—This genus consists principally of tall-growing, perennial, herbaceous plants. The greater part of the old sorts are natives of North America: many, however, of South America, and the West Indies; whence come most of the new sorts. Several are found wild in the East Indies, and one only in Europe. The two first, and a few other species, are shrubby. Some

have weak stems, and support themselves by twining. The leaves in most of the species are opposite, but in a few they are verticillate or alternate. The flowers are most frequently in corymbs at the ends of the stem and branches, or else axillary: the predominant colour of the corolla is purple; some, however, are white.—The species are,

* *Calices four-flowered.*

1. *Eupatorium Dalea*; *Shrubby Hemp Agrimony*. Leaves lanceolate, veined, obscurely serrate, smooth; stem shrubby. This species rises to the height of nine or ten feet or more: it has a moderately thick woody stem, and throws out its branches in a pretty open position. It flowers with us in August, and is frequently met with on the lower hills of Liguanea in Jamaica. This plant is remarkable for the very pleasant odour which it emits from every part, which continues for many years, even when dried.—This, with the second, fifth, sixth, seventh, eighth, ninth, fifteenth, seventeenth, eighteenth, nineteenth, twenty-second, twenty-fifth, twenty-sixth, twenty-seventh, twenty-ninth, thirtieth, thirty-first, second, third, fourth, fifth, and thirty-ninth, forty-first, second, third, fourth, fifth, sixth, seventh, eighth, and forty-ninth species, being tender, should be planted in pots, and kept constantly plunged in the tan-bed in the stove, where they will thrive and flower. These may be propagated by cutting off some of their young shoots, about the middle of June, when they have strength, planting them in pots filled with light earth, and plunging them into a moderate hot-bed, where, if they be shaded from the sun, and gently watered as they may require it, they will put out roots in six weeks, and may then be transplanted into separate pots, and treated like old plants. When the seeds of these tender sorts can be procured from their native countries, the plants raised from them are much preferable to those which are obtained by any other method, and will flower much stronger; but as these seeds seldom grow the first year, few persons have patience enough to wait for the plants coming up. When any of these seeds are brought over, they should be sown as soon as they arrive, in pots, that they may be removed at any time: the pots should be plunged into a moderate hot-bed, and the earth kept tolerably moist; the glasses should also be shaded in the heat of the day, to prevent the earth from drying. In this hot-bed the pots may remain till autumn, when, if the plants are not up, they should be plunged between those in the bark-stove, and removed in the spring to a gentle hot-bed, which will bring up the plants soon after. When they are fit to remove, they ought to be planted in separate small pots, and plunged into the hot-bed again, shading them from the sun till they have taken new root; then they should have a large share of free air admitted to them in warm weather, and frequently refreshed with water. In the winter these plants should be more sparingly watered, especially those the stalks of which decay. In the summer they require a large portion of free air, with which management they will thrive and flower.

2. *Eupatorium Parviflorum*; *Small-flowered Hemp Agrimony*. Shrubby: leaves ovate-lanceolate, serrate, smooth; corymbs spreading; calices three-flowered. This strongly resembles the preceding species; but the leaves are oblong, the flowers smaller, the calices constantly three-flowered, and the plant almost void of scent.—Native of Jamaica, where it is much more common than the first species, growing in the same situations. See the first species.

3. *Eupatorium Hyssopifolium*; *Hyssop-leaved Hemp Agrimony*. Leaves lanceolate-linear, three-nerved, almost entire. This species rises with an upright round stalk, to the height of three feet, sending out several branches towards the top,

which come out regularly by pairs. The flowers stand upon long peduncles at the ends of the branches, some sustaining one, some two, and others three or four flowers, which are white, and appear late in autumn. Native of Carolina, Virginia, and Maryland; and found also in Japan.—This, together with the fourth, tenth, eleventh, fourteenth, sixteenth, twentieth, twenty-fourth, twenty-eighth, thirty-sixth, thirty-seventh, thirty-eighth, and fortieth species, are hardy plants, and are propagated by sowing the seed in the full ground; but there must be care taken in the sowing to keep the sorts separate; for, as the seeds of these plants have a light down adhering to them, they are easily displaced by the least wind: so that the best way will be to sow them in drills, which should be but shallow, for when the seeds are buried too deep, they will not grow. The bed in which these are sown should not be too much exposed to the sun, but rather have an eastern aspect, where the morning sun only reaches it; but where more exposed, they must be shaded with mats in the heat of the day, and the ground should be kept pretty moist; for, as they generally grow in moist shady situations in their native countries, they will of course succeed better where they have a soil and situation somewhat like that; though, as we want their heat in summer, the plants will thrive here when exposed to the sun, provided they have a moist soil, or are supplied with water in dry weather. When the young plants come up, they must be kept clean from weeds, and where they are too close, some of them should be drawn out, to give room for the others to grow, and if these be wanted, they may be planted in another bed, where, if they are shaded and watered, they will soon take root; after which, they will require no farther care but to keep them clean from weeds till the following autumn, when they may be transplanted to the places where they are intended to remain. As the roots of these plants spread out to a considerable distance, they should not be allowed less than three feet distance from any other plants, and some of the largest growing should be allowed four feet. If the soil in which they are planted is a soft gentle loam, they will thrive much better, and flower stronger, than in light dry ground, in which, if they are not duly watered in dry summers, their leaves will shrink, and their stalks will not grow to half their usual height. All the species above enumerated have perennial roots, by which they may be propagated; and as some of them do not perfect their seeds in England, that is the only way of increasing the plants here: some of the sorts have creeping roots, sending out offsets in great plenty, so these are easily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing of which, great care should be taken not to injure the old plants, or cut them too much, which would cause them to flower weak in the succeeding year. The best time to remove these plants is in autumn, as soon as they have done growing, that they may get fresh roots before the frost comes on; but if the frost should commence soon after their removal, if the surface of the ground is covered with tan or dried leaves, to keep out the frost, it will effectually secure them; and if this be done to the old plants in very severe winters, it will always preserve them; however, it may not be injudicious to practise this on the young seedling plants, which have not so good roots, nor are so well established in the ground: the future culture will be only to dig the ground about them every spring, and keep them clean.

4. *Eupatorium Scandens*; *Climbing Hemp Agrimony*. Stem twining; leaves cordate-ovate, attenuated, crenate-toothed; lobes divaricate; branches smooth. Stems annual, twisting about any neighbouring support, to the height of five

or six feet. At each joint two small side-branches come out, terminated by clusters of white flowers, so that the stalks seem covered with them most part of their length; but as these come out late in the season, unless the summer prove warm, this plant does not flower well in England.—Native of Virginia and Carolina; and also, it is supposed, of the East Indies. This species is sometimes killed by severe weather in our climate, when left uncovered. When the stalks therefore decay in autumn, the ground should be covered with some old tanners' bark. It multiplies very fast by its creeping roots, which may be parted every other year. For further particulars respecting its propagation and culture, see the third species.

5. *Eupatorium Volubile*. Leaves cordate-ovate, crenate, acute; lobes parallel; stem twining; branches and petioles villose. This differs from the preceding, in having the branches, petioles, nerves of the leaves, underneath, and peduncles villose, the leaves less attenuated, with the lobes not divaricated, but parallel, the egret purplish, but not hoary. There is another *Eupatorium* from Madagascar, exactly like this, except that it is entirely smooth.—Native of the East Indies. See the first species.

6. *Eupatorium Denticulatum*. Leaves cordate, rugged, minutely toothletted; branches angular; stem climbing. The branches have five acute angles, standing; leaves petioled, two inches long, bluntnish, paler underneath, very finely and thinly haired, sometimes not toothed; corymbs terminating the branches and branchlets; pedicels unbelled, filiform, rugged, angular; calix four-leaved; leaflets linear, equal, shorter than the egret, which is purple.—Native of Surinam. See the first species.

7. *Eupatorium Amarum*. Leaves cordate-ovate, acuminate, quite entire, subtomentose underneath; flowers corymboid; stem climbing; branches the thickness of a swan's quill, smooth, striated; branchlets axillary, a hand in length, flower-bearing. The leaves are petioled, three inches in length and breadth, smooth, and nerved above, beneath slightly tomentose, with stellate hairs, visible only with a magnifier, and having veins standing out; those on the branchlets are an inch long, and become gradually smaller towards the top; corymbs from the extreme axils of the leaves on the branchlets, and from the end; seeds four, angular; egret longer than the calix, purplish.—Found in the Caribbee islands by Martfelt, and in Surinam by Rolander. See the first species.

8. *Eupatorium Houstoni*; *Houston's Hemp Agrimony*. Stem twining; leaves ovate, quite entire; stalks slender, twining, eight or ten feet high, sending out small opposite branches at most of the upper joints; lower leaves heart-shaped, ending in acute points; upper almost triangular, smooth, and of a lucid green. The upper part of the stalks has long branching stalks of white flowers, which are small and sessile.—Imported from Jamaica. See the first species.

** *Calices five-flowered.*

9. *Eupatorium Zeylanicum*; *Ceylon Hemp Agrimony*. Leaves ovate, hastate, petioled, toothed; they are alternate, narrower at the base, with small rounded ears bent in, green, and smooth on the upper surface, tomentose and veined on the lower, like Sage. The corymbs of flowers resemble those of the *Eupatoriums*: the fructifications, however, want to be examined more critically.—Native of Ceylon. See the first species.

10. *Eupatorium Sessilifolium*; *Sessile-leaved Hemp Agrimony*. Leaves sessile, stem-clasping, distinct, lanceolate; stems slender, round, smooth. The leaves are in pairs, at two inches' distance, sessile, two inches long, mucronate, resembling those of Mint, slightly toothed on the edge; flowers

terminating, corymboid, in many little heads, white, slender. It flowers in September and October.—Native of Virginia. See the third species.

11. *Eupatorium Album*; *White Hemp Agrimony*. Leaves lanceolate-serrate; leaflets of the calix lanceolate, scariose at the end, and coloured. The stem is erect, streaked, scarcely pubescent; leaves opposite, subsessile, almost naked; corymb terminating, composed of alternate subdivided branchlets, fastigiate, and white; down simple.—Found in Pennsylvania by Bartram, and by Thunberg in Japan. See the third species.

12. *Eupatorium Chinense*; *Chinese Hemp Agrimony*. Leaves ovate, petioled, serrate; stem somewhat angular, flexuose, erect, smooth, but little branched, a foot high or more. The leaves are opposite, sharp, entire at the base, pale underneath, nerved, smooth, spreading, an inch and more in length; flowers in a fastigiate and roundish panicle.—Native of China and Japan.

13. *Eupatorium Japonicum*; *Japanese Hemp Agrimony*. Leaves undivided, and three-lobed, serrate. The stem is scabrous, round, streaked, erect, branched, two feet and upwards in height; branches alternate, paniced, from erect patulous like the stem; leaves opposite, petioled, the lower three-lobed, the upper undivided, ovate, sharp, unequally serrate, sometimes entire, paler underneath, nerved, scabrous, a finger's length, the upper ones gradually less; petioles half an inch in length; flowers on the branches and branchlets terminating, in ovate panicles, on very short peduncles.—Native of Japan.

14. *Eupatorium Rotundifolium*; *Round-leaved Hemp Agrimony*. Leaves sessile, distinct, roundish-cordate. It rises with upright stalks about a foot high; the joints are near each other, and at every joint is a pair of leaves, of a light green colour, and serrate. The flowers are produced in small loose panicles at the tops of the stalks; they are white, and have two small leaves immediately under them. The flowers appear at the end of June; but the seeds seldom ripen in England.—Native of New England and Virginia. See the third species.

15. *Eupatorium Stipulaceum*. Leaves hastate, acute at both ends, three-nerved, stipuled; flowers corymboid; stem climbing. The stem is very smooth, and very finely streaked; the leaves an inch and a half or more in length, mucronate, acuminate at the base, veined very smooth above, beneath appearing very slightly villose with a magnifier; and the lobes ovate, acute, oblique behind, having frequently one or two minute teeth.—Native of Brazil. For the propagation and culture, see the first species.

16. *Eupatorium Altissimum*; *Tall Hemp Agrimony*. Leaves lanceolate, nerved, the lower ones a little serrate on the outmost part; stem undershrubby. This rises with a single, upright, green stalk, about four feet high; at each joint are four leaves in whorls, they are six inches long, and two inches broad in the middle, lessening to both ends, terminating in acute points, rough, serrate, and on short foot-stalks; the stem is terminated by a close corymb of purple flowers, appearing in July, and continuing till September.—Native of North America. See the third species.

17. *Eupatorium Hastatum*; *Hastate-leaved Hemp Agrimony*. Leaves cordate-hastate, somewhat toothed, naked; stem twining; flowers in spikes. Stem shrubby, branched, striated, pubescent; leaves petioled, opposite, petioles also pubescent; racemes axillary, opposite; flowers spiked, in whorls, four in a whorl, white; calix four leaved; leaflets lanceolate-ovate, convex; corollets four; stamina extremely minute; style longer. The flowers small like those of Caca-

lia Suaveolens, and the taste of the whole herb is bitter. It is a climber, and stretches a great way among the neighbouring bushes.—It is frequent about St. Thomas's, in the East, and Manganese in Jamaica. See the first species.

18. *Eupatorium Syriacum*; *Syrian Hemp Agrimony*. Leaves opposite, subsessile, ternate; stems straight, round, four or five feet high, purplish, striated; the branchlets come out at a right angle almost over the whole stem; flowers in erect compound corymbs. It flowers in October; the flavour is unpleasant, and bitterish.—Native of the West Indies. See the first species.

