COLLECTING THE VARIOUS TREASURES
OF THE VEGETABLE KINGDOM

Wisdom and Activity collecting the various Treasures of the Vegetable Kingdom

BRITISH MUSEUM
LONDON

Faint, illegible text or markings, possibly a title or header, located in the upper middle section of the page.

Several lines of very faint, illegible text or markings, possibly a list or a series of entries, located in the middle section of the page.

Another set of faint, illegible text or markings, continuing the list or series of entries, located in the lower middle section of the page.

Further faint, illegible text or markings, located in the lower section of the page.

Additional faint, illegible text or markings, located in the lower section of the page.

Final set of faint, illegible text or markings, located in the lower section of the page.

Very faint, illegible text or markings at the bottom of the page.

THE

UNIVERSAL HERBAL;

OR,

BOTANICAL, MEDICAL, AND AGRICULTURAL DICTIONARY.

CONTAINING AN ACCOUNT OF

All the known Plants in the World,

ARRANGED ACCORDING TO THE LINNEAN SYSTEM.

SPECIFYING THE

USES TO WHICH THEY ARE OR MAY BE APPLIED, WHETHER AS FOOD, AS MEDICINE, OR IN
THE ARTS AND MANUFACTURES.

WITH THE BEST

METHODS OF PROPAGATION,

AND THE

MOST RECENT AGRICULTURAL IMPROVEMENTS.

Collected from indisputable Authorities.

ADAPTED TO THE USE OF

THE FARMER—THE GARDENER—THE HUSBANDMAN—THE BOTANIST—THE FLORIST—
AND COUNTRY HOUSEKEEPERS IN GENERAL.

BY THOMAS GREEN.

THE SECOND EDITION, REVISED AND IMPROVED.

VOL. I.

P R E F A C E.

THE obvious design of this work is to present the Botanist, Farmer, Gardener, and Country Housekeeper, with a compendium of Botanical, Agricultural, and Medical knowledge, collected from the accumulated labours of the most eminent authors, and hitherto only to be obtained in separate and very voluminous publications.

From the Introduction, which immediately follows this Preface, the Botanist will at once perceive that the Linnean Arrangement is exclusively adopted, not merely because it is most universal, but because, (to adopt the language of the present acute and learned president of the Linnean Society, Sir J. E. Smith, M.D. F.R.S.) "Without wasting any words on those speculative and fanciful changes, which the most ignorant may easily make in an artificial system; and without entering into controversy with the very few competent writers who have proposed any alterations, the discriminating characters of the Linnean System are founded in nature and fact, and depend upon parts essential to every species of plant, when in perfection; and as the application of them to practice is, above all other systems, easy and intelligible; nothing more useful can be done, than to perfect, upon our own principles, any parts of this system, which experience may shew to have been originally defective. Speculative alterations in an artificial system, are endless, and scarcely answer any more useful purpose than changing the order of letters in an alphabet. The philosophy of botanical arrangement, or the study of the natural affinities of plants, is quite another matter."

The general exemplifications of the Introduction—to which the Essay on the Physiology of Plants, in the second Volume, forms an important supplement—are followed by an Analysis illustrating the Linnean System of Classification, and by Rules for Investigation, intended to "explain and apply to practice those beautiful principles of method, arrangement, and discrimination, which render Botany not merely an amusement, a motive for taking air and exercise, or an assistance to many other arts and sciences; but a school for the mental powers, an alluring incitement for the young mind to try its growing strength, and a confirmation of the most enlightened understanding in some of its sublimest and most important truths." The explanatory Plates which exhibit the various kinds of Leaves, Trunks, Roots, Armature of Plants, and more especially those which present the Parts of Fructification, the Classes and Orders of the Sexual System, with the Dictionary of Botanical Terms, will gradually introduce the young student into the midst of this delightful science: and lest he should there find himself bewildered, the Introduction closes with succinct Instructions how he is to ascertain to what Class, Order, Genus, or Section, any known or strange plant he may meet with belongs; an assistance to which will be found in the Index to the Classes and Orders at the close of the second Volume.* To avoid also any perplexity which might arise from the Specific Character not being here printed in a different letter from the general description of each plant, and to account for any apparent repetitions, the reader will only have to bear in mind, that the specific character is always contained in the first sentence, under the name of each plant; what follows being superadded description, or directions for their culture. The notes of interrogation imply that the parts of the plants to which they are subjoined require further investigation, not having yet been perfectly described.

The foreign names of many plants, and, as far as could be ascertained, the *habitats*, or exact places of growth, where those that occur wild in our own country may be found, have been minutely recorded, as they always should be by every lover of Botany; the former for the accommodation of those who may take the UNIVERSAL HERBAL abroad; and the latter, to facilitate the researches of those who botanize at home: to both of whom it is strongly recommended to interleave their copies in the binding, that their own observations, additions, or corrections, may be noted in their proper order, for their individual use. Such persons also as have preferred the plain plates, may find an elegant amusement in occasionally colouring them at their leisure from nature.

* See also the "Table of Genera," published in the Appendix to this work.

PREFACE.

The methods of propagation and culture, when peculiar, will be found under each species: but wherever the same treatment applies to a whole genus, the Farmer, Gardener, and Florist, will find the most explicit directions either immediately following the Essential Character, or subjoined to the description of the first species, to which all the rest are in the latter case invariably referred. Under every species of Grain, and of all plants used for the sustenance of man or beast, as well as under the articles Grass, Land, Moss, Mould, Meadow, Manure, Mowing, Pasture, Blight, Mildew, Vermin, Watering, Warping of Land, Weather, Weeds, Weeding, Wells, Hedges, Fences, &c. the intelligent Farmer may ascertain the opinions, practice, and experience, of the first authorities in every thing that relates to agricultural improvement.

The very copious Catalogue of Trees and Shrubs, given at the end of the second Volume, will at once enable the Gardener and Planter to select such as by their size, qualities, or places of growth, may best suit either general or particular purposes, and will save the intolerable labour and loss of time, that must have been incurred had they been left to examine the whole work in order to make that selection; which, when thus readily made, refers them for further details to the various species under their respective genera. The articles Dwarf Trees, Espaliers, Green-house, Hot-beds, Melonary, Stove, Pine-Stove, Ice-house, Nursery, Orchard, Grafting, Inoculation, Lopping, Planting, Pruning, Gravel and Grass Walks, Avenues, Wilderness Woods and Groves, Yard-manure, &c. with the Plates containing plans of the Conservatory, Hut-house, Stove-Pinery, and those for ornamental laying out of grounds, &c. will be found of essential use to the Planter, Nurseryman, and Gardener: the latter of whom will find the account of every plant with which he can have the most immediate or remote concern, accompanied with copious directions, calculated to advance his useful labours. He may also, under the head of Diseases of Plants, avail himself of all the knowledge and experience of Willdenow, as to the treatment of unhealthy plants, concerning which so much uncertainty has long prevailed. The articles entitled Planting, Timber, and Woods, are peculiarly adapted for those whose attention is principally directed to the propagation of useful trees, especially the Oak, Ash, Beech, Larch, Walnut, Chestnut, &c.: they will there find such general information as could not have been conveniently introduced into the particular description of each kind of Timber-tree, to which, under the names just enumerated, they are further referred for the most important details relative to their several qualities, and to the best means for their propagation. The Florist also, under the various species of flowers, will arrive at the most approved methods of bringing them to perfection, minutely laid down, principally upon the undoubted authority of the late celebrated Philip Miller, to whom this Work, as well as the Science of Botany, is largely indebted.

Interesting notices relative to the Arts, Manufactures, and Commerce, are interwoven, wherever articles of Trade, as Tanners' Bark, &c. have been described; or wherever there appeared any possibility of applying the plant under examination to commercial or economical purposes. In the last place, (but not on that account of the least consequence,) those Country Housekeepers who take delight in Botany, Agriculture, or Gardening, besides sharing the advantages already specified under those particulars, will find throughout this Work, very numerous excellent Recipes, which the copious Indices of Diseases, accompanying each Volume, will readily refer them to, for the cure, or at least the mitigation, of most disorders to which they are exposed. To render this part of the work still more complete, the plates of a certain number of copies have been coloured from nature, which, with the Directions for Gathering and Preserving the various Medicinal Herbs given at the end of the Introduction, will always enable them to collect, and keep ready for use, an ample stock of those simple, but efficacious, remedies.

THE EDITOR.

London, Jan. 7, 1824.

INTRODUCTION.

NATURAL History properly signifies that study by which we learn to distinguish from each other, all bodies, whether animal, vegetable, or mineral, which surround us; to discover as much as possible their nature and properties, and especially their dependence on each other in the general scale of beings. In a more extensive sense, it may be said to teach the secondary properties of natural bodies, or the various uses to which they have been or may be converted, in the service of man; for an acquaintance with their properties is our only sure guide to a knowledge of their artificial uses. But as this definition would include many arts and sciences, each of which would be sufficient to occupy any common mind, such as agriculture, medicine, chemistry, and many others, it is sufficient for a philosophical naturalist to be acquainted with the general principles upon which such arts and sciences are founded.

BOTANY, (from *βοτανη* an herb, from *βορος*, of *βοσκει*, I feed, because vegetables are the natural food of most animals,) is the science of plants; or that part of natural history which relates to vegetables. It may be divided into three branches: 1st. The physiology of plants, or a knowledge of the structure and functions of their different parts; 2dly. The systematical arrangement and denomination of their several kinds; and, 3dly. Their economical or medical properties: all of which should be kept in view by an intelligent botanist. In the utmost extent of the word, Botany signifies a knowledge of plants, and of the uses to which they may be applied, in medicine, chemistry, or the arts in general: but it is commonly restricted to a bare knowledge of the plants themselves, and of the distinguishing marks whereby each species may be known from every other. This knowledge is indispensably necessary. Many animals are endowed with an instinctive faculty of distinguishing salutary from noxious food. Mankind have no such instinct. They must have recourse to experience and to observation. But these are not sufficient guides in every case. A general caution, not to eat any thing but what we know to be salutary, will not answer in every instance. A ship's company, in want of provisions, may be thrown upon an uninhabited coast, or a desert island. Entirely ignorant of the nature of the plants they meet with, disease, or a scarcity of animals, may compel them to have recourse to vegetable food. The consequences may be dreadful—they must first eat before they can form any certain conclusion; and many lives have already been lost in these hazardous experiments. If the whole science of botany were as complete as some of its parts, very little skill in it would be sufficient to guard with certainty from committing such fatal mistakes. There are certain classes and orders which are called *natural*, because every genus and species comprehended under them, is not only distinguished by the same characteristic marks, but likewise possesses the same qualities, though not in an equal degree. For instance: shew a botanist the flower of a plant, the *calix* of which is a *double-valved glume* or husk, with *three stamina*, *two pistilla*, and *one naked seed*; he can pronounce with absolute cer-

tainty, that the plant from which the flower was taken, bears seed of a farinaceous quality, and that it may be safely used as food. In like manner, shew him a flower with *twelve or more stamina*, all inserted into the internal side of the calix, though it belong to a plant growing in Japan, he can pronounce without hesitation, that its fruit may be eaten with safety. On the other hand, shew him a plant whose flower has *five stamina*, *one pistil*, *one petal*, and whose fruit is of the *berry* kind; he will tell you it is poisonous. Facts of this kind render Botany a most interesting science. With respect to medical uses, it is found by experience, that plants, which are distinguished by the same *characters* in the flower and fruit, have the same qualities, though not always in an equal degree; so that upon inspecting the flower and the fruit, a botanist can determine the effects that will result from its use as a medicine. To determine therefore the medical virtues of all the plants belonging to a particular class, the physician has nothing to do but to ascertain, by a set of clear and unquestionable experiments, the virtues of any one of them; and this amazingly shortens the labour of investigation. As the number of species are known to be upwards of 20,000; by ascertaining the virtues of one genus, at a medium, you determine the number of 12 species. But by ascertaining the virtues of one genus belonging to a natural order, the virtues of perhaps 3 or 400 species are ascertained. A natural arrangement of the classes, orders, genera, and species, free in every instance from heterogeneous combinations, and disturbing no real affinities, is the *ne plus ultra* of classification. It is the point of perfection to which every naturalist should labour to approach, though what no one can expect actually to attain. To have formed the idea, is, however, no small advance towards it; and in itself implies a very important acquisition of knowledge.

This elegant science, which so manifestly displays the unbounded goodness and wisdom of God, was cultivated in some degree among the ancients, but chiefly with relation to medicine. As, however, they adopted no regular method of distribution and arrangement, the knowledge they gained was soon and easily lost. It would be as tedious as useless here to detail the various systems of those botanists who preceded the great Linneus, as it is well known that the system which bears his name is greatly superior to all that have been hitherto devised. It is called the *Sexual System*, because founded upon the important discovery, that in *plants*, as well as in *animals*, there is an indisputable distinction of the sexes; the following authenticated proof of which, will probably be acceptable to the intelligent reader. In Vol. xlvii. of the Philosophical Transactions, No. 25, there is a letter from Mr. Mylius of Berlin, concerning a remarkable experiment made upon the palm-tree. He says, "The *sex of plants* is very well confirmed, by an experiment that has been made here upon the *palma major foliis flabelliformis*, or, the *greater fan-shaped leaf palm*. There is a great tree of this kind in the garden of the Royal Academy. It has flowered and borne fruit these thirty years, but the fruit *never ripened*,

and when planted did not vegetate (or produce young plants.) The palm-tree, as you know, is a *planta diacia*, that is, one of those in which the male and female parts of generation are upon distinct plants, (some being males and others females.) We having therefore no male plants, the flowers of our female were never impregnated with the farina of the male. There is a male plant of this kind in a garden at *Leipsic*, twenty German miles from *Berlin*. We procured from thence, in April 1749, a branch of male flowers, and suspended it over our females, and the experiment succeeded so well, that our palm-tree produced more than an hundred perfectly ripe fruit, from which we already have eleven young palm-trees. This experiment was repeated last year, and our palm-tree bore above two thousand ripe fruit."

A plant, like an animal, is a very compound organized living being, in which various operations, both chemical and mechanical, are continually carrying on, from its first production to its final dissolution. It springs from a seed fertilized by the pollen of its parent plant. It takes in foreign substances by its inhaling and absorbent vessels. It extracts from, and assimilates to its own substance, those parts of them that are nutritious, and throws off the rest. It secretes a variety of fluids by the means of glands, and other unknown organs. It gives that motion to the sap, upon which the continuance of its life depends.

Of the theory of vegetation, or growth, propagation, and nutriment of vegetables, our knowledge is very slight and superficial. On making a transverse section of a tree, *i. e.* cutting it through horizontally, it appears to consist of three parts:

I. The **BARK**, which is also subdivided into two parts, 1. The *cuticle*, or external covering, which consists of numerous layers of circular fibres or threads, which are easily separated from each other. 2. The *true bark*, which appears upon removing the former, and is a collection of cellular or spongy substances, containing two kinds of organs; the vessels peculiar to the plants, and the longitudinal fibres or perpendicular threads.

II. On removing the *bark*, the **WOOD** appears. It has been discovered to contain the *vasa propria*, or *proper vessels*, and *longitudinal fibres*, besides large vessels with spiral or curved coats, running from one end of the tree to the other, and are denominated *vasa aëria*, or air-vessels; which are chiefly situated in the wood, leaves, and petals, but are not found in the bark of trees, nor in herbaceous plants. They are called air-vessels, because they contain no liquor, and because large quantities of air are generally found wherever they are placed; and hence they are supposed to be the organs of respiration, or breathing, in vegetables; but in what manner this function is performed, is not clearly understood.

III. In the centre of the tree is the **PITH**, which is of a similar structure in all vegetables; and is very plentiful in young plants, but, as they ripen, dries up, and appears in smaller quantities, and in aged trees altogether disappears. Between the wood and the pith lies a green-coloured substance, called the *corona*, or *crown*, which is said to contain all the parts of young plants in embryo.

These are the solid parts of plants, which likewise contain fluids or juices of two kinds: 1. The *succus communis*, or *common sap*, is of the same nature in all vegetables, and differs little from common water, except that it sooner becomes putrid on exposure to the air. It is supposed to ascend from the root, and to abound in proportion to the humidity of the soil. 2. The *succus proprius*, or *peculiar sap*, which varies according to the different plants in which it exists, giving to each its sensible qualities. It appears from

experiments to proceed from the branches towards the roots, and never in a contrary direction.—Capillary attraction is thought to be the cause of the motion of these juices, the continuance of this power being supposed to depend on the evaporation from the leaves: and of late years a vital power assisting the flow of the juices has been ascribed to plants, because their return from the branches to the roots cannot be otherwise explained.

Every plant is also composed of several external parts, differing from each other in their outward appearance, and which cannot fail to strike the most careless spectator. Many of these parts are themselves compounded, and obviously capable of being separated into subordinate divisions. The first grand division adopted by most botanists, is into the *root*, the *body* of the plant, and the *fructification*, or *flower* and *fruit*. The last, or something equivalent to it, is essential to all plants; the first is visible in almost all, and the second is not wanting in many.

The **ROOT**, is stated by Linneus to consist of the *radicle*, and the *descending caudex*. The *radicle* is that fibrous part, which draws nourishment from the earth, and in many instances constitutes the whole of the root. The *descending caudex* is properly part of the stock or body of the plant, which extends itself below the surface of the ground, as the ascending caudex rises above it. That the ascending and descending caudex have precisely the same nature, is evident, from the well-known fact, that if a young tree be inverted, what was before the root will produce leaves, while the former stem throws out radicles. Roots are divided, according to the term of their duration, into *annual*, *biennial*, and *perennial*. The annual and biennial produce flowers and fruit only once, and then soon die; the former passing through all the stages of vegetable life in one season; the latter throwing out roots and leaves the first year, but not completing the fructification till the next. The *perennial* root has within itself a principle of continued life, and gives being to new flowers and seeds year after year, to an indefinite length of time. Of the roots that are called perennial, some are truly, others imperfectly such. In the true perennial root, the descending caudex and the radicle preserve the same individual organization, and increase in size as long as the plant continues to flourish. The imperfect perennial, are, the bulbous and the tuberous, which perish after producing the bulbs, the tubers or tubercles, which are to be the parents of future plants.

The **BODY** of the plant springs from the root, and is terminated by the fructification. It is called by Linneus the *herb*, and according to him consists of the *trunk*, the *leaves*, the *fulcra*, props or supports, and the *hybernacula*, or buds.

The **FRUCTIFICATION** is a temporary part of the vegetable, designed to perpetuate the species, by producing a perfect seed, in which is contained the rudiment of a plant similar to that by which it was generated. Its essential parts are the *stamen* and the *pistil*; the former corresponding with the male, and the latter with the female, in the animal kingdom. The stamen consists of the *filament* and the *anther*; the pistil, of the *germ* or *seed-bud*, the *style*, and the *stigma*. They are generally protected by two coverings, the outward called the *calix*, and the inward the *corolla*; but in many kinds of plants, either the one or the other, and in some both of them are wanting. The pistil, in the last stage of its growth, is the parent of the seed or seeds, which are either naked, or inclosed in a *pericarp*, or seed-vessel. The *receptacle* or base on which the fructification is situated, is commonly considered as one of its parts; and in many plants there is a *nectary* or honey-cup connected with it.

Upon these parts Linneus has founded his celebrated system of botany, called the Sexual System. To elucidate this, take a Martagon Lily, for instance, class *Hexandria* order *Mono gynia*; which, though deficient in the calix or outer green part, usually consisting of five divisions or small leaves, which embraces and supports the flower, as in the rose, is still the best example; the largeness of its size allowing all the parts of the flower to be distinctly seen. Before it opens, at the top of the stem we find a long greenish bud, which grows whiter the nearer it is to opening; and when quite opened, assumes the form of a cup or basin, divided into several parts. These parts, taken separately, are called *petals*; but as a whole, the *corolla*; and not the *flower*, which is composed of various parts, whereof the corolla only is not the principal. The corolla of the Lily not consisting of one entire cup or piece, but of six divisions or petals, is termed a *hexapetalous*, or *six-petalled corolla*. Exactly from the middle of the bottom of the corolla, or cup of the flower, there rises a sort of little column or pillar, pointing directly upwards. This is called the *pistil* or *pointal*, and is divided into three parts; 1. The swollen base with three blunted angles or corners at the bottom of the corolla, called the *germen*, *pericarp* or seed-vessel, or bud. 2. A thread or small stem rising out of this, called the *style*, or shaft of the column, which, 3. is crowned with a sort of capital or head with three notches, called the *stigma*. Between the pistil and the corolla of the Lily are six other bodies, entirely distinct from each other, and called the *stamina*; one part of which is long and thin, and rising from the side of the seed-bud at the bottom of the corolla, is called the *filament*; the other part, placed at the top of the filament, is thicker, and called the *anther*. Each anther is a box, which opens when it is ripe, throwing out a fine yellow dust with a strong smell, called the *pollen*, *farina*, or *fertilizing dust*, which falls upon and impregnates the germen or seed-bud, as in the instance of the palm-trees before cited, and without which no young plants can be produced. The parts here described are found in the flowers of most other plants, but in different proportion, situation, and number. By the resemblance of these parts, and their different combinations, the *families* of the vegetable kingdom are determined: and these analogies or resemblances are connected with others, in those parts of the plant which often seem destitute of all relation to them. Thus, this number of six stamina, sometimes only three, of six petals or divisions of the corolla, and the triangular or three-cornered form of the germen or seed-bud, distinguish the Lily tribe; the roots whereof are in general bulbous, *i. e.* round, and many-coated, like an onion; while that of the above specimen is individually distinguished by being a squamous bulb, or scaly ball.

A description of the different parts of a plant, must necessarily be obtained before it can be known. It is necessary, therefore, to pursue resemblances and differences through a number of gradations, and to found upon them primary and subordinate divisions; either ascending from particulars to generals, or descending from generals to particulars. Linneus has employed four principal divisions, *Classes*, *Orders*, *Genera*, and *Species*; occasionally introducing an intermediate one between the order and the genus, and another between the genus and the species. To illustrate this, no comparison can be more in point than that which considers the vegetables upon the face of the globe as analogous to the inhabitants, thus:

VEGETABLES resemble the INHABITANTS in general;
Classes resemble *Nations*;—*Orders* resemble *Tribes*;
Genera resemble *Families*;—*Species* resemble *Individuals*.
Varieties are the same *Individuals*, differently apparelled.

A *Class*, is an assemblage of orders, having one or more characters in common, but retaining their specific distinctions; and as it stands at the top of the series, it seizes the most general and most widely-diffused resemblances, and comprehends the greatest number of particular differences.

An *Order*, is a collection of genera connected together by one or more common characters; but, like the classes, still preserving their specific distinctions.

A *Genus*, is an assemblage of species, which, as well as the classes and orders, have some one or more characters in common to connect them, and at the same time retain their specific distinctions.

A *Species*, consists of individuals, resembling each other in the form, position, proportion, and general appearance, of their several parts, produced from similar individuals, and having a power to produce other individuals of the same kind: or, as it is concisely defined by *Jussieu*, it is a perennial succession of similar individuals, deriving their origin from a successive generation. These individuals are not indeed like each other in every minute respect; such a perfect conformity does not exist in any two individuals, either of animate or inanimate organized nature. But the difference between those of the same species, though sufficiently discernible by the eye, cannot easily be expressed in words. With a strongly-marked resemblance in all their parts, there is a perpetual variation in their outline, and other particulars; so that no two individuals, lying one upon the other, will entirely correspond. They are formed after the same model, not cast in the same mould. In the general, an accurate description of all the parts belonging to any individual, will discriminate the whole species. There are, however, some sensible qualities, of importance enough to be distinguished by proper names, which are, in many cases, too uncertain to enter into any specific character. Of these, size, colour, smoothness, or hairiness of surface, and luxuriance of one part at the expense of another, are the chief; and they are owing either to difference of soil, climate, particular exposure, and other accidents; or to artificial cultivation, which is the most abundant source of perpetual varieties.

In the Linnean System, the fructification has been justly considered of the first consequence. The characters of the classes, orders, and genera, are accordingly taken entirely from it.

In the greater number of plants, the parts of fructification may be readily discerned by the naked eye, or with the assistance of a common lens; but there are also not a few in which they have not been satisfactorily discovered, or are too minute to be described with sufficient accuracy for the purposes of systematic arrangement. In most of those whose parts of fructification have been clearly ascertained and distinctly described, the stamina and pistilla are inclosed within the same envelope; or at least are absolutely contiguous; but in some, they are contained in separate flowers, or placed at a distance from each other. In both cases there is much variety with respect to their number, position, and other circumstances. On these distinctions, the distribution into classes and orders is founded.

The characters of the *classes* are taken almost exclusively from the *stamina*; those of the *orders* either from the *stamina* or the *pistilla*, but most generally from the latter.

The *essential* characters, or marks of the genera, are taken from some particulars in the flower before unnoticed; but generic descriptions are designed to contain an account of all the most obvious appearances in every part of the flower.

The *species* are mostly characterized from peculiarities in the *stem* or *leaves*; sometimes from certain parts of the *flower*; and in some instances, though very rarely, from the *roots*.

ANALYSIS OF THE LINNEAN SYSTEM.

Every Vegetable is supposed to have a Flower, which is either,

VISIBLE;

STAMINA AND PISTILLA IN THE SAME FLOWER;

MALE AND FEMALE ORGANS DISTINCT;

STAMINA NOT UNITED ABOVE NOR BELOW;

OF EQUAL LENGTH;

CLASSES.

EXAMPLES.

- | | | | |
|--|-------|--|---|
| } Hermaphrodites, or having both the sexes in each flower. | I. | <i>Monandria</i> . One Stamen or <i>Husband</i> ; as in..... | Ginger, Indian arrow-root, turmeric, blite, [mare's tail. |
| | II. | <i>Diandria</i> .. Two Stamina..... do..... | Jessamine, privet, olive, lilac, speedwell. |
| | III. | <i>Triandria</i> .. Three..do..... do..... | Valerian, tamarind, iris, and the grasses. |
| | IV. | <i>Tetrandria</i> Four...do.....do..... | Scabious, teazel, madder, holly, woodroot. [plantain. |
| | V. | <i>Pentandria</i> Five .. do.....do..... | Bell-flower, bindweed, mullein, thorn-apple, & the rough-leaved and umbelliferous plants. |
| | VI. | <i>Hexandria</i> Six....do.....do..... | Snow-drop, narcissus, tulip, aloe, hyacinth. |
| | VII. | <i>Heptandria</i> Seven do.....do..... | Horse-chesnut. |
| | VIII. | <i>Octandria</i> .. Eight .. do..... do..... | Indian-cross, heath, French willow. |
| | IX. | <i>Enneandria</i> Nine .. do..... do..... | Bay-rhubarb. |
| | X. | <i>Decandria</i> Ten....do..... do..... | Fraxinella, rue, rhododendron, lychnis |
| | XI. | <i>Dodecandria</i> Twelve do.....do..... | Purslane, houseleek, asarabacca. |
| | XII. | <i>Icosandria</i> .. Many <i>Stamina</i> , frequently 20, attached to the <i>calix</i> , and called <i>twenty husbands</i> ; | } Peach, medlar, apple, rose, cinquefoil. |
| | XIII. | <i>Polyandria</i> . Many <i>Stamina</i> , generally more than 20, not attached to the <i>calix</i> , called <i>many husbands</i> ; | |

OR, OF UNEQUAL LENGTH,

- | | | | |
|--|------|--|---|
| } Hermaphrodites, or having both the sexes in each flower. | XIV. | <i>Didynamia</i> .. Two long and two short <i>Stamina</i> , called the <i>superiority of two</i> ; | } Savory, hyssop, ground-ivy, balm, toad-flax, foxglove, agnus castus, bear's breech. |
| | XV. | <i>Tetradynamia</i> . Four long and two short ditto, called the <i>superiority of four</i> ; | |

OR, STAMINA UNITED,

- | | | | |
|--|--------|---|-----------------------------------|
| } Hermaphrodites, or having both the sexes in each flower. | XVI. | <i>Monadelphia</i> . by the filaments into one body, the <i>stamina</i> , joining at the base, called a <i>brotherhood</i> ; | } Geranium, and the mallow tribe. |
| | XVII. | <i>Diadelphia</i> .. by the filaments of two bodies or sets of <i>stamina</i> united, unlimited in number, called <i>two brotherhoods</i> ; | |
| | XVIII. | <i>Polyadelphia</i> . by the filaments into many bodies or sets, called <i>many brotherhoods</i> ; | |
| | XIX. | <i>Syngenesia</i> .. by the antheræ or tips into a cylinder, with the <i>stamina</i> separate, called <i>generating together</i> ; | |

OR, MALE AND FEMALE ORGANS UNITED,

- | | | |
|-----|---|---|
| XX. | <i>Gynandria</i> .. or male organs or <i>stamina</i> joined to and standing upon the female organs or <i> pistilla</i> , hence called <i>wife and husband</i> ; | } Orchis, ladies' slipper, arum, vanellœ, birth-wort, passion-flower. |
|-----|---|---|

OR, STAMINA AND PISTILLA IN DIFFERENT FLOWERS,

- | | | | |
|--|--------|--|--|
| } Hermaphrodites, or having both the sexes in each flower. | XXI. | <i>Monœcia</i> ... the same plant having male and female flowers, called a <i>single house</i> ; | } Mulberry, nettle, oak, cypress, fir, cucumber. |
| | XXII. | <i>Diœcia</i> .. males and females on separate plants, called the <i>two houses</i> ; | |
| | XXIII. | <i>Polygamia</i> .. males, females, or hermaphrodites, found upon the same or different plants, called <i>many marriages</i> ; | |

OR, CONCEALED.

- | | | |
|-------|--|--|
| XXIV. | <i>Cryptogamia</i> , or concealed and cannot be described, called <i>concealed marriages</i> ; | } Ferns, mosses, mushrooms, mould, algæ. |
|-------|--|--|

The Number of the GENERA and SPECIES of PLANTS of the *Phanogamous Kinds, in the following TABLE, are taken from C. H. Persoon's Edition of Linneus, published at Paris in 1805 and 1807. In his Classification of Plants, he has differed in some respects from Linneus; especially in his retrenchment of the Classes Polyadelphia and Polygamia, (the plants of which, he has distributed in what he conceives to be their more proper places in the remaining twenty-one Classes,) and his cutting off the order Monogamia, from the Linnean class Syngenesia. The number of Genera and Species of †Cryptogamous plants, is taken from Turton's Edition of Linneus, Vol. VI. printed at Swansea, in 1803.