19. *Eupatorium Trifidum*. Leaves three-parted, the floral ones undivided; stem climbing; corymbs from the upper axils, and at the top, on long peduncles, compound; partial peduncles and pedicels subpubescent; calix smooth, five-flowered; leaflets smooth, about ten, linear, the five outer ones very short.—Native of the Caribbee Islands. See the first species.

20. *Eupatorium Trifoliatum*; *Three-leaved Hemp Agrimony*. Leaves in threes; stem slender, cylindrical, rigid, hairy on the upper part; flowers very small, as in the other species, but they have not the calices so long, nor are they so exactly disposed in umbels, but rather like the common Red Valerian. Gronovius found it in Virginia; Vernon brought it from Maryland; Miller says that it grows in Pennsylvania; Krockner, that it is found in Silesia, and that it is like our common European sort, except in having leaves in threes, and white flowers. See the third species.

21. *Eupatorium Cannabinum*; *Common Hemp Agrimony*. Leaves digitate; stems three or four, and even six feet high, hairy, reddish, branched; leaflets three or five, lanceolate, sharply serrate on the sides, entire on the base and top, slightly hairy, the middle one much larger than the others; scales of the calix few, not more than ten, unequal, linear, red on the edge, a little hairy; flowers in thick umbels or corymbs at the top of the stem or branches; florets five, and sometimes six together, of a pale red or purple colour; seeds black, streaked, smooth, little more than a line in length; egret sessile, with simple rays, not three lines long; the rays, when viewed with a glass, are finely toothed, or shortly ciliate. The stem has a pleasant aromatic smell when cut. The flowers have a strong smell; and the whole plant has a very bitter taste. An ounce of the root in decoction is a full dose, and is sometimes taken in the jaundice and dropsy; but it is a rough medicine, and ought to be used with caution. Boerhaave gave an infusion of this plant to foment ulcers and putrid sores; and Tournefort informs us, that the Turks cure the scurvy with it. Withering says, that an infusion of about a handful of the leaves vomits and purges briskly; and adds, that the Dutch peasants make use of it in smaller doses, as an alterative or purifier of the blood, and against the scurvy. Meyrick affirms, that the fresh-gathered root boiled in ale purges briskly, but without producing any bad effects; and there are, says he, many instances of its having cured the dropsy. It is also a good wound-herb, whether bruised and applied to the parts, or made into an ointment with hog's-lard. Goats are the only cattle that appear to eat this plant.—Found on the banks both of running and stagnant waters, frequently in most parts of Europe, flowering in July and August. In Johnson's edition of Gerarde, it is named *Common Dutch Agrimony*. There is a variety, which is the seedling, and has oval-lanceolate leaves: it sometimes flowers in that state, but not often; the second year it bears leaves in threes. Professor Martyn found this variety with simple leaves; but forgot the place. Dillenius met with it afterwards, before you come to Lee, in the road to Eltham; and Mr. Woodward has since observed

it near Bungay in Suffolk. For the propagation and culture, see the first species.

*** *Calices eight-flowered.*

22. *Eupatorium Coriaceum*. Leaves elliptic, coriaceous, smooth, toothed on the outside; petioles an inch long, dilated at the base; corymbs terminating, superdecompound; common peduncle pubescent; pedicels having minute scales scattered on them towards the base; calix seven-flowered; the outer scales ovate, shorter, the inner longer, linear; egret purplish, twice as long as the calix, almost simple.—Supposed to be a native of South America. See the first species.

23. *Eupatorium Cinereum*. Calices seven-flowered; leaves opposite, lanceolate, tomentose. This very much resembles an *Athanasia* in its flowers and woody rigid stem.—Thunberg found it at the Cape of Good Hope.

24. *Eupatorium Purpureum*; *Purple Hemp Agrimony*. Leaves in fours, scabrous, lanceolate-ovate, unequally serrate, petioled, wrinkled; stem cylindrical, green, but purplish at the base of the petioles; corymb terminating; calices flesh-coloured; corollas whitish; antheræ purple; style very long. It grows to the height of three feet or more, with a suffruticose, upright, striated stem, but little branched. The leaves are subsessile, and of a very dark green. The corymb of flowers is fastigate. The calix has about eight flowers. The receptacle is narrow, convex, scrobiculate, smooth. The seeds are small, four-cornered, columnar, acuminate at the base, with the streaks and angles rugged with dots, and whitish, the interstices smooth and livid; egret capillary, very minutely toothletted.—Native of North America and Cochin-china. See the third species.

25. *Eupatorium Diffusum*. Leaves ovate, serrate, three-nerved; panicle very much branched and diffused. The whole plant is smooth; panicle terminating, large, a foot long; the last pedicels capillary; at all the ramifications opposite narrow leaves becoming gradually smaller; calicine leaflets lanceolate, the outer ones shorter; corollets eight; egret white, the length of the calix.—Native of South America. See the first species.

26. *Eupatorium Nervosum*. Leaves elliptic-lanceolate, attenuated, toothed, triple-nerved, smooth on both sides; calices many-flowered.—Native of Jamaica. See the first species.

27. *Eupatorium Rigidum*. Leaves petioled, ovate, acute, serrate-toothed, rigid, rugged underneath; stem subherbaceous.—Native of Jamaica. See the first species.

28. *Eupatorium Maculatum*; *Spotted Hemp Agrimony*. Leaves in fives, somewhat tomentose, lanceolate, equally serrate, veined, petioled; stem annual, about two feet and a half high, purple, with many dark spots upon it; leaves rough, placed by threes towards the bottom of the stalk, but near the top by pairs at each joint; flowers purple, terminating in a sort of corymb, appearing in July and August, and in warm seasons ripening the seeds in autumn; egret simple or capillary.—Native of North America. See the third species.

29. *Eupatorium Auriculatum*. Leaves ovate, toothletted, tomentose underneath; petioles eared; stem climbing; flowers in spikes. The stem is woody; branches striated, tomentose, hoary, becoming bald with age; petioles tomentose, half an inch in length, with a half-ovate tomentose earlet at the base on each side, the flat floral-leaves having only a rudiment of these; spike compound, flexuose, axillary, and terminating; spikelets alternate; flowers usually in pairs, distant; in the axils of the branches of the spike single; calix smooth, with eight linear leaflets, of a brown ferruginous colour, and at the base a few minute tomentose scales; corollets seven; style

longer by half than the corollet; egret a little longer than the calix, white, when magnified serrate. Annual.—Native of Brazil, Guiana, Jamaica, &c. See the first species.

30. *Eupatorium Molle*. Leaves petioled, cordate, acute, subserrate, pubescent; stem herbaceous, tomentose.—Native of Jamaica, Guiana, &c. See the first species.

31. *Eupatorium Villosum*. Leaves opposite, decussated, ovate, subserrate, beneath villose-tomentose; calices eight to fifteen flowered; stem shrubby; branches softly villose; corymbs terminating, decomposed; peduncles and pedicels villose-tomentose; at the ramifications short bristle-shaped leaves; calicine leaflets linear, pubescent; corollets small, as far as sixteen; seeds the length of the calix, with a dirty-coloured egret, longer than the calix.—Native of Jamaica and St. Domingo. See the first species.

32. *Eupatorium Cordifolium*. Leaves cordate, serrate, tomentose, hirsute underneath; petioles very short; corymbs subsessile; calices squarrose; stem shrubby.—Native of Jamaica. See the first species.

33. *Eupatorium Montanum*. Leaves cordate, acute, toothletted, petioled, rugged, hirsute underneath; corymbs much spreading; stem shrubby.—Native of Jamaica. See the first species.

34. *Eupatorium Canescens*. Hoary; leaves ovate, sublobed and entire, underneath very soft and three-nerved; corymbs simple. This is a branching shrub, the branches having an ash-coloured bark; branchlets opposite, brachiate, spreading, hoary, and very soft, as are also the tops of the branches; corymbs from the ends of the branches and branchlets, few-flowered; calix cylindrical, subvillose; leaflets linear, obtuse, with pale streaks, the outer ones shorter; florets ten; seed black, when magnified appearing angular, with minute villose hairs scattered over it.—Observed in the island of Santa Cruz. See the first species.

35. *Eupatorium Scabrum*. Villose: leaves opposite, petioled, ovate, mostly entire, wrinkled, scabrous on the upper surface. The stem seems to be undershrubby; it is upright, branched, roundish, streaked, villose-scabrous, leafy, many-flowered; branchlets opposite, angular, bearing flowers at the end. No stipules; panicles terminating, upright, rough with hairs, many-flowered, contracted; peduncles opposite; pedicels mostly alternate; bracts lanceolate, rough with hairs; flowers upright; calix cylindrical, smooth; scales oblong, obtuse, three-nerved, somewhat callous at the tip; the outer ones shorter and broader; florets seven or eight, scarcely longer than the calix, five-sided; seeds black, with a down, scarcely the length of the corolla, serrate, hardly feathered, spreading.—Gathered by Mutis in New Granada. See the first species.

**** *Calices with fifteen or more Floscules.*

36. *Eupatorium Perfoliatum*; *Perfoliate Hemp Agrimony*. Leaves connate, perfoliate, tomentose; stems annual, from two to three feet high, hairy. The upper part of the stalk divides into many slender peduncles, each sustaining a close cluster of white flowers, coming out in July. The seeds, in warm seasons, will sometimes ripen in England.—Native of North America. See the third species.

37. *Eupatorium Cœlestium*; *Blue-flowered Hemp Agrimony*. Leaves cordate-ovate, obtusely serrate, petioled; calices many-flowered. This has a creeping root, which spreads and multiplies very fast. The stalks rise about two feet high. The flowers are produced at the top of the stalks in a sort of corymb, and are of a fine blue colour.—Native of Maryland. See the third species.

38. *Eupatorium Aromaticum*; *Aromatic Hemp Agrimony*. Leaves ovate, obtusely serrate, petioled, three-nerved; calices

simple; stem round, four feet high, strict, brachiate, having the appearance of *Scutellaria*. Leaves somewhat wrinkled; racemes terminating; flowers twice the length of the calix, snow-white, containing from eighteen to twenty-eight florets, the styles scarcely longer than the floret; in this circumstance it differs from the other species, and in having the calix not imbricate, but the leaflets almost equal.—Native of Virginia. See the third species.

39. *Eupatorium Macrophyllum*; *Large-leaved Hemp Agrimony*. Leaves heart-shaped, three-nerved, serrate underneath, pubescent; stem pubescent, the thickness of a swan's quill, striated; petioles from two to three inches in length; corymbs terminating, and axillary, peduncled, decomposed, close; calix loosely imbricate; the leaflets lanceolate, pale green, very finely streaked.—Native of the Caribbee islands. See the first species.

40. *Eupatorium Ageratoides*. Leaves ovate, serrate, petioled; stem smooth, annual, five or six feet high, towards the top putting out side-branches. At the ends of the shoots the flowers are produced in large tufts, and are of a pure white; they appear in October.—Native of North America. See the third species.

41. *Eupatorium Conyzoides*. Leaves ovate, attenuated, sharply serrate, three-nerved, smooth above; calices closely imbricate; branches striated, pubescent; corymb terminating, almost simple, few-flowered; partial peduncles three-flowered; pedicels one-flowered.—Supposed to be a native of South America. See the first species.

42. *Eupatorium Odoratum*; *Sweet-scented Hemp Agrimony*. Leaves deltoid, toothed at bottom, tomentose underneath; calices many-flowered; stem a fathom in height, shrubby, branched, even; flowers terminating, subcorymbed, white; seeds linear, slightly compressed, with a capillary egret. This weakly shrubby plant is generally observed to grow among other bushes, where it frequently casts its long, slender, flexile, opposite branches to a moderate distance. The flowers are sometimes impregnated with a smell resembling that of the European Meadow-sweet.—It flowers in August and September, and is very common in the lower hills of Jamaica. See the first species.

43. *Eupatorium Triplinerve*. Leaves lanceolate, triple-nerved, quite entire, smooth; stem round, smooth, very finely streaked; branches spreading, flower-bearing; panicle terminating, subtrichotomous; partial peduncles scarcely pubescent; the last pedicels an inch long, filiform, with a minute leaf at the base of each; calix many-leaved; leaflets linear, nearly equal, acute, villose, and purplish at the tip; the outermost shorter; florets more than twenty, purple at the top. From the island of Santa Cruz. See the first species.

44. *Eupatorium Ivæfolium*. Leaves narrow-lanceolate, three-nerved, subserrate; calices squarrose, many-flowered; stem subherbaceous, two feet high, erect, strict, branched, hispid; branches simple, elongated; peduncles terminating, and in the axils of the upper leaves opposite, filiform, mostly trichotomous, but the last one-flowered; flowers small, blue.—Common in Jamaica. See the first species.

45. *Eupatorium Urticæfolium*; *Nettle-leaved Hemp Agrimony*. Hispid: leaves petioled, cordate, gash-serrate; panicle terminating; calices many-flowered, awl-shaped, somewhat pungent. This plant appears very much like a Nettle at first sight, but the leaves are three-nerved at the base; stem upright, branched, round, streaked, hairy, leafy; petioles scarcely the length of the leaves, angular, equal. No stipules; panicle like a cyme, upright, hairy; pedicels alternate or crowded; bracts linear, few; flowers upright, pale purple; calix subcylindric, patulous; pubescent; scales

keeled, three-nerved, attenuated at the edge, the outer ones smaller; floscules little longer than the calix; seeds black; down shorter than the corolla.—Native of New Granada. See the first species.

46. *Eupatorium Stoechadifolium*; *Cotton-weed Eupatorium*. Tomentose: leaves petioled, linear, crenate, hoary underneath; panicle terminating; stem upright, roundish, covered with a soft, thick, white down. No stipules: panicles upright, somewhat like corymbs, conglomerate; peduncles opposite, variously divided, woolly; bractes none, except a pair of leaves, smaller than the rest at the base of each panicle; flowers purple; calix cylindric, woolly at the base; scale sharp, with a green line along them, membranaceous and ciliate about the edge, the inner ones somewhat tongue-shaped, the outer lanceolate and smaller; floscules very numerous, the length of the calix, a little swelling, five-sided; segments from erect spreading, sharpish, quite entire, scarcely pubescent; antheræ included; style scarcely half-cleft; down shorter than the corolla, yellowish, scabrous.—Native of New Granada. See the first species.

47. *Eupatorium Microphyllum*; *Small-leaved Hemp Agrimony*. Leaves triangular-ovate, with nine notches, tomentose and veined underneath; panicle conglomerate, terminating; peduncle elongated; stem undershrubby, woody, ascending, a little branched, leafy, round, subhirsute; petioles the length of the leaves, hairy; no stipules; panicle on a long peduncle, resembling a corymb; pedicels variously divided, rough, haired; bractes two at the first ramification of the panicle, usually lanceolate, but sometimes of the same form with the leaves; flowers purple, fewer than in the foregoing; calix subcylindric, scarcely pubescent at the base; all the scales lanceolate, sharp, nerved, attenuated and ciliate at the edge, the outer ones smaller and thicker; floscules scarcely the length of the calix, swelling at top, not angular; segments from erect spreading, bluntish, entire, closely pubescent on the outside; antheræ included; style scarcely half-cleft; seeds brown; egret almost the length of the corolla, hardly rugged when viewed through a glass. The flowers resemble those of the preceding in structure, but differ in several characters.—Native of New Granada. See the first species.

48. *Eupatorium Squarrosum*. Leaves subcordate, ovate-acute, serrate; calices squarrose; stems a fathom in height, round, subtomentose, with opposite branches; flowers in racemes, on axillary three-flowered peduncles; calix cylindric, with many lanceolate-acute, striated leaflets, the outer ones reflex at the tip, and containing about twenty-four florets; corolla twice as long as the calix; florets greenish yellow, with short, ovate-acute, patulous segments; seeds small, oblong, striated, with very small hairs; egret sessile, obscurely feathered, shorter than the corolla.—Native of Mexico. See the first species.

49. *Eupatorium Sinuatum*. Leaves ovate, sinuate, hairy, alternate; calices eight-flowered, or thereabouts; stem suffruticose, three feet high, erect, hispid; leaves toothletted; flowers purplish, in terminating panicles; receptacle concave.—Native of the island of Mozambique.

Besides the species above enumerated, Mr. Miller describes five sorts which were sent to him from Vera Cruz by Dr. Houston, viz.

1. *Eupatorium Fruticosum*; with oblong cordate leaves; flowers in panicles; stem shrubby, climbing. It rises to the height of ten or twelve feet; the leaves are opposite, and about three inches long, and an inch and a half broad, of a lucid green; the panicles are long and branching, and proceed from the side of the stalks; the flowers are white.

2. *Eupatorium Betonicifolium*; with oblong, blunt, crenate,

smooth leaves, and simple calices. It rises with an upright stem nearly two feet high, being towards the bottom leaves of a thick substance; from the upper part, which is naked, the flowers come out in a thick panicle, they are of a blue colour, and appear late in autumn; the root is biennial.

3. *Eupatorium Morifolium*; with heart-shaped serrate leaves, and an upright tree-like stem. It rises twelve or fourteen feet high, sending out many channelled branches, covered with a brown bark; leaves as large as those of the Mulberry-tree, of a light green colour, opposite, on petioles near two inches long. The branches are terminated by four or five peduncles, which come out opposite from the joints, (there is also an odd one at the end,) these sustain branching panicles of white flowers, forming a long, loose, pyramidal thyrse, without any leaves intermixed, and making a fine appearance.

4. *Eupatorium Punctatum*; with ovate-petioled entire leaves; stem shrubby, branching; calices simple. The stems are near five feet high, dividing into many slender branches, the joints of which are three or four inches asunder; at each of these is a pair of leaves about three-quarters of an inch long and half an inch broad, having several black spots on their surface, and upon long slender footstalks; the branches are horizontal, terminated by small bunches of white flowers; the calices are composed of seven narrow lanceolate leaflets, divided to the bottom.

5. *Eupatorium Paniculatum*; with heart-shaped, wrinkled, crenate leaves, and a panicle stem. It rises with an upright branching stem three feet high, sending out two side-branches from the joint, almost the whole length; these are terminated by loose spikes of red flowers, as is also the principal stem; the leaves are rough, sessile, of a light green, and a little hoary.

6. *Eupatorium Conyzoides*, may probably be the same with *Kuhnia Conyzoides* of Linneus.

Euphorbia; a genus of the class Dodecandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, inflated, somewhat coloured, four-toothed at the mouth, and in some few five-toothed, permanent. *Corolla*: petals four, in some few five, turbinate, gibbous, thick, truncate, unequal in situation, alternate with the teeth of the calix, with their claws placed on the margin of the calix, permanent. *Stamina*: filamenta several, twelve or more, filiform, jointed, inserted into the receptacle, longer than the corolla, breaking forth at different times; antheræ twin, roundish. *Pistil*: germen roundish, three-sided, pedicelled; styles three, two-cleft; stigmas obtuse. *Pericarp*: capsule roundish, tricoccus, three-celled, starting open elastically. *Seeds*: solitary, roundish. ESSENTIAL CHARACTER. *Corolla*: four or five-petalled, placed on the calix. *Calix*: one-leafed, bellying; capsule tricoccus.—This genus consists of milky plants, which are mostly herbaceous; several however are shrubby, upright, for the most part very few of them creeping, some leafless, but most of them leafy; stems angular, or tubercled, or more frequently cylindric or columnar, unarmed, or, in the angular sorts, resembling the upright Cactuses, and armed with prickles, which are either solitary or in pairs, placed in a single row on the top of the ridges; such as have leaves have them simple, most frequently alternate and naked; in some sorts, however, they are opposite, and are then commonly attended with stipules, and in a few they are placed by threes in whorls; peduncles in the leafless sorts naked, bearing from one to three flowers, in the leafy ones axillary, but more frequently from two to five or more, in a terminating umbel, each sometimes in a many-flowered head, but more frequently dichotomous, trichotomous, or even tetrachotomous, with single flowers, between the divisions, at the base and in the forkings having bractes, in number the same with

the peduncles, forming a sort of involucre. Jussieu doubts whether each stamen being jointed and accompanied with chaffs, and breaking forth at different times, may not, as in Box, be considered as so many one-stamined male flowers, encircling one female flower in a common calix or involucre; if so, the flowers of Euphorbia should be regarded as compound, and the plants as belonging to the class Monœcia. —The species are,

* *Shrubby, prickly.*

1. *Euphorbia Antiquorum; Triangular Spurge.* Almost naked, triangular, jointed; branches spreading. The stem is triangular, compressed, succulent, rising to the height of eight or ten feet, and sending out many irregular spreading twisting branches, for the most part three-cornered, but having some two and others four angles; at their extremities are a few short roundish leaves, which soon fall off, and near these come out now and then a few flowers, which have five thick whitish petals, with a large three-cornered germen in the centre; they soon drop off without producing seeds. It grows naturally in the East Indies, whence the plants were brought to the gardens in Holland, and thence communicated to most of the curious gardens in Europe.—This has generally been mistaken for the true Euphorbium, and consequently directed to be used in medicine; but it is from the second sort that the drug now imported under that name in England is taken. Linneus supposes the 7th (*Officinarum*) to be the sort which should be used; but as they are all nearly of the same quality, it may be indifferent from which this drug, which is the inspissated juice of the plant, is taken.—There is a variety with a naked, three-cornered, compressed stalk, sending out a great number of erect branches, which are also generally three-cornered, but sometimes four-cornered; they are armed with short crooked spines, but have no leaves, nor have the plants produced here. It is also a native of India.

The plants included from the first to the twenty-fifth species, and which form the two first divisions of this vast genus, are in general known by the name of Euphorbium; the others, before Linneus appeared, were mostly known by the name of *Tithymalus* or *Spurge*. These plants are introduced into the gardens of the curious, principally on account of the oddness of their structure, which is entirely different from that of any European production: they are all full of a milky acrid juice, which will soon raise blisters, and flows out of the plant when wounded in any part. This juice will burn linen almost as much as aquafortis; the plants ought therefore to be handled with great caution, nor should the ends of their branches be ever bruised or injured, for if they be, it frequently causes them to rot down to the next joint, and will sometimes destroy the whole plant, if those injured branches be not cut off in time: so that whenever the branches appear to have been injured, the sooner they are cut off from the plants, the less danger there will be of their suffering from it; nor should any of the branches be cut between the joints, for the same reason. The Dutch imported most of the plants into Europe: that people, it must be confessed, have been very curious to introduce great numbers of plants from India, and also from the Cape of Good Hope; from the last-mentioned place a great variety of curious plants have been recently brought, many of which produce very elegant flowers, and are the greatest ornaments of the conservatory in the winter and spring seasons. These have been brought over in seeds; but most of the different sorts of Euphorbia came over in plants or cuttings; which may be easily transported to any distance, if either of them be secured in boxes, with any soft dry package, to prevent their being bruised, or their spines from wounding each other, and defended from mois-

ture and cold, for they will live thus six months out of the ground, and if carefully replanted take new root, and thrive as well as if they had been just cut off from the old plants, or taken out of the ground, which is a much more expeditious method of obtaining the plants than from seeds, when they can be procured. The greatest part of these succulent plants grow naturally upon barren rocky places, or in dry sandy soils, where few other plants will thrive; therefore they should never be planted in rich or loamy earth in our climate, nor suffered to receive much wet, which will soon rot them. The best mixture of earth for these plants is, about a fourth part of screened lime-rubbish, a fourth part of sea-sand, and half of light fresh earth from a common; these should be mixed well together, and frequently turned over before the mixture is used, that the parts may be incorporated, and the compost sweetened by being exposed to the air. If this mixture be prepared a whole year before it is wanted, it will be the better, that it may have the benefit of the winter's frost and the summer's heat to mellow it; and the oftener it is turned over, and the smaller the heaps are in which it is laid, the air will penetrate it better, and render it more fit for use. These plants are easily propagated by cuttings, which should be taken from the old plants in June; they must be cut off at a joint, otherwise they will rot. When the cuttings are taken off, it will cause the milky juice of the old plants to flow out in plenty, therefore there should be some dry earth or sand applied to the wounded part, which will harden and stop the sap; and the wounded part of the cuttings should also be rubbed in sand, or dry earth applied upon the wounded part, for the same purpose: the cuttings should then be laid in a dry part of the stove for ten days or a fortnight; and some of those whose branches are large and very succulent, may lie three weeks or more before they are planted, that their wounds may be healed and hardened, to avoid rotting. The cuttings should be each planted in small halfpenny pots, laying stones or rubbish at the bottom, and filling them with the mixture before directed; then plunge the pots into a moderate hot-bed, and, if the weather be very hot, the glasses of the hot-bed should be shaded in the middle of the day, and the cuttings gently watered once or twice a week, according as the earth may dry; in about six weeks or two months the cuttings will have put out roots, so, if the bed is not very warm, the plants may continue there, provided they have free air admitted to them every day; otherwise it will be better to remove them into the stove, where they may be hardened before the winter, for if they are too much drawn in summer, they are very apt to decay in winter, unless very carefully managed. During summer these plants require gentle waterings two or three times a week, according to the warmth of the season; but in winter they must be sparingly watered, and only once a week, especially if the stove is not warm. The first species will require more warmth in the winter than any of the others, and also less water, and, if well managed, will grow seven or eight feet high; but the plants must constantly remain in the stove, receiving a large share of air in warm weather, and in winter a temperate degree of warmth. The annual sorts should have their seeds sown in the autumn; they will come up in the spring, and require no farther culture. The perennial sorts may be propagated either by sowing the seeds, or parting the roots, or by cuttings. They are most of them hardy enough to endure the greatest cold of this country, especially if they be planted in a dry soil.

2. *Euphorbia Canariensis; Canary Spurge.* Naked, sub-quadrangular; prickles in pairs.—In its native country, the Canary Islands, this grows to the height of twenty feet or

more, but in England it is rarely seen more than six or seven. The stem is very thick, green, and succulent, and has four or five large angles, closely armed with black crooked spines, which come out by pairs at every indenture; it sends out from every side large succulent branches of the same form, which extend to the distance of two or three feet, and then turn their ends upwards, so that when the plants are well grown, they have some resemblance to a chandelier; they have no leaves, but are closely armed with black spines like the stem; at the ends of the branches come out the flowers, which are shaped like those of the first species. It flowers in March and April. For its culture and propagation, see the first species.

3. *Euphorbia Edulis*; *Five-angled Spurge*. Prickly, leafy, five-angled; peduncles many-flowered, terminating; flowers apetalous; stem six feet high, with prickles in pairs, and ascending branches; leaves many, scattered, almost wedge-shaped, rounded at the tip, three inches long, quite entire, fleshy, smooth; corolla none; calix fleshy, ventricose, red within, green without; stamina short, about forty.—Native of Cochin-china, where the leaves are eaten boiled with other herbs. For the culture and propagation, see the first species.