CLASS		Total Genera.	Total Species.
I.	Order I. Monogamia; 21 Genera, 77 Species.—Order II. Digynia; 6 Genera, 13 Species.	30	90
II.	Order I. Monogamia; 41 Genera, 470 Species.—Order II. Digynia; 2 Genera, 7 Species.—Order III. Trigynia; 1 Genus, 105 Species.	44	582
III.	Order I. Monogamia; 65 Genera, 666 Species.—Order II. Digynia; 62 Genera, 730 Species.—Order III. Trigynia; 11 Genera, 37 Species.	138	1433
IV.	Order I. Monogamia; 116 Genera, 741 Species.—Order II. Digynia; 8 Genera, 15 Species.—Order III. Trigynia; 1 Genus, 1 Species.—Order IV. Tetragynia; 10 Genera, 62 Species.	135	819
V.	Order I. Monogamia; 287 Genera, 2253 Species.—Order II. Digynia; 90 Genera, 699 Species.—Order III. Trigynia; 20 Genera, 140 Species.—Order IV. Tetragynia; 1 Genus, 3 Species.—Order V. Pentagynia; 11 Genera, 189 Species.—Order VI. Decagynia; 1 Genus, 1 Species.—Order VII. Polygynia; 3 Genera, 3 Species.	413	3288
VI.	Order I. Monogamia; 112 Genera, 907 Species.—Order II. Digynia; 3 Genera, 4 Species.—Order III. Trigynia; 20 Genera, 105 Species.—Order IV. Hexagynia; 3 Genera, 3 Species.—Order V. Polygynia; 1 Genus, 9 Species.	139	1028
VII.	Order I. Monogamia; 9 Genera, 17 Species.—Order II. Digynia; 1 Genus, 3 Species.—Order III. Tetragynia; 2 Genera, 2 Species.—Order IV. Heptagynia; 3 Genera, 7 Species.	15	29
VIII.	Order I. Monogamia; 58 Genera, 540 Species.—Order II. Digynia; 4 Genera, 13 Species.—Order III. Trigynia; 9 Genera, 121 Species.—Order IV. Tetragynia; 8 Genera, 15 Species.	79	689
IX.	Order I. Monogamia; 6 Genera, 46 Species.—Order II. Trigynia; 2 Genera, 9 Species.—Order III. Hexagynia; 1 Genus, 1 Species.	9	56
X.	Order I. Monogamia; 103 Genera, 611 Species.—Order II. Digynia; 11 Genera, 162 Species.—Order III. Trigynia; 14 Genera, 246 Species.—Order IV. Tetragynia; 1 Genus, 3 Species.—Order V. Pentagynia; 17 Genera, 232 Species.—Order VI. Decagynia; 2 Genera, 7 Species.	143	1261
XI.	Order I. Monogamia; 35 Genera, 124 Species.—Order II. Digynia; 2 Genera, 6 Species.—Order III. Trigynia; 4 Genera, 157 Species.—Order IV. Tetragynia; 1 Genus, 3 Species.—Order V. Pentagynia; 4 Genera, 9 Species.—Order VI. Dodecagynia; 1 Genus, 13 Species.	47	312
XII.	Order I. Monogamia; 27 Genera, 250 Species.—Order II. Digynia; 3 Genera, 41 Species.—Order III. Trigynia; 1 Genus, 3 Species.—Order IV. Tetragynia; 8 Genera, 152 Species.—Order V. Polygynia; 10 Genera, 176 Species.	49	622
XIII.	Order I. Monogamia; 72 Genera, 364 Species.—Order II. Digynia; 7 Genera, 17 Species.—Order III. Trigynia; 3 Genera, 37 Species.—Order IV. Tetragynia; 5 Genera, 23 Species.—Order V. Pentagynia; 8 Genera, 123 Species.—Order VI. Polygynia; 29 Genera, 291 Species.	124	855
XIV.	Order I. Gymnospermia; 53 Genera, 634 Species.—Order II. Angiospermia; 116 Genera, 800 Species.	169	1334
XV.	Order I. Siliculosa; 26 Genera, 217 Species.—Order II. Siliquosa; 13 Genera, 297 Species.	39	514
XVI.	Order I. Diandria; 2 Genera, 12 Species.—Order II. Triandria; 2 Genera, 2 Species.—Order III. Pentandria; 18 Genera, 252 Species.—Order IV. Heptandria; 1 Genus, 150 Species.—Order V. Octandria; 2 Genera, 2 Species.—Order VI. Decandria; 7 Genera, 53 Species.—Order VII. Dodecandria; 13 Genera, 54 Species.—Order VIII. Polyandria; 32 Genera, 483 Species.	77	1008
XVII.	Order I. Pentandria; 1 Genus, 5 Species.—Order II. Hexandria; 3 Genera, 33 Species.—Order III. Octandria; 5 Genera, 109 Species.—Order IV. Decandria; 92 Genera, 1548 Species.	101	1695
XVIII.	Order I. Aequalia; 79 Genera, 894 Species.—Order II. Superflua; 77 Genera, 1265 Species.—Order III. Frustranea; 18 Genera, 255 Species.—Order IV. Necessaria; 24 Genera, 194 Species.—Order V. Segregatae; 20 Genera, 63 Species.	218	2671
XIX.	Order I. Diandria; 34 Genera, 477 Species.—Order II. Triandria; 2 Genera, 2 Species.—Order III. Hexandria; 2 Genera, 41 Species.	38	520
XX.	Order I. Monandria; 11 Genera, 46 Species.—Order II. Diaandria; 3 Genera, 10 Species.—Order III. Triandria; 18 Genera, 294 Species.—Order IV. Tetrandria; 18 Genera, 157 Species.—Order V. Pentandria; 11 Genera, 58 Species.—Order VI. Hexandria; 10 Genera, 25 Species.—Order VII. Polyandria; 40 Genera, 257 Species.—Order VIII. Monadelphia; 42 Genera, 401 Species.—Order IX. Gynandria; 3 Genera, 3 Species.	156	1251
XXI.	Order I. Monandria; 8 Genera, 13 Species.—Order II. Diaandria; 7 Genera, 144 Species.—Order III. Triandria; 10 Genera, 150 Species.—Order IV. Tetrandria; 16 Genera, 54 Species.—Order V. Pentandria; 24 Genera, 67 Species.—Order VI. Hexandria; 15 Genera, 108 Species.—Order VII. Octandria; 5 Genera, 44 Species.—Order VIII. Eucandria; 3 Genera, 9 Species.—Order IX. Decandria; 5 Genera, 13 Species.—Order X. Dodecandria; 5 Genera, 33 Species.—Order XI. Icosandria; 6 Genera, 17 Species.—Order XII. Polyandria; 10 Genera, 48 Species.—Order XIII. Monadelphia; 20 Genera, 85 Species.—Order XIV. Gynandria; 1 Genus, 17 Species.	135	802
XXII.	Order I. Filices; 38 Genera, 560 Species.—Order II. Musci; 23 Genera, 555 Species.—Order III. Hepaticæ; 7 Genera, 118 Species.—Order IV. Algæ; 8 Genera, 871 Species.—Order V. Fungi; 52 Genera, 819 Species.	128	2923

SYNOPSIS OF THE PRECEDING TABLE.

* Phanogamous Plants.	
Total of Genera.....	2303 : of Species.....20,859
† Cryptogamous Plants.	
Total of Genera.....	128 : of Species.....2923
Grand Total of Phanogamous and Cryptogamous Plants.....	2431.....23,782

†† These Orders are named from the *Pistillum*, or female part of a plant, which is usually reckoned from the base of the Style, if there be any; if that be wanting, it is fixed from the *Stigmata*.—*Monogynia* therefore means one wife, female, or style; *Digynia*, two; *Trigynia*, three; *Tetragynia*, four; *Pentagynia*, five; *Hexagynia*, six; *Decagynia*, ten; *Polygynia*, many.

* *Phanogamous*,—from φαίνω to appear, and γαμος marriage:—Plants in which the parts of fructification are visible and distinct.
 † *Cryptogamous*,—from κρυπτω to hide, and γαμος a marriage:—Plants in which the parts of fructification are either totally concealed, or imperfectly visible.
 * Dr. Edward Smith, President of the Linnean Society, has removed the plants of the Monogamia order of class Syngenesia into their proper place in the class Pentandria, because the flowers of its different genera are not composite, or compounded.

RULES FOR INVESTIGATION.

WHEN a plant offers itself to our investigation, the first thing to be determined is, the class to which it belongs. This is to be done by observing the number of stamina, and referring to the preceding Tables of the Classes. Should there be a difficulty in ascertaining the number of stamina, on account of the number appearing different in different flowers, though belonging to the same plant, it is advisable to examine one or more of the flowers which are yet unopened; for the antheræ are in that state more distinct, and we may be certain that none of them have been lost. Having fixed upon the class, we must again refer to the preceding Tables, where we shall find of how many orders the class consists; and, after observing the circumstances of the pistilla, or other characters by which the orders are determined, we must compare these, and we shall readily discover the class and order to which it systematically belongs.

If the order we refer it to has any subdivisions, we shall soon perceive under which of the subdivisions the genus should be found: and as this Dictionary presents the student with the characteristics of the orders and their respective subdivisions, and also with the genera belonging to each order or subdivision alphabetically arranged, after having discovered the class by the assistance of the preceding analysis, he will easily ascertain the order in this table under the class to which it belongs, and will there find himself at once referred to the genera and species in the body of the work.

After comparing the flowers with the characters of the different genera contained in the order, or in the particular subdivision of the order, it will soon be seen with which of them it best corresponds; and if any one agree pretty exactly with our specimen in all the leading characters, we are then certain of the genus. Doubtful matters will sometimes arise; but these are for the most part made clear, by observations subjoined to the generic descriptions. In consulting these generic descriptions, the learner is advised to pay particular attention to the structure of the *pistil*, and especially to that of its *germen*, when it begins to ripen into a *seed-vessel*; because these parts being most essential to the continuation of the species, are less liable to variation, than those which are less important.

If none of the generic characters at the beginning of the class agree with the flower, we must then look at the end or subdivision of the order to which it was referred, and see what plants are there mentioned. If we have not found the plant before, it must be some one of these; looking therefore for these, and comparing the generic descriptions with the specimen in hand, we shall not only discover the genus, but the circumstance which produced our perplexity.

The young student is also recommended to practise the investigation of *genera* only, for a considerable time, before he attempts to ascertain a *species*; and when by this means he has attained a pretty accurate knowledge of classes and orders; also of the parts composing a flower, and its subsequent state of fruit, or fructification, and likewise with the terms employed in describing them; he may next proceed to determine the *species* and *varieties*.

Whenever the *species* are numerous, they are subdivided. Consider with which of these subdivisions it agrees; and having determined that, compare it with the several *specific* characters, as it will probably agree with some one of these. If you are still in doubt, guided by the references to figures which commonly follow the specific character, turn to such figures as you possess; and to make the point still more certain, compare your plant with the descriptions which follow the references to figures; for these will remove many an existing doubt, and obviate many a possible mistake. If the plant in question be any remarkable variety, you will probably find it introduced after the additional descriptions above alluded to.

Make it an invariable rule, not to pass over a single term, the precise meaning of which you do not thoroughly understand: always consult the Botanical Dictionary, at the end of this Introduction, which will soon remove the necessity of consulting it at all.

Lastly; When gathering plants for examination, collect a considerable number of the flowers, and, if possible, some just opening, others fully expanded, and others with the seed-vessels almost ripe: take care also to gather one specimen of the plant, at least, as perfect and entire as possible.

It is deemed necessary to subjoin various examples for investigation: the student will, however, do well, after examining, to try his strength by examining any unknown flowers he may pick up in his walks.

EXAMPLES.

COMMON PRIVET.—*Ligustrum Vulgare*.

This shrub is found in hedges and shrubberies in many parts of England. It generally blossoms in June, and its blossoms are white. Having obtained a branch of it in blossom, we proceed to investigate it; and looking into several blossoms, find two stamina in each, by which we know it belongs to the Diandria class. This class contains three orders, which depend upon the number of pistilla; looking again at the flowers, we discover one pistil in each: so that the plant evidently belongs to the order Monogynia.—This order is subdivided into several parts; and observing the marks of these subdivisions, we find that in our specimen the blossom is formed of one regular corolla, fixed beneath the germen; which corresponds with the first subdivision, and that contains only one English genus, so that there can be no doubt but the plant is a *Ligustrum*. We shall also find that the blossom is cloven into four parts, and that it is succeeded by a berry containing four seeds. Referring to the genus *Ligustrum*, and comparing it with the generic description, we have the satisfaction to perceive a perfect coincidence. Having ascertained the genus, we proceed to discover the species; and as there are only two species of that genus, we know the shrub in question, from its lanccolate leaves, must be the common Privet, or *Ligustrum Vulgare* of Linneus.

REED.—*Arundo*.

The Reed is plentiful upon the banks of rivers, on borders of pools, and in wet ditches; it is a sort of large grass, five or six feet high, and flowers in June. Having gathered a specimen of this, we proceed to examine it systematically. At first sight we observe that the flowers grow in panicles, and that each flower contains three stamina. We therefore refer it to the third or Triandria class, which is divided into three orders, depending upon the number of pistilla. Each of the flowers contains two pistilla, and therefore belongs to the order Digynia. This order is subdivided into several parts. The first subdivision contains the plants with flowers scattered, or irregularly disposed, *one* only in the calix. Our plant agrees with the first circumstance, but not with the last, for we find five flowers in each calix. Another subdivision contains only two flowers in a calix; we therefore pass that over, and come to the third with scattered flowers, and *several* in each calix. Before we proceed further, we just look at the remaining subdivision, but finding those flowers in the form of a spike, or a long and slender receptacle, we immediately recur to the third subdivision. This subdivision contains several genera, and we compare the characters of each with the plant in hand: the want of an awn, and the woolliness at the base of the blossoms, determines us to call it *Arundo*. Turning therefore to the genus *Arundo*, we compare it accurately with the generic description, and find it correspond with it. But as the parts constituting the flowers of grasses are frequently very minute, we make use of the botanical microscope and dissecting instrument,* to display them more clearly to the eye. Having discovered it to be an *Arundo* or Reed, we next proceed to ascertain the species. There are four only natives of Great Britain; and each calix containing five florets upon a flexible panicle, which is observed to be waved about with every wind, decides that it is the common Reed, or *Arundo Phragmites* of Linneus.

PLANTAIN.—*Plantago*.

The Plantain flowers in June and July, and is very common in mowing grass, and upon the road-side. It is frequently stuck in the cages of linnets and canary birds, who are fond of the seeds. Examining a specimen of this, we find each flower to contain four stamina nearly of the same length; it therefore belongs to the fourth or Tetrandria class. This class contains four orders, depending upon the number of pistilla. Each of our flowers contains only *one* pistil, and therefore belongs to the first order, which admits of twelve subdivisions. Our specimen presents blossoms of *one* petal, fixed *beneath* the germen: this induces us to seek it in the fourth subdivision; and finding, by cutting across the seed-vessel, that it is divided into two cells,† we conclude that it is a *Plantago*. We now compare it with the generic description, and as that agrees, try next to determine the species. There are thirty-five species of Plantain; these are subdivided into plantains with naked scapes, and those furnished with a stem. Our plant has a naked scape, and therefore belongs to the first subdivision. It agrees with the *Plantago Lanceolata* in every particular; and hence we call it the Ribwort Plantain, or *Plantago Lanceolata* of Linneus.

* The botanical microscope, and dissecting instruments, may be purchased for about two guineas. The microscope is of a form suited to the pocket, and is also made to stand steady while in use.

† To judge whether a capsule consists of one or more cells, the best method

BIRCH.—*Betula*.

This tree is very generally known. The flowers are disposed in catkins, which appear in April and May. Some of these catkins contain only stamina with their scales, and others on the same tree only pistilla. In the former, each floret contains four stamina, and in the latter two pistilla. These agree with the twenty-first or Monœcia class, and with the order Tetrandria, which contains twelve genera. Attention to the other parts of the character, and a comparison with the generic description, will determine it to be of the *Betula* genus, which having fifteen species, the shape of the leaves will prove the specimen to be the common Birch-tree, or *Betula Alba* of Linneus.

HONEYSUCKLE.—*Lonicera*.

This plant is common in our hedge-rows, and is very universally known: but let us suppose a person, who never saw it before, struck with the beauty and fragrance of its blossoms, carrying a piece of it home for examination. Finding five stamina in each flower, and the antheræ not united, he refers it to the fifth or Pentandria class. The orders in that class being determined by the number of pistilla, he knows it belongs to the order Monogynia, for he finds only one pistil in each flower. This order is subdivided into eleven parts. The absence of the *four naked seeds*, and the *ROUGH LEAVES*, immediately determine him to reject the third subdivision. The blossom being *fixed beneath the germen*, does not correspond with his flower; hence he rejects the fourth and fifth subdivisions, and passes on to the sixth, where he finds flowers of one petal superior. This flower consists of one petal, and this petal is fixed *superior* to, or *above*, the germen. This subdivision containing many genera, he observes in his plant the seed-vessel is a berry with two cells; this circumstance, added to the equality of the blossom, and the knob at the top of the pistil, induces him to think it a *Lonicera*, which, upon comparing the flower with the generic description, he finds to be correct. Under this genus he finds twenty species; he compares it with the specific character of each, and thereby determines it to be the Woodbine Honeysuckle, or *Lonicera Periclymanum* of Linneus.

SNOWDROP.—*Galanthus*.

The Snowdrop, though not frequent in a wild state, is to be found in almost every garden, and is among the first of our spring flowers. When we examine it attentively, the first thing that strikes us, is the want of a cup; but instead of that, we find upon the fruitstalk a sheathing substance, which covers the blossom in its infant state. The six stamina direct us to the sixth or Hexandria class, and the single pistil fixes it upon the first order of that class. This order is subdivided into, 1. Flowers with a cup and blossom. 2. Flowers with calix, corolla, or spathe. 3. Flowers with a sheath or husk. 4. Flowers naked. 5. Flowers without petals. The want of a cup, and the presence of the sheath, teach us to expect it in the third subdivision, which contains several genera. In the *Allium*, the blossom is fixed *beneath* the germen, but in our plant it is *above* it. In the *Narcissus* there is a bell-shaped

is, to cut it through horizontally with a sharp knife, then carefully to pick out the seeds, leaving the dividing membranes entire. If it be very minute, cut off a thin slice horizontally, place it on the stage of the microscope, view it through the magnifier, and at the same time dissect it with the instrument.

nectary, and six petals; but our plant has six petals only, and no such bell-shaped nectary. The circumstance of three *inner* petals, shorter and notched at the end, is sufficiently observable in our specimen, and clearly distinguish it from the *Leucojum*; it agrees only with the *Galanthus*. The generic character answers the description; and the three inner and shorter petals may be considered as a nectary. As there is but one species, it must therefore be the *Galanthus Nivalis* of Linneus, or common Snowdrop.

PEAR.—*Pyrus*.

Finding about twenty stamina in each flower, we know it must belong either to the twelfth or thirteenth classes. In the twelfth, or *Icosandria* class, the number of stamina alone will not sufficiently distinguish it from the classes *Dodecandria* and *Polyandria*; but as the calix is formed of a single concave leaf, the petals fixed to the sides of the calix, and the stamina do not stand upon the receptacle, we conclude that it belongs to that class. Each flower having five pistilla, we look for the genus under the order *Pentagynia*. This order contains six genera. The calix being cloven into five parts, and the blossoms being composed of five petals, are circumstances common to three. But the fruit of one is a berry containing five seeds, and the fruit of another is a pomum or apple, with five cells and many seeds. Hence it appears, that our plant is undoubtedly the *Pyrus*; and turning to the generic description, we are confirmed in this opinion. We next compare it with the twenty-four species, and are soon able to determine whether we have got the *Pyrus Communis* or the *Pyrus Malus*; i. e. the Pear or the Apple.

CROWFOOT.—*Ranunculus*.

The beautiful shining yellow blossoms of Crowfoot, and the frequency of it in pastures in the months of June and July, will probably attract our notice, especially as cattle leave it untouched, even when the pasture is bare. We therefore collect some of it, and finding a great number of stamina in each blossom, refer it to the thirteenth or *Polyandria* class, the stamina of which stand upon the receptacle, and not upon the cup or blossom. As this must be the class, we next examine the pistilla, and finding them more than can readily be counted, turn to the order *Polygynia*. This order includes twenty-one genera. Upon an accurate examination we observe a little pore or nectary within the claw of each petal; and governed also by a number of leaves forming the cup, and of petals composing the blossom, we turn to the generic description of the *Ranunculus*. Quite satisfied about the genus, we observe the species are numerous, and arranged according as the leaves are *divided* or *not divided*. In our specimen the leaves are divided. We then compare it with each of the species; and from its open or expanded calix, its cylindrical fruit-stalks, its leaves with three divisions, many clefts, &c. find it to be the upright Crowfoot, or *Ranunculus Acris* of Linneus.

WALL-FLOWER.—*Cheiranthus*.

This plant is very generally known. It grows wild upon old walls, and is frequently cultivated in gardens. Carefully remove the calix and the petals, and you will find six stamina, two of which are shorter than the other four. It therefore belongs to the fifteenth class, or *Tetradynamia*. The orders of this class depend upon the form of the seed-vessel; and after examining the specimen, you necessarily refer it to the

first subdivision of the second order; for the seed-vessel is a *long* pod, and the leaves of the cup stand upright, and close to the blossom. It is possible you may have to dissect several flowers, before you can ascertain the genus; for this class, like the preceding, is composed of a natural assemblage of plants, whose flowers bear a strong resemblance to each other; and the differences, when this is the case, are not very obvious. At length, however, the small glandular substance on each side the base of the germen, determines you to refer it to *Cheiranthus*. Upon a comparison with the generic description, you find it corresponds; and the shape of the leaves, &c. puts it beyond all doubt, that it is the Wall July-flower, or *Cheiranthus Cheiri* of Linneus.

DANDELION.—*Leontodon*.

This plant is in blossom during great part of the spring and summer; it grows in pastures, road-sides, and the uncultivated parts of gardens. At the first view we perceive its structure to be very different from any we have ever examined before; we hardly know what to call stamina, or what pistilla. The fact is this, it is a true *COMPOUND FLOWER*, or a flower formed of a number of little flowers (or florets) sitting upon one *common* receptacle, and inclosed by one *common* calix. Separating one of the florets, and examining it carefully, we find five stamina, with the antheræ united, and the pistil passing through the cylinder formed by the union of the antheræ. We therefore refer it to the nineteenth or *Syngenesia* class: finding that all the florets are furnished with stamina and pistilla, we perceive that it belongs to the first order. From the shape of the blossoms of the florets, which are all long and narrow, we know that we must look in the first subdivision of that order. Perceiving that the receptacle is an important circumstance in the character of compound flowers, we pull off all the florets in one of the flowers, and expose the receptacle to view. We find it naked, that is, not beset with chaffy or bristly substances. We find too a sort of down adhering to the seeds; and observe the scales of the calix laid one over another, like the tiles on a roof; the outer scales loose, flexible, and turned back. These characters corresponding pretty well with the *Leontodon*, we fix upon that as the genus; we look forward to the generic description, where we are informed, that in the *Leontodon Taraxacum*, the down of the seed is supported on a long pedicel, which we had already remarked in the flower before us. We next read the characters of the different species; and, from the deep notches in the leaves, judge our plant to be the *Leontodon Taraxacum* of Linneus, or common Dandelion.

MILK-VETCH.—*Astragalus*.

This genus is very common every where, in Great Britain. Examining a specimen of it when in flower, we immediately collect from the papilionaceous, or butterfly-shaped blossoms, that it must belong to the *Decandria* order of the *Diadelphia* class of plants. In referring to the Linnean classification of the plants in this order, we find that there are not fewer than six grand subdivisions. Our plant cannot belong to the two first, because in the former all the stamina are united, and in the latter the stigma is pubescent; nor with the three last, which consist of plants with the legume mostly one-celled, without the marks of the two first subdivisions; of plants with the loment separating into joints; and of plants with the legume one-celled and many-seeded. Our plant having a two-celled legume, without the marks of the

two first subdivisions, it must necessarily be one of those in the third subdivision. In this there are only three genera, viz. Phaca, Biserbula, and Astragalus. The plant in question not having a half-two-celled inflated legume, it cannot be the Phaca; it must therefore be either the Biserbula or Astragalus. The gibbous shape of the legume, leaves no doubt of its being an Astragalus; but as the species of this genus are extremely numerous, in order to determine the species, we must pay very particular attention to the minute circumstances by which they are distinguished. The species of Astragalus are divided into not fewer than seven subdivisions. The specimen before us cannot belong to the six first subdivisions, because the first consists of Astragali, with leafy erect stems and axillary flowers; the second of leafy erect stems, with spikes cylindrical, axillary, sessile, or nearly so; the third of leafy erect stems, with spikes and racemes peduncled; the fourth of leafy diffuse stems; the fifth of leaflets placed in whorls; and the sixth of a naked scape, without a leafy stem. Our plant must therefore be a species of Astragalus, in the seventh subdivision, containing shrubby plants with the petioles permanent, and becoming spinous. As the species of Astragali in this subdivision are numerous, we must be very careful in examining all the specific characteristics. The leaflets being in ten pairs, determine it to be either the Astragalus Longifolius, or Astragalus Pugniformis. It cannot be the latter, which has oblong mucronate glabrous leaflets; therefore there is not the least doubt that the plant in question is the Astragalus Longifolius, from the lanceolate mucronate glabrous leaflets, the flowers being in oblong heads, and the calix having filiform villous teeth.

STARWORT.—*Aster*.

Upon the first sight of this plant, we refer it to the class Syngenesia, because of its composite flowers. As this class is subdivided into five orders, we soon perceive, by a careful inspection of the florets, that it cannot belong to the first order, which consists of plants having florets all hermaphrodite and fertile. Neither can it belong to the third order, which consists of plants with the florets of the centre hermaphrodite, and those of the ray neuter and barren; neither can it be one of the fourth order, which consists of plants having the florets of the centre hermaphrodite and barren, and those of the margin, female and fertile; nor can it belong to the last order, which consists of plants with the florets separated by a proper perianth, containing one or more florets, and placed within a common calix. The florets of the disk, in the specimen before us, being hermaphrodite, and those of the margin female, and all fertile, leave not the least shadow of doubt of its being in the order Polygamia Superflua. This order has three grand subdivisions. In the first, all the florets are tubular, which is not the case with the plant in question; in the second, the florets are semi-floscular, and somewhat two-lipped, circumstances not in our specimen. The radiate florets of our specimen, is the striking characteristic of the third subdivision, and is decisive of its being in this subdivision. Its naked receptacle is a proof that it cannot be the Boltonia, Siegesbeckia, Anthemis, Achillea, Tetragonotheca, Ximenesia, Georgina, Relhania, Pascalia, Buphthalmum, Rhanterium, Amellus, Tridax, Rosenia, Verbesina, Schlechtendalia, Galinosogea, Zinnia, Balbisia, nor Starkea. Its simple down, in union with its naked receptacle, confines it to the Doronicum Arnica, Inula, Erigeron, Solidago, Cineria, Senecio, Tussilago, Aster, and Boebera. Its imbricate calix, with the lower scales spreading, and the florets of the margin more than ten, restrict it entirely to the Aster. The

species of this genus are very numerous, and are divided into seven grand subdivisions. It cannot belong to the first, which consists of species more or less shrubby; nor to the second, consisting of herbaceous plants, with the stem one or two flowered; nor to the third, containing herbaceous species, with linear or lanceolate leaves very entire; nor to the fourth, consisting of herbaceous plants, with heart-shaped, ovate, and serrate leaves; nor to the fifth, containing herbaceous plants, with ovate very entire leaves; nor to the sixth, which contains herbaceous plants, with lanceolate leaves, the lower ones more or less serrate. Our plant being herbaceous; with pinnate leaves, must belong to the last subdivision, in which there are only two species, the Aster Aurantius, and Aster Pinnatus. The pinnate leaves, with the midriff winged, leave no doubt of its being the Aster Pinnatus; and the additional circumstances of the leaflets being linear wedge-form, and serrate at top, put the matter beyond all controversy.

TRUMPET-FLOWER.—*Bignonia*.

The stamina of this plant being two longer and two shorter, is sufficient to determine it to be in the Didynamia class; and the seeds being inclosed in a capsule, shew it to be of the Angiospermia order. The plants of this order are numerous, and subdivided into seven parts, all of which, except the last, depend upon the form of the calix. The plant in question is not in the first subdivision, which consists of plants with undivided calixes; nor in the second, consisting of bifid calixes; nor in the third, containing plants with three-cleft calixes; nor in the fourth, which contains plants with four-cleft calixes; nor in the sixth, containing plants with many-clefted calixes; nor in the seventh, containing plants with more than one petal. Our plant having a five-clefted calix, there can be no doubt of its belonging to the fifth subdivision. The genera in this subdivision are numerous, which are generally distinguished from each other by the capsule and corolla. Our specimen has a two-celled capsule and a Campanulate Corolla; the union of which particulars, restrict it to the following genera: Capraria, Digitales, Bignonia, Incarvillea, Ruellia, Sesamum, and Gloxinia. The imbricate-winged seeds and the filaments, with the rudiment of a fifth, shew it can be no other than the Bignonia. The species of this genus are very numerous, and are subdivided into seven parts; all of which depend upon the shape or number of the leaves. The plant in question consequently cannot be in the first subdivision, which contains plants with simple leaves; nor in the second, consisting of plants with two leaves on each petiole; nor in the third, having plants with three leaves, on a common stalk; nor in the fourth, with leaves in finger-like divisions; nor in the fifth, with pinnate leaves; nor in the seventh, with doubly pinnate leaves. The decomposed leaves of our specimen, shew it to be in the sixth subdivision. In this there are only three species. The decompositely pinnate leaves, with knotty petioles and axillary corymbs, shew it to be no other than the Bignonia Alba. The additional circumstance of its having white flowers on a many-flower-forked axillary peduncle, puts the question beyond all dispute.

SEDGE-GRASS.—*Carex*.

Upon a minute investigation of the apetalous flowers of this plant, we discover that some are male and others female, growing from the same root; but we are not able to find any hermaphrodites; consequently it must belong to the Monœcia

class. As the orders of this class depend upon the number or position of the stamina, our plant must be in the order Triandria, from the circumstance of its having three stamina. The want of a corolla, the imbricate ament, the calix being a one-valved scale, the three stigmata, and the coated seed, are sufficient in warranting us to call it a *Carex*. The species of this genus are very numerous, (upwards of 200,) and are parted into five grand subdivisions. The plant in question is not in the first subdivision, which consists of species with simple solitary spikes; nor in the second, with compound androgynous spikes; nor in the last, with male and female spikes distinct, and the males several. The male and female flowers growing on distinct spikes, and nearly of equal number, each shew that our specimen must be either in the third or fourth grand subdivision. As the species of *Carex*, in these two subdivisions, are distinguished from each other by the female flowers being sessile in one, and peduncled in the other, we are assured that our plant, from its sessile, female, apetalous flowers, must belong to the third subdivision. Its short sheaths nearly equalling the peduncles, its female roundish spikes, beaked fruit curved downwards, and nearly smooth stem, leave no doubt of its being the *Carex Flava*, or Yellow Sedge-grass.

It will be very proper for the learner thus to examine several more genera of this class, as the Coltsfoot, the Burdock, the Thistle, the Tansy, the Daisy, and the Groundsel; for by doing this, he will soon overcome the difficulties which present themselves; and it will be satisfactory to compare the plant with the figures in the plates of English plants in this work.

To a superficial and thoughtless mind, the study of Botany, and the investigation of plants, may appear a light and frivolous employment: but if we reflect on the great benefits derived from a due knowledge of the cultivation and properties of herbs and plants, as well on the score of supplying food for men and cattle, as for the extensive purposes of medicine, we shall find few pursuits more pregnant with intellectual improvement, or more conducive to the public good. The Saviour of mankind descended to the lifeless emblems of Seed sown,—of the Fig-tree,—and of a single grain of Mustard-seed,—to enlighten our understandings; and if we wish to improve by the parable, and accompany nature in this solitary yet pleasing walk, we shall find it an innocent and healthful amusement.

The Compiler cannot conclude with more appropriate words than those of the justly admired author, who has supplied him with several of the above rules and exemplifications.—“After having passed in this familiar though cursory manner, through the different parts of the system, I must suppose that the Reader no longer stands in need of my assistance; and that he will soon find himself equal to the investigation of every useful plant which may come before him. But this is not all; he will find that the study of Nature is ever attended with pleasing reflections; that the study of Botany in particular, independently of its immediate use, is as healthful as it is innocent; that it beguiles the tediousness of the road; that it furnishes amusement at every footstep of the solitary walk; and, above all, that it must fill our hearts with gratitude, while we discover the bounty, wisdom, and power, of the great CREATOR.”

EXPLANATION OF THE PLATES.

PLATE I.

SIMPLE LEAVES.