4. *Euphorbia Heptagona*; *Seven-angled Spurge*. Naked, seven-angled; spines solitary, subulate, flower-bearing; stem roundish, upright, succulent, about three feet high, putting out several branches on the side, of the same form; the angles are armed with long, single, black spines; at the ends of the branches come out small flowers, which are sometimes succeeded by small fruit.—Native of the Cape of Good Hope. This species is at present exceedingly rare in England; those procured from Holland have been most of them destroyed by placing them in stoves, where, by the heat, they have in one day turned black, and rotted immediately after. It will, however, thrive well, if placed in a dry airy case, with other succulent plants, where they may have free air in mild weather, and be protected from frost; in summer the plants may be exposed in the open air in a warm situation, but should be screened from much wet: with this treatment the plants will thrive much better than when they are more tenderly nursed. For further particulars, see the first species.

5. *Euphorbia Mammillaris*; *Warty-angled Spurge*. Naked; angles tubercled, with spines between. This differs from the preceding, in having the angles doubled, and swelling a little, and the spines single between the tubercles, which are placed longitudinally.—It flowers in July and August, and is a native of the Cape of Good Hope. This species, like the eleventh and fourteenth, is pretty hardy, and will live in a good glass-case in winter, without fire, provided the frost be entirely excluded. In summer they may be placed abroad in a warm situation; and as they are very succulent plants, they should not have too much wet; if therefore the summer turn out very moist, it will be very proper to place these plants under some shelter, where they may enjoy the free air, and be screened from the rain, otherwise by receiving too much wet they will soon begin to rot, especially in winter. For further particulars respecting its propagation and culture, see the first species.

6. *Euphorbia Cereiformis*; *Naked Spurge*. Naked, many-angled; spines solitary, subulate. This sort has stalks and branches very like those of the next, but much more slender; the spines of this are single, and those of the others double; and the ends of the branches in this are closely set with flowers on every angle. It flowers in June and July, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species.

7. *Euphorbia Officinarum*; *Official Spurge*. Naked, many-angled; prickles doubled. This puts out many stalks, just above the surface, which are thick, succulent, and roundish, having eight or ten angles whilst they are young, but as they grow old they lose their angles and become round; the branches grow distorted and irregular, first horizontal, but afterwards turning upwards; the angles are armed with small crooked spines, and on the upper part of the branches, in June and July, come out the flowers; they are small, and of a greenish white.—Native of Africa. For its propagation and culture, see the first species. Gerarde calls it the *Poisonous Gum Thistle*.

8. *Euphorbia Triaculeata*; *Three-prickled Spurge*. Prickly, naked; stem round, grooved; prickles in threes. This is a shrub of a cubit high, spreading and branchy; branches about the thickness of a finger, sulcated longitudinally; in the interjacent channels are inserted three prickles, of which the exterior are very short, and bent downwards; the middle one about an inch long, subulate, spreading, and curving downwards. The flowers spring by threes from the bosoms of the prickles, and are sessile; the stamina, six in number, two in each angle of the flower; the pistil does not arise from the side, as in many others.—Native of Arabia. For its propagation and culture, see the first species.

9. *Euphorbia Neriifolia*; *Oleander-leaved Spurge*. Angles obliquely tubercled; stem upright, strong, five or six feet high, with irregular angles, and protuberances oblique to the angles; the lower part is naked, and the upper part branching; the branches are armed with crooked spines; at every protuberance, and at the top, are oblong leaves of a lucid green, very smooth, entire, and rounded at the end; these fall off in spring, and the plants remain naked for some months, and then, in June and July, the flowers come out; they sit close to the branches, and are of a greenish white colour; the leaves come out in the autumn.—Native of the East Indies and Cochin-china, where it is much used for hedges, on account of its strong thorns. For its propagation and culture, see the first species.

** *Shrubby, unarmed: Stem neither dichotomous nor umbelliferous.*

10. *Euphorbia Meloformis*; *Melon Spurge*. Subglobose, many-angled: trunk fleshy, three inches in diameter, smooth; ridges eight, ten, or more, broad at the base, and keeled; keels flower-bearing, marked with scars of the peduncles and with glands alternately; peduncles cylindrical, the thickness of a pigeon's quill, jointed, with very short villose hairs scattered over them, usually first trichotomous, then dichotomous, seldom simple.—It flowers from May to September, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species.

11. *Euphorbia Caput Medusæ*; *Medusa's Head Spurge*. Imbricate: tubercles furnished with a linear leaf; flowers subpeduncled; petals palmate. It has thick, roundish, succulent stalks, which are scaly; they send out many branches from their sides of the same form, which are twisted, and run over one another, so as to appear like a parcel of serpents, which give it the name of Medusa's Head; at the end of these are narrow, thick, succulent leaves, which drop off, and round the upper part of them the flowers come out; these are white, and of the same form with those of the other sorts, but larger, and are frequently succeeded by fruit.—There are several varieties of this species; that called *Little Medusa's Head*, has a thick short stalk, seldom more than eight or ten inches high, from which come out a great number of slender trailing branches, about a foot in length, intermixing and having the same appearance with the other, but smaller, and much

horter; the ends are beset with narrow leaves, between which the white flowers come out.—It is a native of Africa. This species will require to be supported, to prevent the weight of the branches from drawing them upon the pots, and by training the stems up to stakes, they will grow four or five feet high, and a great number of side-branches will be produced. For further particulars respecting its propagation and culture, see the first and fifth species.

12. *Euphorbia Clava*; *Club Spurge*. Imbricate: tubercles furnished with a lanceolate leaf; flowers peduncled; petals quite entire. This is a perfectly smooth species, abounding with a milky juice, which seems to be but slightly acrid; stem and branches erect, and round, gradually thickening upwards, till they arrive at the diameter of an inch; leaves sessile, spatule-shaped, and elongated, very entire, and about four inches long, with a prominent back-rib; peduncles one-flowered, axillary, solitary, coated with lanceolate bracts.—It flowers from January to August, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species.

13. *Euphorbia Anacantha*; *Scaly Spurge*. Imbricate: tubercles furnished with a roundish leaflet; flowers terminating, solitary, sessile; petals palmate. This is one of the smaller shrubby species, and has a scaly and tuberous branched stem; the petals are each three-toothed; the leaves are extremely small, few, and are chiefly produced towards the top of the branches; the flowers are large in proportion to the plant, and spring to the number of three or four, from the top of some of the upper branches, which in this species are covered over with prominent tubercles, and thick scales. It flowers in September and October.—Native of the Cape. For its propagation and culture, see the first species.

14. *Euphorbia Mauritanica*; *Barbary Spurge*. Half-naked, shrubby, filiform, flaccid; leaves alternate; stems many, taper, succulent, about four feet high, and requiring support; they have a light green bark, and their lower parts are naked, but their upper parts have oblong, smooth, entire leaves, placed alternately on every side; flowers in small clusters at the ends of the branches, of a yellowish green colour, and sometimes succeeded by smooth round fruit; but the seeds rarely ripen in England.—It grows naturally on the African shore of the Mediterranean. For its culture and propagation, see the first and the fifth species.

15. *Euphorbia Piscatoria*; *Smooth Spear-leaved Spurge*. Shrubby, strict; umbels five-cleft, terminating; involucels oblong; leaves linear, even.—Native of Madeira, and the Canaries. For its propagation and culture, see the first species.

16. *Euphorbia Glabrata*; *Smooth Spurge*. Unarmed, shrubby, branched; leaves opposite, ovate-acute, smooth, quite entire. The whole of this plant is smooth; stem erect, unarmed, jointed, purplish; branches dichotomous, covered with leaves at bottom; flowers at the ends of the branchlets, axillary, and at the divisions solitary, small, peduncled; capsule nearly the size of a Coriander seed, smooth, and quite even.—Native of the Caribbee islands. For its propagation and culture, see the second species.

17. *Euphorbia Linifolia*; *Flax-leaved Spurge*. Stem suffruticose, woody at the base, round and smooth at bottom, striated-angular and subserrate above; leaves opposite and alternate, linear-lanceolate; peduncles from the top of the stem and branches, in fives or thereabouts, umbelled; calix smooth, as is also the throat; petals obovate, truncate, yellowish-green; capsules smooth, quite even, the size of a small pea.—Native of the island of Dominica. For its culture and propagation, see the first species.

18. *Euphorbia Cuneata*. Shrubby: leaves obovate: ne-

duncles lateral, three-flowered; stem unarmed; branches round, smooth, with an ash-coloured bark. Leaves petioled, several from the tubercles of the branches, unequal, smooth, veinless, quite entire.—Native of Arabia Felix. For its propagation and culture, see the first species.

19. *Euphorbia Balsamifera*; *Balsam Spurge*. Shrubby, strict: head terminating; leaves lanceolate, even, glaucous.—Native of the Canary islands. For its propagation and culture, see the first species.

20. *Euphorbia Tirucalli*; *Indian-tree Spurge*. Half-naked, shrubby, filiform, erect: branches patulous, crowded in an orderly manner; stem taper, succulent, eighteen or twenty feet high, sending out many branches of the same form, subdividing into many smaller; they are jointed, but at a great distance, smooth, and of a deep green colour, having a few small leaves at their extremities, which soon fall off. As the plants grow older, their stalks become stronger and less succulent, especially towards the bottom, where they turn to a brown colour, and become a little woody. It does not produce any flowers here. Native of the East Indies. For its propagation and culture, see the first species.

21. *Euphorbia Tithymaloides*. Shrubby: leaves in a double row, alternate, ovate. This is a wandlike suberect plant, six feet high, the whole of it abounding in a white, bitterish, milky juice. Stems numerous, round, smooth, weak, very pliant, branched, the thickness of a finger or of the thumb, the older ones ash-coloured, the younger green; peduncles one-flowered, short, aggregate about the extremities of the branchlets, coming out principally when the plant is without leaves; flowers void of scent, of a beautiful scarlet colour, and on account of their singular structure, perhaps rightly claiming to form a distinct genus, although possessed of the same characters with the other *Euphorbia*. The South Americans give a strong decoction of this plant, particularly of the stalks, in venereal cases, and in suppressions of the menses.—It is a native of the Caribbee islands, and of the neighbouring continent. Mr. Miller makes two species of this, under the names of *Tithymalus Myrtifolius*, and *Lauro Cerasifolius*, or *Myrtle-leaved* and *Laurel-leaved Spurge*. The first grows naturally near Carthage in South America, whence Mr. Robert Miller, surgeon, sent the branches, which were planted here, and succeeded, rising into shrubby succulent stalks to the height of twelve or fourteen feet; but though often as large in circumference as a man's little finger, were too weak to sustain the weight of their succulent leaves, which bore down the unsupported branches. The leaves are oval, and terminate in acute points; they are two inches and a half long, and one inch and a half broad near their base, about the thickness of bay-leaves, and are ranged alternately on two sides of the branches, to which they sit close. The flowers are produced at the ends of the branches, three or four together; they are of a scarlet colour, of one petal in the shape of a slipper.—The *Laurel-leaved Spurge* grows naturally in Barbadoes, and most of the other islands in the West Indies, where the English inhabitants know it by the title of *Poison-bush*: this has thick, shrubby, succulent stalks, which will grow to the height of ten or twelve feet; these are larger than those of the first sort, and are garnished with oblong oval leaves, ending with blunt points; they are above three inches long, and an inch and a half broad in the middle, of a very thick consistence, and of a dark green colour, ranged alternately on two sides of the stalk. The flowers grow at the ends of the branches, are of a deep red colour, and shaped like the other variety. This variety abounds with an acrid milky juice, which will draw blisters wherever it is

applied to the flesh; and, says Mr. Miller, I have been credibly informed, becomes a deadly poison, when mixed with the blood, so that if the points of arrows, or the edges of swords, be rubbed with this juice, it ensures the death of any animal wounded by those weapons.—For the propagation and culture of this species and its varieties, see the first species.

22. *Euphorbia Heterophylla*; *Various-leaved Spurge*. Leaves serrate, petioled, difform, ovate, panduriform, or dichotomous with a bifid umbel. This is an annual plant, from two to three feet high. Some of the leaves are narrow, and entire, others ovate, and divided in the middle almost to the midrib, in the shape of a fiddle; they also vary in colour, some being inclinable to purple, others of a light green, and their footstalks are short. The flowers are produced in small umbels at the ends of the branches; they are of a greenish white, and are succeeded by small round capsules.—It grows naturally at La Vera Cruz. For its propagation and culture, see the first species. Morison speaks with admiration of the heterogeneous leaves in this plant, a circumstance which is since found not to be uncommon, particularly in plants from the South Seas. He speaks of this species of Spurge as attaining the height of a man, even in this country, with a trunk an inch or more in thickness, spreading out into straight, long, plicat branches, having some leaves three or four inches long, and narrow, resembling those of the Narrow-leaved Willows; others on the same branch soft, like those of an Atriplex or Orach, tending to a sea-green colour, sinuated, and from an inch to two inches in breadth. Varieties are observed in this plant; some having a reddish and somewhat wrinkled bark, whilst in others it is green and smooth; the leaves also being subject to vary much. This being shrubby, and so large a plant, cannot be the annual species first described; and is introduced here for the sole sake of the curious and intelligent botanist.

23. *Euphorbia Cotinifolia*; *Venice-Sumach-leaved Spurge*. Leaves opposite, subcordate, petioled, emarginate, quite entire: stem shrubby; upright, six or seven feet high, covered with a light brown bark, and divided at top into many branches; leaves smooth, and of a beautiful green, but falling away in winter; flowers from the ends of the branches, yellow and small, soon falling away without fruit.—Native of the islands and continent of South America. For its propagation and culture, see the first species.

24. *Euphorbia Ocyroides*; *Basil-leaved Spurge*. Herbaceous, branching: leaves subcordate, quite entire, shorter than the petiole; flowers solitary. This is an annual plant, rising with an upright stalk about a foot high, and dividing into a great number of branches, which spread very wide on every side; leaves roundish, heart-shaped, on pretty long footstalks. The flowers come out singly from the divisions of the stalk; they are small, of an herbaceous colour, and are succeeded by small round capsules.—Native of South America. This, with the twenty-fifth, twenty-eighth, thirtieth, thirty-second, third, fourth, fifth, and sixth, and the forty-sixth, are annual, and must have their seeds sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be planted separately in small pots filled with light earth, and plunged into the hot-bed again; they must afterwards be treated in the same manner as other tender annual plants from hot countries.

25. *Euphorbia Lævigata*. Shrubby, branched: leaves opposite, oblong, obtuse, smooth, quite entire. The whole of this plant is smooth; stem unarmed; branches dichotomous at the end, three and four times divided; leaves on short petioles, longer than the internodes, shorter and narrower on one side of the base, terminated by a minute dagger-point,

even, veinless, glaucous, green: peduncles at top, from the forks of the branchlets, solitary; flowers small; capsule smooth, even, the size of a coriander-seed.—Native of the East Indies. For its propagation and culture, see the preceding species.

*** *Dichotomous, with a bifid umbel, or none.*

26. *Euphorbia Origanoides*; *Marjoram Spurge*. Leaves serrulate, ovate, obtuse, three-nerved; panicle terminating; stems simple. This plant cannot at first sight be distinguished from Marjoram.—It is a native of the island of Ascension, and the Friendly Isles.

27. *Euphorbia Atoto*. Dichotomous: leaves ovate, quite entire; umbel terminating.—This is an annual plant, and a native of the Friendly Islands.

28. *Euphorbia Hypericifolia*; *St. John's-wort-leaved Spurge*. Leaves serrate, oval-oblong, smooth; corymbs terminating; branches divaricate. It rises about two feet high, with a branching stalk; peduncles axillary, alternate, erect, dichotomous, commonly longer than the leaves, with the flowers crowded together; calix very minute. This is an annual plant, found in most of the cultivated grounds in the West Indies; every part of it is poisonous to hogs.—For its propagation and culture, see the twenty-fourth species.

29. *Euphorbia Mellifera*; *Honey-bearing Spurge*. Leaves scattered, lanceolate-acute, even; peduncles dichotomous; capsules muricated. It flowers in April and May.—Native of Madeira.

30. *Euphorbia Prostrata*; *Trailing Red Spurge*. Leaves oval, obscurely serrate; peduncles axillary, with about three flowers; stems diffused, smooth, herbaceous, a span in length; flowers on short pedicels, often in threes, but sometimes solitary; petals purple.—Native of the West Indies. For its culture and propagation, see the twenty-fourth species.

31. *Euphorbia Maculata*; *Spotted Spurge*. Leaves serrate, oblong, hairy; flowers axillary, solitary; calix green, petals red; capsule hairy; branches patulous. This is an annual, acrid, and milky plant, flowering in gardens in the open air, and readily springing from seed. The stems are very numerous, spreading closely on the ground.—Native of Jamaica.

32. *Euphorbia Hirta*; *Creeping Hairy Spurge*. Leaves serrulate, ovate, acuminate; peduncles in axillary heads; stems hairy; flowers crowded together, pedicelled, minute; calix blood-red.—It is a native of both Indies; and is recommended by Browne as a powerful resolutive and deobstruent, operating by promoting perspiration and the urinary discharge very abundantly. For its propagation and culture, see the twenty-fourth species.

33. *Euphorbia Pilulifera*. Leaves serrate, oval-oblong; peduncles in two axillary heads; stem upright.—Native of India. See the twenty-fourth species.

34. *Euphorbia Hyssopifolia*; *Hyssop-leaved Spurge*. Leaves subrenate, linear; flowers fascicled, terminating; stem upright.—It flowers in August and September, is annual, and a native of the West Indies. Browne extols a decoction of this plant as an active warm medicine, after a passage is procured in the dry belly-ache by bathing in warm water, or on any occasion where resolutive medicines are required. See the twenty-fourth species.

35. *Euphorbia Thymifolia*; *Thyme-leaved Spurge*. Leaves serrate, oval-oblong; heads axillary, glomerate, sessile; stems procumbent. The whole plant resembles Thyme, is annual, and a native of India. For its propagation and culture, see the twenty-fourth species.

36. *Euphorbia Parviflora*; *Small-flowered Spurge*. Leaves serrate, oblong, smooth; flowers solitary; stem erectish, alternately branched; peduncle axillary, an inch long, alternate,

sustaining a few very small flowers. The leaves have frequently a brown spot; calices purple; petals white.—Annual; and a native of India. See the twenty-fourth species.

37. *Euphorbia Canescens*. Leaves entire, roundish, hairy; flowers solitary, axillary; stems procumbent.—Annual; and a native of Spain, particularly in the province of La Mancha.

38. *Euphorbia Chamæsyce*; *Crenated Annual Spurge*. Leaves crenulate, roundish, smooth; flowers solitary, axillary; stems procumbent; seeds roundish, angular, black.—Native of the south of Europe, especially of the kingdom of Valencia in Spain, also of Siberia and Mesopotamia; and by way-sides and barren fields in the West Indies.

39. *Euphorbia Rubra*. Leaves wedge-shaped, emarginate, imbricate; umbels bifid; corollas five-petalled; root annual; seeds whitish, with red grooves.—Native of Spain, near Aranjuez, flowering in April and May.

40. *Euphorbia Granulata*. Dichotomous; leaves opposite, oblong, quite entire; flowers solitary, axillary; stems procumbent.—Native country unknown.

41. *Euphorbia Peplis*; *Purple Spurge*. Leaves quite entire, semicordate; flowers solitary, axillary; stems procumbent; root long, slender, fibrous; seeds smooth, tipped with purple. It is annual, and flowers in July and August. Gerarde calls it *Isope Spurge*.—Native of the south of France, Spain, Carniola, and found also on the sea-coast of England, between Penzance and Market-jew in Cornwall, and near Exmouth in Devonshire.

42. *Euphorbia Polygonifolia*; *Knotgrass-leaved Spurge*. Leaves opposite, quite entire, lanceolate, obtuse; flowers solitary, axillary; stems procumbent. Annual.—Native of Maryland and Virginia.

43. *Euphorbia Graminea*. Leaves lanceolate, elliptic, petioled, quite entire; stem upright; peduncles dichotomous; calix bell-shaped, hirsute within; petals two, roundish, quite entire, white; capsules shining, smooth, small.—Native of wet grassy places near Carthage in New Spain.

44. *Euphorbia Ipeacuanhæ*. Leaves quite entire, lanceolate; peduncles axillary, one-flowered, equalling the leaves; stem upright; root creeping; calix thick.—Native of Virginia and Canada.

45. *Euphorbia Portulacoides*; *Purslain-leaved Spurge*. Leaves quite entire, oval, retuse; peduncles axillary, one-flowered, equalling the leaves; stem upright, nearly a foot high.—Native of Philadelphia.

46. *Euphorbia Myrtifolia*; *Myrtle-leaved Spurge*. Leaves quite entire, roundish, emarginate, hoary underneath; flowers solitary; stem upright, shrubby, one to two feet high.—Native of the cooler mountains of Jamaica. See the 24th species.

47. *Euphorbia Imbricata*. Umbel dichotomous, bifid; involuclers roundish, mucronate; leaves obovate, imbricate, serrulate; stem fruticulose. This is a small shrub, a little more than a hand in height, branched at the base; branches simple, round, covered with leaves, toothleted where the leaves fall, smooth, as is the whole plant; petals quite entire; stamina numerous; filaments whitish.—Native of Portugal.

**** *Umbel trifid.*

48. *Euphorbia Peplus*; *Petty Spurge*. Umbel dichotomous; involuclers ovate; leaves quite entire, obovate, petioled; root annual. Stem upright, nine inches high, round, smooth, and branched; at bottom harder, more slender, and of a reddish colour, leafy, and milky; branches few, not growing in any regular order, the lower ones longest. It is a native of most parts of Europe, in kitchen gardens, and other rich cultivated soil. It flowers in July and August. There is a variety of this species, which has ovate-lanceolate sharp leaves. The involucre is of the same form with the leaves;

but the involuclers are obliquely cordate.—Found in Savoy, and about Montpellier.

49. *Euphorbia Falcata*. Umbel dichotomous; involuclers subcordate, mucronate; leaves lanceolate, bluntish.—Native of the south of France, Switzerland, Germany, and Austria.

50. *Euphorbia Exigua*; *Dwarf Spurge*. Umbel dichotomous; involuclers lanceolate; leaves linear; root annual; stem upright, branched, very leafy, about six inches high; branches from the lower part of the stem; leaves pressed to the stem, ending very sharp; umbel trifid, quadrifid, seldom quinquefid, dichotomous.—This small and delicate species is found in corn-fields in many parts of Europe, flowering from July to September. There is a variety, which Linneus affirms to be sharp-leaved on hills, and retuse in meadows. Cavanilles, on the contrary, says, that he has found the latter on sandy hills, and the former in corn-fields; and Krocker observed both in corn-fields.

51. *Euphorbia Obliterata*. Leaves oblong, trapezoid, serrate, pubescent, obliterated on one side of the base; stems hirsute.—Native of Carthage in New Spain, on the sandy coast: found also in Jamaica.

52. *Euphorbia Tuberosa*. Involucre four-leaved; stem naked; leaves oblong, emarginate; root tuberosa. The leaves are nearly an inch and a half in length, and almost half an inch in breadth, on petioles two or three inches long, springing from the root; they are blunt at the end, and sometimes emarginate. The stems are scarcely a hand and a half in height, naked, dividing at top into two peduncles, each sustaining two flowers; there are two leaves at the division; capsules large, hairy.—Native of Africa.

53. *Euphorbia Divaricata*. Umbel trifid or quadrifid; stem shrubby, trichotomous. This is a smooth lactescent species, with round shrubby branches; the older ones ash-coloured, the younger reddish brown, marked by the cicatrices of the fallen leaves; leaves very narrow, and lanceolate, obtuse, entire, with very short footstalks, and very numerous; the terminating umbels are generally trifid, with dichotomous rays; the leaves forming the smaller umbels are roundish; petals four, sometimes five, dull yellow, roundish, flat, and obtuse; perianth hairy; antheræ yellow, green; germen pale green; capsule smooth.—Native country unknown.

**** *Umbel quadrifid.*

54. *Euphorbia Lathyris*; *Caper Spurge*. Umbel dichotomous; leaves opposite, quite entire. The stem is upright and succulent, from three to four feet high, with oblong, smooth, sessile leaves, the upper part dichotomous; an umbel comes out from each division, that in the first division being the largest, and those in the upper the smallest. The flowers are of a greenish yellow colour, appear in June and July, and the fruit follows soon after. It was common in our English gardens in the time of Gerarde, and is a native of France and Italy.—This plant is vulgarly called the *Caper Bush*, and will become a weed in gardens where it is allowed to scatter its seeds; and when once introduced, requires no care, but to keep the young plants clean from weeds.

55. *Euphorbia Terracina*; *Doubtful Spurge*. Umbel dichotomous; leaves alternate, lanceolate, retuse, mucronate, a finger broad; root annual; stem herbaceous, more than half a foot in height, round; involucre consisting of about four leaves, which are oblong, ovate, blunt, broader than the leaves, scarcely serrate; involuclers ovate-truncate at the base; petals yellowish, with two or three teeth; capsules smooth. From the lower axils of the leaves proceed barren branches.—Native of Spain, and the south of France.

56. *Euphorbia Diffusa*; *Spreading Spurge*. Umbel four

or five-cleft, dichotomous; stem very much diffused; leaves wedge-form, quite entire, alternate; root annual, of a slender fusiform figure; umbels four-cleft or five-cleft, with the rays several times dichotomous; the branches are sometimes divided into a similar umbel, and are sometimes very dichotomous; hence the plant when grown up becomes so spreading, and has such an abundance of branchlets and rays, as to give it an appearance quite different from what it had when young; flowers all fertile, solitary, in the divisions small, sessile; calix smooth, pale; petals four, yellow, two broader; germen smooth; seeds brown, much wrinkled.—Found near Vienna, flowering from July to September.

57. *Euphorbia Apios*; *Pear-rooted Spurge*. Umbel four-cleft, bifid; involuclers kidney-form, the first orbiculate. It has a knobbed pear-shaped root, from which arise two or three stalks, about a foot and a half high; leaves oblong, hairy, alternate, on every side of the stalk; flowers in small umbels from the divisions of the stalk, small, greenish-yellow, seldom producing seeds here.—Native of the island of Candia. It may be increased by offsets from the main root: these may be taken off in autumn, and planted in a shady situation, where they will thrive better than in full sun.

58. *Euphorbia Læta*; *Mezereon-leaved Spurge*. Umbel quadrifid or quinquefid, twice dichotomous; first involuclers oblong, upper ones rhomb-roundish; leaves linear-lanceolate, submarginate, quite entire. The whole plant is smooth; stem shrubby, round; leaves scattered, sessile, an inch and a half in length. The universal involuclers resemble the leaves; the involuclers of the first division are oval, oblong, somewhat emarginate, half the length of the leaves; those of the second division, and the floral ones, elliptic, roundish, emarginate. It flowers in June and July.—Native place unknown. This species, with the following, together with the ninety-second, and ninety-fifth, may be propagated by cuttings during any of the summer months, and all require protection from frost in winter. The other perennials may be increased by parting the roots, or sowing the seeds in autumn. They are most of them hardy enough to endure the greatest cold of this country, especially if they be planted in a dry soil.