- | | |
|--|---|
| <p>Fig.
1. <i>Folium orbiculatum</i>, a circular leaf, or that is perfectly round.</p> <p>2. ——— <i>subrotundum</i>, a leaf approaching to a circular figure.</p> <p>3. ——— <i>ovatum</i>, an egg-shaped leaf.</p> <p>4. ——— <i>ovale</i>, a leaf having an oval or elliptical form.</p> <p>5. ——— <i>oblongum</i>, an oblong leaf, in which the length greatly exceeds the breadth.</p> <p>6. ——— <i>lanceolatum</i>, a lance-shaped leaf.</p> <p>7. ——— <i>lineare</i>, a leaf of equal breadth throughout.</p> <p>8. ——— <i>subulatum</i>, an awl-shaped leaf, which gradually tapers towards the top.</p> <p>9. ——— <i>reniforme</i>, a leaf in figure resembling a kidney.</p> <p>10. ——— <i>cordatum</i>, a heart-shaped leaf.</p> <p>11. ——— <i>lunulatum</i>, a leaf resembling a crescent.</p> <p>12. ——— <i>triangulare</i>, a three-angled leaf.</p> <p>13. ——— <i>sagittatum</i>, a leaf which in form resembles the head of an arrow.</p> <p>14. ——— <i>cordato sagittatum</i>, a leaf which partakes of both shapes delineated in the tenth and thirteenth figures.</p> <p>15. ——— <i>hastatum</i>, an halberd-shaped leaf.</p> <p>16. ——— <i>fissum</i>, a leaf that is parted about half way down, with straight margins.</p> <p>17. ——— <i>trilobum</i>, a leaf divided to the middle into three parts, with convex margins; three-lobed.</p> <p>18. ——— <i>premorsum</i>, a leaf so blunted at the apex as to give the appearance of being bitten off.</p> <p>19. ——— <i>lobatum</i>, a leaf divided to the middle into several parts, with convex margins; a lobed leaf.</p> <p>20. ——— <i>quinquangulare</i>, a five-angled leaf.</p> <p>21. ——— <i>erosum</i>, an eroded leaf; a sinuated leaf, in which the margin is broken by smaller hollows, as if gnawed, or eaten away.</p> <p>22. ——— <i>palmatum</i>, a palmate or hand-shaped leaf.</p> | <p>Fig.
23. <i>Folium pinnatifidum</i>, a simple leaf resembling a pinnate or winged compound one.</p> <p>24. ——— <i>laciniatum</i>, a leaf that is irregularly cut; a jagged leaf.</p> <p>25. ——— <i>sinuatum</i>, a leaf that has hollows, or wide gaping breaks, on the sides, (<i>sinus</i>, a bay.)</p> <p>26. ——— <i>dentato-sinuatum</i>, a leaf, the <i>sinuses</i> of which are indented.</p> <p>27. ——— <i>retrosum-sinuatum</i>, a leaf, the <i>sinuses</i> of which are turned backwards.</p> <p>28. ——— <i>partitum</i>, a leaf deeply divided.</p> <p>29. ——— <i>repandum</i>, a waved, scalloped, or serpentine-edged leaf.</p> <p>30. ——— <i>dentatum</i>, an indented leaf.</p> <p>31. ——— <i>serratum</i>, (<i>serra</i>, a saw,) a leaf having teeth resembling those of a saw, which point to the apex.</p> <p>32. ——— <i>duplicato-serratum</i>, a leaf that has a row of lesser serratures placed upon the greater ones; twice-serrated.</p> <p>33. ——— <i>duplicato-crenatum</i>, a leaf in which there is a double row of the segments termed <i>crena</i> or notches, the lesser placed upon the greater; twice-notched. Vide Fig. 38.</p> <p>34. ——— <i>cartilagineum</i>, a leaf having a cartilaginous or gristly edge.</p> <p>35. ——— <i>acutè-crenatum</i>, a leaf acutely notched.</p> <p>36. ——— <i>obtusè-crenatum</i>, a leaf obtusely notched.</p> <p>37. ——— <i>plicatum</i>, a leaf plaited like a fan, or a candle-shade.</p> <p>38. ——— <i>crenatum</i>, (<i>crena</i>, a notch) a leaf, the edges of which are cut into small segments, whether acute or obtuse, which point not to either extremity. Vide Fig. 33. and 36.—a notched leaf.</p> |
|--|---|

PLATE II.

SIMPLE LEAVES *continued.*

- Fig.
39. *Folium crispum*, a curled leaf.
40. ——— *obtusum*, a leaf which terminates obtusely.
41. ——— *acutum*, a leaf which terminates in an acute angle.
42. ——— *acuminatum*, a leaf whose apex is subulate or awl-shaped. (Vide Fig. 8.)—an acuminate leaf.
43. ——— *obtusum acumine*, a sharp-pointed leaf, which does not begin to taper till very near the apex—obtuse with a point.
44. ——— *emarginatum acutè*, a leaf, the apex of which is deficient in its margin, and ends sharply.
45. ——— *cuneiforme emarginatum*, a leaf that is shaped like a wedge, and has a rounded notch or deficiency at the apex.
46. ——— *retusum*, a leaf which ends in an obtuse sinus.
47. ——— *pilosum*, a leaf, from the surface of which proceed long distinct hairs.
48. ——— *tomentosum*, a leaf whose surface is covered with a beautiful white down. Vide *tomentum*.
49. ——— *hispidum*, a leaf whose surface is covered with hard bristles.
50. ——— *ciliatum*, a leaf, the margin of which is fringed like an eye-lash, (*cilium*.)
51. ——— *rugosum*, (*ruga*, a wrinkle) a wrinkled leaf.
52. ——— *venosum*, a leaf whose surface abounds with veins or branched vessels.
53. ——— *nervosum*, a leaf whose surface abounds with nerves, ribs, or simple unbranched prolongations of the pedicle.
54. ——— *papillosum*, a leaf, from the surface of which arise little bladders or blisters, (*papilla*, a nipple.)
55. ——— *linguiforme*, a tongue-shaped leaf.
56. ——— *acinaciforme*, a leaf shaped like a Persian scimitar, (*acinaces*.)
57. ——— *dolabriforme*, a leaf which in figure resembles a hatchet, (*dalabra*, a carpenter's axe.)
58. ——— *deltoides*, a leaf imagined to resemble the Greek delta, as in black poplar.
59. ——— *triquetrum*, a three-sided leaf, as in *anthericum ossifrugum*.
60. ——— *canaliculatum*, (*canaliculus*, a little pipe, or channel) a channelled leaf; a leaf that has one longitudinal groove, running from the base to the apex on the upper surface, the lower being convex.

Fig.

61. *Folium sulcatum*, a furrowed or fluted leaf; a leaf that has several deep grooves or furrows, and in the same direction as the channelled leaf.
62. ——— *teres*, a cylindrical or pillar-shaped leaf.
63. ——— *panduraforme*, a leaf shaped like a violin, or Spanish guitar, as in *rumex pulcher*, (*pandura*, a musical instrument with three strings.)
64. ——— *lyratum*, a lyre-shaped leaf.

COMPOUND LEAVES.

1. *Folium binatum*, a fingered leaf with two leaflets.
2. ——— *ternatum foliolis sessilibus*, a fingered leaf with three leaflets that are sessile. See fig. 12. and 14 in Plate VI.
3. ——— *ternatum foliolis petiolatis*, a fingered leaf having three stalked leaflets; the reverse of the preceding term.
4. ——— *digitatum*, in general a fingered leaf; in the figure before us, in particular, a leaf of that description with five sessile leaflets.
5. ——— *pedatum*, a leaf somewhat resembling a bird's foot; exemplified in the passion flower, and black hellebore.
6. ——— *pinnatum, cum impari*, a pinnate or winged leaf with an odd leaflet at the apex.
7. ——— *abruptè pinnatum*, a pinnate leaf, which at the apex has neither an odd leaflet nor tendril.
8. ——— *pinnatum, alternatim*, a pinnate leaf having the leaflets placed alternately along the mid-rib.
9. ——— *pinnatum foliolis oppositis*, a pinnate leaf with opposite leaflets.
10. ——— *interruptè pinnatum*, a pinnate leaf with unequal leaflets—interruptedly winged.
11. ——— *pinnatum cirrhosum*, a pinnate leaf terminated by a tendril.
12. ——— **pinnatum conjugatum*, a pinnate leaf with only two pair of leaflets.
13. ——— *pinnatum decursivè*, a leaf decursively pinnate, that is, in which the leaflets run down or extend themselves into the stalk.
14. ——— *pinnatum articulatè*, a pinnate leaf, in which the common footstalk connecting the leaflets is articulate or jointed.

* The reader must be careful to distinguish betwixt *folium binatum* and *folium conjugatum*; the first being the lowest modification of the digitate or fingered leaf, the second the lowest of the pinnate or winged one.

Simple Leaves.

Compound Leaves.

Disposition of Leaves.

T. Sw. sculp.

PLATE III.

COMPOUND LEAVES *continued.*

- Fig.
16. *Folium biternatum*, a re-compounded leaf that is doubly-ternate, that is, has the common footstalk divided into three parts, each of which has three leaflets.
17. ——— *triternatum*, a leaf that is triply-ternate, that is, has the common footstalk divided into three parts, each of which is doubly-ternate.
18. ——— *bipinnatum*, a doubly-pinnate leaf.
19. ——— *tripinnatum sine impari* a triply-pinnate leaf, each pinna of which terminates abruptly.
20. ——— *tripinnatum cum impari*, a triply-pinnate leaf, with an odd leaflet at the apex of each pinna or wing.

DETERMINATION OR DISPOSITION OF LEAVES.

1. ——— *inflexum*, a leaf bent inwards, or towards the stalk.
2. ——— *erectum*, an erect leaf, or that is nearly perpendicular.
3. ——— *patens*, a leaf bent outwards, or declining from the stalk at an acute angle; a spreading leaf.
4. ——— *horizontale*, an horizontal leaf, which is placed at right angles with the stalk.
5. ——— *reclinatum*, a leaf that is bent downwards.

- Fig.
6. *Folium revolutum*, a leaf whose summits are rolled inwards.
7. ——— *seminale*, a seed-leaf.
8. ——— *caulinum*, a stem-leaf.
9. ——— *rameum*, a branch-leaf.
10. ——— *florule*, a leaf that is stationed near the flower.
11. ——— *decurrens*, a decurrent or running leaf; a leaf which extends itself downwards along the stalk beyond its proper basis.
12. ——— *petiolatum*, a leaf supported on a *petiolus* or footstalk.
13. ——— *peltatum*, a target-shaped leaf.
14. ——— *sessile*, a leaf that is seated immediately on the stem or branch, without any manifest footstalk; opposed to *petiolatum*.
15. ——— *amplexicaule*, a leaf which transversely embraces the stem by its base.
16. ——— *perfoliatum*, a perforated leaf. This leaf differs from the preceding chiefly in the perforation, which is likewise transverse, taking place at a greater distance from the margin.
17. ——— *connatum*, a leaf formed by the union of two leaves at the base.
18. ——— *vaginans*, a leaf, the base of which longitudinally surrounds the stem like a sheath. By the circumstance of its longitudinal perforation, this species of leaf may be easily distinguished from those described at No. 15. and 16.

PLATE IV.

DETERMINATION OF LEAVES *continued.*

- Fig.
19. *Folium articulatum*, a jointed leaf, a species of compound leaf, in which the leaflets are produced each from the summit of that immediately under it, as in *Cactus opuntia*. This singular appearance Berkenhout very properly compares to the links of a chain.
20. *Folia stellata*, leaves surrounding the stem in the form of a radiant star; synonymous to *verticillata*.
21. ——— *quaterna*, leaves growing by fours; a modification of the two former terms.
22. ——— *opposita*, leaves growing in pairs.
23. ——— *alterna*, leaves ranged singly in succession on both sides of the stalk; the reverse of the preceding term.
24. ——— *imbricata*, leaves laid over one another like tiles, (imbrex, a gutter tile) as in the genus *Saxifraga*.
25. ——— *acerosa*, chaffy leaves; leaves that are slender and of equal breadth throughout, somewhat hard, evergreen, pointed like pins, and surrounded at the base by chaffy scales. The term is exemplified in Fir, Pine, Yew, and Juniper.
26. ——— *fasciculata*, leaves which proceed in bundles (*fasciculi*) from the same point, as in the larch tree, and some pines.
27. *Frons*, a composition of a leaf and branch. The trunk of the palms and ferns is so termed by Linneus. This term serves as a connecting link betwixt leaves and trunks. The two following terms belong to the division containing simple leaves.

- Fig.
28. *Folium spathulatum*, a leaf shaped like a spatula, as in *Cistus incanus*, and *Phlomis purpurca*.
29. ——— *parabolicum*, a leaf which, in figure, somewhat resembles the geometrical curve termed a parabola.

TRUNKS.

1. *Culmus squamosus*, a scaly culm, straw, or haulm; a species of that trunk or stem which is peculiar to the grasses.
2. *Caulis repens & scandens*, a creeping and climbing stem, exemplified in *Bignonia* and Ivy.
3. *Scapus*, a species of trunk which elevates the fructification, but not the leaves; a naked flower-stalk, exemplified in *Auricula*, and many of the liliaceous plants.
4. *Culmus articulatus*, a culm or straw that has knots or joints at certain intervals.
5. *Caulis volubilis*, a twining stem, exemplified in *Convolvulus*, *Black Bryony*, and *Hop*.
6. ——— *dichotomus*, (*διχα*, in two parts, and *τεμνω*, to cut) a forked stem; a compound stem, the divisions of which are always by pairs; as in *Cerastium dichotomum*, and *Valeriana locusta*.
7. ——— *brachiatus*, (*brachium*, the arm) a simple stem, whose branches grow by pairs, resembling arms; as in *Mercurialis annua*.
8. *Stipes*, the trunk of a fungus. The term is likewise used for the *basis* or stalk of that peculiar species of trunk called a *frons*. See fig. 27. in the opposite column.

PLATE V.

SUPPORTS AND ARMATURE OF PLANTS.

Fig.

1. *Stipula*, { a stipule; a scale or scales at the insertion of the footstalks of the leaves and flowers.
- Cirrus*, { a clasper or tendril.
2. *Aculeus simplex*, that species of vegetable armature called prickles, (*aculei*) in which the weapons in question proceed singly from the stem or branch.
3. ——— *triplex*, prickles which grow by threes; a three-pronged prickle.
4. *Spina simplex*, a simple or single thorn.
5. ——— *triplex*, a triple thorn.
6. *Stimuli*, stings, as in the Nettle, *Acalypha* and *Tragia*.
7. *Bractea*, floral leaves; leaves which differ in colour and shape from the other leaves of the plant. In some species of Sage, Lavender, and Crown-

Fig.

- Imperial, they assume the appearance of a tuft of hair at the end of the flower-stem, and hence have obtained the name of *coma*.
8. *Glandula concava*, concave glandular appearances, seated on the footstalk of the leaves.
 9. ——— *pedicellata*, glands placed on short footstalks, and which likewise have their seat on the *petiolus*.
 10. *Pili*, hairs; a species of pubescence.
 11. A thorny leaf and branch.
 12. The prickly capsule of the Beech.
 13. *Pedunculus*, a flower-stalk.
 14. The thorny fruit of the Horse-chestnut.
 15. The prickly fruit of the Chestnut.

PLATE VI.

PLANTS AND USE OF PLANTS
ROOTS.

- Fig. 1. *Radix fusiformis*, a spindle-shaped root, as in Carrot.
 2. ——— *subrotunda*, a roundish root, as in Turnip.
 3. ——— *fibrosa*, a fibrous or stringy root, as in *Senecio vulgaris*.
 4. ——— *granulata*, a granulated root—a root consisting of a number of little knobs resembling grain, which are fastened to one another by small fibres or stings, as in *Saxifraga granulata*.
 5. ——— *præmorsa*, a root which ends abruptly, having the appearance as if bitten off. The term is exemplified in Plantain, and *Scabiosa succisa*.
 6. ——— *tuberosa, pendula*, a tuberous and pendulous root; as in *Spiræa filipendula*, or Dropwort.
- Fig. 7. *Radix fascicularis*, a species of tuberous root, in which the knobby parts grow in bundles. This is sometimes termed a grumous root, and is exemplified in *Ranunculus* and Peony.
 8. *Bulbus squamosus*, a scaly bulb, as in the White Lily.
 9. ——— *solidus*, a solid bulb, as in Tulip.
 10. ——— a transverse section of a solid bulb.
 11. ——— *tunicatus*, a coated bulb, as in Onion.
 12. ——— a transverse section of a coated bulb.
 13. The roots, or pattes, as they are termed, of Anemone.
 14. *Radix testiculata*, a twin-root, as in Orchis.
 15. The root of bird's nest, a species of *Ophrys*, which is evidently a modification of the fascicular or bundled root.

PLATE VII.

ROOTS continued.

Fig.