***** *Umbel quinquefid.*

59. *Euphorbia Genistoides*; *Broom-like Spurge*. Umbel quinquefid, bifid; involuclers ovate; leaves linear, erect; stem becoming shrubby. This is an upright shrub, with branches alternate, strict, very simple, short, bearing flowers at the very tip; involucler four-leaved; leaflets lanceolate, the length of the umbel; petals in form of a crescent; capsules smooth.—Native of the Cape of Good Hope. See the preceding species.

60. *Euphorbia Spinosa*; *Prickly Spurge*. Umbel subquinquefid, simple; involuclers ovate, the primary ones three-leaved; leaves oblong, quite entire; stem shrubby. The branches, as they grow old, dry away, and continue on the plant, so that it appears as if it had thorns. The flowers are usually solitary; petals round; capsules warted.—Native of the Levant.

61. *Euphorbia Epithymoides*. Umbel quinquefid, bifid; involuclers ovate; leaves lanceolate, obtuse, villose underneath.—Native of Italy and Austria.

62. *Euphorbia Nicænsis*; *Nicene Spurge*. Umbel quinquefid, bifid; involuclers cordate, roundish, quite entire; leaves lanceolate, mucronate, subcoriaceous; root perennial; stems several, smooth, firm, somewhat woody, green, or reddish; either simple, or a little branched near the umbel, but without any involucler on the branches; rays of the umbel twice dichotomous, the last division two-flowered; in the axil one flower; on the extreme branches two flowers, one yellow, with horned

petals, and naked, the other green, supported with two bractes, and abortive; capsules smooth, not grooved, large; universal involucler ovate, terminating in a prickle. It abounds in milk.—Native of the county of Nice; found also by Vahl about Pampeluna.

63. *Euphorbia Dulcis*; *Sweet Spurge*. Umbel quinquefid, bifid; involuclers subovate; leaves lanceolate, obtuse, quite entire; petals entire; fruit red, mucronate. It varies with villose leaves; root consisting of little scaly bulbs; stem smooth, upright, simple, a foot high, red at bottom; involuclers five-leaved, but sometimes four, three, and even two leaved; flowers sessile; petals red, crescent-shaped, two-horned; stamina two to five; capsule villose, warted below the middle. The milk of this plant is mild.—Native of the south of Europe.

64. *Euphorbia Carniolica*; *Carniola Spurge*. Rays of the umbel nodding; involuclers, involuclers, and leaves, lanceolate. The peculiarities of this species are, that the leaves are quite entire, spreading, sessile, acuminate, with the edges pellucid and red; that the leaves and rays of the umbels are very lax; that the colour is yellowish; that the flowers are all peduncled, and most of them barren, except those at the end; they have five rounded, shining, yellow petals; and the capsule is warted. The milk is mild. It flowers after the end of April.—Native of the shady meadows of Idria, in Friuli.

65. *Euphorbia Pithyusa*; *Jumper-leaved Spurge*. Umbel quinquefid, bifid; involuclers ovate, mucronate; leaves lanceolate, the lowest rolled in, imbricate backwards; stems shrubby, simple, many, villose, a foot high. The flowers from the first division of the rays fertile, peduncled; petals reddish brown, hemispherical; capsules the size of a pea, echinated with soft reddish prickles.—It flowers in June and July, and is a native of the south of Europe.

66. *Euphorbia Portlandica*; *Portland Spurge*. Umbel dichotomous; involuclers subcordate, concave; leaves linear-lanceolate, smooth, spreading; stems rather shrubby, a handbreadth or more high, smooth, cylindric, red, especially during the winter; branchlets lateral, those from the lower axils barren, at length growing up so as to overshadow the stem; flowers subsessile, yellow; the first and second male, having very blunt petals, without horns; the rest hermaphrodite, with horned petals. In the central flowers, the calix has five sides, and five blunt corners, with five slight clefts, and the segments are more or less toothed at the end; the petals are hairy within; the filamenta in number eight or nine; the germen subsessile on the lateral flowers; the segments of the calix are four; the petals four; the stamina fourteen or more; the filamenta surrounded at top with a ring. In all, at the base of the flower, are several flat, slender, shining, woolly substances, cloven at the end; fruit smooth, with the angles mucronate. It flowers from May till September; is marked as a shrub by Linneus; as perennial in the Kew catalogue; and as annual by Hudson and Withering. It abides two or three years in gardens.—It was first found upon the narrow neck of land which joins Portland to Devonshire; and since that near Exmouth in the same county; in abundance upon the Cornish coast; and near Carnarvon in North Wales.

67. *Euphorbia Saxatilis*; *Rock Spurge*. Umbel quinquefid, bifid; involuclers and involuclers cordate; leaves oblong, smooth; stems five or six inches long, procumbent, and but very few in number; smaller or secondary branches more numerous, each terminated by a rose of leaves, while the older or lower leaves fall away in succession, so as to leave numerous scars; branch-leaves lanceolate; top and flower-leaves round-cordate, all sessile; flowers smallish and yellow:

the plant is glaucous, except the bractes or round leaves, supporting the flowers.—Native of Austria, in stony places.

68. *Euphorbia Paralias*; *Sea Spurge*. Umbel subquinquefid, bifid; involuclæ cordate, reniform; leaves imbricate upwards; root perennial; stems upright or ascending, numerous, generally red at bottom, thickly imbricated, with smooth fleshy leaves pointing upwards when wild, but open when cultivated, gradually increasing in size from the lower part of the stem upwards; the lower ones linear, linear-lanceolate, or oblong, sessile, the upper ones oval, lanceolate, half stem-clasping; involucre of five heart-shaped leaves; petals entire; capsulae very large, smooth, according to Dr. Withering, rough, though all others say smooth. The juice of *Sea Spurge* is highly acrid, and, according to Gerarde, the most so of any species. He relates, that putting a single drop into his mouth, his throat inflamed so, that he hardly escaped with his life by riding to the next farm-house, and drinking milk.—It is found on the sandy shores of Europe; and in Great Britain on the coasts of Essex and Kent, and between Southwold and Dunwich in Suffolk; and also in Cornwall.

69. *Euphorbia Juncea*; *Linear-leaved Spurge*. Umbel dichotomous; leaves and involuclæ linear-lanceolate, acute; involuclæ ovate-oblong, acuminate.—It is perennial, flowers in July, and is a native of the island of Porto Santo, near Madeira.

70. *Euphorbia Aleppica*; *Aleppo Spurge*. Umbel dichotomous; involuclæ ovate-lanceolate, mucronate; lower leaves bristle-form; stems a foot and a half high; flowers in large umbels, from the divisions of the stem, yellow, appearing in June, but rarely producing seeds in this country.—Native of Aleppo, and other parts of the Levant. The roots, which are perennial, should be confined in pots; for when planted in the full ground, they creep to a great distance.

71. *Euphorbia Pineæ*; *Pine Spurge*. Umbel dichotomous; involuclæ cordate; leaves linear, acuminate, crowded; capsulae smoothish.—Native country unknown.

72. *Euphorbia Segetalis*; *Corn Spurge*. Umbel dichotomous; involuclæ cordate, acute; leaves linear-lanceolate, the upper ones broader; root annual; petals crescent-shaped; fruit smooth, except that it is scabrous at the corners. Villars describes it as from six to ten inches high; the lower stem-leaves fall very soon, and sometimes barren branches spring from the bottom of it.—Native of Barbary and Russia, of the south of France, Austria, Silesia, and the county of Nice.

73. *Euphorbia Taurinensis*; *Piedmont Spurge*. Umbel quinquefid, bifid; involucre four-leaved, hanging down; leaves linear-lanceolate; stem branched, eight or ten inches high, erect, smooth, round, red at bottom; root annual. The terminating umbel has generally four rays, three or four inches in length, naked, and dividing again into pairs; where these divide, a single flower sits on a peduncle, about an inch in length; petals crescent-shaped; the fruit is smooth, except at the angles.—It flowers from the beginning of April to the end of June, and is a native of Dauphiny.

74. *Euphorbia Helioscopia*; *Sun Spurge*, or *Wartwort*. Umbel quinquefid, trifid, dichotomous; involuclæ obovate; leaves wedge-form, serrate, smooth; capsulae even; root annual; stem upright, from six to nine inches high, round, slightly hairy, having opposite branches at bottom; involucre of five leaves like the other leaves; calix greenish-yellow, with four or five yellow segments; petals or nectaries four, entire, roundish, or oval, yellowish-green; filaments fourteen, two, three, or more, visible at a time; capsule smooth; all the flowers hermaphrodite.—Native of most parts of

Europe, in cultivated grounds, flowering from July, through the autumn. The country people call it *Wart-wort*, *Churn-staff*, and *Cat's-milk*. The juice is very acrimonious, and hence is often applied to warts for the purpose of destroying them. It should be cautiously used where the parts are tender, particularly near the eyes, as it will inflame the face to a great degree. Linnæus informs us, that when sheep eat it, they are purged by it, and their flesh acquires a bad taste; but that this is not the case with cows.

75. *Euphorbia Pubescens*; *Hairy Spurge*. Umbel quinquefid, trichotomous; involuclæ semicordate; leaves wedge-shaped, hairy, serrulate; capsulae muricate; root annual. The top of the stem, the leaves, peduncles, and pedicels, are villose, and the capsulae muricated with small tubercles.—Found in cultivated grounds about Tunis.

76. *Euphorbia Serrata*; *Narrow Notch-leaved Spurge*. Umbel quinquefid, trifid, dichotomous; involuclæ two-leaved, kidney-form; leaves stem-clasping, cordate, serrate. This is a foot high, and easily known by its oblong leaves, with frequent and sharp serratures. The leaves, however, vary very much, being sometimes cordate on the flowering stems, and linear on the branches and barren stems, and sometimes linear on all. The umbels are also sometimes three-rayed and bifid, with the involuclæ and involuclæ cordate-attenuate.—Native of the south of Europe.

77. *Euphorbia Verrucosa*; *Warty-fruited Spurge*. Umbel quinquefid, subtrifid, bifid; involuclæ ovate; leaves lanceolate, serrate, villose; capsulae very much warted; root biennial; stem from eight inches to a foot in height, simple, cylindric, decumbent; flowers of the first, second, and third rank abortive; petals four, entire, yellow.—It flowers in July, and is a native of corn-fields in the south of Europe, and the Levant. In England, it is found in Essex, near Gransden Lodge in Cambridgeshire, and also near York.

78. *Euphorbia Punicea*; *Scarlet-flowered Spurge*. Umbel quinquefid, trifid; involuclæ ovate, acuminate, coloured; capsulae smooth; leaves obovate, lanceolate. This most splendid plant, by far the most beautiful of the genus, is the height of a man; the stem shrubby, rather fleshy, full of milky juice, round, abruptly branched; the branches curved upwards, three together; the smaller branches sometimes four or five together; bark smooth, whitish, marked with spots or scars where former leaves have grown; leaves on the summits of the smaller branches crowded together, almost sessile, spreading in every direction, bluish, ending in a small point, smooth, opaque, dark green, glaucous underneath; the younger ones turned inwards, and those nearest the umbels coloured; principal nerve of all the leaves dull yellow, and in the younger ones near the umbels it is besides stained with red; umbels terminating, erect, having five, six, or seven rays; peduncles club-shaped, smooth, dichotomous; involuclæ two or three together under each flower, of a most vivid scarlet; flowers solitary, turbinate, yellowish, soon turning reddish; calix five-toothed; petals five, divaricated, yellow, full of very sweet pellucid honey; stamina fifteen or twenty, fertile, many, abortive; germen reflex; styles reflex, red; receptacle occupied by chaffy branched filaments; capsule smooth.—It flowers in January; and was discovered in Jamaica, where it is not easily procured. It must be kept in the hot-house, and being so eminently beautiful, it is to be lamented that it is yet confined to the most choice collections; which is the more remarkable, as it not only may be increased by cuttings, but also grows readily from seeds, both sent from Jamaica, and produced in England.

79. *Euphorbia Corollata*. Umbel quinquefid, trifid, dichotomous; involuclæ and leaves oblong, obtuse; stem-leaves

lanceolate, very obtuse; petals membranaceous, erect, snow-white, spread out flat in fives, not shaped like a petal, but very slender.—Native of Virginia and Canada.

80. *Euphorbia Coralloides*; *Coral-stalked Spurge*. Umbel quinquefid, trifid, dichotomous; involuclers ovate; leaves lanceolate; stems quite simple, annual, round, rush-like, upright; petals four, entire; capsules globular, scarcely grooved, covered with a thin long white wool.—Native of Sicily, Barbary, and the Levant.

81. *Euphorbia Pilosa*; *Hairy Spurge*. Umbel quinquefid, trifid, bifid; involuclers ovate; petals entire; leaves lanceolate, somewhat hairy, serrulate at the tip; root perennial. The umbels are so confounded with the lateral umbellets, that the primary one is distinguished with difficulty; the petals and involuclers are yellow; the primary flowers are male, and five-petalled, the rest hermaphrodite, and four-petalled; the petals are transversely oval; capsules warted, with very fine white hairs scattered over them; there are barren branches from the lower axils of the leaves.—It flowers from May to August, and is a native of Siberia.

82. *Euphorbia Orientalis*; *Willow-leaved Spurge*. Umbel quinquefid, quadrifid, dichotomous; involuclers roundish, acute; leaves lanceolate; root perennial; stems many, succulent, three feet high, covered with a purple bark; the upper part of the stalks divides, and in the fork is situated an umbel of flowers of a greenish yellow colour, appearing in June, and ripening seed in August.—Native of the Levant.