16. *Radix dentata*, a root whose knobs resemble teeth; a species of the granulated root, and exemplified in *Primula*.
17. ——— *palmata*, a hand-shaped root, as in the genus *Orchis*.
18. ——— *repens*, a creeping root; a root which extends in a horizontal direction, and sends forth radicles at certain intervals, as in the Couch-grass.
19. Bulbs produced in the angle formed by the leaf and branch, as in *Ranunculus ficaria*, or Pilewort.
20. Roots sent forth from the midrib of the leaf, as in Cuckoo-flower, (*Cardamine*.)
21. Roots produced from the joints of the stalk, as in *Potentilla reptans*.
- ~~~~~

PARTS OF FRUCTIFICATION.

a CALIX.

Fig.

1. *Perianthium*, the flower-cup properly so called.
2. *Amentum*, a catkin.
3. *Spatha*, a sheath; as in *Narcissus*.
4. { *Calix auctus*, an increased calix; a perianth, which has a row of leaves distinct from the flower-cup surrounding the base, as in *Dianthus*.
5. }
6. *Involucrum universale*, the universal *calix*, or cover of an umbelliferous flower, which is placed under the large or general umbel.
7. ——— *partiale*, the partial *calix*, or cover of an umbelliferous flower, which is placed under the smaller or partial umbel.
8. *Calyptra*, the calix of the Mosses.
9. *Volva*, the calix of the *fungi*, or mushroom tribe.
10. *Gluma*, the husky *calix* of the grasses.

PLATE VIII.

PARTS OF FRUCTIFICATION *continued.*

Fig.

1. *Corolla monopetala*, a corolla or flower of one petal.
2. ——— *hexapetala*, a corolla or flower of six petals.
3. ——— *polypetala serie duplici*, a corolla or flower of many petals, in a double series or row.
4. ——— *ringens*, a gaping or grinning flower; *a*, the upper lip, termed *galea* or helmet; *b*, the under lip.
5. ——— *papilionacea*, a butterfly-shaped flower.
6. Exhibits the several parts of a papilionaceous flower :
a, representing the *vexillum*, or banner;
bb the *alæ*, or wings;
c, the *carina*, or keel;
d, the *stamina*.
7. { *Corolla personata*, a masqued flower, or which resembles the snout of an animal;—*a*, the upper lip;
8. { *b*, the under lip.

(COMPOUND FLOWERS.)

Fig.

9. *Corolla composita flosculis ligulatis*, a compound flower with flat, tongue, or strap-shaped florets; the semifloscular flower of Tournefort.
10. *Flosculus ligulatus*, a flat or tongue-shaped hermaphrodite floret; the semi-floret of Tournefort.
11. *Corolla composita radiata*, a compound radiated flower, having semi-florets in the *radius* or circumference, and florets in the disk or centre.
12. The ligulated floret of a radiated flower, which wants both the sexual organs.
13. *Corolla composita flosculis tubulosis*, a compound flower with tubular or hollow florets; the floscular flower of Tournefort.
14. *Flosculus tubulosus*, a tubular or hollow floret; the floret properly so called.

Compound Flowers.

PLATE IX.

PARTS OF FRUCTIFICATION.

COROLLA continued.

- Fig.
 14. *Corolla campanulata*, a bell-shaped flower.
 15. } Different modifications of the same.
 16. }
 17. *Corolla infundibuliformis*, a funnel-shaped flower.
 18. ——— *hypocrateriformis*, a salver-shaped flower:
 a, the limb, (*limbus*) or upper spreading part
 of the petal;
 b, the tube, (*tubus*) or lower hollow part.
 19. ——— *cruciformis*, a cross-shaped flower.
 20. The petal of a cross-shaped flower, the upper spreading
 part of which, as of the petals of all polypetalous flowers,
 is termed *lamina*, the plate or border; the
 lower tapering part, *unguis*, or the claw.
 21. *Corolla rotata*, the back or under side of a wheel-shaped
 flower.
 22. The front or upper surface of a flower of the same
 description.

γ NECTARIUM.

- Fig.
 1. The flower of Aconite or Monk's-hood.
 2. The horned nectaries of the same, being two fistular
 nodding bodies, resembling stamina, with an oblique
 mouth and recurved tail, seated on long awl-shaped
 footstalks, and completely hid by the upper hel-
 met-shaped petal.
 3. A bell-shaped nectary, exemplified in *Narcissus triandrus*.
 4. The glandular nectary of Willow (*Salix*).
 5. *Nigella*, Fennel flower, or Devil-in-a-bush.
 6. The eight-lipped nectaries of the same.
 7. *Tropaecolum*, or Indian Cress, the nectary of which ter-
 minates the calix, and resembles a cock's spur.

PLATE X.

PARTS OF FRUCTIFICATION *continued.*

♂ SEXUAL ORGANS.

- Fig.
1. The germen or seed-bud of poppy, crowned with its flat, radiated, and target-shaped *stigma*.
 2. Exhibits the different parts of a pistillum, viz. *stigma*, style, and *germen*.
 3. Another illustration of the same.
 4. *Pistillum* of *Iris*.
 5. A *pistillum* with a three-cornered *stigma*, germen, and no style.
 6. *Pistillum* of *Oenothera*, or Tree-primrose:
 - a, the quadrifid *stigma*.
 - b, the style.
 - c, the germen.
 7. *Oenothera*:
 - a, the *pistillum*.
 - b, the *stamina*.
 - c, the petals.
 - d, the upper spreading part of the *calix*.
 - e, the tube, or long cylindrical lower part.
 - f, the *germen*.
 3. The parts of a stamen or male organ of fecundation, in which,
 - a, represents the *anther*,
 - b, the filament,
 - c, the pollen or fertilizing dust.

NECTARIUM *resumed.*

- Fig.
8. } Represent the singular nectaries of *Parnassia*.
 9. }
 10. Passion-flower with its nectary, termed by Linneus a triple crown.
 11. The nectary of Crown Imperial, being a *fovea* or pit in the base of each petal.
 12. The five-horned nectaries of Columbine, as connected with the flower.
 13. One of the horned nectaries of Columbine detached from the flower.
 14. The fringed or bearded nectarium in *Iris*.

MODES OF FLOWERING.

1. VERTICILLUS, a whirl or whorl.
2. FASCICULUS, a bundle or bunch.
3. SPICA, a mode of close inflorescence resembling a spike or ear of Wheat, Rye, or Barley.
4. RACEMUS, a cluster; as of Currants, Grapes, &c.
5. PANICULA, a panicle; a mode of loose inflorescence resembling that of Oats, and some other Grasses.

Sexual Organs.

Nectarium resumed.

Modes of Flowering.

Parts of Fructification resumed.

PLATE XI.

MODES OF FLOWERING *continued.*

- Fig.
6. **THYRSUS**, a panicle contracted into an oval form.
7. { **CYMA**, a cyme; a mode of inflorescence which differs
8. { from an umbel, in having the partial footstalks
placed without any regular order.
9. **CORYMBUS**, a mode of flowering, which, like the preceding, resembles an umbel in its general appearance, but may easily be distinguished by the unequal length of the footstalks, which do not, as in the umbel, proceed from the same centre, but are produced from different parts on both sides of the stalk.
10. **CAPITULUM**, a little head.

PARTS OF FRUCTIFICATION *resumed.*

ε PERICARPIUM, OR SEED-VESSEL.

1. A Capsule, with an undivided cavity or single cell.
2. ——— with two cells.
3. ——— with three cells.
4. ——— with four cells.
5. ——— with six cells.

- Fig.
6. A capsule with many cells.
7. That species of pod termed *legumen*, in which the seeds are fastened along one suture only.
8. *Folliculus*, a species of dry seed-vessel, which opens longitudinally on one side from bottom to top, and has the seeds loose within it.
9. Represents that pulpy kind of pericarpium termed *pomum*, with its inclosed capsule, having five cells, in which are contained the seeds.
10. *Drupa*, a pulpy seed-vessel of the Cherry kind, containing a nut or stone.
11. The section of a *drupa*, exhibiting the pulpy part and the stone.
12. A nut or seed covered with a shell.
13. *Strobilus*, a cone.
14. *Bacca*, a pulpy pericarp without valves, inclosing naked seeds.
15. The transverse section of a *bacca*, to exhibit the disposition of the seeds within the pulp.
16. { That species of pod termed *siliqua*, in which the
17. { seeds are fastened to both sutures or joinings of
the valves alternately.

PLATE XII.

THE CLASSES OR PRIMARY DIVISIONS OF THE SEXUAL SYSTEM.

The reader is referred to the Analysis or general scheme of this celebrated method, prefixed to the present work; as likewise to the explanation of each class in the Dictionary, under its respective title.

Fig.		Fig.	
1.	<i>Monandria.</i>	13.	<i>Polyandria.</i>
2.	<i>Diandria.</i>	14.	<i>Didynamia.</i>
3.	<i>Triandria.</i>	15.	<i>Tetradynamia.</i>
4.	<i>Tetrandria.</i>	16.	<i>Monadelpia.</i>
5.	<i>Pentandria.</i>	17.	<i>Diadelphia.</i>
6.	<i>Hexandria.</i>	18.	<i>Polyadelphia.</i>
7.	<i>Heptandria.</i>	19.	<i>Syngenesia.</i>
8.	<i>Octandria.</i>	20.	<i>Gynandria.</i>
9.	<i>Enneandria.</i>	21.	<i>Monœcia.</i>
10.	<i>Decandria.</i>	22.	<i>Diœcia.</i>
11.	<i>Dodecandria.</i>	23.	<i>Polygamia.</i>
12.	<i>Icosandria.</i>	24.	<i>Cryptogamia.</i>

THE ORDERS OR SECONDARY DIVISIONS OF THE SEXUAL SYSTEM.

- Fig.
1. The Order *Monogynia*, containing hermaphrodite flowers with one *pistillum* or female organ.
 2. *Digynia*, hermaphrodite flowers with two pistilla;—*a*, the pistilla detached from the flower.
 3. *Trigynia*, hermaphrodite flowers with three pistilla;—*a*, the pistilla separated.
 4. *Tetragynia*, hermaphrodite flowers with four pistilla;—*a*, the pistilla separated.
 5. *Pentagynia*, hermaphrodite flowers with five pistilla;—*a*, the pistilla separated.
 6. *Hexagynia*, hermaphrodite flowers with six pistilla;—*a*, the pistilla separated from the flower.
 7. *Heptagynia*, hermaphrodite flowers with seven pistilla;—*a*, the pistilla detached from the flower.
 8. *Decagynia*, hermaphrodite flowers with ten pistilla;—*a*, the pistilla separated.
 9. *Dodecagynia*, hermaphrodite flowers with twelve female organs.
 10. *Polygynia*, hermaphrodite flowers containing an indefinite number of pistilla, or female organs.
- Fig.
11. *Gymnospermia*, the name of the first order in the class *Didynamia*, in which *a* represents a longitudinal section of the flower, to display the four naked seeds in the bottom of the calix.
 12. *Angiospermia*, the name of the second order in the class *Didynamia*, containing such hermaphrodite flowers with four stamina, two longer than the others, as have their seeds contained in a vessel;—*a*, the pericarp, or vessel.
 13. *Siliculosa*, the first order in the class *Tetradynamia*, containing such flowers possessed of the classical character, as have their seeds contained in a short round pod;—*a*, the *silicula*, or pod, divided to shew the seeds.
 14. *Siliquosa*, the second order in the class *Tetradynamia*, containing such plants possessed of the classical character, as have their seeds contained in a *siliqua* or long slender pod, to each suture of which they are alternately attached;—*a*, the *siliqua*.
 15. *Polygamia æqualis*, the first order in the class *Syngenesia*;—*a*, a floret separated from the aggregate.
 16. ——— *superflua*, the second order in the class *Syngenesia*:—*a* represents a female floret in the circumference or ray; *b*, an hermaphrodite floret in the centre or disk.
 17. ——— *frustranca*, the third order in the class *Syngenesia*.
 18. ——— *necessaria*, the fourth order in the class *Syngenesia*.
 19. — — — *segregata*, the fifth order in the class *Syngenesia*.
a, a floret with its proper flower-cup detached from the aggregate.
 20. *Monogamia*, the sixth order in the class *Syngenesia*; *a*, representing a section of the flower, to exhibit the union of the stamina by the anthera.
 21. { *Triœcia*, the third order in the class *Polygamia*, in
 22. { which hermaphrodite flowers are intermingled with
 23. { male or female flowers, or both, on one, two, or three plants.
 24. *Filices*, Ferns, the first order,
 25. *Musci*, Mosses, the second order,
 26. *Algæ*, Sea-weed, the third order,
 27. *Fungi*, Mushrooms, the fourth order, } in the class *Cryptogamia*.

BOTANICAL TERMS.

A.

ABBREVIATUS, short.

Acalices, having no calix. See *Calix*.

Acaulis, stemless; wanting the caulis or stalk.

Acerosus, chaffy.

Acini, the small berries that compose the fruit of mulberry, strawberry, and bramble.

Acorn, the seed of the oak.

Acotyledones, plants not furnished with cotyledons or lobes, and which consequently do not put forth seminal leaves. See *Cotyledones*.

Acicularis, needle-shaped.

Acinaciformis, scymetar-shaped.

Acini, granulations.

Aculei, prickles; a species of weapon wherewith the stems and branches of several plants are furnished. See *Arma*.

Acuminatum, pointed, tapering to a point.

Acutus, (acute,) sharp, ending with an acute angle.

Adnatus, connected.

Adpressus, contiguous, laid to.

Adversifolia, plants whose leaves stand opposite to each other upon the same branch.

Aggregatus, (aggregate,) a flower consisting of a number of smaller flowers, collected into one head by means of some part common to them all.

Air-bag. See *Foliculus*.

Ala, wing; the name of a membrane affixed to some species of seeds, and which, by its flying, helps to disperse them.

Alatus. See *Winged Seed*, *Stem*, or *Leaf-stalk*.

Alburnum, the soft white substance which in trees is found between the inner bark and the wood, which in process of time acquiring solidity, becomes itself wood.

Algæ, flags, rushes; plants whose roots, leaves, and stem, are all in one.

Amaræ herbæ, bitter herbs.

Amentaceous, having that kind of calix termed *Amentum*, which see.

Amentum, or *catkin*; a species of calix consisting of many chaffy scales, dispersed along a slender thread or receptacle, and so called from its resembling the tail of a cat.

Amplexicaulis, embracing the stem.

Anceps, two-edged.

Androgyna, androgynous.

Androgynous, producing male and female flowers from the same roots.

Angiospermia, the second order of the class *Didynamia* in the Sexual System, consisting of plants whose characteristic it is to have four stamina, two of which are long and two short.

Angular stem, having edges or corners, opposed to cylindrical or round.

Angustifolius, narrow-leaved.

Annulus, a ring.

Anomalous, irregular; subject to no certain order.

Anther, *anthera*, or *apex*; the anther, summit, or top, of the stamen, connected with the flower, and elevated upon the filament or thread. See *Stamen* and *Filamentum*.

Apetalous, having no petals or corolla.

Apex. See *Anther*.

Aphyllous, leafless.

Aquaticæ, aquatics; plants which grow in or near the water.

Arachnoideus, cobwebbed.

Arbor, a tree; a perennial plant, which rises to a very great height, with a simple, woody, and durable stem or trunk. See *Herba*.

Arborescent, from herbaceous becoming woody.

Aril, a seed-coat, which covers the seed partially, or falls off spontaneously.

Arilled, seeds covered with outer coats.

Arista. See *Awn*.

Arma, arms; offensive weapons of plants, such as aculei or prickles. See *Aculei*: *Spinæ*, thorns; see *Spina*: *Furcæ*, forks: and *Stimuli*, stings; see *Stimuli*.

Articulus, a joint; that part of the culmus or stalk in grasses, which is intercepted, or lies between two joints or knots. See *Culmus*.

Asper, rough.

Asperifolia, rough-leaved plants.

Auriculatus, ear-shaped.

Autumnales, plants which flower in autumn.

Awl-shaped, slender, and becoming finer towards the end like an awl.

Awn, or *arista*, the slender sharp substance growing to the valves of corn or grass, and frequently called a beard.

Axilla, an armpit; the angle formed by the branch and stem, or by the leaf with either. Leaves are said to be axillary, which proceed from the angle formed by the stem and branch.

Axillaris, axillary.

Axillary, (axillaris) the base or bottom of the leaves, or branches, on the upper and inner side.

Axis, an axle-tree.

B.

Bacca, a berry; defined by Linneus to be a pulpy pericarpium or seed-vessel, without a valve or covering, and inclosing several naked seeds.

Barba, a beard; a species of pubes or down, with which the surfaces of some plants is covered. See *Pubes*.

Barbatus, bearded.

Bark. See *Cortex*.

Barren, such flowers or florets as produce no perfect seed.

Base. See *Axillaris*.

Battledore-shaped. See *Spatulatum*.

Beaded, granulated; consisting of many little knobs connected by small strings.

- Beak, or bill*, a long projecting appendage to some seeds, resembling the beak of a bird.
- Bell-shaped*, shaped like a bell.
- Berry*. See *Bacca*.
- Bicapsularis*, having two capsules. See *Capsule*.
- Biennial Plants*, those which continue alive two years.
- Bifarius*, pointing from opposite sides.
- Biferae*, plants which flower twice a year, in spring and in autumn, as is common between the tropics.
- Bifidus*, cleft, or cloven in two.
- Biflorus*, double-flowered.
- Bigeminum*, twin fork.
- Bijugum*, in two pairs.
- Bilabiata*, double-lipped (blossoms.)
- Bill*, (rostrum) a substance attached to a seed resembling a woodcock's bill.
- Bilobum*, two-lobed (leaves.)
- Biloculare*, two-celled seed-vessel.
- Binatus*, (binate) paired.
- Bipartitum*, deeply divided into two parts.
- Bipinnatum*, doubly-winged.
- Bird-footed*, (pedatus) bearing some resemblance to the feet of land-fowl, like the leaves of the passion-flower.
- Biternatus*, doubly three-fold.
- Bitten*, (præmorsus) appearing as if bitten off.
- Bivalve*, double-valved; a seed-vessel.
- Bladders*, (vesiculæ) a kind of air-bags.
- Bladder-shaped*, (inflatus) distended like a blown bladder.
- Blistered*, (bullatus) when the surface of a leaf rises high above the veins, like blisters.
- Blossom*. See *Corolla*.
- Blunt*, (obtusus) opposed to acute; sharp.
- Boat-shaped*, (navicularis) like a keel-bottomed boat.
- Border*, the upper-spreading part of the one-petalled corolla.
- Bordered*, (marginatus) having a border.
- Bowed*, (arcuatus) bent like a bow.
- Bractea*, a floral leaf; the name of one of the seven fulcra or props of plants, enumerated by Linneus.
- Branched*, (ramosus) having lateral divisions.
- Bristles*, strong stiff cylindrical hairs.
- Broad-topped spike*. See *Corymbus*.
- Brumales*, plants which flower in winter; common about the Cape of Good Hope.
- Bud*. See *Gemma*.
- Bulbus*, a bulb; a large kind of bud, generally produced under the ground, upon or near the roots of certain herbaceous plants, hence denominated bulbous.
- Bulbus articulatus*, a jointed bulb, composed of several plates or layers, closely linked together.
- Bulbus caulinus*, a bulb upon the stalk, instead of the root.
- Bulbus duplicatus*, or *testiculatus*, double or testicle bulb, two solid bulbs connected together.
- Bulbus solidus*, a solid bulb; as in the Tulip.
- Bulbus squamatus*, or *squamosus*, a scaly bulb, consisting of thin plates, or scales, laid over each other like tiles; as in the Lily.
- Bulbus tunicatus*, or *coated bulb*, as in the Onion.
- Bulging*, (gibbus) swoln out irregularly on one or more sides.
- Bullatum*. See *Blistered*.
- Bunch*, (racemus) a fruit-stalk furnished with short lateral branches.
- Bundle*. See *Fasciculus*.
- Bundled*, fasciculatus.
- Butterfly-shaped*, (papilionaceous) from an imaginary resemblance which some blossoms bear to that insect.

C.

- Caducous*, shedding; a term expressive of the shortest period of duration, which has different meanings, according to the different parts of the plant to which it may be applied.
- Cæspitosus*, matted together.
- Calcar*, the spur of the corolla; the nectarium, so called, which terminates the corolla behind, like a cock's spur, as in calve's-snout, violet, &c.
- Calcaratus*, spurred.
- Caliculatus*, double calix.
- Caliculus*, seed-coat cover.
- Calidæ*, plants that are natives of warm climates, such as the East Indies, South America, &c.
- Calix*, the outer covering of the flower, commonly called the flower cup, which in the greater number of plants incloses and supports the bottom of the corolla.
- Calyptra*, a veil or covering, placed over the antheræ or summits of the mosses, and in figure resembling an extinguisher, hood, or monk's cowl.
- Campanulatus*, bell-shaped.
- Canaliculatum*, channelled (leaf.)
- Cancellatus*, latticed.
- Candor*, the whites; a disease incident to trees.
- Capillaris*, hairlike; capillary or hair-shaped plants.
- Capitatus*, a knob of many flowers upon one stalk.
- Capitulum*, a little head, in which many flowers are connected together, as in the gomphrena, or globe amaranth.
- Capreolus*. See *Cirrus* and *Tendril*.
- Caprifigation*, the management of fig-trees.
- Capsule*, or capsula, a little chest or casket; it denotes a dry hollow seed-vessel, that cleaves or splits in some determinate manner.
- Carina*, a keel.
- Carinatus*, boat-shaped, or keeled.
- Carnosum*, fleshy, of a thick pulpy substance.
- Cartilagineum*, (cartilaginous) having a hard or horny edge.
- Castratio*, or the castration of plants, which is effected by cutting off the antheræ before they have attained maturity.
- Catkin*. See *Amentum*.
- Catulus*, catkin.
- Cauda*, a tail.
- Caudex*, the stock or body of the root, part of which ascends to produce the trunk of the plant, and part descends to form its roots.
- Caulescens*, having a stem or trunk, as most plants; opposed to *Acaulis*, which see.
- Caulis*, a stalk or stem, which elevates the leaves, flower, and fruit.
- Caulinus*, belonging to the stem.
- Cavus*, hollow.
- Cell*. See *Loculamenti*.
- Central florets*, those which occupy the central part of a compound flower.
- Central leaf-stalk*, is fixed not to the base, but to the middle part of a leaf.
- Cernuus*, bent (fruit-stalk.)
- Chaffy*, (acerosus.)
- Chaffy receptacle*, flower, or husk; set with a substance like chaff.
- Channelled*, (canaliculatus,) having a deep furrow from the base to the end.
- Characters*, marks or signs; the description of the genera of plants. See *Genus*.

Chive. See *Stamen*, *Stamina*.
Cicatrisated, scarred.
Ciliated, fringed, bordered with soft parallel hairs.
Cingent, binding round.
Circular, (*circularis*) round and flat, nearly in the form of a circle.
Circumcissa, cut round.
Circumference, (*circulus*) the part of a circle most distant from its centre.
Cirrosium folium, (*cirrose*) a leaf which terminates in a tendril.
Cirrus, a clasper or tendril; the fine spiral string or fibre by which some plants, as the ivy and vine, fasten themselves to trees or walls, &c. for support.
Clommy, viscous; adhesive, like bird-lime.
Clasper. See *Cirrus*.
Class A. the first and highest division in every botanical system, denotes the agreement of several genera in the parts of fructification, according to the principles of nature distinguished by art.
Clausus, closed.
Clavated, club-shaped.
Clavicula. See *Cirrus*.
Clavus, a species of disease, to which the grains of many grasses, particularly those of Rye, are subject.
Claw, (*unguis*) blossoms composed of several petals, which petals are often so formed as to admit of two distinct names, the claw and the limb; the claw is the lower part, by which it is connected with the base.
Cleft. See *Cloven*.
Climbing, (*scandens*) a term applied to plants which take the advantage of some adjoining body, to raise and support themselves, as the ivy.
Close. See *Conglomerated*.
Clothing, means every kind of hairiness on the surface of plants. See *Bristles*, *Cotton*, *Hair*, *Wool*.
Cloven, (*fissus*) divided half way down.
Club-shaped, (*clavatus*) flowers thicker at the base, and thinner upwards.
Cluster, (*thyrsus*) a collection of flowers, somewhat in an egg-shaped form.
Coadunate, jointed together at the base.
Coarctated, compact.
Coated, (*tunicatus*). See *Bulbus tunicatus*.
Cob-webbed, (*arachnoidens*) covered with a substance like a cobweb.
Coccum. See *Loculamenti*.
Cochleated, pod; convoluted like a snail-shell.
Coloratus, coloured.
Coloured, (*coloratus*) when a leaf or cup is of any other colour than green.
Column, (*columnella*) the upright little pillar in the centre of some capsules, to which the seeds are fixed.
Columnar, differs from cylindrical, by tapering upwards, like the shaft of a column, and is thus applicable to stems, some leaves, &c.
Columnella, a column; the substance that passes through a capsule, and connects the several internal partitions with the seeds.
Coma, a bush of hair, or collection of floral leaves; a comb. See *Bractea*.
Comb-like, a sort of winged leaf, the leaflets of which are like the teeth of a comb.
Common fruit-stalk, bearing several flowers.
Compact, firm
Compact, (*coarctatus*) growing close, and as if were pressed together.

Complectus, a complete flower; viz, one provided with both the covers, namely, the calix or flower-cup, and the petals, i. e. both a cup and a blossom.
Complicated, doubled together.
Composite, a compound flower, formed from the union of several lesser flowers, within the same calix, each of which has five stamina, distinct at bottom, but united at the top by the antheræ, and forming a cylinder, through which a style, considerably longer than the stamina, passes, and is crowned by a stigma or summit, with two divisions rolled backwards.
Compound berry, where one large berry is composed of several small ones, as in the raspberry.
Compound bunch, composed of several lesser bunches.
Compound corymbus, composed of several small corymbs.
Compound flowers. See *Composite*.
Compound leaf, when each leaf-stalk supports more than one leaf; or when one leaf is inserted into another.
Compound spike, composed of several little spikes or spikets.
Compound umbel, when each umbel is subdivided into other little umbels, or umbellules.
Compressed, (*compressus*) a term applied to a cylindrical surface more or less flattened.
Compressed leaf, one that is thicker than it is broad.
Concave, hollowed out like a bowl.
Conceptaculum, a receiver, or species of seed-vessel, with one valve, opening from top to bottom on one side, and having no suture to fasten the seeds within it.
Conduplicate, doubled, or folded together.
Cone. See *Strobilus*.
Cone-shaped, leaves rolled up like cones.
Confertus, crowded.
Confluent leaves, (*confluentia folia*) leaves running into each other at the base.
Congestus, heaped together.
Conglobate. See *Conglomerate*.
Conglomerated, flowers heaped or wound together, and growing upon a branched foot-stalk, to which they are irregularly but closely connected.
Congregata. See *Composite*.
Congregated. See *Conglomerated*.
Conical, (*conicus*) in the form of a sugar-loaf.
Conifera, cone-bearing plants.
Conjugate, a winged leaf, with only one pair of leaflets.
Connate, united at the base.
Connected, (*adnatus*) leaves or stipulæ, such as have their upper surface at the base, growing to the stem or branch.
Connivent, converging or approaching; closing.
Contiguous, (*adpressus*) when a leaf, branch, or seed-vessel rises up so perpendicularly, as to stand almost parallel, and close to the stem, as if pressed to it.
Contortæ, twisted plants.
Contrarium. See *Transverse*.
Conus, a cone. See *Strobilus*.
Converging, approaching each other at top.
Converging antheræ, leaning towards each other.
Converging filamenta, as in borage.
Converging leaves, bent inwards towards the stem.
Converging petals, leaning towards the centre of the flower.
Convex, opposed to concave; like the surface of a globe.
Convolute, rolled or twisted spirally.
Corculum, corcle, or heart of a seed.
Cordated, heart-shaped.
Coriaceous, stiff; leather-like.
Cornuted, horn-shaped.

Corolla, Linneus's name for the beautiful coloured leaves of the flowers which individually are called petals, standing within the calix, and being supported by it. See *Petalum*.

Corollula, a little corolla.

Corona, a crown.

Coronariæ, a wreath, chaplet, or garland.

Cortex, the rind, or coarse outer bark of plants.

Corticose, full of bark, barky.

Corymb, differs from a spike, in having the flowers whereof it is composed, not sitting, but standing, each on its proper fruit-stalk, each of which again springs out of one common fruit-stalk.

Costated, ribbed (leaf).

Cotton. See *Tomentum*.

Cotyledons, the perishable, porous side-lobes of the seed, which involve, and for some time furnish nourishment to, the embryo plant.

Creeping stem, creeping along the ground, and sending forth little roots.

Creeping root, as in the spearmint.

Crenated, scolloped.

Crescent-shaped, (lunularis) shaped like a new moon.

Crested, (cristatus) flowers furnished with a tuft or crest, as milk-wort.

Cross pairs, (decussatus) when leaves grow in pairs, and each pair points in a different direction to the pair next above or below it.

Cross-shaped, (cruciat.) See *Cruciform*.

Cruciated, cross-shaped.

Cruciform, a cross-shaped flower, formed of four equal petals, which spread at top, in form of a cross.

Cryptogamia, a concealed marriage. The name of the 24th class of the Linnean system.

Cryptogamous, those plants whose fructifications are invisible or undiscovered.

Cubit, about half a yard.

Cucullated, hooded, cone-shaped.

Culm, the straw or trunk of the grasses, which elevates the leaves, flower, and fruit.

Cuneiform, wedge-shaped.

Cup. See *Perianth*.

Cup, double, when one cup has another surrounding its base.

Curled, (crispus.)

Curtain, (volva.)

Cuspidated, prickly-pointed.

Cut round, (circumcissus) when a seed-vessel does not open longways, in the usual manner, but in a circle surrounding it, like a snuff-box or ivory egg, as in pimperl.

Cyathiform, glass-shaped.

Cylindrical, round.

Cyma, a tuft; a mode of flowering, in which a number of slender foot-stalks proceed from a common centre, and rise to the same height.

D

Dagger-pointed, not gradually tapering to a point, but ending suddenly, like a dagger's blade.

Decagynia, from *δεκα*, ten; and *γυνη*, a woman: the name of an order, or secondary division, in the class Decandria, consisting of plants whose flowers have ten stamina, and the same number of styles.

Decandria, from *δεκα* ten; and *ἀνηρ*, a husband: the name of the tenth class in Linneus's Sexual System, consisting of plants whose flowers have ten male organs or stamina.

Decaphyllous, ten-leaved.

Decemfidus, a cup with ten clefts.

Decemlocular, ten-celled.

Deciduous, or *Deciduus*, a term expressive of the second stage of duration in plants: thus a leaf is said to be deciduous which drops in autumn; as are also petals which fall off with the stamina and pistillum. The calix of the Thornapple, which falls off before the blossom, is said to be deciduous.

Declining, (declinatus) bent like a bow, with the arch downwards.

Decomposite flowers, those which contain within the same common calix a number of lesser or partial flower-cups, that are each of them common to many florets.

Decumbent, lying down; a drooping flower, in which the stamina and pointal are inclined toward the lower side, as in pea-bloom, wild senna, &c.

Decurrent, (decurrens) leaf; when there is no leaf-stalk, but the base of the leaf runs down the stem.

Decussated, cross-pairs.

Deflex, down-hending.

Deflexus, bending rather outwards.

Deflorated, applied to antheræ which have shed their pollen.

Defoliation, the falling off of the leaves.

Dehiscentia, the bursting open of the antheræ for dispersing the male dust; as likewise of the seed-vessel called a capsule, for discharging the seeds when ripe. See *Anther*, and *Capsule*.

Dehiscent, opening or standing open. See *Dehiscentia*.

Deltoides, triangular; spear-shaped, or trowel-shaped.

Demersus. See *Submersus*.

Dendroides, shrub-like.

Dentato-serrated, tooth-serrated.

Dentato-sinuated, toothed and indented.

Dentated, toothed.

Dented, (retusus,) a blunt leaf, with a dent or blunt notch at the end.

Denticulated, set with little teeth.

Dependent, hanging down.

Depressed, (depressus) when the surface of a leaf, &c. is in a small degree concave; pressed down, flatted.

Diadelphia, from *δῖς*, twice; and *ἀδελφία*, a brotherhood; two brotherhoods: the seventeenth class of the Sexual System, consisting of plants whose flowers are hermaphrodite, and have the stamina, or male organs, united below into cylindrical filaments.

Diamond-shaped, (rhombus) leaves whose figures resemble the diamonds upon cards.

Diandria, from *δῖς*, twice; and *ἀνηρ*, a husband: the name of the second class of Linneus's Sexual System, consisting of hermaphrodite plants, which have flowers with two stamina or male organs.

Dichotomous, forked.

Dicoccus, two capsules, united each with one cell.

Dicotyledons, plants whose seeds have two side-lobes, and consequently rise with two seminal leaves: most plants are of this kind.

Didyma, double.

Didynamia, from *δῖς*, twice; and *δυναμις*, power; two powers; the fourteenth class of the Linnean system, which has four stamina, or male organs, two long and two short.

Difform, irregular in shape; of different shapes.

Diffuse, spreading.

Digitated, finger-like.

Digynia, *δύς*, twice; and *γυνή*, a woman: the name of an order, or secondary division, in each of the first thirteen classes in Linneus's Sexual System, except the ninth and twelfth. It consists of plants, which, to their respective classic characters, add the having two styles or female organs.

Dimidiated, half-round; extending half way round.

Dimpled, (umbilicated) having a little hollow dot.

Diœcia, from *δύς* twice; and *οἰκία*, a house; two houses: the twenty-second class of the Sexual System, containing plants which, having no hermaphrodite flowers, produce male and female flowers on separate roots.

Dipetalous, double-petalled.

Diphyllous, double-leaved.

Discus, or *disk*, signifies the centre of a radiated compound flower, and generally consists of small florets, with a hollow regular petal.

Disk, (discus.)

Dispermous, double-seeded.

Dissectum. See *Laciniatum*.

Dissemination, the scattering abroad the seeds of vegetables, for the purposes of increase.

Dissepimentum, a partition, which in dry seed-vessels, as capsules and pods, divides the fruit internally into cells.

Dissilient, bursting suddenly asunder.

Distant, far asunder.

Distented, (ventricosus) or bellying, as the cup of the rose.

Distichous, double-rowed.

Distinct, unconnected; separated from each other.

Divaricate, straddling.

Diverging, (divergens) spreading wide from the stem, almost horizontally.

Divided, (partitus) applied to a leaf, a cup, or a petal, signifies them to be parted more than half way down.

Divisions. See *Divided*.

Dodecagynia, the name of one of the orders in the eleventh class, having twelve to eighteen pistils in each flower.

Dodecandria, from *δωδεκα*, twelve; and *ἀνὴρ*, a husband: the name of the eleventh class of the Sexual System, consisting of plants with hermaphrodite flowers, which have twelve stamina or male organs.

Dodrans, a palm; about a quarter of a yard.

Dolabriform, hatchet-shaped leaf.

Dorsal, fixed to the back.

Dotted, (punctatus) marked with little hollow dots.

Double, (didymus) applied to the antheræ, where two are united like a double nut.

Double calix, when one calix has another outer one surrounding it.

Doubled, (conduplicatus.)

Double germen, when two germina are united together.

Double compound, (decompositus) leaves with the primary leaf-stalk divided, so that each division forms a compound leaf.

Down. See *Pappus*.

Down-bending, deflex.

Downy, (leaf.) See *Tomentum*.

Drooping, (nutans) grass panicles, whose spikets often hang down in a beautiful pensile form.

Drupe, a pulpy seed-vessel without valves, consisting of a hard nut or stone, surrounded by a pulpy substance; as cherries, plums, &c.

Dumosa, bushy plants.

Duplicate. See *Duplicated*.

Duplicated, doubled; having the corolla doubled: or, in other words, the term is expressive of the least degree of

luxuriance of which the petals are susceptible, and is exemplified in campanula with a nettle-leaf, and thorn-apple with a violet flower; it is very common in flowers of one petal.

Duplicato-crenated, doubly scalloped.

Duplicato-pinnated, doubly serrated.

Duplicato-ternated, doubly-threefold.

Dust. See *Pollen*.

Dusted, (pulveratus) some plants appear as if covered with a kind of dust or powder.

E

Ear-shaped, (auriculatus) like a human ear; also used to signify a little appendage at the base of a leaf or leaflet.

Ebracteated, without any floral leaf.

Ecalcarated, without a spur or thorn.

Echinated, set with prickles.

Efflorescent, blooming; a term expressive of the precise time of the year and month, in which every plant throws its first flowers. See *Florescent*.

Egg-shaped, (ovatus) a shape resembling the solid substance of an egg.

Elliptic, of an equal breadth at each end. See *Oval*.

Emarginatum, (emarginate) end nicked or notched.

Embracing, (amplexicaulis) when the base of a leaf nearly surrounds the stem.

Enervious, nerveless.

Enneandria, from *ἐννέα*, nine; and *ἀνὴρ*, a husband; the name of the ninth class in Linneus's Sexual System, consisting of plants with hermaphrodite flower, with nine stamina, or male organs.

Enodis, without joints.

Ensiform, sword-shaped, tapering to a point.

Epidermis, the scarf-skin, or outer covering of the bark of plants.

Equitant, folded upon one another, laminated.

Erect, in opposition to decumbent, or a nodding or drooping flower.

Erose, gnawed, irregularly cut or notched.

Essential Character, the circumstance which distinguishes one genus from every other.

Eumuch, full flowers so called, which, by multiplying the petals altogether, exclude the stamina or male organs of generation, and thus render the seed barren.

Even surface, level, regular, in opposition to scored or furrowed.

Evergreen, bearing green leaves throughout the year.

Exarated. See *Furrowed*.

Extrafoliaceous, underneath the leaves.

Eye. See *Hilum*.

F

Fartus, or *Farcitus*, filled full.

Farina. See *Pollen*.

Fasciated, bundled; plants so called, which consist of several stems or stalks growing close together, so as to form a compact bundle.

Fasciculated, bundled.

Fasciculus, a little bundle, in which the flower-stalks are erect, parallel, placed close to one another, and of the same height, as in sweetwilliam.

Fastigated, flat-topped.

Fauces, the jaws or chaps, otherwise the gaping at the top of the tube of a monopetalous flower.

Favosum, honey-combed.

- Feathered*, (plumosus): the down of seeds, which sometimes consists of fine, simple, or undivided hairs; in other instances, sends out lateral hairs, and is then said to be feathered.
- Feeble*, (debilis) too weak to stand upright.
- Femineus*, a female flower, which is furnished with the pistillum, or female organ of generation, but wants the stamina, or male organ.
- Ferruginous*, of the colour of rust of iron.
- Fibrous*, composed of small threads or fibres.
- Filament*, a thread; the lower slender thread-shaped part of the stamina, that serves as a foot-stalk for elevating the antheræ, and connecting them with the vegetable.
- Filiform*, thread-shaped.
- Fimbriate*. See *Fringed*.
- Fingerlike*, compound leaves, like the expanded fingers of a man's hand.
- Fissum*, cloven, or split.
- Fistulose*, hollow.
- Flagellum*, a runner.
- Florescent*, the act of flowering, which Linneus compares to the act of generation in animals; as the ripening of the fruit, in his judgment, resembles the birth.
- Floret*, a little flower. See *Floscule*.
- Flos*, the flower, according to the Linnean system, consists of the antheræ and stigma, whether the covers, i. e. the calix and petals, are present or not.
- Floscule*, a partial or lesser floret of an aggregate flower. See *Aggregate*.
- Foliaceous*, leafy.
- Folium*, a leaf; according to Miller, a part of a plant extended into length and breadth, so as to have one side distinguishable from the other. According to Linneus, leaves are the organs of motion, or muscles of the plant.
- Folliculus*, air-bag; a species of seed-vessel. See *Conceptaculum*.
- Forked*, (furcatus.)
- Fornicated*, vaulted.
- Four-cornered*, (tetragonus.)
- Frigida*, plants that are natives of cold climates, as Siberia, Canada, Germany, Holland, England.
- Fringed*, (ciliatus.)
- FronDESCENT*, a term signifying the precise time of the year and month in which each species of plants unfolds its first leaves.
- Fructescent*, comprehends the precise time in which, after the fall of the flowers, the fruits arrive at maturity, and disperse their seeds.
- Fructification*, comprehends the flower and the fruit, and is defined to be a temporary part of plants, appropriated to generation, ending the old vegetable and beginning the new.
- Frutex*, a shrub; a plant which rises with a woody durable stem, higher than that of under-shrubs, but inferior to that of trees. Trees always rise with a single body or trunk; many shrubs have several stems growing out of the same root.
- Fruticose*, shrub-like.
- Fulcra*, props, supports; certain minute external parts, which serve either to support or defend the plants, or to promote some necessary secretion.
- Fuliginose*, sooty.
- Fungi*, mushrooms.
- Funnel-shaped*, a monopetalous blossom, of which the lower part is tubular, and the upper part conical; as in Hounds-tongue, Bugloss, Cowslip, &c.
- Furca*, a fork; *furcæ* forks.
- Furcated*, forked.
- Furrowed*, (sulcatus) marked with deep lines running lengthways.
- Fusiform*, spindle-shaped.

G

Gemma, a bud; a compendium of a plant, seated upon the stem and branches, and covered with scales to defend it from cold and injuries till the time of unfolding. It is generally gummy and resinous.

Geniculated, knee-jointed.

Geniculum, knee-joint.

Genitalia, genitals, i. e. the antheræ and stigmata of flowers, the former being the male, and the latter the female organs of generation in plants.

Genus, a race or kind; the third of the five numbers of the Linnean system, is an assemblage of several species, that is, of plants resembling each other in their most essential parts. *Genus* is the singular of *Genera*.

Germen, the seed-bud; the base of the pistillum, containing the rudiments of the seeds.

Gibbous, swelling.

Gills, (lamellæ) thin plates on the under side of the pileus or hat of a mushroom.

Glabrous, smooth.

Glaucous, clothed with a fine mealiness.

Glands, a species of secretory or excretory vessels found on the surface of some plants.

Glandular, bordered with pores.

Glass-shaped, tubular; like a drinking-glass; as the calix of Jacob's ladder.

Globular, like a round ball.

Globulous, globular.

Glochis, a barbed point.

Glomerate, congregated.

Glossy, smooth, shining.

Glume, a husk; the calix of the grasses, composed of one, two, or three valves; a kind of scale commonly transparent in the margin, and most frequently terminated by a pointed thread, termed a beard.

Glutinous, covered with a slippery or adhesive slime.

Grain. See *Beaded*.

Granulated. See *Beaded*.

Gristly, cartilaginous, as in the edge of some leaves, which are stronger and more transparent than the rest.

Gymnospermia, from *γυμνος*, naked; and *σπέρμα*, seed: the name of an order or secondary division belonging to the Linnean class Didynamia, the plants of which have four stamina, two long and two short, and four naked seeds.

Gynandria, from *γυνή*, a woman; *ἀνὴρ*, a husband: the name of the twentieth class in the Sexual System of Linneus, the plants whereof have hermaphrodite flowers, in which the stamina are placed upon the style, or upon a pillar-shaped receptacle resembling a style, which rises in the middle of the flower, and supports both the stamina and pointal.

H

Hair-like, slender; undivided and cylindrical.

Hairs, (pili) are supposed to be the excretory ducts of vegetables.

Halbert-shaped, (hastatus) as the floral leaves of the pansie.

Hamosus, or *Hamatus*, hooked.

Hamus, a hook, or species of bristly armour, in which each bristle is bowed inwards at the top.

Handbreadth, (palmus.) See *Dodrans*.
Hand-shaped, (palmatus) resembling a human hand with the fingers expanded.
Hastated, halbert-shaped, triangular.
Hat, (pileus) the top of mushrooms, &c. sometimes called the flap.
Heads, (capitatus) of flowers; where flowers grow together in compact knobs.
Heart. See *Corculum*.
Helmet, (galea) the upper part of a gaping blossom.
Hemispherical, in the shape of half a globe.
Heptandria, from ἑπτα, seven; and ἀνὴρ a husband: the seventh class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, which have seven stamina or male organs.
Herb, that portion of every vegetable which arises from the root, and is terminated by the fructification.
Herbacea, herbaceous plants, which perish down to the root every year.
Herbaceous stem, one that is succulent and tender, not hard and woody.
Hermaphroditus, hermaphrodite; a flower which contains both the antheræ and stigma, the organs of generation, within the same calix and petals.
Hexagynia, from ἕξ, six; and γυνή, a woman: an order or secondary division in the Sexual System, consisting of plants which, besides their classic distinctions, have their flowers furnished with six styles, or female organs.
Hexandria, from ἕξ, six; and ἀνὴρ, a husband: the name of the sixth class of the Linnean system, the plants of which have hermaphrodite flowers, furnished with six stamina, or male organs, of an equal length.
Hexagonous, hexagonal; six-sided.
Hexapetalus, six petals.
Hexaphyllous, six-leaved.
Hians, open, in opposition to closed.
Hilum, the external mark or scar of a seed, in the place where it was fastened within the pericarpium, as in the bean, &c.
Hirsutus, strong-haired, shaggy.
Hirtum, hairy, clothed with soft hairs.
Hispid, bristly.
Hoary, (incanus) covered on one or both sides, with a very fine white silvery-looking substance.
Hollow, (cavus) as is a straw.
Hooded. See *Cucullatus*.
Hoof-shaped, (ungulatus).
Hook, (hamus).
Horizontal, parallel to the ground.
Hunched. See *Bulging*.
Husk. See *Glume*.
Hybernaculum, winter-quarters; that part of a plant which defends the bud from injuries during the severities of winter.
Hibrida, hybrid; a monstrous production of two different species of plants, analogous to a mule among animals: the seed of hybrid plants will not propagate.
Hypocrateriformis, salver-shaped.

I & J

Jagged, leaves divided into lobes, which are again subdivided in an irregular manner.
Icosandria, from εικοσι, twenty; and ἀνὴρ, a husband: the twelfth class of the Linnean stem, consisting of plants with hermaphrodite flowers, furnished with twenty or more stamina, that are inserted into the inner side of the calix, or petals, or both.

Imberbis, beardless.
Imbricate, (imbricatus).
Imbricatus, indented.
Imperfect flowers, wanting either pistil or anther, or both.
Inæqualis, unequal.
Inanis, pithy.
Incanus, hoary.
Incisus, cut or jagged; snipt.
Inclinans, leaning.
Includens, enclosing.
Incompletus, incomplete.
Incrassatus, thickest upwards.
Incurvatus, bowed inwards.
Indented, hollowed, deeply scolloped.
Indivisum, leaf undivided.
Inermis, unarmed.
Inferus, beneath. *Inferior*, is applied principally to the germen when it is placed below the cup.
Inflated, distended like a bladder.
Inflexus, bent inwards.
Inflorescentia, a mode of flowering; the manner in which flowers are supported on their foot-stalks.
Integrum, undivided.
Intorsio, twisting.
Intrafoliaceus, within the leaves.
Involucrum, rolled up; a species of calix, restricted by Linneus to umbelliferous flowers. See *Umbella*.
Involutus, (involute) rolled inwards.
Joint, (articulus).
Jointed, (articulatus) stem, as in a wheat straw.
Irregularis, an irregular flower, which wants uniformity: the term generally applies to the petals.
Juga, pairs; *bi-juga*, two pairs; *tri-juga*, three pairs: applied to the leaflets of a compound leaf.

K

Keel, (carina) a name given to the lowermost petal in a butterfly-shaped blossom, from its supposed resemblance to the keel of a ship.
Keeled, (carinatus) bent like the keel of a ship or boat.
Kidney-shaped, (reniforme) as the seed of the French bean.
Knee-jointed, (geniculatus) when a straw or stem is a little bent at the joints.
Knob, a head. See *Capitulum*.
Knot, (nodus) a joint; remarkable in the stems or straws of (the grasses and reeds.)

L

Labiatus, (labiate) a flower having lips.
Labium. See *Lip*.
Lacerus, ragged.
Lacinia, segments.
Laciniatum, cut, or as it were torn.
Lactescentia, producing milk; a term applied to the juices or liquors, of whatever colour, which flow out of plants when any injury is done to them.
Lacunosum, pitted.
Lævis, level, smooth.
Lamellæ, gills.
Lamina, a thin plate or border; the upper spreading part of a flower, consisting of more than one petal.
Lana, wool: a kind of down or velvet, which serves as a veil to screen the leaves and branches, which are covered with it from the extremities of heat.
Lanatus, woolly.

Lanceolatus, spear-shaped.
Lanceolato-ovatum, spear egg-shaped.
Lanugo, soft wool or down.
Lateral, branches or flowers; those growing from the sides of the stem, opposed to terminating.
Latticed, (cancellatus) open like lattice-work.
Laxus, limber, loose.
Leaf. See *Folium*.
Leaflet, a little leaf; a single leaf, or part of a compound leaf.
Leaf-stalk, (petiolus) the foot-stalk of a leaf.
Leather-like, tough and pliable like leather.
Legumen, that species of the seed-vessel termed a pod, in which the seeds are fastened along one suture only.
Leprosus, rough like the skin of a leper.
Liber, the inner bark or rind of plants.
Lignosus, woody.
Lignum, wood.
Ligulatus, strap-shaped.
Limbus, (limb) the limb or upper expanded part of a flower, consisting of only one petal, opposed to the tube, which is the lowest part.
Linear, narrow, with the sides as nearly parallel as possible.
Lingulate, tongue-shaped.
Lip, (labium) the upper or under division of a gaping blossom.
Lobatus, lobed, with the margins of the segments rounded.
Lobes, divisions nearly half way down the leaves, which are convex at the edges, and distant from each other.
Loculamenti, and *loculi*, cells or pockets: the internal divisions of a capsule, or other dry seed-vessel, so termed.
Lopped, (truncatus) appearing as if cut off.
Lucidum, transparent.
Lunatum, *Lunulatum*, crescent-shaped.
Luxuriant, (luxurians.)
Luxurians, luxuriant, or double flower, some of whose parts are increased in number, to the diminution or entire exclusion of others.
Lyre-shaped, (lyratus) as the leaves of Herb Bennet.

M

Maculated, spotted; sprinkled with spots or stains.
Marcescens, shrivelling.
Marginatus, bordered.
Masculus, male; a flower which contains the stamina, or male organs of generation: but not the stigma, or female organ.
Matted, (cæspitosus) thickly interwoven together, as the fibres in turf-bogs.
Medulla, pith.
Membranaceous, (membranaceus) thin, shining, and semi-transparent, like parchment.
Mid-rib, the principal nerve which runs from the base towards the end of a leaf, along its middle.
Monadelphia, from *μονος*, alone; and *ἀδελφία*, a brotherhood: a single brotherhood. The sixteenth class in Linneus's Sexual arrangement; in which the plants have hermaphrodite flowers, with all the stamina or male organs of generation united below into one body or cylinder, through which the pointed or female organ passes.
Monandria, from *μονος*, alone; and *ἀνὴρ*, a husband: the first class of the Sexual System of Linneus; in which the plants have hermaphrodite flowers, with only one stamina or male organ.

Monocotyledones, single cotyledons; plants whose seeds have only one lobe, and consequently rise with a single seed-leaf.
Monæcia, from *μονος*, alone; and *οἰκία*, a house: the name of the twenty-first class of the Sexual System. The plants have male and female flowers placed apart; that is, within different covers on the same root.
Monogynia, from *μονος*, alone; and *γυνή*, a woman; the name of the first order of subdivision, in the first thirteen classes of the Linnean System. It consists of plants, which, besides their agreement in their classic distinctions, generally derived from their number of stamina, have only one pistil, or female organ.
Monopetalous, having only one petal. See *Petalum*.
Monophyllous, one-leaved.
Monosperma, one-seeded.
Monostachyos a single spike.
Mouth. See *Fauces*.
Mucronate, (mucronatum) sharp-pointed.
Mucronatum, mucronate; a dagger-pointed-leaf, sharp-pointed at the end.
Mules. See *Hybrida*.
Multangularis, many-cornered.
Multifidum, many-clefted.
Multiflores, many-flowered.
Multiloculare, many-celled.
Multipartita, having many deep divisions.
Multivalvis, many-valved; more than two.
Muricatus, covered with sharp points.
Musci, mosses.
Muticus, awnless. See *Awn*.
Mutilus flus, a mutilated flower; so called, when deprived of the whole or a greater part of its petals.

N

Nail. See *Claw*.
Naked, (nudus) destitute of leaves; as the tulip or cowslip stalk.
Nap. See *Tomentum*.
Narrow, (ligulatus) the florets in some compound flowers, one tubular at the bottom, but flat and narrow, like a strap or fillet at the top.
Natans, floating.
Nectarium, (nectary) or honey-cup, a part of the corolla, containing that species of vegetable salt, called honey, or nectar, which oozes from the plant in a fluid form, and is the principal food of bees and other insects.
Nervosum, fibrous, ribbed.
Neutral, flowers or florets, such as contain neither stamina nor pistilla, and therefore produce no seeds.
Nidulata semina, seeds dispersed in pulp.
Nitidus, glossy.
Nodding, (nutans) when the flower or the fruit stalk is bent near the end, as in the Narcissus.
Nodus, a knot.
Notched, (emarginatus) leaves; the edges cut something like the teeth of a large timber saw.
Nucleus, kernel; the seed enclosed in a nut, or hard bony shell. See *Nux*.
Nudum, naked.
Nutans, nodding; but, applied to a panicle, more properly drooping.
Nux, nut; a species of seed, covered by a hard bony shell which is also sometimes covered with a fleshy substance, and is then called a stone.

O

- Obcordate*, *Obcordatum*; an obcordate or inversely heart-shaped leaf: having the point of the heart next to the stem or branch.
- Obovate Obovatum*; an obovate or inversely egg-shaped leaf: having the narrow end downwards, or next to the branch or stem.
- Obtusus*, blunt, terminating in the segment of a circle.
- Oclandria*, from ὀκτώ, eight; and ἀνὴρ, a husband: the eighth class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, which are furnished with eight stamina, or male organs of generation.
- Octofidus*, eight-clefted.
- Octopartitus*, having eight divisions.
- Oculus*, an eye; a species of bud.
- Ordor*, smell, which is too variable and indeterminate to be employed in the discrimination of plants.
- Open*, (*patulus*) standing open, or spreading wide.
- Operculatum*, covered with a lid.
- Orbiculatus*, round and flat.
- Orders*, subdivisions of classes.
- Ordo*, an order; the first subdivision of a class, in the Sexual method, which parcelling out the genera of any class into several distinct lots, gives perspicuity to the method, and facilitates its distinctions.
- Ore*, rim of the cup. See *Fuuces*.
- Osseous*, hard as bone.
- Oval*, (*ovale*) leaf; as the leaves of the box.
- Ovarium*, the ovary; the germen, or seed-bud, containing the rudiments of the future seed.

P

- Pagina*, surface of a leaf.
- Pairs*. See *Juga*.
- Palatum*, the palate of the flower; the name applied to any prominence or gibbosity in the jaws of the corolla.
- Palea*, chaff.
- Palm*. See *Dodrans*.
- Palmate*, hand-shaped.
- Palmæ*, palm-trees; under this name Linneus has arranged several genera, which, although admissible into separate classes of his system, he has chosen rather, on account of their singular structure, to place apart in an appendix to his work.
- Panduriformis*, fiddle-shaped.
- Panicula*, or *panicle*, a mode of flowering, in which the fructifications are dispersed upon foot stalks variously subdivided. It is, in fact, a sort of branching, or diffused spike, composed of a number of small spikes, that are attached along a common foot-stalk.
- Papilionaceous*, butterfly-shaped.
- Papillosus*, pimpled.
- Pappus*, down; a sort of feathers or hairy crown, with which many seeds, particularly those of compound flowers, are furnished, for the purpose of dissemination.
- Parallelus*, parallel.
- Parasitical*, (*parasiticus*) vegetables not taking root in the earth, but growing upon other vegetables.
- Partial*, (*partialis*) expressive of a part, not of the whole.
- Partition*, (*disseppimentum*) the substance dividing seed-vessels into different cells.
- Partitus*, divided.
- Patens*, expanding
- Patulus*, open.

- Pectinatum*, (*pectinate*) a comb-like leaf.
- Pedatum*, bird-footed.
- Pedicellus*, a partial flower-stalk; the proper stalk of any single flower in an aggregate or head of flowers.
- Pedicle*. See *Pedunculus*.
- Pedunculus*, the foot-stalk or fruit-stalk of a flower, or head of flowers.
- Pelta*, a short buckler or target; the name of the flower, or flat fructification, of the genus lichen, or liver-wort.
- Peltatum*, target-shaped leaf.
- Pencil-shaped*, (*penicilliformis*) like a camel-hair pencil: as the summit of a millet.
- Penicilliformis*, pencil-shaped.
- Pendant*, hanging down.
- Pentagonous*, five-cornered.
- Pentagynia*, the name of one of the orders in the fifth, tenth, eleventh, twelfth, and thirteenth classes, having five pistils in each flower.
- Pentandria*, from πεντε, five; and ἀνὴρ, a husband: the name of the fifth class in the Linnean system, consisting of plants which have hermaphrodite flowers, with five stamina or male organs.
- Pentapetala*, five-petaled.
- Pentapetali*, flowers having five petals.
- Pentaphyllous*, five-leaved cup.
- Perennial*, (*perennis*) continuing for several years; at least more than two.
- Perfect*, (*completus*) a flower having both a cup and a blossom, and also one or more stamina and pistilla.
- Perforated*, (*perfoliatus*) leaves; when the stem seems to go through the leaves.
- Perfoliatum*, perforated leaf.
- Perianthium*, the flower-cup, properly so called; the most common species of calix, placed immediately under the flower, which is contained in it as in a cup.
- Pericarpium*, the seed-vessel; an entrail of the plant, big with seeds, which it discharges when ripe.
- Permanent*, (*persistens*) cup; remaining till the fruit is ripe.
- Personatus*, gaping, (*blossom*.)
- Pes*, a foot; twelve inches.
- Petaliformis*, resembling a petal.
- Petals*. See *Petalum*.
- Petalum*, a petal, or coloured leaf of the flower; a single part or subdivision of the *Corolla*, which see.
- Petiolaris*, having leaf-stalks.
- Petiolus*, the foot-stalk of the leaves; one of the fulcra, or parts that serve for support, for protection, and for defence.
- Phanogamous*; plants in which the parts of fructification are visible and distinct.
- Pileus*, a hat or bonnet; the upper part of a mushroom covering the fructification.
- Pili*, hairs; one of the species of pubes, or defensive weapons, with which several plants are furnished.
- Pillar*, (*stipes*) the little shaft or pedicle, upon which the down of some seeds is placed, as in dandelion.
- Pilosus*, hairy.
- Pimples*, (*papillosus*) beset with pimples, or hard little protuberances.
- Pinna*, a leaflet of a winged leaf.
- Pinnatifid*, wing-cleft, cut transversely.
- Pinnatus*, winged leaf; whereas *alatus* relates only to the seed-stem, or leaf-stalk. See *Alatus*.
- Pinnulatus*, when a leaflet of a winged leaf is again subdivided.
- Pistil*, or *pointal*. See *Pistillum*.

Pistilliferous, flowers or florets, such as contain one or more pistilla, but no stamina.

Pistillum, the pestle, pistil, or pointal; an erect column, generally placed in the centre of the flower, within the stamina, and called the female organ of generation in plants.

Pitcher-shaped, (urceolatus) swelling or bellying out like a common jug.

Pith, medulla.

Pitted, (lacunosum) when the surface of a leaf lies in hollows between the veins.

Plenus, a full flower; a term used to express the highest degree of luxuriance in flowers.

Plicatus, plaited.

Plumosus, feathered.

Plumula, a little feather; the scaly part of the corculum, or embryo plant within the seed, which ascends, and becomes the stem or trunk. See *Corculum*.

Pod, (siliqua) a seed-vessel of two valves, within which the seeds are fixed alternately to each seam or suture.

Pointal. See *Pistil*.

Pollen, small dust; fecundating or fertilizing dust, contained within the antheræ or tips of the stamina, and dispersed upon the female organ when ripe, for the purposes of impregnation.

Polyadelphia, from *πολυς*, many; and *ἀδελφία*, a brotherhood: the name of the eighteenth class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, in which several stamina or male organs are united by their filaments, into three or more distinct bundles.

Polyandria, from *πολυς*, many; and *ἀνὴρ*, a husband: the name of the thirteenth class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, furnished with more than twenty stamina, that are inserted into the common receptacle of the flower.

Polygamia, from *πολυς*, many; and *γάμος*, marriage: polygamy, the name of the twenty-third class in the Sexual System of Linneus, consisting of polygamous or mongrel plants; that is, plants having hermaphrodite flowers, and likewise male or female flowers, or both. The term is applied also to each of the orders of the class Syngenesia, and signifies that several florets are enclosed within one common calix.

Polypetalous, many-petalled.

Polyphyllous, many-leaved.

Polysperma, many-seeded.

Polystachyous, many-spiked.

Pomaceæ, pomaceous; fruit of the apple, berry, and cherry kind.

Pomaceous. See *Pomaceæ*.

Pomum, an apple; a species of seed-vessel, composed of a succulent, fleshy pulp, in the middle of which is generally found a membranous capsule, with a number of cavities for containing the seeds.

Pores, little holes.

Posticus, hinder part.

Pauch, a short *Pod*, which sec.

Præmorsus, as if bitten off, or jagged-pointed.

Pressed to, (adpressus.) See *Contiguous*.

Prickles, (aculei) sharp-pointed weapons of defence, formed from the bark, and not from the wood of a plant, as in the rose.

Prickly, (aculeatus) armed with prickles.

Prickly-pointed, (cuspidatus) ending suddenly in a hard sharp point.

Prismaticus. See *Prism-shaped*.

Prism-shaped, (prismaticus) differing from cylindrical in the circumference being angular.

Procumbens, (procumbent) trailing, lying on the ground.

Prolifer, prolific; a prolific flower, which from its own substance produces another; a singular degree of luxuriance, to which full flowers are chiefly liable.

Prominens, projecting partition; when it stands out beyond the valves.

Pronus, the under surface of a leaf.

Propago seed; Linneus's name for the seeds of the mosses.

Proprius, belonging to an individual.

Props. See *Fulcra*.

Protruding, (exsertus) standing out of the blossoms, like the stamina of some of the grica's.

Protuberances, (torasus) in seed-vessels; occasioned by the swelling out of the enclosed seeds.

Pubes, hair, down; a general term, expressive of all the hairy and glandular appearances on the surface of plants, supposed by naturalists to serve the double purpose of defensive weapons, and vessels of secretion.

Pubescent, (pubescens) clothed with soft wool or hair.

Pulmanes, lungs; the leaves called the organs of perspiration and respiration in plants.

Pulpy, (pulposus) soft and tenacious; a cherry is pulpy, but an apple fleshy.

Pulpy seed-vessel. See *Drupa*.

Pulveratus, dusted.

Punctatus, dotted.

Purse-shapen, (scrotiformis) like a purse that draws together with strings at the top.

Q

Quadrangularis, four-cornered.

Quadridentatus, four-toothed.

Quadrifidus, four-clefted.

Quadrilobum, four-lobed.

Quadrioculare, four-celled.

Quadripartitum, with four divisions.

Quadrivalve, four-valved.

Quaterna, by fours.

Quina, by fives.

Quinatum, (quinate) five leaved.

Quinquangulare, five-cornered.

Quinquefidum, five-clefted.

Quinquelobum, five-lobed.

Quinqueloculare, five-celled.

Quinquepartitum, with five divisions.

Quinquevalve, five-valved.

R

Racemus, a cluster; in which the flowers placed along a common foot-stalk, are furnished with short proper foot-stalks, proceeding as lateral branches from the common flower-stalk. See *Bunch*.

Rostrum. See *Beak*.

Radiate, (radiatus) a sort of compound flowers, in which the florets of the centre differ in form from those in the circumference; thus the daisy and sunflower are radiate flowers, the florets in the centre being all tubular, but those in the circumference are narrow and strap-shaped.

Radiate summits; placed in a circle, as in the poppy.

Radicalis, (radicle) issuing immediately from the root.

Radicula, radicle, a little root; the stringy or fibrous part of the root, which, penetrating the soil, attracts moisture and nourishment for the support of the vegetable flower.

Radii, rays; the outer florets in a radiate compound flower: they may be called the florets of the circumference, and the inner ones the central florets.

Radii, spokes; the fruit-stalks of an umbel. See *Umbella*.
Radius, the semi-diameter of a circle.
Radix, root; the lower part of the plant, generally hid below the surface of the earth, to attract the moisture from the soil, and communicate it to the other parts of the plant.
Rameus, belonging to a branch.
Ramus, a branch.
Ramulus, the branch of a branch.
Receptacle. See *Receptaculum*.
Receptaculum, (receptacle) one of the seven parts of fructification, defined by Linneus to be the base which connects or supports the other parts.
Reclinatus, reclining.
Reclining, (reclinatus) bent back a little, so that the extremity is lower than the base.
Rectus, straight.
Recurvatus, recurved, or bowed back.
Reflexus, reflected; bent back rather angularly, as the petals of the fleur-de-lis.
Refractus, bent back as if broken.
Regular (regularis) blossom; one that is regular in the figure, size, and proportion of its parts.
Remote (remotus) whirls; when there is a considerable length of stem between each whirl.
Reniforme, kidney-shaped.
Repandum, wavy, bent backwards.
Repens, *Reptans*, creeping.
Replicatus, folded or plaited, so as to form a groove or channel.
Resupinatum, horizontally turned upside-down.
Reticulata, veined like net-work.
Retrofaetus, broken back.
Retrorsum serratum, inversely serrated.
Retrorsum sinuatum, crookedly bent back.
Retusum, (retuse) bluntly notched at the end, and sometimes merely blunt.
Revolute, turned or rolled back.
Rhombous, or *Rhomboid*, diamond-shaped.
Rhomboidous, rhomboidal; nearly diamond-shaped, but broader one way than the other.
Rigid, (rigidus) stiff, not easily bent.
Rimose, full of cracks.
Ring, (annulus.)
Ringent, gaping or grinning.
Rising, upwards, differs from *ascending*, in first inclining downwards, and then rising upwards.
Rod-shaped, (virgatus) having many slender and nearly straight parallel branches or shoots.
Rolled back, (revolutus) with respect to the leaf in general means rolled downwards like the leaves of Sweet-william.
Root. See *Radix*.
Root-leaves, (radicalia) the leaves which proceed immediately from the root, without the intervention of the stem.
Rostellum, the sealy part of the coraculum, or embryo of the seed, which shoots downward into the soil, and becomes the root.
Rostratum, having a bill.
Rostrum, a bill or beak.
Rotula, wheel-shaped (blossom.)
Rough, asper.
Round. See *Globular*.
Round, (obicularis) rough and flat.
Ruffle, or *Ring*; the part of the curtain of an Agaric, which adheres to the stem after the outer part of it has vanished.
Rugose, rugged or wrinkled.

Rumer, (flagellum) a barren twig or shoot, lying upon the ground, as in the garden Strawberry, and Stone Bramble: they are sometimes called wires.

Runcinated, notched.

Rundle. See *Umbel*.

Rundlet. See *Umbellule*.

Running, along the stem. See *Decurrent*.

S

Sagittated, arrow-shaped.

Salver-shaped, (hyposerteriformis) the shape of a blossom of one petal, the lower part of which is tubular, the upper flat, and expanded; as in the blossom of the Periwinkle.

Sapor, taste; which is too uncertain to be of any utility in discriminating plants.

Sarmentose, having runners.

Saucer, (scutellum) like a china saucer; a circular and concave fructification of some of the lichens.

Scaber, rough like a file.

Scabridæ, plants with rough leaves.

Scabrities, roughness.

Scabrous, rough, rugged.

Scaly, (squamosus) like the skin of a fish.

Scandent, climbing.

Scape, stalk; such as supports the flower, but not the leaves of a plant, and rises immediately from the root.

Scariose, skinny.

Scarred, (cicatratus) marked with scars, where the leaves have fallen off.

Scattered, disposed without any regular order.

Scalloped, (crenatus) as the leaves of bird's-eye and gill.

Seored, (striatus) marked with superficial parallel lines, as the cup of a pink.

Serobiform, like fine saw-dust.

Scrotiform, purse-shaped.

Scurfy, (squarrosus) applied to a cup in compound flowers, the scales of which are bent outwards at the end, so as to give the whole a rough, ragged appearance.

Seymetar-shaped leaf, (acinaeiforme) a long fleshy leaf, thick and straight at one edge, thin and arched at the other.

Scyphifer, glass-shaped, as the fructification of some of the lichens.

Seam, or *suture*, the line formed by the union of the valves of a seed-vessel.

Secund, pointing one way.

Securiform, axe-shaped.

Seed, see *Semen*; a deciduous part of a vegetable, containing the rudiments of a new plant.

Seed-bud. See *Germen*.

Seed-coat, (axillus) the proper coat of a seed which falls off spontaneously.

Seed-cover, (calyculus) the real cover of the seed.

Seed-lobes, (cotyledones) the perishable parts of a seed, designed to afford nourishment to the young plant when it first begins to expand.

Seed-vessel. See *Pericarp*.

Segment, (lacinium) the small parts of a leaf, cup, or petal, included between the incisions.

Semen, seed; the essence of the fruit of every vegetable, containing the rudiments of a new vegetable, and fertilized by the sprinkling of the male dust.

Semi-cylindrical (semi-teres :) if the trunk of a tree was sawn lengthwise through the middle, each part would be semi-cylindrical.

- Seminal leaves*, those which rise immediately from a seed, or rather from the seed-lobes.
- Semi-orbiculated*, shaped like half a globe.
- Semi-sagittated*, shaped like half the head of an arrow.
- Semi-teres*. See *Semi-cylindrical*.
- Sempervirent*, evergreen.
- Senis*, (follis) growing in sixes.
- Separate*. See *Mænæcia*.
- Sericeous*, silky.
- Serpentine*, (repandus) the edge of some leaves is formed like a serpentine line, without any angles or corners.
- Serrated*, (serratus) like the teeth of a common saw.
- Serrulated*, (serrulatum) very minutely serrated.
- Sessile*, sitting.
- Setaceous*, bristle-shaped.
- Seta*, bristles.
- Setose*, bristly, or set with bristles.
- Serangular*, six-sided, or cornered.
- Sex-fid*, six-clefted.
- Sex-locular*, six-celled.
- Shaft*. See *Style*.
- Sheath*. See *Spatha*.
- Sheathed*, fruit-stalk. See *Spadix*.
- Sheath-scale*, a membrane found at the top of the sheaths, which surround the stem of the grasses, just where the sheath ends, and the proper leaf begins.
- Sheathing* (vaginans) leaves; when the base of a leaf infolds the stem, as in most of the grasses.
- Shedding*. See *Caducous*.
- Shell*. See *Legumen*.
- Shoot*, (surculus) the branch of a moss.
- Short*, (abbreviatus :) a cup is said to be short, when it is shorter than the tube of the blossom.
- Shrivelling*, (marcescens) fading and withered, but not falling off.
- Shrubby*, (fruticosus) somewhat woody and perennial, as the stems of the rose.
- Silicula*, a broad and short pod or pouch.
- Siliqua*, see *Pod*; in which the seeds are alternately fixed to either suture or joining of the valves; in this it differs from the legumen, which has its seeds attached to one suture only.
- Silky*, (sericeus.)
- Simple*, (simplex) undivided.
- Simple cup*, one that consists of a single series of segments, as goats' beard.
- Simple leaf*, when there is only one upon a leaf-stalk.
- Simple stalk*, undivided, as in the Tulip.
- Simple stem*, one that is undivided, or only sends out small branches.
- Simplicissimus*, very simple, absolutely undivided.
- Single*, (unicus) one flower only upon a stalk, as the Tulip.
- Sinuate-angulose*, indented and angular.
- Sinuate-dentated*, indented and toothed.
- Sinuated*, indented, cut along the margin.
- Sitting leaves*, (sessilis) having no leaf-stalks.
- Skinny*, or *skin-like*, (scariosus) tough, thin, and semi-transparent, like gold-beater's skin.
- Slanting*, (obliquus) straight, but in a direction between horizontal and perpendicular.
- Smooth*, (glaber) the surface smooth to the touch, without any hairiness or other inequality.
- Snipt*, cut at the edges without any regularity.
- Solid root*, fleshy and uniform, like a turnip.
- Solid stem*, without a cavity, opposed to hollow
- Solitary*, (solitarius) only one in a place, having but one flower on a fruit-stalk; or only one fruit-stalk proceeding from the same part of a plant.
- Sooty*, (fuliginosus) dark and dirty as if sooted, as are some of the Lichens.
- Spadiceous*, sheathed; an aggregate flower, in which the receptacle is enclosed within a spatha or sheath, that is common to many florets.
- Spadix*, a flower-stalk that is protuded out of a spatha or sheath.
- Spadilated*, battledore-shaped
- Span*, seven inches.
- Sparsus*, scattered.
- Spatha*, a sheath; a species of calix which bursts lengthways and protudes a stalk, supporting one or more flowers which commonly have no perianthium or flower-cup.
- Spatulatum*, roundish, or obovate.
- Spear-shaped*, (lanceolatus.)
- Spear-egg-shaped*, (lanceolato-ovatum) applied to a leaf, signifies that it is shaped like a spear towards the base, and like an egg towards the extremity.
- Species*, a set of plants which agree in the general structure of their flowers and fruit, and therefore belong to the same genus; but differ in their stem, leaves, and other particulars. See the *Introduction* to this work.
- Specific character*, one or more circumstances of a plant, sufficient to distinguish it from any other of the same genus.
- Spherical*, (spherica) globular.
- Spike*, a mode of flowering in which the flowers are ranged alternately upon both sides of a single common flower-stalk.
- Spicula*. See *Spikelet*.
- Spikelet*, *spicula*, or little-spike; constituting part of a larger composition of florets.
- Spike stalk*, (rachis) a long, rough, slender receptacle, upon which the flowers composing a spike are placed. Take a spike (or, as it is commonly called, an ear) of wheat; pull off all the seeds and chaff; what remains is a spike-stalk.
- Spine*, a thorn; a species of armature or offensive weapon, protuded from the wood of the plant, and therefore of a stronger and harder nature than prickles, which are only detached portions of the bark.
- Spindle-shaped*, (fusiformis) a gradually tapering root.
- Spinescent*, becoming hard and thorny.
- Spinose*, thorny.
- Spinous*, beset with prickles.
- Spiral*, (spiralis) twisted like a corkscrew.
- Spokes*, (radii) the foot-stalks of flowers collected into umbels and umbellules.
- Spreading*, (diffusus) not rising high, but spreading wide upon the ground, as the stems of fumitory and pansie.
- Spur*, (calcar) shaped like the spur of a cock, as the nectaries of the larkspur.
- Squamated*, *Squamose*, scaly.
- Squarrose*, scurfy.
- Stalk*, (scapus) that species of trunk which elevates and supports the flowers, but not the leaves of a plant.
- Stamens*, (stamina) threads or chives; the slender threads which support the antheræ, and in most flowers are placed round the seed-bud.
- Staminiferous flowers*, or *florets*, such as contain one or more stamina, but no pistilla, and are necessarily barren.
- Standard*, (vexillum) the upright petal of a butterfly-shaped blossom, very remarkable in a pea.

Starry, (stellatus) plants whose leaves grow in whorls round the stem, as the goosegrass, cheese-rennet, and several other plants in the class Tetrandria.

Stellate, starry, or star-like.

Stem, (caulis) the proper trunk of a plant, supporting the leaves, branches, and flowers.

Stem-clasping, (amplexicaulis.)

Stem-leaves, (caulina) such as grow immediately upon the stem, without the intervention of branches.

Stemless. See *Acaulis*.

Sterile, barren.

Stiff. See *Rigid*.

Stigma, the summit of the style: the female organ of generation in plants, which receives the fecundating dust of the tops of the stamina, and transmits its vapour or effluvia through the style, into the heart of the seed-bud, for the purpose of impregnating the seeds.

Stimuli, stings; a species of offensive weapon, designed to keep off naked animals that would approach and injure certain plants.

Stings, (stimuli) sharp-pointed substances, conveying poison into the parts they penetrate, as in the nettle.

Stipes, a pillar or pedicle.

Stipes, the trunk of a tree or plant, sometimes the foot-stalk; likewise the slender thread which elevates the pappus, or hairy crown, in many compound flowers.

Stipitated, standing on a pillar or pedicle.

Stipulate, a sort of props; small leaves or scales, situated on each side the base of a leaf-stalk or fruit-stalk; for the purpose of supporting them in their first appearance, as in the garden pea.

Stolo, a sucker.

Stoloniferous, putting forth suckers.

Stone. See *Nux*.

Straddling, (divaricatus) branches standing wide from each other.

Straight, (rectus) not bending.

Strap-shaped, (linearis) long and narrow, like a strap or fillet; as in the crocus leaf.

Strap spear-shaped. See *Spear egg-shaped*.

Straw. See *Cubn*.

Streaked, marked with depressed, but not always parallel lines.

Striated, scored.

Strictus, stiff and straight.

Strigæ, strong spear-shaped bristles or thorns

Strigose, furnished with strigæ.

Strings, fibres. See *Filament*.

Strobiliform spike, a cone-shaped spike.

Strobilus, a cone; a species of seed-vessel, composed of woody scales which are placed against one another, and split only at top, being fixed below to an axis, which occupies the centre of the cone.

Style, the slender part of the pistillum, or female organ resembling a pillar, which stands upon the seed-bud, and elevates the stigma, or summit.

Subdivisus, subdivided.

Submersus, under water.

Subovate, nearly egg-shaped.

Subramose, a little branched.

Subrotund, nearly globular.

Subuluted, awl-shaped.

Succulent, juicy.

Succus, sap; the juices of plants.

Suckers, (stolones) shoots which rise from the root, spread along the ground, and then take root themselves, as in the sweet-violet.

Suffruticose, somewhat woody, nearly shrubby, as sage and lavender.

Sulcated, furrowed.

Summit, (stigma) the upper part of the *Pistil*, which see.

Superficies, the surface.

Superflua, superfluous.

Superior (superus) *cup* or *blossom*; when the calyx or corolla is situated above the germen, it is said to be superior; as in the Honeysuckle.

Superus, superior, above.

Supine, the upper surface.

Supra-decomposita, more than doubly compound.

Supra-foliaceous, placed above the leaf.

Surculus, a shoot; the branch of a Moss.

Suture, a seam.

Sword-shaped, (ensiforme) as the leaves of the Iris, or Fleur-de-lis.

Syngenesia, from *συν*, together; and *γενεσις*, generation: the name of the nineteenth class in the Sexual System of Linnæus; it consists of plants in which the antheræ or male organs of generation are united into a cylinder, the filaments by which they are supported remaining separate and distinct.

T

Tail, (cauda) a sort of slender-pointed appendage to some seeds.

Taper leaf, (acuminatum) gradually tapering to a point.

Target, (pelta) a kind of fructification on the leaves of some of the Lichens, which is circular, and a little convex.

Target-shaped, (peltatum) applied to a leaf having its leaf-stalk fixed, not at the edges, but nearly in its centre.

Target-shaped summit, one that is circular and flat.

Tendril. See *Cirrus*.

Tenuis, thin, slender.

Teres, columnar.

Teretisculus, roundish.

Tergeminum, (leaf) doubly twin fork.

Terminal, terminating.

Terminating, (terminalis) opposed to lateral; standing at the end of the stem or branches, as the fruit-stalks of Borrage.

Ternate, growing three together from the same point.

Ternis, by threes; three in a place.

Tessellated, chequered.

Tetradynamia, from *τεσσαρες*, four; and *δυναμις*, power: four powers; the name of the fifteenth class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, having six stamina, four of which are longer than the rest.

Tetragynia, from *τεσσαρες*, four; and *γυνη*, a woman: the name of an order or secondary division in the fourth, fifth, sixth, eighth, and thirteenth classes, of the Linnean System; it consists of plants, which, to the classic character, whatever it be, add the circumstance of having four styles or female organs, as its name imports.

Tetragonous, four-cornered.

Tetrandria, from *τεσσαρες*, four; and *ανηρ*, a husband: the name of the fourth class in Linneus's Sexual System, consisting of plants whose flowers are hermaphrodite; and have four stamina or male organs of equal length.

Tetrapetalous, four-petalled.

Tetraphyllous, four-leaved.

Tetraspermous, four-seeded.

Thalamus. See *Receptacle*.

Thorn. See *Spine*.

- Thread*. See *Filament*.
Thread-shaped, (filiformis) of the same thickness from top to bottom, like a piece of packthread; like the leaves of Fennel, the style of Crocus, or of Honeysuckle.
Three-edged, (trigonus) or three-cornered; a stem having three corners or angles, and the sides not flat.
Three-fibred, (trinervatus) having three veins or nerves, running from the base to the end of a leaf, without branching off.
Three-lobed, (trilobatum).
Thronging, (confluentia) assembled in close parcels, with intervening naked places.
Thyrus, a cluster; according to Linneus, is a panicle contracted into an oval or egg-shaped form.
Tiled, (imbricatus) one leaf or scale partly covering another, like the tiles of a house; as the cup of dandelion or burdock.