83. *Euphorbia Platyphyllos*; *Broad Notch-leaved Spurge*. Umbel quinquefid, trifid, dichotomous; involuclers hairy along the keel; leaves serrate, lanceolate; capsules warted; root annual; stem upright, from a foot to two or three feet high, smooth; petals entire, suborbiculate, yellow; germina obscurely warted; a trifid umbellet grows from the axils of the leaves. The upper part of the plant is of a greenish-yellow.—Native of England, France, Germany, Switzerland, Austria, Carniola, and Piedmont, in corn-fields. It has been found in England, at Black Notley in Essex; between Harefield common and Battle's-well; near Northfleet; at Ripton in Huntingdonshire; and in the Isle of Wight.

84. *Euphorbia Glauca*. Umbel subquinquefid; involuclers and involuclers ovate; leaves scattered, oblong-lanceolate, quite entire; stem frutescent.—Native of New Zealand.

***** *Umbel multifid.*

85. *Euphorbia Esula*; *Gromwell-leaved Spurge*. Umbel multifid, bifid; involuclers subcordate; petals obscurely two-horned; leaves on the barren and fertile branches the same. Perennial; stem a foot, eighteen inches, or two feet in height, upright, round, smooth, sea-green; much branched, leafy. All the flowers fertile, according to Linneus; but Scopoli says, that those on the first divisions are male; petals four, yellowish, obscurely horned; capsules smooth, somewhat warted on the prominent parts. The milk is very acrid.—Native of France, Holland, Germany, Switzerland, Carniola, and Savoy.

86. *Euphorbia Seguierii*. Umbels multifid, bifid, dichotomous; involuclers kidney-form, acuminate; petals mooned; capsules smooth; leaves lanceolate, acuminate. The lateral umbels are so crowded together at the top of the stalk as hardly to be distinguished from the primary one; the rays half a foot long, angular, twice bifid; flowers between the branches barren and deciduous, the rest fertile and peduncled; petals four, red; capsule without warts or hairs, but somewhat wrinkled on the back of each lobe.—Native of Istria, Verona, and Piedmont.

87. *Euphorbia Gerardiana*. Umbel dichotomous; involuclers roundish; petals quite entire; branches none; leaves

all of one form. Perennial; stems procumbent, a foot in length; peduncles from the upper axils simple, fertile; flowers sessile, in threes; petals four, broad, blunt, truncated; capsules smooth.—Native of Provence and Austria.

88. *Euphorbia Cyparissias*; *Cypress Spurge*. Umbel dichotomous; involuclers subcordate; branches, barren with setaceous, fertile with lanceolate leaves. This bears a great resemblance to the eighty-fifth species, and in the spring the umbels are very much alike; this however differs in being larger; in having leaves not all alike, but the upper ones, or those of the branches, bristle-shaped or linear; the lower, or those of the stem, lanceolate; the involucre consisting of about twenty leaves, which are broader; the involuclers two-leaved, ovate-cordate, yellowish or reddish; the petals crescent-shaped, yellow; capsules smooth according to some, and warted according to others. As the umbel withers, lateral branches with very narrow filiform leaves grow up, resembling the Pine.—It is a native of the South of France, Germany, Austria, Carniola, Switzerland, and Piedmont, where it is found on hills, by road-sides, and in dry barren places. It flowers from May to September in England; and Parkinson informs us, that it was often found in the country gardens of poor folks, who knew it by the name of *Welcome-to-our-house*; from which we may presume it was a favourite plant, and probably then much used as a purgative. The Spurges were at that time also much in request, not only for taking away warts, but for curing the leprosy, and other cutaneous disorders.

89. *Euphorbia Myrsinites*; *Glaucous Spurge*. Umbel with about eight bifid rays; involuclers subovate; leaves spatulate, spreading, fleshy, mucronate, scabrous at the edge; root perennial; stems many, a foot long, trailing, with scars at bottom from the fallen leaves; these are alternate, succulent, concave, sea-green, sessile, the upper ones reflex; flowers within the primary and secondary involuclers male, the rest hermaphrodite; calices serrate about the edge; petals four, yellow, horned with round tips, shining; capsules smooth. It flowers from April to June.—Native of the South of France, Spain, and Italy.

90. *Euphorbia Palustris*; *Marsh Spurge*. Umbel multifid, subtrifid, bifid; involuclers ovate; leaves lanceolate; branches barren; root perennial; stem three, four, or five feet high; round, smooth, with branches towards the top, which are alternate, and shorter than the stem. The primary flowers male, five-petalled, abortive; the secondary hermaphrodite, four-petalled; calix very pale yellow; petals entire, yellow, blunt, not horned; capsules warted.—Native of Sweden, Denmark, Germany, Holland, Switzerland, France, and Piedmont.—It flowers from May to August.

91. *Euphorbia Hibernica*; *Irish Spurge*. Umbel multifid, bifid; involuclers ovate; leaves oblong, emarginate, somewhat villose underneath; stem simple; capsules warted-ramentaceous; root perennial; stems several, a foot or more in height, upright, unbranched, round, smooth, very light green, with red blotches here and there. The number of rays in the umbel is usually five, but sometimes on the middle and stronger stems another ray or two branches out, with a leaf or two under each somewhat bigger than the rest; of the two flowers on each ray, one only usually comes to maturity; the flower has usually five petals, but sometimes only four. Mr. Ray relates the case of a boy who was killed by a dose of the juice of this plant.—Native of Ireland, in the mountains of Munster, where it is known by the name of *Makinboy*. It flowers in May and June; and is said to have been found near Twickenham park, over against Richmond; near Otterspool, Herts; and between Feversham and Sittingbourn, in Kent.

92. *Euphorbia Dendroides*; *European Tree-Spurge*. Umbel dichotomous; involuclers subcordate, the primary ones three-leaved; stem arborescent. It rises to the height of four feet, with an upright branching stem; the leaves are oblong, pointed, and alternate; flowers in umbels from the forks; they are small and yellow, and rarely produce seeds in England.—Native of Italy, Sicily, and Candia. See the fifty-eighth species.

93. *Euphorbia Amygdaloides*; *Wood Spurge*. Umbel dichotomous; involuclers perfoliate, orbiculate; leaves obtuse; root perennial; stem herbaceous, not woody, slightly downy, purple, two or three feet high; the flowering part, during the time of flowering, grows to more than twice its original length; leaves alternate, remote, thin, slightly downy, especially the root-leaves underneath.—It is common in woods and hedges in a clayey soil, and flowers in May, and sometimes before, and continues to July. This, with the two following species, being inhabitants of woods, require a shady situation. They will come up from scattered seeds, and may be increased by the roots.

94. *Euphorbia Sylvatica*. Umbel quinquefid, bifid; involuclers perfoliate, subcordate; leaves lanceolate, quite entire; stems shrubby, proliferous, thick; petals crescent-shaped, erose, or gnawn, whereas those of the next species are entire. Scopoli says, the leaves are very finely serrate at the tip; the flowers between the rays and the branches male and sessile, with most of the stamina imperfect, and five petals; the other flowers fertile, and four-petalled; germen neither villose nor warted.—Native of woods in the southern countries of Europe. See the preceding species.

95. *Euphorbia Characias*; *Red Spurge*. Umbel multifid, bifid; involuclers perfoliate, emarginate; leaves quite entire; stem becoming shrubby, four feet high; flowers small, those within the first involuclers male, the rest perfect; petals four, purple; styles scarcely cloven; germen villose. The whole plant is very downy.—Native of France, Spain, Italy, and Germany, in woods and hedges. It flowers in June, and is seldom seen in England. See the ninety-third species.

96. *Euphorbia Cretica*. Umbel multifid, bifid; involuclers orbiculate; leaves linear-lanceolate, villose. This rises with a shrubby purple stem nearly three feet high; umbels terminating, and forming a sort of spike; the flowers appear in May, and the seeds ripen in July.—It may be propagated from seeds or from cuttings, and will live abroad, if planted in a dry rubbishy soil and warm situation, otherwise the plants are frequently killed by severe frost. The young plants raised from seed are generally very fruitful; but the old ones, and those raised from cuttings, are barren.

97. *Euphorbia Linearis*. Dichotomous; peduncles solitary; leaves opposite, linear, quite entire; stem round, naked, jointed; petals entire; capsules seem to be smooth.—Native of the island of Santa Cruz.

98. *Euphorbia Rosea*. Dichotomous; leaves obovate, oblique at the base, toothletted at the tip; stem depressed, diffused; root almost simple, a span in length, going straight down, a little writhed; flowers heaped at the ends of the branches, males mixed with hermaphrodites; the petals of a beautiful rose-colour; capsules smooth.—Native of the East Indies, in driving sand.

Euphrasia; a genus of the class Didynamia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth one-leafed, cylindrical, four-cleft, unequal, permanent. *Corolla*: one-petalled, ringent; tube length of the calix; lip superior, concave, emarginate; lip inferior, expanding, three-parted; divisions equal, obtuse. *Stamina*: filaments four, filiform, inclined under the upper lip; antheræ two-lobed, of which

the inferior are sharpened into a little spine on the lower lobe. *Pistil*: germen ovate; style filiform, of the situation and figure of the stamina; stigma obtuse, entire. *Pericarp*: capsule ovate-oblong, compressed, two-celled. *Seeds*: numerous, very small, roundish. ESSENTIAL CHARACTER. *Calix*: four-cleft, cylindrical. *Capsule*: two-celled, ovate-oblong. *Lower Antheræ*: have a little thorn at the base of one of the lobes.—The plants of this genus are all annuals, and can only be propagated from seed, sown soon after they are ripe, or in the spring, in the borders of the garden. All, except the second and fourth species, are natives of the southern countries of Europe, and are not easily preserved in gardens.—The species are,

1. *Euphrasia Latifolia*; *Broad-leaved Eyebright*. Leaves tooth-palmate; flowers in a kind of head; root annual; stem a handbreadth high, or less, square, reddish, slightly hairy, simple, or dividing at bottom into two small branches, not more; corolla purple, sometimes white; bractes palmate, subhirsute.—Found about Montpellier. It spreads a purple carpet on many of the hilly pastures of Italy; it is found in Montferrat, the county of Nice, and near Turin; Verona; on Monte Testaccio, near Rome; in Apulia; and in the Spanish kingdom of Castile, particularly near the palace of the Escorial.

2. *Euphrasia Officinalis*; *Common Eyebright*. Leaves ovate, marked with lines, sharply toothed; root annual; stem from two to four inches high or more, upright, round, hoary, purple, for the most part branched, in opposite pairs; flowers from the axils of the leaves, on short peduncles, opposite, forming a spike or raceme at the tops of the branches and stem; corolla-tube rather crooked, a little hairy, white, stained with yellow at the mouth; border bluish white, with purple streaks; germen bearded, or a little hairy at the top; style pubescent on the upper part; stigma fringed, with very minute glands round the edge. It varies much in size, and in the colour of the corolla, which changes to quite white and yellow; it is more or less branching, and sometimes wholly unbranched.—This plant is common on heaths, and other dry pastures, especially on a chalky soil, flowering from July to September. It seems to have been unnoticed by the ancients, but the Arabians mention it under the name of *Adhil*. Mattheus Sylvaticus, a physician of Mantua, who lived about the year 1320, recommended this plant in disorders of the eyes. It is still in use, particularly as an ingredient in British herb tobacco; and Mr. Lightfoot informs us, that the Highlanders in Scotland make an infusion of it in milk, and anoint the patient's eyes with a feather dipped in it. It is, however, neglected by the faculty, and even thought by some to be injurious, at least in inflammations of the eyes. Meyrick, however, assures us, that it is famous for curing disorders of the eyes, and the common method of using it is, to apply the recently expressed juice, by way of collyrium, twice or three times a day; but where the disorder is bad, or of long standing, the whole herb, dried and reduced to powder, should be taken for a long time together, in the quantity of half a drachm twice or thrice daily. It also promotes evacuation by urine.—This species will not grow in a garden, unless it has grass or some other herbs to protect it.

3. *Euphrasia Tricuspidata*. Leaves linear, three-toothed; corolla like that in the preceding species.—Annual, and a native of Italy.

4. *Euphrasia Odontites*; *Red Eyebright*. Leaves linear, all serrate; root annual. The whole plant is commonly of a brownish red; stem upright, stiff, very much branched, from six inches to a foot or more in height, hispid, obtusely four-cornered; branches opposite; flowers in long leafy spikes,

pointing one way, nodding a little at top, in pairs or single, on short peduncles; calix hairy on the outside, the teeth equal and sharp; corolla dusky red or purple, sometimes varying to white, hairy, very differently formed from the preceding, the upper lip being compressed, and scarcely emarginate, the three lobes of the lower lip shorter than the upper, equal, truncate, crenulate; all the lobes of the antheræ are thorny at the tip, and bearded at the base; at the back, where the filament is inserted, are several small club-shaped threads or appendages; seeds ovate, very white, with a membranaceous margin on one side, elegantly latticed, with longitudinal ridges, and similar transverse streaks.—It is common both in corn-fields and pastures, especially those that are moist, and flowers from July to September.

5. *Euphrasia Lutea*; *Yellow Eyebright*. Leaves linear, serrate, the upper ones quite entire. This resembles the fourth species, but differs from it in having yellow flowers; the upper lip bearded or villose within and without, and emarginate; the lower lip concave, trifid, with the segments equal; stem one, seldom more, rough, hard, woody, upright, wandlike, dusky red; style yellow; stigma simple, both permanent; antheræ beardless; capsule smooth, and green at bottom, at top villose, blackish-red; seeds brown, oblong.—Native of Switzerland, Savoy, Austria, Friuli, Silesia, the Palatinate, Piedmont, Tuscany, and the south of France.