Tip. See *Anther*.
Tomentose, cottony or downy.
Tomentum, short wool; a species of hoary or downy pubescence, which covers the surface of many plants.
Tongue-shaped, (lingulatum) applied to express a thick fleshy leaf, somewhat in the shape of a tongue.
Toothed, (dentatus) when the edges of a leaf are set with little teeth, as in primrose.
Tooth-serrated, (dentato-serratum) when the edge of a leaf is set with serrated teeth.
Top-shaped, (turbinatus) nearly conical.
Torose, protuberating.
Torulose, a little swelling out.
Tortile, twisting.
Trailing stems, (procumbens) lying along upon the ground, and not sending out roots, as common Speedwell.
Transverse, crosswise.
Trapeziform, the shape of a flat leaf, having four unequal sides.
Treble-compound. See *Triply compound*.
Triangular leaf, stem, or stalk, having three sides, and three angles or corners.
Triandria, from τρεις, three; and ἀνὴρ, a husband: the name of the third class in Linneus's Sexual System, consisting of plants with hermaphrodite flowers, with three stamina or male organs.
Triangularly spear-shaped, (deltoideus) leaves broad at the base, and nearly triangular, but spear-shaped at the point.
Trichotomous, dividing by threes.
Tricoccos, three-celled, three-seeded, swelling out.
Tricuspidated, three-pointed.
Tridentated, three-toothed.
Trifid, three-clefted.
Trigonal, three-cornered.
Trilobate, three-lobed.
Trilocular, three-celled.
Trinerved, three-fibred, three-ribbed.
Tripartite, with three divisions.
Triphyllous, three-leaved.
Tripinnated, triply winged.
Triply compound leaves, (folia supra decomposita) are of three kinds:—1. *Double Twin-fork*, (tergeminus) leaf-stalk, with two leaflets at the end of each, and two more at the division of the fork.—2. *Triply three-fold*, (tritermatus triplico-ternatus) the divisions of a triple leaf-stalk, again subdivided into threes, and three leaflets at the end of each subdivision.—3. *Triply-winged*, (tripinnatus triplicopinnatus) when the lateral ribs of a doubly-winged leaf, have themselves other leaf-stalks with winged leaves
- Triqueter*, with three flat sides, as the stem of the pansie
Trispermous, three-seeded.
Triternate triply threefold.
Trivalved, three-valved.
Trowel-shaped. See *Triangularly spear-shaped*.
Truncated, lopped.
Trunk, that part of the herb which rises immediately from the root, and is terminated by the fructification.
Trygynia, the name of one of the orders in several of the classes, having three pistils in each flower.
Tube, the lower hollow part of a flower with one petal; opposed to unguis, the claw of a polypetalous flower.
Tubercle, (tuberculus) a little solid pimple.
Tuberculate, tubercled.
Tubulated, *Tubulose*, tubular.
Tuerosous root, (tuberosus) consisting of many rounding knobs, collected into a bundle, as the root of peony and dropwort.
Tubular, (tubulosus) in the shape of a hollow tube, as the cup of the Privet, the blossom of the Honeysuckle, or the nectary of the Hellebore.
Tubular florets, are shaped like a hollow tube.
Tuft. See *Cyma*.
Tunicated, coated.
Turbinated, top-shaped, nearly conical.
Turgid, swollen, turgid.
Turis, a young unexpanded shoot, as is the Asparagus before it is gathered for eating.
Twining, (volubilis) twisting round other bodies, and ascending in a spiral line.
Twin-fork, (bigeminus).
Two-edged, (anceps) as the stem of Tutsan.
Two-rowed, (distichus) like the teeth in a double box or ivory comb, as in the leaves of the common fir.

U & V

- Vagina*, a sheath formed by a part of a leaf, distinct from the sheath (spatha) which is a species of calix.
Vaginant, sheathing.
Vaginated, sheathed.
Valve, (valvula) the different pieces that compose a capsule are called valves; thus, in Thornapple there are four, in Loosestrife ten, in Jacob's Ladder, Daffodil, and Hyacinth, three. The petals and empalements that constitute the flowers of Grasses are called valves; thus, in the Common Meadow-grass the calix or empalement is a dry chaffy husk composed of two valves, and the blossom is formed of two other valves. The mouth of the tube of a blossom is frequently closed by several projecting substances: thus, in the blossoms of Borrage and Jacob's Ladder, the tube is closed by five of these substances, which are also called valves.
Valvula, a little valve or opening: the external division of a dry seed-vessel, as a capsule or pod, which splits when the seeds are ripe for dissemination.
Vane-like, (versatilis) turning about like a vane, as the antheræ of geranium and crown imperial.
Vaulted, (fornicatus) like the roof of one's mouth.
Veil, (calyptra) the calix of mosses covering the tips. It is generally in a conical form like an extinguisher.
Veined, (venosum) a leaf is said to be veined when its fibres are branched.
Venose, veined.
Ventricose, distended; bellying.

Varieties, plants of the same species, but which differ slightly from each other.

Vernatio, a term used by Linneus, to express the curious manner in which the leaves are folded or wrapped up in their buds.

Verrucose, warty.

Versatile, vane-like.

Verticillated, growing in whorls.

Verticilli, whorls.

Verticillus, a little whorl, hinge, axis, axle-tree, or spindle.

Vesicules, bladders.

Vexillum, a standard; the upper petal of a pea-bloom, or butterfly-shaped flower, which is generally larger than any of the others.

Vigilia, (plantarum) the vigils of plants; under this term botanists signify the precise time of the day in which the flowers of different plants open, expand, and shut.

Villi, soft hairs.

Villoes, covered with soft hairs, like the Furze-leaf.

Vimen, a slender and flexible twig.

Virgated, rod-shaped.

Viscid, (viscidus) clammy.

Viscosity, clamminess.

Viviparus, (viviparus) a term applied to stems or stalks producing bulbs that are capable of vegetation.

Volubile, twining.

Volva, a curtain or screen.

Unguis. See *Claw*.

Umbel, a composition of flowers, in which a number of slender fruit-stalks grow from the same centre.

Umbelliferous, plants which produce their flowers in umbels.

Umbellule, a little umbel.

Umbilicated, resembling a navel; dimpled.

Umbo. See *Disk*.

Unangulated, one-edged.

Unarmed, (inermis) without weapons of defence.

Uncinnated, hooked at the end.

Undated, waved.

Under-shrub, (suffrutex) like a shrub in its woody texture at the bottom, but the top-shoots herbaceous, tender, and dying in the winter; lavender is an instance.

Undivided, simple.

Unequal florets, (radiati) when an umbel is not composed of equal florets, but those in the circumference are larger than those in the centre, and the outer petals are larger, and different in shape from the inner petals.

Ungulated, hoof-shaped.

Unicus, single; only one.

Uniflorous, one-flowered.

Uniform, (equalis) a term applied to compound flowers, when the florets which compose them are all alike.

Unilateral, growing from one side only.

Unilocular, one-celled.

Univalve, one-valved.

Universal, general.

United leaves, (connatus) two opposite leaves growing together at the base.

Upright, (erectus) standing upright or nearly so, as the cups of the periwinkle, the antheræ of the polyanthus, the stalks of tulips, and the stems of asparagus.

Urceolated, pitcher-shaped.

Urens, stinging.

Utriculus, a little bag or hollow vesicle.

W

Warty, (verrucosus) having little hard lumps or warts upon the surface.

Waved, (undatus) when the surface of the leaf towards the edge does not lie flat, but appears waved and full, like a ruffle.

Weapons. See *Arma*, *Prickles*, *Thorns*, and *Stings*.

Wedge-shaped, (cuneiformis) as the leaves of the garden Spurge, and the garden Purslain.

Wheel-shaped, (rotatus) a term used to express a blossom of one petal, with a flat border and a very short tube.

Whirls, (verticilli) of branches, leaves, or flowers; the branches of fir, the leaves of Ladies Bedstraw, and the flowers of the Deadnettle, grow in whirls round their respective stems, and somewhat resemble the spokes round the nave of a wheel.

Winged leaf-stalk, (alatus) flattish, with a thin membrane or leafy border on each side:—*Leaf*, when an undivided leaf-stalk has many little leaves growing from each side:—*Stem or leaf-stalk*, such as have a thin flat membrane on each side.

Wing-cleft, (pinnatifidus) is applied to a leaf that is cut and divided so deeply on each side down towards the middle rib, as almost to resemble a winged leaf.

Winged-shoots, (surculipinnati) when the roots strike out from the sides, like the plumage along the sides of a quill.

Wings. See *Ala*; the lateral petals of a butterfly-shaped blossom, as in the Pea.

Wires, (flagelli.) See *Runners*.

Woody, (arboreus) opposed to herbaceous.

Wool. See *Lana*.

Woolly, (lanatus.)

Wrapper, volva; but not the volva of Linneus; a tough membrane, which envelops the whole plant of some of the Fungusses in its younger state.

Wrinkled, (rugosus) as the leaves of Sage, Primrose, Wood-Strawberry, Hazel, &c.

Z

Zigzag, (flexuosus) having many contrary turnings and bendings, as the stems of the rough bindweed, woody night-shade, or the branches of golden rod.

GENERAL RULES

FOR

GATHERING AND PRESERVING HERBS,

ROOTS, BARKS, SEEDS, AND FLOWERS

Together with the Methods of Making such Preparations from them, as may best retain their Virtues, or be most useful to be kept in Families.

THE intention of the author is, to inform those who live in the country, and are desirous of being useful to their families and friends, or charitable to the poor in relieving their disorders, of the virtues of those plants which grow wild about them; that they may be able to supply the necessary assistance, in places where apothecaries are not at hand, without putting themselves to the expense of costly medicines, when the common herbs, that may be had for gathering, will answer the same purpose. However, as there are cases wherein more help may be obtained from foreign drugs, than from any thing produced at home, an account of those roots, barks, seeds, gums, and other vegetable productions, kept by the druggists and apothecaries, is added, together with their virtues, and those of the several trees and plants from which they are obtained.

The plants are alphabetically arranged, according to their English names, that they may be the more readily found. With regard to the virtues of plants, too many have been attributed to most of them, but here their real virtues only, as ascertained by the experience of the best judges, are introduced, and placed in the most conspicuous light.

Nature has, in this country, as well as in all others, provided, in the herbs of its own growth, the remedies for the several diseases to which it is most subject; and although the addition of what is brought from abroad, should not be supposed superfluous, there is no occasion that it should cause the other to be neglected. This neglect has been the consequence of the too great respect shewn to them; which, with the present universal use of chemical preparations, has almost driven the whole Galenical medicine out of our minds.

To restore this more safe, more gentle, and often more efficacious part of medicine to its natural credit, has been one great intent in writing this treatise; and it is the more necessary for the service of those, who are intended most to be directed in this matter, since this is much less dangerous than the other: for in most instances it is hard to say that this is dangerous at all.

The apothecaries are apt, in their unfeeling mockery, to say, that they are obliged to the good persons who give medicines to their sick neighbours, for a great deal of their business; for out of little disorders they make great ones. This may be the case where their shops supply the means; for chemical medicines, and some of the drugs brought from abroad, are not to be trusted with those who have not great experience; but there will be no danger of this kind, when the fields afford the supply. This is the medicine of nature, and as it is more efficacious in most cases, it is more safe in

all. If opium may be dangerous in an unexperienced hand, the person who will give in its place a syrup of the wild lettuce, (a plant not known in common practice at this time, but recommended from experience in this treatise) will find that it will ease pain, and that it will cause sleep, in the manner of that foreign drug, but will never find any ill consequences from it; and the same might be said in many other instances.

As the descriptions in this work very readily distinguish what are the real plants that should be used, the great care will remain, in what manner to gather and preserve, and in what manner to give them; it will be useful to add directions upon those heads. As to the *former*, it should be perfectly understood, because a great deal depends upon it; the *latter* cannot easily be mistaken.

Having displaced the drugs brought from abroad in a great measure from charitable practice, every person who has the spirit of true benevolence, should keep a kind of druggist's shop, which should be supplied from the neighbouring fields, and from their own gardens. There is no reason the drugs should not be as well preserved, and as carefully laid up, as if the product of a different climate, though the use of the fresh plants will in general be best when they can be had.

As there are some which will not retain their virtues in a dried state, and can be met with only during a small part of the year; it will be proper to add the best methods of preserving these in some way, according to the apothecaries' manner; with the method of making the preparations from them for ready service, which will be sufficient to lead to the perfect use of the medicines of our own growth; and it will be found upon experience, that those who sufficiently know how to make a proper use of these, need seldom have recourse to any others.

Concerning the Methods of Collecting and Preserving Plants, and Parts of them, for Use.

THE virtues of different plants residing principally in certain parts of them, and those differing according to the nature of the herb, these several parts are to be selected, and the rest left; and these are in some to be used fresh, and just gathered; in others, either necessity, or the natural preference, make it proper to dry and preserve them.

In some only the leaves are to be used; in others, the whole plant cut from the root; in others, the flowers only; in others, the fruits; in others, the seeds; in some, the roots; and of

some trees, the barks; some, the woods; and only the excrescences of others: while some vegetables are to be used entire, whether fresh gathered, or dried and preserved. Of all these, instances will be given in great number in the following sheets, and the matter will be specified under each article, as the part of the plant to be used will always be named; and it will be added whether it be best fresh, or best or necessarily dried or otherwise preserved; but it will be proper in this place to enter into the full examination of this matter, to save unnecessary repetitions under the several particular articles.

The whole of most plants native of our country, dies off in winter, except the root; and in many, that perishes also, leaving the species to be renewed from the fallen seeds. When the whole plant dies, the root is seldom of any virtue; but when the root remains many years, and sends up new shoots in the spring, it commonly has great virtue. This may be a general rule: for there is very little to be expected in the roots of annual plants; their seeds, for the most part, contain their greatest virtues.

In others, the root lives through the winter, and there arise from it large leaves in the spring, before the stalk appears. These are to be distinguished from those which afterwards grow on the stalk, for they are more juicy, and for many purposes much better. In the same manner, some plants, from their seeds dropped in autumn, produce a root and leaves which stand all the winter, and the stalk does not rise till the succeeding spring. These are of the nature of those leaves which rise from the root of other plants before the stalks in spring; and are in the same manner to be distinguished from those which grow upon the stalks; they have the full nourishment from the root, whereas the others are starved by the growth of the stalk and its branches, and the preparations made by nature for the flowers and seeds; which are the great purpose of nature, as they are to continue the plant.

For this reason, when the leaves of any plant are said to be the part fittest for use, they are not to be taken from the stalk, but these large ones growing from the root are to be chosen; and these where there is no stalk, if that can be; for then only they are fullest of juice, and have their complete virtue; the stalk running away with the nourishment from them. This is so much done in some plants, that although the leaves growing from the root were very vigorous before the stalk grew up, they die and wither as it rises. When the juice of the leaves of any plant is required, these are the leaves from which it is to be pressed: when they are ordered in decoction, notice is always taken in this work, whether they be best fresh or dried; if fresh, they should be just gathered for the occasion; they should be cut up close from the root, and only shook clean, not washed; for in many, that carries off a part of the virtue: they are to be cut into the pot. If they are to be dried, the same caution is to be used; and they are best dried by spreading them upon the floor of the room, with the windows open, often turning them. When thoroughly dried, they should be put up in a drawer, pressing them close down, and covered with paper. When the entire plant is to be used except the root, care is to be taken that it be gathered at a proper season. Nature, in the whole growth of plants, tends to the production of their flowers and seeds, but when they are ripe, the rest begins to decay, having done its duty; so that the time when the entire plant is in its most full perfection, is when it is in the bud; when the heads are formed for flowering, but not a single flower has yet disclosed itself: this is the exact time:

When herbs are to be used fresh, it is best not to take them entire, but only to cut off the tops; three or four inches long,

if for infusion, and if for other purposes, less: if they are to be beaten up with sugar, they should be only an inch, or less: just as far as they are fresh and tender. The tops of the plant thus gathered, are always preferable to the whole plant for immediate use.

When the entire herb is to be dried, the season for gathering is to be as just described, when the flowers are budding; and the time of the day must be when the morning dew is dried away. This is a very material circumstance, for if they be cut wet with the dew, herbs will not dry well, and if they be cut at noon-day, when the sun has made the leaves flag, they will not have their full power. Care must also be taken to cut them in a dry day; for the wet of rain will do as much harm as that of dew.

When the herbs are thus gathered, they are to be looked over, the decayed leaves to be picked off, and the dead ends of the stalks cut away: they are then to be tied up in small bunches, (the smaller the better,) and hung upon lines drawn across a room, where the windows and doors are to be kept open in good weather; the bunches are to be half a foot asunder, and they are to hang till perfectly dry. They are then to be taken softly down, without shaking off the buds of the flowers, and laid evenly in a drawer, pressing them down, and covering them with paper. They are thus ready for infusions and decoctions, and are better for distillation than when fresh.

The flowers of plants are principally used fresh, though several particular kinds retain their virtue very well dried; they are on these different occasions to be treated differently.

Lavender flowers, and those of *Stœchas*, (*Graphalium Stœchas*) keep very well; they are therefore to be preserved dry. The Lavender flowers are to be stripped off the stalks, and spread upon the floor of a room to dry. The *Stœchas* flowers are to be preserved in the whole head; this is to be cut off from the top of the stalk, and dried in the same manner: when dry, they are to be kept as the herbs.

When Rosemary flowers are dried, they are generally taken with some of the leaves about them; and this is very right, for the leaves retain more virtue than the flowers. Some dry Borage, Bugloss, and Cowslips, but they retain very little virtue in that condition. Rose-buds are to be dried, and to this purpose, their white heads are to be cut off; and the full-blown flowers may be preserved in the same manner. The Red Rose is always meant, when we speak of the dried flowers.

For the rest of the flowers used in medicine, they are best fresh; but as they remain only a small part of the year in that state, the method is to preserve them in the form of syrups and conserves. Such as the syrup of Cloves and Poppies, the Conserves of Cowslips, and the like. Of these, a short general account shall be subjoined, that nothing may be wanting to make this work as useful for families as the nature of it will admit.

Among the fruits of plants, several are to be used fresh, as the hip for conserve, and the Quince, Mulberry, and Black Currant; from the juices of which, syrups are made. As to those which are to be dried, as the Juniper berries, the Bay berries, and the like, they are only to be gathered when just ripening, not when quite mellow, and spread upon a table or floor, often turning them till they are dry. But of these we use very few of our own growth; most of the fruits used in medicine are brought from abroad, and must be purchased of the druggist or apothecary.

With respect to the seeds and plants, it is otherwise; many of them are of our own growth, and nothing is so easy as to preserve them. These are all to be used dry; but nature

has in a manner dried them to our hands: for they are not to be gathered till perfectly ripe, and then they need very little farther care. They are only to be spread for three or four days upon a clean floor, where the air has free passage, but where the sun does not come; and they are then ready to be put up.

The seeds used in medicine, may be referred to three general kinds. They either grow in naked heads or umbels, as in Fennel, Parsley, and the like; or in pods, as in Mustard and Cresses; or in large fleshy fruits, as in Melon and Cucumbers. In each case they must be left upon the plant till perfectly ripe; then they are only to be shook from the heads upon the floor, or if in pods, a smart stroke or two of the plant upon the floor, when they are thoroughly ripe, will dislodge them. In the other case, the fruit must be cut open, and they must be taken out from among the wet matter, separated from the membranes that are about them, and spread upon a table, in a dry place, where they must be often turned and rubbed as they grow dry, that in the end they may be perfectly dry and clean.

Among the roots, a great many may be used fresh, but a greater number are best dried. The black and white Briony, the Arum, and some others, lose all their virtues in drying; and many that retain some, yet lose the greater part of it: there are others which are excellent, both fresh and dried, as the Marshmallow and some more.

As to the few which lose their virtue entirely in drying, it will be best to keep some of them always in the garden, that they may be taken up as they are wanted. The others are to be managed according to their several natures, and they do a great deal towards furnishing the druggist's shop, which should be filled with medicines, the produce of our own country.

The best season for gathering roots for drying, is in the early part of the spring: what nature does for plants when they are just going to flower, she does for roots when the leaves are just going to bud; the juices are rich, fresh, and full, and the virtue is strongest in them at this season; therefore they are to be then taken up.

In the end of February and the beginning of March, the ground should be searched for the first budding of leaves, and the roots taken up. They are to be wiped clean, not washed; and, according to their several natures, prepared for drying.

Some are full of a mucilaginous juice, as Marshmallow, and above all other roots, the Squill, and in some degree many others of that kind; these must be cut into thin slices crosswise, and they will dry best if laid upon a hair-cloth stretched across a frame. They must be frequently turned, and be very thoroughly dry before they are put up, else they will become mouldy; but, rightly prepared, they keep very well.

Other roots have juices that evaporate more easily. These have the virtue either throughout the whole substance, or only in the outer part, and they are to be prepared accordingly. When roots are of one uniform substance, they generally have the virtue equal, or nearly so, in all parts. These should be split open lengthwise, first cutting off the head, and the little end; or if considerably thick, they may be quartered; when this is done, they are to be strung upon a line, by drawing a needle, threaded with a small twine, through their thickest part, and they are then to be hung up to dry in the manner of the herbs; the line being stretched across a room, the doors and windows of which are to be kept open in good weather.

When roots consist of a sort of thick rind, or fleshy substance within the rind, and a hard sticky part in the middle,

this fleshy substance under it possesses all the virtues; the hard inner substance having none: in this case, the root is to be split longwise as before, and the hard woody part is to be taken out and thrown away: the rest is to be strung, as before described, and dried in the same manner.

When roots consist of fibres, these are generally connected to a head, if it be ever so small, and the best method is to split this in two, and then string up the separate parts for drying.

It is needless to enumerate the examples of the several kinds of roots here; they follow in their places: but if charitable people would, on first looking over this book to see what are most useful, order their gardener to take out of his ground, and to seek in the fields the several roots there mentioned, and see them dried and preserved according to these directions, they would be possessed of a set of drugs of a new kind indeed; but they would save the price of many brought from other countries, and might be used with less danger.

The barks of trees make but a small part of the English drugs, and most of them are best fresh; but such as will preserve and retain their virtues dried, are very easily prepared that way: nothing more is required than to cut them into moderate pieces, and string them up in the same manner as the roots. When they are dry, they are to be put up as the others, and they will keep ever so long; but in all this time they are for the most part losing their virtues.

It may be prudent to preserve drugs brought from abroad a great while, because of their price; but as these cost only the trouble of gathering and preserving them, it is advisable that the whole shop be renewed every year; what is left of the old parcel of every kind, being thrown away as the fresh one is collected in its season.

The place for keeping these should be a dry room, neither damp nor hot; and they should now and then be looked at, to see that they are in order; that they do not grow mouldy or smell musty through damp, or become lighter, and lose their virtue by too much heat.

It may be proper just to mention, that the woods which we use are best kept in the block, and shaved off as they are wanted; for being kept in shavings, they lose their virtue: and in the same manner as to the foreign woods, it is best to keep a block of Sassafras, and of Ligaum Vitæ, in the house, and cut them as they are wanted.

As to the excrescences, such as the galls of the Oak, and the burr upon the wild Briar, they are naturally so dry, that they only require to be exposed a few days to the air upon a table; and then they may be put up with safety, and will keep a long time.

Lastly, the Funguses, such as Jew's-ears, and the like, are to be gathered when they are full grown, and strung upon a line: they must dry leisurely, or else they spoil: they must be very well dried before they are put up, else they will grow mouldy in damp weather; and if once that happen, no art can recover their virtues.

Thus may a druggist's shop of a new kind be filled, and it will consist of as many articles as those which receive their furniture from abroad; and there will be this advantage in having every thing ready; that when custom has made the virtues of the several things familiar, any person may do from his judgment as the physician in his prescription—mix several things of like virtue together, and not depend upon the virtues of any one singly, when the case requires something of power. These roots and barks powdered, will make as handsome and as efficacious boluses and mixtures as any furnished by the apothecary.

Concerning the various Methods of preparing Simples for present Use.

THERE IS NO form of medicines sent from the apothecary, which may not be prepared from the herbs of our own growth, in the same manner as from foreign drugs. Electuaries may be made with the powders of these barks, roots, and seeds, with conserves of flowers, and of the tops of fresh herbs; and syrups, made from their juices and infusions; the manner of making which is very simple, and shall be subjoined to this chapter, that all may be understood before we enter on the book itself: and in the same manner their boluses may be made, which are only some of these powders mixed up with syrup: and their draughts and juleps, which are made from the distilled waters of these herbs, with spirit, or without these, syrups being added; and the tinctures of the roots and barks; the method of making which shall be also annexed in a familiar manner.

But beside these several forms of giving them, there are others much more simple, easy, and ready, and these are generally more efficacious. We shall arrange these under three kinds; juices, infusions, and decoctions. These are the forms of giving the medicines most frequently mentioned in the course of the work, and there is less trouble in them than in the others. They are not indeed contrived for show, nor would they answer the purpose of the apothecary, for his profits would be small upon them: but when the design is only to do good, they are the first to be chosen.

Juices are to be expressed from leaves or roots; and in order to this, they are to be first beaten in a mortar. There is no form whatever in which herbs have so much effect, and yet this is in a manner unknown in the common practice of physic. The juices are to be obtained in some plants from the entire herb, as in Watercresses, Brooklime, and others that have juicy stalks; in others the leaves are to be used, as in Nettles, and the like, where the stalk is dry, and yields nothing, but is troublesome in the preparation. When the juice of a root is to be had, it must be fresh taken up, and thoroughly beaten. A marble mortar and wooden pestle serve best for this purpose, for any thing of metal is improper; many plants would take a tincture from it, and the juice would be so impregnated with it, as to become a different medicine, and probably very improper in the case in which it was about to be given.

As these juices have sometimes an ill taste, and as some of them are apt to be cold upon the stomach, or otherwise to disagree with it, there are methods to be used to make them sit better upon it; and in some cases these increase their virtues.

When the thick juice, fresh drawn, is too coarse for the person's stomach, it may be suffered to settle and grow clear: a little sugar may be added also in beating the herb, and in many cases, as in those juices given for the scurvy, the juice of a Seville orange may be added, which will greatly improve the flavour.

To the roots it is often proper to add a little white wine in the bruising, and they will operate the better for it. Thus, for instance, the juice of the Flower-de-luce root will not stay upon many stomachs alone; but with a little white wine added in the bruising, all becomes easy, and its effects are not the less for the addition. The same addition may be made to some of the colder herbs; and if a little sugar, and, upon occasion, a few grains of powdered ginger, be added, there will be scarce any fear of the medicine disagreeing with the stomach, and its effects will be the same as if it had been bruised and pressed alone.

Infusions are naturally to be mentioned after the juices, for they are in many cases used to supply their place. Juices can only be obtained from fresh plants, and there are times of the year when the plants are not to be had in that state. Recourse is then to be had to the shop, instead of the field; the plant whose juice cannot be had, is there to be found dried and preserved; and if that has been done according to the preceding directions, it retains a great part of its virtues: in this case it is to be cut to pieces, and hot water being poured upon it, extracts so much of its qualities, as to stand in the place of the other. Often, indeed, the virtues are the same, in some plants they are greatest from the infusion; but then some others lose so much in drying, that an infusion scarce has any thing. But it is not only as a help in the place of the other, that this preparation is to be used, for infusions are very proper from many fresh herbs; and are of great virtue from many dry ones, of which, when fresh, the juice would have been worth little.

Infusions are the fittest forms for those herbs whose qualities are light, and whose virtue is easily extracted: in this case, hot water poured upon them takes up enough of their virtue, and none is lost in the operation; others require to be boiled in the water. From these are thus made what we call decoctions: and as these last would not give their virtues in infusion, so the others would lose it all in the boiling; it would go off with the vapour. We know very well, that the distilled water of any herb is only the vapour of the boiled herb caught by proper vessels, and condensed to water: therefore, whether it be caught or let to fly away, all that virtue must be lost in boiling. It is from this, that some plants are fit for decoctions, and some for infusions. There are some which, if distilled, give no virtue to the water; and those are fit for decoctions, which will retain all their virtue, as Bistort, and Tormentil roots, and the like. On the contrary, an infusion of Mint, or Pennyroyal, is of a strong taste, and excellent virtue; whereas a decoction of these herbs is disagreeable, or good for nothing.

There are herbs also, which have so little juice that it would be impossible to get it out; and others, whose virtue lies in the husks and buds, and this would be lost in the operation. An infusion of these is the right way of giving them. Thus, Mother of Thyme is a dry little herb, from which it would be hard to get any juice, and when gotten, it would possess very little of its virtues; but an infusion of Mother of Thyme possesses it entirely.

Infusions are of two kinds. They are either prepared in quantity, to be drank cold; or they are drank as they are made, in the manner of tea. This last method is the best; but people will not be prevailed upon to do it, unless the taste of the herb be agreeable; for the flavour is much stronger hot than it is cold.

Infusions in the manner of tea, are to be made just as tea, and drank with a little sugar; the others are to be made in this manner:—A stone jar is to be fitted with a close cover; the herb, whether fresh or dried, is to be cut to pieces; and when the jar has been scalded out with hot water, it is to be put in: boiling water is then to be poured upon it, and the top is to be fixed on: it is thus to stand four, five, or six hours, or a whole night, according to the nature of the ingredient, and then to be poured off clear.

It is impossible to direct the quantity in general for these infusions, because much more of some plants is required than of others: for the most part, three quarters of an ounce of a dried plant, or two ounces of the fresh gathered. The best rule is, to suit it to the patient's strength and palate. It is

intended not to be disagreeable, and to have as much virtue of the herb as is necessary: this is only to be known in each kind by trial; and the virtue may be heightened, as well as the flavour mended, by several additions. Of these, sugar and a little white wine are the most familiar, but lemon juice is often very serviceable, as we find in sage tea; and a few drops of oil of vitriol give colour and strength to tincture of roses. Salt of tartar makes many infusions stronger also than they would be, but it gives them a very disagreeable taste. It is therefore fit only for such as are to be taken at one draught, not for such as are to be swallowed in large quantities time after time.

Among the herbs that yield their virtues most commodiously by infusion, may be accounted many of those which are pectoral, and good in coughs, as Coltsfoot, Ground-ivy, and the like: the light and aromatic, good in nervous disorders, as Mother of Thyme, Balm, and the like: the bitter are also excellent in infusion, but very disagreeable in decoction; thus boiling water poured upon Roman Wormwood, Gentian root, and Orange peel, makes a very excellent bitter. It need only stand till the liquor is cold, and may then be poured off for use. It is often proper to add some purging ingredient to this bitter infusion; and a little fresh Polypody root excellently answers that purpose, without spoiling the taste of the medicine.

Several of the purging plants also do very well in infusion, as Purging Flax, and the like; and the fresh root of Polypody alone is a very good one: a little lemon-juice added to the last-named infusion does no harm; and it takes off what is disagreeable in the taste, in the same manner as it does from an infusion of Senna.

Thus we see what a great number of purposes may be answered by infusions, and they are the most familiar of all preparations. Nothing is required, but pouring some boiling water upon the plants fresh or dried, as already directed, and pouring it off again when cold.

Decoctions are contrived to answer the purpose of infusions, upon plants which are of so firm a texture, that they will not easily yield forth their useful parts. In these the ingredients are to be boiled in the water; as, in the others, the boiling water was to be poured over them. In general, leaves, flowers, and entire plants, whether fresh or dried, are used in infusions; the roots and barks in decoctions.

An earthen pipkin, with a close cover, is the best vessel for preparing these; for many of those medicines which are little suspected of it, will take a tincture from the metal; and it would be as improper to boil them in a copper pan, (as it is too common a custom,) as to beat the herbs and roots in a metal mortar.

Fresh roots are used in decoction, as well as those which are dried; and the barks and other ingredients in like manner. When the fresh are used, the roots are to be cut into thin slices, and the barks and woods should be shaved down; as to the leaves and entire plants, they need be cut but slightly. When dry ingredients are used, the roots and barks are best pounded to pieces; and as to the herbs and flowers, little is to be done to them, and in general, they are best added toward the end of the decoction.

It is always best to let the ingredients of a decoction stand in the water cold for twelve hours, before it is set on the fire, and then it should be heated gradually, and afterwards kept boiling gently as long as is necessary: and this is to be proportioned to the nature of the ingredients. Generally a quarter of an hour is sufficient, sometimes much longer is necessary. They are then to be strained off while

they are hot, pressing them hard, and the liquor set by to cool: when they are thoroughly cold, they are to be poured off clear from the settlement, for they always become clear as they cool, and sweetened with a little sugar. Frequently also, it is proper to add to them a little white wine, as to the infusions.

~~~~~  
*Concerning distilled Waters, and other Preparations to be kept in the House.*

That spirit is best which is called molasses spirit; it is to be bought at a small price at the distillers; and as to the sugar, the most ordinary loaf kind will do for most purposes; where other is necessary it will be particularly named.

Few families are without an alembic or still; and that will be of material service. With that instrument the simple waters are to be made, with no expense beside the fire; and it will be proper to keep those of the following ingredients.

Mint-water, Peppermint-water, and Pennyroyal-water, are to be made of the dry herbs. Three pounds of each are to be put into the still, with four gallons of water, and two gallons is to be distilled off. Milk-water is to be made thus: a pound and a half of Spear-mint, a pound of Rue, half a pound of Roman Wormwood, and half a pound of Angelica leaves, are to be put into the still with five gallons of water, and three gallons are to be distilled off. Common Mint-water is good in sicknesses of the stomach, Peppermint-water in colics, and Pennyroyal to promote the menses. Milk-water is good in fevers, and to make juleps. It used to be made with milk, but that answers no purpose. Only one simple water more need be kept, and that for colics; it is best made of Jamaica pepper: a pound of Jamaica Pepper is to be put into a still over night, with three gallons of water; and the next morning two gallons of water distilled off.

It has been customary to keep a great many simple waters, but these are all that are necessary or proper. The other herbs are better to be given in infusion and decoction.

As for cordial waters, they are made as the others, only with the addition of spirit. It may be proper to keep the following; and no more are necessary,

1. Cinnamon-water; which is made by putting into the still a pound of cinnamon, a gallon of spirit, and a gallon of water, and the next day distilling off a gallon. This is good in sickness at the stomach, and is a fine cordial.

2. Spirituous milk-water; made from a pound of Spear-mint, half a pound of Angelica, and a quarter of a pound of Roman Wormwood, all green: to these is to be put a gallon of spirit, and a gallon of water, and a gallon to be distilled off; to which is to be added a pint of vinegar; this is good to promote sweat, and is used instead of treacle-water, being better.

3. Strong Pennyroyal-water, (which is used instead of hysteric water in all hysteric cases, and to promote the menses) is made of a pound and a half of dry Pennyroyal, a gallon of spirit, and six quarts of water, drawing off a gallon.

4. Aniseed water, (which is good in the cholic,) is made with a pound of Aniseed, a pound of Angelica seed, and two gallons of spirit, with one gallon of water, distilling off two gallons.

No more of these are necessary: but it may be acceptable to add the making of Lavender water, spirit of Lavender, and Hungary water, which are preparations of the same kind, and very easy.

Lavender-water is made from a pound of fresh Lavender flowers, and a gallon of molasses spirit, with two quarts of water; five pints are to be distilled off. Hungary-water is made of a pound and half of Rosemary tops with the flowers,

a gallon of spirit, and a gallon of water, distilling off five pints: and to make the spirit of Lavender, or palsy drops, mix three pints of Lavender-water, and one pint of Hungary-water, and add to this half an ounce of Cinnamon, the same quantity of Nutmegs, and three drachms of red Saunders-wood; these are to stand together till the spirit is well coloured.

This is all the family practitioner will need with distilling: a short account, but sufficient.

As for *Tinctures*, which are a great article with the apothecary and chemist, making a great show, and really very useful; I would have several of them kept, and they are as easily made as the waters, nay, more easily. Molasses spirit is all that is necessary for this purpose.

It would be well to keep tinctures of all roots and barks which are recommended to be dried in the course of this work, for a tincture will contain more or less of the virtue of every one of these, and be often convenient, where the powder or decoction could not be given. It is needless to enumerate these, and one rule of making serves for them all: two ounces of the ingredient is to be cut into thin slices, or bruised in a mortar, and put into a quart of spirit; it is to stand a fortnight in a place a little warm, and be often shook: at the end of this time, it is to be taken out, strained off, and made to pass through a funnel, lined with whitish brown paper, and put up with the name of the ingredient.

To these tinctures of roots, barks, and seeds, it would be well to add a few made of foreign ingredients. As,

1. The bitter tincture for 'the stomach, is made of two ounces of Gentian, an ounce of dried Orange peel, and half an ounce of Cardamom seeds, and a quart of spirit: or it may be made in white wine, allowing two quarts.

2. Tincture of Castor, good in hysteric complaints; and made with two ounces of Castor, and a quart of spirit.

3. Tincture of Bark, which will cure those who will not take the powder; made of four ounces of bark, and a quart of spirit.

4. Tincture of Soot, for fits; made with two ounces of wood-soot, one ounce of assafetida, and a quart of spirit.

5. Tincture of Steel, for the stoppage of the menses; made of flowers of iron four ounces, and spirit a quart.

6. Tincture of Myrrh, good for curing the scurvy in the gums; made of three ounces of Myrrh, and a quart of spirit.

7. Tincture of Rhubarb; made of two ounces of Rhubarb, half an ounce of Cardamom seeds, and a quarter of an ounce of Saffron, with a quart of spirit.

8. Elixir Salutis; made of a pound of stoned Raisins, a pound of Senna, an ounce and a half of Carraway seeds, and half an ounce of cardamoms, in a gallon of spirit.

9. Elixir of Vitriol; made of six drachms of Cinnamon, three drachms of Cardamoms, two drachms of long pepper, and the same of ginger; and a quart of spirit: to a pint of this tincture strained clear off, is to be added four ounces of oil of vitriol: this is an excellent stomachic.

Lastly, to these it may be well to add the famous Friar's Balsam, which is made of three ounces of Benjamin, two ounces of strained Storax, one ounce of Balsam of Tolu, half an ounce of aloes, and a quart of spirit of wine, such as is burnt under lamps. This spirit may be made by putting a gallon of molasses spirit into the still, and drawing off two quarts, and this will be useful for spirit of wine and camphire, which is made by dissolving an ounce of camphire in a quart of the spirit. And what is called the Asthmatic Elixir, made with the flower of Benjamin and Opium, of each a drachm, Camphire two scruples, oil of Aniseed forty drops, Liquorice root half an ounce, honey one ounce, and a quart

of spirit. This is a gentle opiate, and is much better in families than the strong laudanum.

As to the tinctures made with white wine instead of spirit, a few are sufficient. Steel wine is made of a quarter of a pound of filings of Iron, and half an ounce of Mace, and the same quantity of Cinnamon, put into two quarts of Rhenish. Hiera Picra is made of half a pound of Aloes, two ounces of Winter's bark, and five quarts of white wine. The first is a restorative cordial and strengthener: the latter is sufficiently known as a purge.—Laudanum is made of two ounces of Opium, a drachm of Cloves, and a drachm of Cinnamon, and a pint of wine.—Viper wine is made of two ounces of dried viper, and two quarts of white wine: and the tincture of Ipecacuanha for a vomit, of two ounces of that root, half an ounce of dry Orange peel, and a quart of sack.—Lastly, what is called Elixir Proprietatis, is made of Aloes, Myrrh, and Saffron, of each an ounce, Sal Ammoniac six drachms, and Salt of Tartar eight ounces, in a quart of mountain wine.

These are all the tinctures and wines that need be kept in a family, whose charity is designed to be very extensive; the expense of the whole is a trifle not worth naming, and the trouble scarce any thing. Books are full of directions in particular for every tincture, as if every one were to be made a different way; but the best method is to give a good deal of time, and frequently shaking, and that will stand in the place of heat in most things of this kind: nevertheless, they should stand in a room where a fire is kept while they are making; and those which require heat, that is, those that take a colour most slowly, are to be placed nearest to it.

Easy as these are, they are by far the most difficult part of the task, the rest is at it were nothing. Conserves, syrups, and ointments will be wanting; but in the same manner one direction will serve for the making the whole assortment of each, and the ingredients will be at hand. As to plasters in general, they do more harm than good. Surgeons at this time make very little use of them; and in the course of this work, many herbs will be named, the bruised leaves of which are better than all the plasters in the world.

*Conserves* should be made of Rue, Mint, Scurvy Grass, Wood Sorrel, and Roman Wormwood. As to the four first, the leaves are to be picked off from the stalks, and beaten up with three times the weight of sugar. The tops of the young shoots of the latter are to be cut off, and they are to be heat up in the same manner. In the course of this work, many plants will be named, the green tops of which contain their virtue, these may all be made into conserves in the same manner, or as many of them added to those here named as shall be thought proper.

Conserves of the flowers of Rosemary, Mallows, Archangel, and Lavender, are to be made also in the same manner, and of Red-rose buds. These last are to be picked from the husk, and the white heels are to be cut off. They are all to be beat up with three times their weight of sugar; and in the same manner may be made conserves of Cowslip flowers, and of those of many other plants mentioned in the following pages.

The outer rind of Seville Oranges and Lemons, are also to be made into conserves in the same manner, beating them first to a pulp, and then adding the sugar; and to these must be added the conserve of Hips and Sloes, which are to be made in a particular manner. The Hips are to be gathered when fully ripe, afterwards set by in a cellar till they grow very soft; then they are to be laid upon the back of a large hair sieve, a dish being put underneath; they are to be broke with the hand or a wooden pestle, and rubbed about till all the soft matter is forced through the hair-cloth, the seeds and skins

only remaining. This soft matter is to be weighed, and to be beat up in a mortar with twice its weight of loaf sugar, first powdered. Sloes are to be gathered when they are moderately ripe, and they are to be set over the fire in water, till they swell and are softened, but not till the skin bursts; they are then to be laid upon a sieve, and the soft matter driven through, as in the other case; and three times the quantity of sugar is to be mixed with this, that it may make a conserve by beating together.

*Syrups* are to be made of many ingredients: they may be made indeed of any infusion, with sugar added to it in a due quantity; and the way to add this, so that the syrups shall keep and not candy, is to proportion the sugar to the liquor very exactly. One rule will serve for all this matter, and save a great deal of repetition. The liquor, of which a syrup is to be made, may be the juice of some herb or fruit, or a decoction, or an infusion; whichever it be, let it stand till quite clear; then, to every wine pint of it, add a pound and three quarters of loaf sugar, first beat to powder; put the sugar and the liquor together into an earthen pan that will go into a large saucepan; put water in the saucepan, and set it over the fire. Let the pan stand in it till the sugar is perfectly melted, scumming it all the time; then, as soon as it is cold, it may be put up for use, and will keep all the year round.

This being set down as the general method of making the liquor into a syrup, the rest of the descriptions of them will be easy. They are to be made in this manner: For syrup of Cloves, weigh three pounds of Clove, July-flowers picked from the husks, and with the white heels cut off; pour upon them five pints of boiling water. Let them stand all night, and in the morning pour off the clear liquor, and make it into a syrup, as directed above: in the same manner are to be made the syrups of Violets and Red Poppies: but less of the Violet flowers will do, and more of the Poppies may be added: thus, also, are to be made the syrups of Damask Roses, Peach-blossoms, Cowslip-flowers, and many others which will be recommended for that purpose in this book.

Syrup of Buckthorn is to be made by boiling the juice down to half its quantity, with a little cinnamon, ginger, and nutmeg, and then adding the sugar.

The Syrups of Lemon juice, Mulberries, and the like, are to be made with a pound and half of sugar to every pint of the clear juice, which is to be melted, as in the former manner.

Syrup of Garlic, Leeks, Orange-peel, Lemon-peel, Mint, and many other things, are to be made of strong infusions of those ingredients, made as before directed, with the first-mentioned quantity of sugar added, when they have stood to settle.

Syrup of Marshmallows, and of Poppy heads, and some others, are to be made in the same manner with the strongest decoctions that can possibly be made from those ingredients, with the same quantity of sugar as is first mentioned.

Syrup of Balsam is made by boiling a quarter of a pound of Balsam of Tolu, in a pint and half of water, in a close vessel, and then making the water into a syrup, with the usual quantity of sugar: and thus may be made syrups of any of the balsams.

Syrup of Saffron is made of a strong tincture of Saffron in wine. An ounce of Saffron being put to a pint of mountain, and this, when strained off, is to be made into a syrup with the usual quantity of sugar.

At one time it was a custom to keep a quantity of syrups of a particular kind under the name of honeys. They were made with honey instead of sugar, and some of them, which had vinegar in the composition, were called oxymels. A few

of the first kind, and very few, are worth keeping, and two or three of the latter, for they have very particular virtues. The way of making them is much the same with that of making syrups; but, to be exact, it may be proper just to give some instances of it.

Honey of Roses is the most useful, and is to be made of an infusion of the flowers and honey in this manner. Cut the white heels from some red-rose buds, and lay them to dry in a place where there is a draught of air; when they are dried, put half a pound of them into a stone jar, and pour on them three pints of boiling water; stir them well, and let them stand twelve hours; then press off the liquor, and when it has settled, add to it five pounds of honey, boil it well, and when it is of the consistence of a thick syrup, put it by for use. It is good against sore mouths, and on many other occasions. In the same manner may be made the honey of any flower; or with the juice of any plant thus mixed with honey, and boiled down, may be made what is called the honey of that plant.

As to the oxymels, they are also made in a very uniform manner. The following are so useful, that it will be proper always to keep them in readiness.—For Oxymel of Garlic, put half a pint of vinegar into an earthen pipkin, boil it in a quarter of an ounce of Carraway seeds, and the same quantity of sweet Fennel seeds, at last add an ounce and a half of fresh Garlic root sliced; then let it boil a minute or two longer, then cover it up to stand till cold, then press out the liquor, and add ten ounces of honey, and boil it to a consistence.

For Vinegar of Squills, put into a pint of vinegar three ounces of dried Squills; let it stand two days in a gentle heat, then press out the vinegar, and when it has stood to settle, add a pound and half of honey, and boil it to a consistence. Both these are excellent in asthmas.

To these also should be added, the common simple oxymel, which is made of a pint of vinegar, and two pounds of honey boiled together to the consistence of a syrup.

Finally, as to *Ointments*, nothing can be so easy as the making them of the common herbs; and the expense is only so much hog's lard. The lard is to be melted, and the fresh-gathered leaves of the herb are to be chopped to pieces, and thrown into it: they are to be boiled till the leaves begin to feel crisp, and then the lard is to be strained off. It will be green, and will have the virtues of the herb, and must be called ointment of such an herb.

To these we shall add, the way to make two or three more, which, though not the produce of English herbs, are very useful, and no family should be without them.

1. The white ointment, called Unguentum: this is made by melting together four ounces of white wax, and three ounces of spermaceti, in a pint of salad oil, and adding, if it be desired, three ounces of eeness, and a drachm and half of camphire; but it is better, for all common purposes, without these.

2. Yellow Basilicon; which is made by melting together yellow wax, resin and burgundy pitch, of each half a pound, in a pint of oil of olives, and adding three ounces of turpentine.

3. Black Basilicon; which is made by melting together, in a pint of olive oil, yellow wax, resin, and pitch, of each nine ounces.

4. The Mercurial Ointment, which is thus made: rub together, in an iron mortar, a pound of quicksilver, and an ounce of turpentine; when they are well mixed, add four pounds of hog's-lard melted, and mix all thoroughly together. The Ointment of Tutty is prepared with levigated tutty, and as much viper's fat as will make it into a soft ointment: these

are only to be mixed together upon a marble, by working them with a thin knife. This is for disorders of the eyes; the foregoing for the itch, and other complaints, but it must be used cautiously; and those before named, for old sores.

Of the same nature with the ointments, are, in some degree, the Oils made by infusion of herbs and flowers in common oil. These are also very easily prepared, and an instance or two will serve to explain the making of them all.

1. The most regarded among these is the Oil of St. John's-wort, and that is thus made: pick clean a quarter of a pound of the flowers of Common St. John's-wort, pour upon them a quart of olive oil, and let them stand together till the oil is of a reddish colour.

2. Oil of Elder is made of a pound of Elder flowers, which are to be put into a quart of olive oil, and boiled till they are crisp, and the oil is to be then strained off.

3. What is called the Green Oil, is thus made: bruise in a marble mortar three ounces of green Camomile, with the same quantity of Bay leaves, Sea-wormwood, Rue, and Sweet Marjoram; then boil them in a quart of oil of olives, till they are a little crisp. The oil is then to be poured off, and when cold, put up for use.

These oils are used to rub the limbs when there is pain and swellings; their virtues will be found at large, under the several herbs which are the principal ingredients: and after one or other of these methods, may be made the oil by infusion, or by boiling of any plant, or of any number of plants, of like virtue.

Lastly though herbs are now left out of the composition of *Plaisters*, even the melilot being now made without the herb from which it was first named, it may be proper to add the way of preparing a few that are most useful, and ought to be kept in families.

1. The common plaister is thus made; boil together a gallon of oil, five pounds of powdered litharge, and a quart and four ounces of water. When the water is boiled away, the rest will be united into a plaister, but it must be stirred all the time: this used to be called diachylon. To make diachylon with the gums, add to a pound of the last described, two ounces of galbanum, and an ounce of common turpentine, and the same quantity of frankincense. Melt them all together, the gums first, and then add the plaister.

2. For a strengthening plaister; melt two pounds of the common plaister, and add to it half a pound of frankincense, and three ounces of dragon's blood.

3. For a drawing plaister; melt together yellow wax and yellow resin, of each three pounds, and a pound of mutton suet. This is used, instead of the old melilot plaister, to dress blisters; and the blister plaister itself is made of it, only by adding half a pint of vinegar, and a pound of Spanish flies in powder, to two pounds of it, just as it begins to cool from melting. The quicksilver plaister is thus made: rub three ounces of quicksilver, with a drachm of balsam of sulphur, till it no longer appears in globules, then pour in a pound of the common plaister melted, and mix them well together.

A few recipes for making *waters* without distillation, are added, which being cheap and very serviceable, ought not to be omitted.

1. Lime-water; this is made by pouring gradually six quarts of water upon a pound of quick lime; when it has stood to be clear, it must be poured off. If a pound of *Lignum-vitæ* wood, an ounce of Liquorice root, and half an ounce of Sassafras bark, be added to three quarts of

lime-water, it is compound lime-water, and is excellent in foulnesses of the blood.

2. The blue eye-water; this is made by putting a drachm of sal ammoniac into a pint of lime-water, and letting it stand in a brass vessel, till it is of a sky-blue colour.

3. Alum-water is made by boiling half an ounce of white vitriol, and the same quantity of alum, in a quart of water, till they are dissolved.