6. *Euphrasia Linifolia*; *Flax-leaved Eyebright*. Leaves linear, all quite entire; calices smooth. This is a little stiff, narrower, finer, but frequently higher, than the common sort; the leaves are entire; the flowers yellow.—Native of France and Italy.

7. *Euphrasia Viscosa*; *Clammy Eyebright*. Leaves linear; calices glutinous-hispid. This plant is described by Gouan to be only three inches high, and simple, or a foot high and branched, smooth or villose. All the leaves are broader at the base, thence gradually attenuated, and rough with hairs, most frequently quite entire, but sometimes toothed, the lower ones are opposite, the rest alternate, whence the branches themselves are seldom opposite; flowers on a very short peduncle, alternate, each within a single bracte.—Native of Provence, Dauphiny, Switzerland, Savoy, Piedmont, and the county of Nice.

8. *Euphrasia Cuneata*; *Wedge-leaved Eyebright*. Leaves somewhat wedge-shaped, gashed.—Native of New Zealand.

9. *Euphrasia Longiflora*; *Long-flowered Eyebright*. Pubescent, viscid; leaves linear, quite entire; tube of the corolla filiform, three times as long as the calix. Cavanilles describes the stem as a foot high, of a dark red colour; the branches decussate and four-cornered. Flowers axillary, in spikes; calix cut half way; tube of the corolla half an inch long, lower lip broader, with rounded segments; filamenta short, fastened to the upper part of the tube, within the upper lip; antheræ ovate, twin, two-awned at the base, and perforated; style red, the length of the corolla; stigma club-shaped; seeds longitudinally streaked.—It flowers in September, in Spain, where it is a native, having been found there, near Espexa, Rivas, and in the kingdom of Arragon.

Eurya; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, concave, obtuse, smooth, surrounded at the base with a two-leaved similar calicle, one-third only of the size of the calix. *Corolla*: petals five, roundish-ovate, concave, the size of the calix; nectary, dots on a purple rim, at the base of the filamenta. *Stamina*: filamenta thirteen, very short, so as to be scarcely any; antheræ upright, four-sided, almost the length of the corolla. *Pistil*: germen superior, convex, smooth; style subulate, shorter than the antheræ;

stigmas three, reflex. *Pericarp*: capsule globular, with the style permanent, sharp, smooth, five-celled, five-valved. *Seeds*: somewhat three-cornered, dotted, very many. *Observe*.. The flowers seem very frequently to be diœcous. ESSENTIAL CHARACTER. *Calix*: five-leaved, calicled. *Corolla*: five-petalled. *Stamina*: thirteen. *Capsule*: five-celled.—The only known species is,

1. *Eurya Japonica*. All parts of the plant are smooth: stem shrubby; branches and twigs alternate, lax, from upright, bent in, ash-coloured; leaves on the twigs alternate, frequent, petioled, elliptic or oblong, drawn to a point at both ends, serrate, a little turned back at the edge, entire at the base, very smooth, thickish, evergreen, in two rows, upright, with an emarginate point, nerved, the upper surface green, but underneath yellowish, an inch or more in length; flowers axillary, in pairs, peduncled, drooping, seldom either single or in threes; peduncles filiform, one-flowered, scarcely longer than the petioles.—It flowers in September and October, and is a native of Japan.

Euryandra; a genus of the class Polyandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets roundish, concave, the two outer smaller. *Corolla*: petals three, roundish, concave, longer than the calix. *Stamina*: filamenta very many, capillary, very much dilated at the tip; antheræ twin, with the cells disjointed. *Pistil*: germen three, ovate; styles three, very short; stigmas two, slightly divided. *Pericarp*: follicles three, ovate, divaricate, opening longitudinally on the inner side. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: three-petalled. *Filamenta*: much dilated at the tip, with twin disjointed antheræ; follicles three.—The only known species is,

1. *Euryandra Scandens*; which is a climbing plant, and a native of New Caledonia.

Exacum; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets ovate, obtuse, from erect spreading, permanent. *Corolla*: one-petalled, permanent; tube globose, length of the calix; border four-parted; divisions roundish, spreading. *Stamina*: filamenta four, filiform, sitting on the tube, length of the border; antheræ roundish. *Pistil*: germen roundish, filling the tube; style filiform, upright, length of the border; stigma headed. *Pericarp*: capsule roundish, compressed, two-furrowed, two-celled, length of the calix. *Seeds*: numerous; receptacle filling up the capsule. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Corolla*: salver-shaped, with an inflated tube; capsule two-furrowed, two-celled, many-seeded, bursting at the top. For the propagation and culture of this genus, see *Gentiana*.—The species are,

1. *Exacum Albens*. Leaves subdecurent; stamina protruded; root annual; stem a handbreadth high, dichotomous, herbaceous, four-sided, smooth, fastigate; corolla salver-shaped, white; tube cylindrical, longer than the calix, border the length of the tube; filamenta very short; antheræ oblong; stigmas two, thickish.—Native of the Cape of Good Hope.

2. *Exacum Pedunculatum*. Flowers four-cleft, terminating; calicine leaflets ovate; leaves lanceolate, three-nerved, undotted; root annual; stem upright, a palm in height, four-cornered, with acute angles, branched, very smooth, as is the whole plant; branches few, simple, opposite, shorter than the stem; peduncles from the top of the stem and branches, solitary, one-flowered, short; calix four-parted, four-cornered; the parts ovate-acuminate, membranaceous at the edge; corolla subcampanulate, violet-coloured, larger than in the other sorts, permanent; tube the length of the calix; segments of the border lanceolate-obtuse; antheræ linear, a little shorter than the border;

style the length of the corolla; stigma thickened.—Native of the East Indies.

3. *Exacum Aureum*. Leaves sessile; stamina protruded; root annual; stem a handbreadth high, dichotomous, slightly four-cornered, smooth, brachiata; peduncles from the divisions one-flowered, the length of the flower; calix five-leaved; corolla yellow, salver-shaped, four-cleft; segments lanceolate, sharp; filamenta bristle-form; antheræ oblong.—Native of the Cape of Good Hope.

4. *Exacum Sessile*. Flowers four-cleft, lateral, and terminating; capsules nodding; leaves heart-shaped; stem erect, a span high, four-cornered, even, simple, dichotomous; flowers from the divisions of the stem, solitary, sessile, larger than the leaves.—Native of the East Indies.

5. *Exacum Cordatum*. Flowers five-cleft; calicine leaflets heart-shaped, striated; corolla yellow, salver-shaped; tube cylindrical, longer than the calix; border five-parted, obovate; filamenta short, in the throat of the corolla; antheræ oblong; style the length of the stamina.—Native of the Cape.

6. *Exacum Guianense*. Corollas four-cleft; calices membranaceous, keeled, even. This plant is often scarcely a finger's height, with a stem either quite simple or very little branched, and quite smooth, upright, and sharply four-cornered; leaves lanceolate, opposite, attenuated, the lower ones shorter and sharp; peduncles terminating, or from the upper axils, solitary, one-flowered, very short, angular.—Native of Cayenne.

7. *Exacum Spicatum*. Flowers spiked, in whorls of threes; leaves lanceolate; stem herbaceous, two feet high, erect, quite simple, except that sometimes there are two flowering branches from the last axils, obscurely four-cornered, without decurrent lines, smooth, the whole plant also is very smooth; spike terminating, erect, pyramidal, almost a span long, with abundance of flowers; corolla twice the length of the calix, with a cylindrical tube; border, before it is unfolded, four-cornered, attenuated, rolled up spirally at the top; divisions lanceolate, the length of the tube; antheræ sagittate.—Native of Cayenne.

8. *Exacum Ramosum*. Flowers subspliked, opposite; leaves lanceolate; stem erect, branched. The whole plant is smooth; flowers distant, on very short pedicels, with two bristle-shaped appressed bractes at the base of the calix, which is one-leaved, oblong, four-cleft; the clefts lanceolate, attenuated, membranaceous at the edge; segments of the corolla ovate-acute.—Native of Guiana.

9. *Exacum Punctatum*. Leaves on very short petioles, oblong, three-nerved, dotted; stamina protruded. This is larger than the other species; corolla bluish; stamina yellow.—Native of the East Indies.

10. *Exacum Viscosum*. Leaves oblong, nerved, embracing; flowers five-cleft; bractes heart-shaped, perfoliate, longer than the calix; root perennial; stem somewhat shrubby, erect, roundish; three feet high; branches opposite, erect, slightly quadrangular, green, leafy, many-flowered; flowers of an elegant golden colour, inodorous, slightly drooping.—Native of the Canary Islands.

F A G

FAGARA; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-cleft, very small; leaflets concave, permanent. *Corolla*: petals four, oblongish, concave, spreading. *Stamina*: filamenta four, or from three to eight, longer than the corolla; antheræ ovate. *Pistil*: germen ovate; style filiform, length

Excœcaria; a genus of the class Diœcia, order Triandria.—GENERIC CHARACTER. *Male*. *Calix*: ament cylindrical, covered with floscules. *Corolla*: none. *Stamina*: filamenta three, filiform; antheræ roundish. *Female*. *Calix*: ament as in the male. *Corolla*: none. *Pistil*: germen roundish, slightly three-sided; styles three; stigmas simple. *Pericarp*: berry tricocous, smooth; divisions marked out by a furrow. *Seeds*: solitary, smooth. ESSENTIAL CHARACTER. *Ament*: naked. *Calix* and *Corolla*: none; styles three; capsules tricocous.—The species are,

1. *Excœcaria Agallocha*. Capsule small, the size of a juniper-berry, subglobular, three-grooved, smooth, black, three-celled, of a papery substance, not divided within into three distinct grains, but merely opening when pressed by three valves; seeds one in each cell; subglobular, acuminate at top, convex on one side, very bluntly angular on the other.—Native of Amboyna and Tongataboo.

2. *Excœcaria Cochinchinensis*. Leaves two-coloured, shining; scales of the ament many-flowered. This species is an arboreous shrub, about eight feet high, with the stem and branches irregular, spreading, reclining. The female flowers have three long, awl-shaped, reflex stigmas; capsule three-lobed, somewhat fleshy, red, small, three-celled; seeds ovate, smooth and even. It has an astringent agglutinating quality; the whole plant abounds in a glutinous milky juice, which has not the reputation of destroying the sight, nor is the agallochum, even of a bastard sort, found in it.—Native both of China and Cochinchina, where it is cultivated for the beauty of its red leaves.

Exoacantha; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal manifold, spreading, the inner rays gradually smaller, the inmost very short; partial manifold; involucre universal with rays, usually twelve, channelled, spiny at the end; partial halved, with the middle ray very long, similar to the rays of the involucre; perianth proper scarcely observable. *Corolla*: universal uniform; proper five-petalled; petals inflex, heart-shaped, equal. *Stamina*: filamenta five, capillary, longer than the corolla; antheræ roundish. *Pistil*: germen inferior, ovate; styles two, shorter, straight; stigmas two, simple. *Pericarp*: fruit subovate, striated, bipartite. *Seeds*: two, ovate, convex and striated on one side, flat on the other. *Observe*. This genus is allied to *Echinophora*, but with unequalled flowers, all hermaphrodite, equal petals, and naked seeds. ESSENTIAL CHARACTER. *Involucre*: spiny; involucels halved, with unequal rays; flowers all hermaphrodite, with equal inflex heart-shaped petals. *Seeds*: ovate, striated.—The only known species is,

1. *Exoacantha Heterophylla*. Leaves pinnate; smooth; root-leaflets ovate, toothed, gashed; stem-leaves lanceolate, acute, usually entire, with the middle leaflet very long; root simple, thickish, biennial; stem two feet high or more, striated, subflexuose, smooth; the two umbels have about forty rays; those of the umbellule nearly equal; antheræ yellowish.—Found near Nazareth, in Judea.

Eyebright. See *Euphrasia*.

F A G

of the corolla; stigma two-lobed, obtusish. *Pericarp*: capsules globular, one-celled, (or two-celled, according to Gærtner,) and two-valved. *Seed*: single, round, bright. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Corolla*: four-petalled. *Capsules*: two-valved, with one seed.—These are tender plants, and must be kept constantly in the bark-stove.

They may be increased by seeds, and also by cuttings properly managed.—The species are,

1. *Fagara Eudodia*; *Sweet-scented Fagara*. Leaves simple, lanceolate, elongated, opposite; racemes branched, axillary, solitary. Forster made a new genus of this species, under the title of *Eudodia*, from its fine smell. But it has no distinct marks, except that the stigma is four-cleft, whereas in *Fagara* it is two-cleft; and that it has four capsules, whereas *Fagara* has but one.—Native of the Friendly Isles, and the New Hebrides.

2. *Fagara Trifoliata*; *Three-leaved Fagara*. Leaves ternate; leaflets obovate, subemarginate, entire, shining, dotted underneath.—This is a native of the island of Dominique.

3. *Fagara Pterota*; *Lentiscus-leaved Fagara*, or *Bastard Ironwood*. Leaflets emarginate. It rises, by a branched and somewhat prickly stalk, frequently to the height of eight or ten feet; the wood is very hard, and the branches are abundantly furnished with little leaves, and small white flowers, that rise on double spikes from the axils of the ribs. It has a goatish smell; and is very common in the lower lands of Jamaica. It flowers in August and September.