Thus have we described all the drugs and compositions, that need be kept for family use, or to relieve the neighbouring poor in their greatest of all distresses, that of sickness. The diseases for which these remedies are to be used, will be found enumerated at large under the several heads of the principal ingredients as described in the succeeding pages. It only remains to say a few words about the manner of putting these things most conveniently together, and we then shall have prepared for all that follows.

~~~~~

Concerning the best Methods of putting Medicines together for present taking.

IN the first place, although these several forms of syrups, conserves, and the like, have been named as what will be sometimes necessary; the great practice in the country will lie in the infusions and decoctions of the fresh plants and roots.

The strength of these infusions and decoctions is to be proportioned to the taste: for as they are made to be swallowed in quantities, if they be made so strong as to be very disagreeable, that end will be defeated: they may be rendered more pleasant by sweetening them with sugar, about an ounce of which is to be allowed to a quart; and occasionally a little white wine, or a small quantity of some of the cordial waters, may be added to them. The dose of either decoction or infusion, will be in general about half a pint, except where they are intended to purge or vomit; there they must be more carefully and exactly proportioned to the strength, than can be told in this general manner.

Of the simple waters, about a quarter of a pint is a dose; and of the cordial waters, less than half that quantity. These may be occasionally given alone; but they are mostly intended for mixing with other ingredients.

The tinctures are to be given in drops, from ten to an hundred, according to their strength and nature; but to name a general dose it is about five and twenty drops. These, however, will be also more serviceable in mixtures, than singly.

Of the purging tinctures in wine, and the elixir salutis, three, four, or more spoonfuls, is the dose.

It would be well to keep tinctures of many of the roots recommended in nervous cases, as cordials, astringents, and of many other kinds; and also to keep powders of these roots in readiness: and thus the common forms of medicines, as sent from apothecaries, will be very easy.

For julep, six ounces of one of the simple waters, two ounces of one of the compound waters, or those made with spirit, two drachms of a syrup, and fifty drops of a tincture, make a very agreeable one. Thus, for an hysteric julep, let the simple water be Pennyroyal, the strong water the strong Pennyroyal, the syrup that of Saffron, and the tincture of Castor; and it is a very pleasant julep: and so of all the rest. If a pearl cordial be desired, it is only mixing the simple and strong waters without syrup or tincture and adding two drachms of sugar, and half a drachm levigated oyster-shells.

Draughts are only little juleps, with more powerful ingredients added to them. An ounce and half of a simple water, three drachms of a strong water, one drachm of a syrup, and forty drops of a tincture, make a draught; but to these may be added a simple of some power, to increase the virtue. What waters, tinctures, syrups, or powders, shall be used, will be determined from the case itself.

Boluses are made with these powders in a certain dose. A scruple, or half a drachm, is made into a sort of paste with syrup. The common custom is to cover it with a little leaf-gold, but this is better let alone: some use leaf-brass, which is very pernicious.

Electuaries are to be made of powders, conserves, and syrups; they differ from boluses in this, as well as in the size, that the dose is smaller, although the piece taken be as large; which is owing to the conserve, that having in general little virtue in comparison of the other ingredients. This is the form most convenient for medicines that are to be taken for a continuance of time, and the dose of which needs not be so very punctually regarded.

Thus, for an electuary against an habitual looseness, when it exceeds the proper bounds; mix together an ounce of conserve of Red Roses, and six drachms of syrup of Cloves; add to these, two drachms of powdered Bistort root, one drachm of powdered Tormentil, and half a drachm of toasted Rhubarb. This makes an electuary, a piece of which, of the bigness of a nutmeg, taken once in two days, will check the abundance of stools, without stopping the customary looseness entirely: it will also be a pleasant medicine. If a draught of tincture of Roses be taken after this, it will increase the power.

In this manner any person may supply the place of the apothecary, to those who could not afford such assistance: and experience is so good a guide, that they will be able in most cases to save the expense of the doctor also; with very little danger of doing harm. The Galenical physic, perhaps, will be found effectual in many more cases, by those who stick to it solely, than they are aware who do not use it: as to the mischief of medicine, that is almost entirely chemical. It would be idle to say that chemical medicines do not do great good; but they require to be in skilful hands: when the ignorant employ them, death is more likely to be the consequence, than relief from the disorder any other way.

One useful observation may serve well to close this Introduction. Opiums, and medicines of that kind, to compose persons to rest and to take off pain, will be often necessary; but as they are the most powerful medicines the family practitioner will have to do with, they are the most capable of doing harm: the greatest care will therefore be required in the right use of them.

As there are three different preparations described in this book for answering this purpose, beside the opium, and that solution of it in wine which is called laudanum; these two latter should be used very seldom. A syrup made of the juice of the wild Lettuce, is an excellent medicine; the syrup of Diacodium, which is made of a strong decoction of Poppy heads, is a little stronger than this; and if something more powerful than these is required, there is the Asthmatic Elixir. One or other of these may almost on every occasion serve the purpose; and it is almost impossible that the use of them should be attended with danger. Let opium or laudanum therefore be very rarely used; perhaps it might be well to say, not used at all; for the others will be able in almost all cases, if not universally to answer the purpose.

Concerning the Virtues of Plants which have not yet been tried.

THE number of English plants, whose virtues are ascertained, scarcely exceeds one thousand, while the catalogue of those which are natives of our own country, as published by Mr. Ray, amounts to many thousands: great numbers therefore remain yet untried, and present an ample field for our researches.

To what purpose can a man devote the hours of his leisure better, than to the discovering, among the number of the unregarded, virtues which may farther supply the catalogue of our own remedies, and make the roots and seeds brought from remote countries less necessary? What encouragement to the attempt, that there are such multitude of objects for the trial! and that the discovering but one remedy among them all, for a disease we knew not how so well to cure before, is a source of more true honour, than can be derived from all the useless knowledge in the world.

If any suppose the trial dangerous, they mislead themselves; and to encourage so laudable an undertaking, let it be observed, how little is the hazard, and how considerable the advantages, from what we know already.

If a man were to be turned loose upon an island where no person had set foot before, he might dread to taste of any plant he saw, because he might not know but every one he saw was fatal: and supposing him to have got over this fear, the ignorance of the virtues of all would keep him backward: but this is not at all the case with him who shall at this time set about inquiring into the virtues of plants in England. The poisonous plants, native of our soil, are hardly a dozen, and these are characterized even to the eye, by something singular or dismal in the aspect. They are well known, and he has nothing to do but to avoid them. For the rest, he has so many, whose uses and qualities are already perfectly known, that he has a great foundation to go upon in the search, because he can compare those he does not know with them. Their tastes will go a great way toward informing him: but this is not all, their very outward figures will direct him; for in general those plants which agree in the external aspect, agree likewise in their virtues.

To give an instance in the Marshmallow. It is known to work by urine, and to be good against the gravel. We will suppose no more known concerning this kind. A person desirous of extending this useful knowledge, finds that by the taste of the root, which is insipid, and its mucilaginous quality, he might have guessed this to be its virtue, from what he before knew of medicine. The next plant he meets, we will suppose is the common Mallow, and afterwards the little white-flowered Mallow, which lies upon the ground; he tastes the roots of these, and he finds they are like the other: he will therefore guess that they have the same virtues, and upon trial he will find it is so.

But this is not all: if he had examined the flower of the Marshmallow, in what manner it was constructed, and how the little threads grew within it, he would have found that the flowers of these other two Mallows were, in all respects, like those of the other; and farther, he would have found, that the seeds of these two kinds were in the same manner disposed in circular bodies: from this, he might, without tasting their roots, have been led to guess that their virtues were the same: or having guessed so much from this, he might have been thence led to taste them, and by that have been confirmed in it: but he might be carried farther; he would find the same sort of round clusters of seeds in the Hollyhock in his garden; and upon examining

the single flowers, he would see they were also alike: and hence he would discover that it was of this kind; and he would rightly judge that the Hollyhook also possessed the same virtues.

There is this great use in examining other plants which have the same sort of flowers and fruits with those which we know to have virtues, that we may in this way discover plants at home, to supply the place of those we have from other countries. It is certain the sun in warmer climates does ripen the juices of vegetables faster than in ours, but yet we find the plants of the same kind, from whatever part of the world they come, to possess nearly the same kind of virtues; generally indeed they are the same, only differing in degree. Thus all the Mallows of Spain and Italy, to bring the trial to the before-named instance, possess the same virtues with the Marshmallow, Mallow, and Hollyhook of England; and the case is the same with those which are truly Mallows of the East and West Indies; though this does not hold good with respect to some of the plants of those countries which have been brought hither under that name. Thus the Senega Rattle-snake root, which was once much in use amongst us, has been discovered to belong to a kind of Milkwort, or Polygala. The roots of the common Milkwort of our pastures being tried have been found to possess the same virtues, though in a less degree. This plant would not have been regarded, if the other had not been found to be of the same kind; but to that we owe the knowledge of its virtues.

There is this great reason for seeking in our own climate, plants of the same nature, form, and kind, with those which in other countries, afford us remedies—that they are generally of the same kind, and may be fitter for our constitutions; for as it has been before observed, the productions of each respective country, are always best suited to supply the wants of its inhabitants both for food and medicine: and it is certain, that as the sun ripens the juices of plants in hotter countries to more virtue than with us, so it makes men's constitutions more able to bear their effects.

The Chinese will swallow such doses as would poison one of us. This we know in many instances, and it ought to encourage us in the present research: because, if the same doses which agree with them are too much for us, we may also find that other medicines of our own growth, and of the same kind of virtues, though in a less degree, may also be found to agree better with our constitutions. Therefore, notwithstanding that it may be necessary in some cases, and convenient in many, for us to have drugs from abroad, yet in general it will be better for us to be cured by those herbs we may find at home; and they will be found upon trial more sufficient for that purpose than we at present imagine. The means are at hand, but we have made very little use of them, proportioned to their number and their value.

The observation already made, that the external form of plants may very well give the hint for a conjecture about

their virtues, is much more general than might be imagined. Almost all the plants of the same kinds are of the same virtues. But that is not all; for, in general, those of the same class possess the same qualities, though different in degree: and this is a great help to him who shall set out upon the generous and useful plan of adding to the number of the useful plants. It is also singular, that what might appear objections in this case, being brought to the trial, will often be found confirmations of the truth there is in the observation.

Thus, suppose a man, observing that Lettuce is eatable, should inquire into all the plants like Lettuce, which are those that have flowers composed of many parts, and have the seeds winged with a white downy matter, to find whether they were eatable: let us examine how he would succeed. The plants of this class native of England, are the Sowthistle, the Hawkweeds, the Dandelions, Goats-beards, Succory, and Endive, all eatables. The Hawkweeds are less agreeable in the taste, but wholesome; and as to the wild Lettuces, those who would bring the opiate quality of the principal of them as an objection, strengthen the observation, for the garden Lettuce also has an opiate quality. This wild one possesses it in a greater degree, but still in such a degree, that it is an excellent medicine, not at all dangerous. Its bitter taste would prevent people's eating it, for it is disagreeable; but its virtues are the same with those of Lettuce, only greater. There are some kinds of Hawkweed also, which have a bitter milky juice, altogether like that of this Lettuce; and they also have the same opiate quality.

This general observation may be carried a great deal farther. In general, the seeds of umbelliferous plants, that is, those which have little flowers in rounded clusters, each succeeded by two seeds, are good against colics; those of Carraway, Anise, Cummin, Coriander, and all of that kind, are produced by plants of this figure. In the same manner the verticillate plants, as they are called, that is, those which have the flowers surrounding the stalks, as in Mint and Thyme, are of a warm nature; and however they differ in degree and circumstance, they have the same general virtues. Farther, such plants as are insipid to the taste and smell, have generally little virtues; and, on the contrary, those which have the most fragrant smell and sharpest taste, have the greatest virtues, of whatever kind.

In general also, those plants which have a strong but an agreeable taste, are most worthy to be examined with respect to their virtues; for they are generally the most valuable: and, on the contrary, when a very strong taste is also a very disagreeable one; or, in the same manner, when the strong smell of a plant has also something heavy, disagreeable, and overpowering in it: there is mischief in the herb, rather than any useful quality. The poisonous plants of this country are very few; but they are for the most part characterized after this manner: so that they are known as it were at sight, or by the first offer of a trial.

Instructions

FOR FINDING ANY PLANT, KNOWN OR UNKNOWN,
IN THE FOLLOWING WORK.

WHEN you have the English name of the Plant, or the Linnean name of the Genus to which it belongs, it will only be necessary to refer to it in the alphabetical order of the Dictionary;—but if you should meet with a Flower or Plant to which you are an entire stranger, you must first determine its Class and Order, according to the Rules already laid down in the preceding Introduction; (see page 6.) and having found them, inspect the Table of Orders and Genera at the end of this Work, observing to which Genus of its Order your Plant belongs. When this is done, you must refer to the description of the Genus by the alphabetical arrangement of the body of the Work; and if that Genus contain only one Species, that is the Plant in question; but if it contain many Species, particular attention must be paid to the circumstances which distinguish these Species; and when you have ascertained to which Section of the Genus (if it be divided into Sections) your Plant belongs, and that Section only includes one Species, which is often the case, you have found the Plant; but if each Section includes several Species, very close attention must be paid to the characteristics of each, as they are in general extremely minute, depending principally upon the shape of the leaves and the roots.

THE

UNIVERSAL HERBAL;

OR,

BOTANICAL, MEDICAL, AND AGRICULTURAL DICTIONARY.

VOL. I.

A B R

ABEL-Tree, or *Abelc-Tree*. See *Populus*.
Abies; the Fir-tree. See *Pinus*.

Abroma; a genus of the class Polyadelphia, order Dodecandria.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets spear-shaped, acute, spreading, permanent, *Corolla*: petals five, larger than the calix; claws obovate, arched, concave, obtuse, hairy at the end, erect, inserted at the base into the nectary; borders oval, obtuse, spreading, ciliate, contracted at the base into very short, ciliate, recurved, small claws, upon which the principal claws are placed. Nectary, short, small, pitcher-shaped, divided into five segments, which are obcordate, hairy, erect, recurved and arched, alternate with the claws of the petals. *Stamina*: filamenta five, membranaceous, very small, growing on the nectary between the segments, emarginate-trifid; antheræ on each filament three, twin, kidney-form. *Pistil*: germen almost cylindrical; styles five, awl-shaped, approximating; stigmas acute. *Pericarp*: capsule egg-shaped, membranaceous, veined, five-winged, five-beaked, five-celled, gaping at top into five parts between the beaks; partitions folded. *Seeds*: very many, nearly egg-shaped, with an oblique seed-coat, fixed in a double row to the central edge of the partitions, which is thickened, and longitudinally bearded. *Receptacle of the seeds*: none. **ESSENTIAL CHARACTER.** *Pistils*: five. *Capsule*: five-celled, one-valved, gaping at top. *Seeds*: subovate, incompletely arilled.—This genus contains the following species:—

1. *Abroma Augusta*; *Maple-leaved Abroma*, with leaves heart-shaped or angular, sharply serrulate. A tree with a straight trunk, yielding a gum when cut, and filled with a white pith like the elder.—It is a native of New South Wales and the Philippine Islands; and was introduced into England about 1770. It is propagated by cuttings, but requires a strong heat, and abundance of water. The seeds will not easily ripen with us, and can seldom be obtained in a state fit for vegetation.

2. *Abroma Wheleri*; *Wheler's Abroma*. Its leaves are spear egg-shaped, sharp-pointed, and slightly toothed. A shrub—native of the East Indies. It is unknown in Europe.

VOL. I.—5.

A C A

Abrus; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-shaped, obscurely four-lobed; teeth blunt, the upper one broadest. *Corolla*: papilionaceous; banner roundish, entire, ascending, flattened at the sides, longer than the wings and keel; wings oblong, blunt; keel oblong, sickle-shaped, gibbous, longer than the wings. *Stamina*: filamenta nine, united into a sheath, cloven above, free at the end, unequal, rising; antheræ oblong, erect. *Pistil*: germen cylindrical, hairy; style subulate, rising shorter than the stamina; stigma in the form of a head, and small. *Pericarp*: legume like a rhomb, compressed, coriaceous, double-valved, four or five celled, sharp-pointed, with a little awl-shaped deflexed claw. *Seeds*: solitary, and nearly globular.—**ESSENTIAL CHARACTER.** *Calix*: obscurely four-lobed; the upper lobe broadest. *Filamenta*: nine, united into a sheath at bottom, gaping at the back. *Stigma*: blunt. *Seeds*: subglobose.—There is but one species.

1. *Abrus Precatorius*, or *Jamaica Wild Liquorice*, which is indigenous in the East and West Indies, Guinea, and Egypt. The seeds of this plant are commonly strung, and worn as ornaments by the natives of those countries. Linneus says they are extremely deleterious, although they are eaten in Egypt: however, authors agree that they are the hardest and most indigestible of all the pulse tribe, producing violent flatulencies in the bowels.—This plant may be propagated by seeds which have been soaked twelve or fourteen hours in water, before they are sown, which must be in a good hot-bed in the spring. If sown without soaking, they frequently lie a whole year without vegetating, but will appear in a fortnight, if the seed be good and well soaked, and the bed in a proper temperature of heat. When the plants are two inches high, they should be transplanted each into a separate pot, filled with light earth. They flower in the second year, and sometimes ripen their seeds in England.

Acana, a thorn; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved; leaflets ovate, concave, equal, permanent. *Corolla*: none, unless the calix be termed one. *Stamina*: filamenta

O

equal, of middle length, opposite the calix; *antheræ* four-cornered, twin, erect. *Pistil*: germen inferior, obovate, bristled; style very small, bent in on one side; stigma a small, many-cleft, thickish, coloured membrane. *Pericarp*: a dry, obovate, one-celled berry, beset with thorns bent backwards. *Seed*: single. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: four-petalled. Berry dry, inferior. one-seeded, with spines bent backwards.—The only species in this genus is the *Acæna elongata*, a Mexican plant.

Acalypha; a genus of the class *Monœcia*, order *Monadelphia*.—**GENERIC CHARACTER.** *Male* flowers crowded above the *Females*. *Calix*: perianth three or four leaved; leaflets roundish, concave, and equal. *Corolla*: none. *Stamina*: filamenta eight to sixteen, short, crowded, connected at the base; *antheræ* roundish. *Female* flowers fewer, below the others, received into a large undivided involucre. *Calix*: perianth three-leaved; leaflets subovate, concave, converging, small, permanent. *Corolla*: wanting. *Pistil*: germen roundish; styles three, branching, usually three-parted, long; stigmas simple. *Pericarp*: capsule roundish, three-furrowed, three-celled; the valves gaping two ways. *Seeds*: solitary, roundish, very large. **ESSENTIAL CHARACTER.** *Male. Calix*: three or four leaved; no *Corolla*; from eight to sixteen stamina. *Female. Calix*: three leaved; no *Corolla*; three styles. *Capsule*: three-grained, three-celled. *Seed*: one.—The species are as follows:

1. *Acalypha Virginica*; *Virginian Acalypha*: with female involucre, heart-shaped, gashed; leaves ovate-lanceolate, longer than the foot-stalk.—It grows naturally in Virginia, and other parts of North America, and even in Ceylon. It is an annual plant, seldom above a foot high, and in its leaves much resembles Pellitory. All the culture it requires, is to keep it free from weeds, and to let it remain where sown, as it does not bear removing well. It flowers in August, and the seeds ripen in October.

2. *Acalypha Virgata*; *Jamaica Acalypha*: has female spikes with heart-shaped involucre, serrate; males distinct, naked; leaves spear egg-shaped.—It is a native of the warmest countries, and grows plentifully in Jamaica: it is an annual plant, which seldom exceeds a foot high in England. The leaves are very like those of the annual Nettle, and will sting as much when touched. It will not thrive in the open air in this country, but must be sown in pots, and plunged into hot-beds.

3. *Acalypha Indica*; *Indian Acalypha*. Female involucre heart-shaped, and slightly notched; leaves ovate, shorter than the petiole.—It grows about three feet high; and was discovered in great plenty at Vera Cruz. It inhabits marshy places; but is found upon dunghills in the East Indies: it is an annual plant, which flowers in July.

4. *Acalypha Villosa*; *Villose Acalypha*. Female involucre very small, toothed, and extremely villose; spikes elongate; leaves ovate, pointed, serrate, longer than the foot-stalk.—Grows in the woods of Carthægena.

5. *Acalypha Australis*; *South American Acalypha*. Female involucre quite entire; leaves lanceolate-obtuse.—It is a native of South America.

6. *Acalypha Hernandifolia*. Female spikes very long; involucre cordate, serrate; males distinct, naked; leaves subcordate, serrate, on very long petioles.—It is a native of the West Indies.

7. *Acalypha Corensis*. Female flowers terminating, distinct; involucre three-leaved; males, spikes axillary, involucre; leaves ovate serrate.—Grows in the West Indies.

8. *Acalypha Lævigata*. Female spikes with many-parted involucre; male spikes lax, naked; leaves wedge-ovate,

acuminate, serrulate, very smooth.—It is found in the West Indies.

9. *Acalypha Elliptica*. Female spikes with involucre shorter than the germs, ovate-toothed, hirsute; males naked, lax; leaves elliptic, acuminate-toothed.—It is a native of the West Indies.

10. *Acalypha Reptans*. Spikes terminating, erect; flowers mixed; females lower; involucre cordate, serrate; males leafless; leaves ovate, serrate; stem creeping.—Grows in Hispaniola and Jamaica.

11. *Acalypha Tomentosa*. Female spikes terminating, solitary; involucre many-parted; males in spikes; leaves ovate-lanceolate, serrate, scabrous, villous, tomentose underneath.—It is a native of the West Indies.

12. *Acalypha Angustifolia*. Female flowers subsessile, terminating; involucre serrate; males in spikes; leaves linear, serrate.—Found in the West Indies.

13. *Acalypha Scabrosa*. Female spikes with cordate gashed involucre; leaves oblong-lanceolate, serrate, scabrous.—It is a native of the West Indies.

14. *Acalypha Betulæfolia*. Female flowers axillary, sessile; involucre cordate, crenate; males in spikes; leaves roundish, crenate, smooth.—Native of the West Indies.

These plants having neither use nor beauty to recommend them, they are preserved in botanic gardens for the sake of variety.

Acanthus; a genus of the class *Didynamia*, order *Angiospermia*.—**GENERIC CHARACTER.** *Calix*: perianth with leaflets in three alternate pairs, unequal, permanent. *Corolla*: one-petalled, unequal; tube very short, closed with a beard; upper lip none, under lip very large, flat, straight, very broad, three-lobed, obtuse, the length of the upper lip of the calix. *Stamina*: filamenta four, subulate, shorter than the corolla, the two upper rather longer, recurved, incurved at the top; *antheræ* oblong, compressed, obtuse, the lateral ones parallel, villous before. *Pistil*: germen conical; style filiform, length of the stamina; stigmas two, acute, lateral. *Pericarp*: capsule subovate with a point, two-celled, two-valved, with a contrary partition; claws alternate, curved, fastened to the partition. *Seed*: ovate, gibbous, single, sometimes two. **ESSENTIAL CHARACTER.** *Calix*: two-leaved, bifid. *Corolla*: one-lipped, bent down, trifold. *Capsule*: two-celled.—The species of this genus are,

1. *Acanthus Mollis*; *Smooth Acanthus*, *Brank Ursine*, or *Bear's Breech*. Its leaves are sinuate and unarmed. The flowers are white. This species is used in medicine, under the name *Branca Ursina*. Wherever it abounds, it is used for the same purposes as the *Althæa*, or the *Marshmallow*. The roots and leaves abound with a soft slippery mucilage, which is readily extracted, either by boiling, or infusing them in water; and is of singular efficacy in tickling coughs, catarrhs, defluxions on the lungs, hoarseness, erosions of the bowels, and the strangury, and for lubricating the urinary passages, in nephritic and calculous disorders. It may be propagated either by seeds, or by parting the roots. The seeds should be sown towards the end of March, and if the season be favourable, they will appear in May; they only require to be kept six inches asunder, and free from weeds, till autumn, when they should be transplanted whither they are intended to remain. They take deep root, and when once established in a garden, are hard to eradicate. It requires a warm situation. It is said that the leaves of this species of the *Acanthus*, found accidentally growing round a basket covered with a tile, gave occasion to *Callimachus* to invent the *Corinthian capital*.—It is a native of Naples, Sicily, Provence, and the Archipelago.

2. *Acanthus Carduifolius*; *Thistle-leaved Acanthus*. Leaves sinuous-toothed, thorny; spike of flowers radical.—This was found at the Cape of Good Hope: respecting its culture and propagation, see the preceding species.

3. *Acanthus Spinosis*; *Prickly Acanthus*. Leaves pinnatifid, thorny.—It grows wild in Italy and Provence, and flowers from July to September. It requires the same treatment in cultivation as the two preceding species.

4. *Acanthus Dioscoridis*; *Acanthus of Dioscorides*. Leaves lanceolate, quite entire, and thorny on the margin.—According to Rauwolf, this species, which Linneus supposed to be the genuine species of Dioscorides, grows naturally on mount Lebanon in the East.

5. *Acanthus Illicifolius*; *Holly-leaved Acanthus*. Leaves repand, tooth-thorny; stem shrubby, prickly. It is an evergreen, rising about four feet high, very like the common Holly, and armed with spines in the same manner.—Native of the East and West Indies, and of some of the islands in the South Seas. It is too tender to thrive without a stove in England, and can only be propagated by seeds, which do not ripen in Europe.

6. *Acanthus Integrifolius*; *Entire-leaved Acanthus*. Leaves oblong, entire; stem herbaceous, procumbent.—It is a native of the Cape.

7. *Acanthus Procumbens*; *Procumbent Acanthus*. Leaves oblong, serrate, and ciliate; stem procumbent, shrubby.—Native of the Cape.

8. *Acanthus Furcatus*; *Forked Acanthus*. Leaves oblong, tooth-thorny; stem shrubby; bractes terminated by a three-forked thorn.—Native of the Cape.

9. *Acanthus Capensis*; *Cape Acanthus*. Leaves oblong, toothed, thorny; stem shrubby, erect; bractes terminated by a simple thorn.—Native of the Cape.

10. *Acanthus Maderaspatensis*; *Madras Acanthus*. Leaves four-fold; flowers axillary; calices ciliate, with an herbaceous dichotomous stem.—It is a native of the East Indies; and will not thrive in England without a stove.

Acer; a genus of the class Polygamia, order Monœcia. —GENERIC CHARACTER. *Hermaphrodite Flowers*. *Calix*: perianth one-leafed, five-cleft, acute, coloured, flat and entire at the base, permanent. *Corolla*: petals five, ovate, broader outward, obtuse, scarcely larger than the calix, spreading. *Stamina*: filamenta eight, subulate, short; antheræ simple; pollen cruciform. *Pistil*: germen compressed immersed in a convex, perforated, large receptacle; style filiform, advancing in height daily; stigmas two (or three), pointed, slender, reflex. *Pericarp*: capsules two or three, growing together at the base, roundish, compressed, each terminated by a very large membranous wing. *Seeds*: solitary, roundish. N. B. The male flowers are the same with the hermaphrodites, except that they have neither germen nor style, but only a bifid stigma. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Corolla*: five-petalled. *Stamina*: eight (or ten); *Germena*: two (or three), superior. *Style*: simple. *Capsules*: two, sometimes three, with one seed in each, terminated by a wing. *Males*: without germen or style.—This genus consists of hardy deciduous trees, easily propagated by sowing their seeds soon after they are ripe, in a bed of common earth, covering them half an inch thick with light mould. In the spring they will appear above ground, and if kept clear from weeds, and watered in dry weather, some of the sorts will grow above a foot high the first summer. The autumn or spring following, if they are close in the seed-bed, it will be proper to transplant them into a nursery, in rows at three feet distance, and two feet asunder in the rows. They may remain there three or four years, in which time they will

become large enough to plant out for continuance.—The species are,

1. *Acer Sempervirens*; *Evergreen Maple*. Leaves ovate, quite entire, evergreen, this is thought to be a variety of the Cretan Maple: see the seventeenth species.

2. *Acer Tataricum*; *Tartarian Maple*. Leaves heart-shaped, undivided, serrate; lobes obscure; flowers in racemes.—It is a native of Southern Russia, by the Tanais, Volga, &c. The wood is whitish; but with some brownish veins. The seeds, boiled with mild and butter, are used as astringents by the Calmuck Tartars. It is very difficult to raise in England.

3. *Acer Pseudoplatanus*; *Great Maple*, or *Sycamore*. Leaves five-lobed, unequally serrate; flowers in racemes. This tree grows wild in mountainous situations, in Switzerland, Austria, Germany, and Italy. In England it is vulgarly called the *Sycamore*, and sometimes the *Mock Plane-tree*, and in Scotland it is termed the *Plane-tree*. It was formerly much used for planting walks and avenues, and is excellent for plantations near the sea, or for sheltering other trees from the spray, which they resist with less injury than most trees. In pastures, also, they are least injurious to the grass. The wood was once much in request for trenchers, being very white and soft. It is still used by turners for bowls, dishes, &c. by saddlers for saddle-trees; and is recommended for cart and plough timber, being light and tough, though inferior to Ash. It is a quick-growing wood, thriving wonderfully on warm, sound, rich land, rising so as to make excellent walks and shady bowers; useful for inward building, where better timber is wanting; and for firing, when wood grows scarce; hence it is generally reckoned proper for underwood, because it shoots fast from the stool, and makes good fuel. In spring and autumn this species will pour forth from the wounded stem abundance of saccharine juice, in the same manner as the Birch; from which Mr. Ray, on the authority of Dr. Martin Lister, says that a good wine may be made.

4. *Acer Rubrum*; *Scarlet-flowering Maple*. Leaves five-lobed, slightly toothed, glaucous underneath; peduncles very simple and aggregate. Of this tree there are two varieties in nurseries. 1. The Virginian Scarlet-flowering Maple. 2. Sir Charles Wager's Flowering Maple. With us it is propagated for the sake of the scarlet flowers which appear in the spring. In Pennsylvania, where it grows in the swamps, the natives use it for almost all sorts of wood-work; with the bark they dye a dark blue, and make a good black ink. The Canadians tap the tree, and make sugar and treacle from the juice.

5. *Acer Saccharinum*; *American Sugar Maple*. Leaves five-parted, palmate, point-toothed, pubescent. These trees grow forty feet high. In North America, they tap the trees early in the spring, and make a very good sort of sugar in large quantities by boiling the juice. Large tracts of that country are covered with this tree, which yields a sugar equal to the best cane, and in great quantities, with no other labour than what women and girls can bestow, in drawing off and boiling the liquor. Dr. Rush assures us, that this tree is so far from being injured by the tapping, that it has flourished after forty-two annual operations; it is therefore concluded, by judicious persons, that the inhabitants of that country can, not only supply their own demands, but even make sugar for exportation. In all sugar plantations, it will be necessary to cut out the different sorts of timber which grow intermixed with the Maple-tree, and even such of that species as are not thriving trees. The timber so cut will serve as fuel for the boilers, and leave openings for the rays of the sun to enter which improve and enrich the sap. The season for tapping is in February, March, and April, according to the weather. Warm days and frosty nights are the most favourable to a plen-

tiful discharge of the sap. The perforation is made with an axe or an augur, but the latter is preferred. The augur is introduced about three quarters of an inch in an ascending direction; and is afterwards deepened gradually to the extent of two inches. A spout is introduced about half an inch, and projects from three to twelve inches; it is generally made of the Sumach or Elder. The tree is first tapped on the south side, and afterwards on the north side; and the sap flows from four to six weeks, according to the temperature of the weather. Troughs large enough to contain three or four gallons are placed under the spout to receive the sap, which is taken every day to a large receiver, from whence it is conveyed to the boiler, after having been strained.

6. *Acer Dissectum*; *Cut-leaved Maple*. Leaves many-parted, palmate; the divisions sub-pinnatifid and serrate.—It was found by Thunberg in Japan. It flowers in May.

7. *Acer Japonicum*; *Japanese Maple*. Leaves many-parted, gashed, and villous; flowers sub-umbelled.—It flowers in April and May; and is a native of Japan.

8. *Acer Palmatum*; *Hand-leaved Maple*. Leaves palmate serrate, smooth; flowers in umbels.—It flowers in May; and was discovered by Thunberg in Japan.

9. *Acer Septemlobum*; *Seven-lobed Maple*. Leaves seven-lobed; smooth; lobes pointed, regularly and sharply serrate.—This species also was seen by Thunberg in Japan.

10. *Acer Pictum*; *Painted Maple*. Leaves seven-lobed, smooth; lobes pointed, entire.—It was found by Thunberg, in Japan.

11. *Acer Platanoides*; *Norway Maple*. Leaves five-lobed pointed, sharply toothed, smooth; flowers in corymbs. This tree grows to a large size. Hanbury says, it is quick of growth, arrives at great bulk; and is one of the best trees for sheltering habitations. Linaeus recommends it for walks and plantations; as yielding a juice from which sugar may be made, if it be wounded in the winter; and as cutting out into a white smooth wood, fit for the stocks of guns, and for the joiner and turner. Dr. Hunter observes, that as it is a quick grower, arrives at a great bulk, and answers all the purposes of the Sycamore, the raising it for use, as well as ornament and variety, should not be neglected.—Norway Maple is found on the mountains in the north of Europe, in Germany, Switzerland, Stiria, Carniola, and Savoy.

12. *Acer Montanum*; *Mountain Maple*. Leaves slightly five-lobed, acute, serrate; racemes compound; calices hairy.—It is a native of North America.

13. *Acer Pennsylvanicum*; *Pennsylvanian Maple*. Leaves three-lobed, acuminate, sharply double-serrate; racemes simple; calices smooth. It is a small tree, which in some situations may be considered rather as a shrub.—It is a native of Pennsylvania, Virginia, and Canada. The thickness of the shade, the beauty of the bark, and the tree not being liable to insects, would make it desirable for plantations, were it not for the litter occasioned by the abundance of the leaves and fruit which it produces, and its being subject to be torn by storms. It delights in a firm dry mould.

14. *Acer Campestre*; *Common or Small Maple*. This species is chiefly seen in hedgerows and coppices. Its timber is far superior to that of the Beech, for all the uses of the turner, particularly dishes, cups, trenchers, and bowls; and when it abounds in knots, as it very frequently does, it is highly esteemed by the joiners for inlaying, &c. The wood is often used by musical instrument makers for its lightness; for gun stocks, on account of its hardness; and it was formerly in great request for tables, on account of its whiteness. This tree will flourish in very coarse land.

15. *Acer Opalus*; *Italian Maple*. Leaves roundish, five-

lobed, loosely serrate; capsules ovate, smooth, almost upright.

—This tree was first discovered at the foot of the Alps, and afterwards in abundance near Pissevache in the valley of Trient; and near Olon: it is common in many parts of Italy, particularly near Rome and Viterbo. It acquires a considerable stature, and as its leaves are large, and afford a great shade, it is frequently planted on the road side and near habitations, for which purposes it well deserves the attention of ornamental planters, especially as although it be seldom seen in England, it is nevertheless hardy enough to bear the open air of our climate.

16. *Acer Monspensulanum*; *Montpelier Maple*. Leaves three-lobed, very entire, smooth, annual. Its leaves resemble the Common Maple, but are of a much thicker substance, smaller, and of a shining green colour. They retain their verdure very late in autumn, which renders this tree more valuable, although it is not common in England.—It abounds in the south of France and in Italy.

17. *Acer Creticum*; *Cretan Maple*. Leaves three-lobed, very entire, pubescent, perennial. This tree resembles the Montpelier Maple, and attains to the same height. Its leaves are distinguished by a thinner texture, and their footstalks are covered with a soft hairy down. When well sheltered, they continue green most part of the year.—It is a native of the Levant.

18. *Acer Trifidum*; *Trifid-leaved Maple*. Leaves undivided and trifid, without indentations on the edge. It is of inferior growth, seldom attaining to more than between twenty and thirty feet.

19. *Acer Negundo*; *Virginian Ash-leaved Maple*. Leaves compound; flowers racemed. Three and four pistilla have been observed in the female flower; no corolla, and four or five stamina, in the males. This is a strong-shooting tree, of quick growth, and in Virginia and Carolina is one of the largest trees of this kind. Its leaves fall soon in autumn, and when planted, it must not be exposed to violent winds as it is subject to sprit. The wood is used for the same purposes as the Sycamore and Norway Maple, but it is soft and brittle. The tree grows to the height of forty feet and upwards, and is fit for large plantations.

20. *Acer Pinnatum*; *Wing-leaved Maple*. Leaves pinnate; leaflets oblong, quite entire.—This is a native of the woods of Cochin-China. It is a middling-sized tree, with spreading branches, white flowers, and a very hard wood.

Achania; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth double. Outer many-leaved; leaflets linear, permanent, slightly coalescing at the base. Inner one-leaved, subcylindric, streaked half way, five-cleft, permanent. *Corolla*: almost club-shaped convoluted; petals five, obovate-oblong, erect, with a lobe at the base on one side, involving the column of stamina. *Stamina*: filamenta numerous, coalescing into a writhed tube, longer than the corolla, free at top, capillary; antheræ oblong. *Pistilla*; germes subglobular; style filiform, the same length with the tube of the stamina, ten-cleft at the top, the segments spreading; stigmas headed. *Pericarp*: berry subglobular, fleshy, five-celled. *Seeds*: solitary, convex on the one side, angular on the other. ESSENTIAL CHARACTER. *Calix*: double; outer many-leaved. *Corolla*: convolute. *Berry*: five seeded.—Plants of this genus are generally propagated by cuttings; because the seeds do not often ripen here. These are placed in pots of light earth, and plunged into a gentle hot-bed, where, if the air be kept from them, they soon take root, and may afterwards be gradually inured to the open air. When placed abroad, they seldom succeed well even in sheltered situations. It requires a moderate stove to preserve

T. Smith del.

them during the winter ; and unless kept warm in summer they will not flower, much less ripen fruit.—The species are,

1. *Achania Malvaviscus*; *Scarlet Achania*, or *Bastard Hibiscus*. Leaves somewhat scabrous, acuminate; leaflets of the outer calix erect.—It flowers most part of the year; and is a native of Mexico and Jamaica.

2. *Achania Mollis*; *Woolly Achania*. Leaves tomentose; leaflets of the outer calix spreading.—A native of South America, and the West India Islands.

3. *Achania Pilosa*; *Hairy Achania*. Leaves hairy, obtuse, and acute. The flowers are small, and the corolla closed.—It is a native of Jamaica.

Achillea; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common, ovate, imbricate; scales ovate, acute, converging. *Corolla*: compound radiate; corollets hermaphrodite, tubular, in the disk. Females ligulate, five to ten in the ray. Proper of the hermaphrodite, funnel-shaped, five-cleft, spreading. Female obcordate, spreading, trifid; the middle cleft less than the others. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: in the hermaphrodites; germen small; style filiform, the length of the stamina; stigma obtuse, emarginate. In the females, germen small; style filiform, the length of the stamina; stigmas two, obtuse, reflex. *Pericarp*: none. *Calix*: scarcely changed; receptacle filiform, elongate, as the disk of the seeds, ovate, twice the length of the calix. *Seeds*: solitary, ovate, furnished with flocks, but having no down. *Receptacle*: chaffy, elevated; chaffs lanceolate, the length of the florets. ESSENTIAL CHARACTER. *Calix*: ovate, imbricate. *Florets* of the ray, about four. *Down*: none. *Receptacle*: chaffy. Every species of this genus may be propagated by parting the roots either in spring or autumn. Many of them ripen their seeds, and may therefore be increased that way, by sowing them in March or April, and transplanting them at Michaelmas. They will flower the summer following. Some also will grow from slips or cuttings, planted in a shady border in summer. They are in general hardy, and need little care in the cultivation. Those commonly seen in gardens are, the purple variety of Common Milfoil, the double variety of common Sneezewort, called Double Ptarmica, and Woolly Milfoil. Whatever merit the Alpine sorts may possess as medicines, it cannot answer to cultivate them with that view in gardens, for they owe their efficacy to their peculiar situation: but they who are desirous of having them for variety, will find that they are very hardy, and will thrive almost in any soil, but that they love an open exposure.—The species are,

* *With yellow Corollas.*

1. *Achillea Santolina*; *Lavender-Cotton-leaved Milfoil*. Leaves bristle-shaped, toothed; toothlets nearly entire, subulate, reflex. The leaves of this plant are like those of Lavender-cotton, which, when rubbed, emit a strong oily odour.—It flowers in June and July; and is an inhabitant of the Levant.

2. *Achillea Ageratum*; *Sweet Milfoil*, or *Maudlin*. Leaves lanceolate, obtuse, sharply serrate.—This plant is a native of Italy, and Spain, by the road sides. It was brought into England in 1570, but being now seldom used in medicine, it is not cultivated in the gardens for sale; or if asked for, the market people give the thirteenth species of this genus, which is a hardier plant, and more easily propagated: for though the Sweet Maudlin will bear cold well, yet wet winters often kill the roots in good ground; although when the plants grow out of the joints of a wall, or in rubbish, they will live many years without care. It has a sweet smell, a bitter taste, and is aromatic. Liancus calls it obsolete and superfluous.

VOL. I.—5.

Allione recommends it in all disorders of the nerves, and prefers it before Tansy. Culpeper commends it as a *diuretic*, and says that the seeds, as well as an infusion of the flowers in white wine, are excellent for the worms in children, when given in *two ounces per dose*. Meyrick and Hill agree that “the whole plant has a pleasant smell, and may be used either fresh or dried, but is most efficacious in its recent state.” A strong infusion of it, taken for a length of time, is good in obstructions of the liver, and considerably increases the discharge by urine.

3. *Achillea Falcata*; *Sickle-leaved Milfoil*. Leaves linear, toothed, obtuse, flat; toothlets crenate.—This species is a native of the East, and is there used in medicine.

4. *Achillea Tomentosa*; *Woolly Milfoil*. Leaves pinnate, hirsute; pinnae linear, toothed. This plant is about a foot high, its whole flower is of a fine yellow colour, with a pleasant aromatic smell. It is often planted in gardens for the sake of variety, as the flowers retain their beauty for a long time.—It grows naturally in Spain, the south of France, the Valais, and Italy; but bears the open air very well in England.

5. *Achillea Pubescens*; *Downy Milfoil*. Leaves pinnate; leaflets lanceolate, gash-serrate, wool-bearing beneath.—This plant is a native of the Levant. It has no chaffs to the receptacle, and in that respect differs from the generic character. This and the following species are easily propagated and cultivated both by roots and seeds: they are sufficiently hardy to endure the open air, and when intermixed with other plants, form a pleasing diversity by their hoary leaves; and as their flowers are of long continuance, they produce an agreeable contrast, though not remarkable for beauty in themselves.

6. *Achillea Abrotanifolia*; *Southernwood-leaved Milfoil*. Leaves pinnate, super-decompound; divisions linear, distant.—It is a native of the Levant, and flowers in June and July.

7. *Achillea Bipinnata*; *Bipinnate Milfoil*. Leaves bipinnate, tomentose; leaflets ovate, entire.—Native of the Levant.

8. *Achillea Ægyptiaca*; *Egyptian Milfoil*. Leaves pinnate; leaflets obtusely lanceolate, serrate-toothed.—This plant, which is also a native of the Levant, rises from nine inches to a foot in height. It has finely-cut silvery leaves, which remain all the year; and the plant growing close and low, makes a pretty appearance at all seasons. The flowers are produced in corymbs on the top of the stalks, and appear from June to September, and some of them frequently continue the greatest part of the winter. It rarely perfects seeds in England, and is therefore propagated by slips. In a dry soil and a warm situation, it will endure the cold of our ordinary winters in the open air; but being often destroyed in very severe frosts, a few plants ought to be sheltered under a frame.

** *Corollas white in the ray.*

9. *Achillea Macrophylla*; *Feverfew-leaved Milfoil*. Leaves pinnate; pinnae gash-serrate, the outmost larger, and connected. It has many stalks which rise near three feet high, with loose branching corymbs of white flowers, like those of the common Sneezewort, which they also resemble in smell, but are much pleasanter.—It is a native of the Alps, very hardy, thrives in almost any soil, but loves an open exposure; flowers in July and August, and deserves a place in gardens.

10. *Achillea Impatiens*; *Impatient Milfoil*. Leaves pinnate; pinnae distant, linear lanceolate, acute from the base upwards.—This species is frequent throughout Siberia.

11. *Achillea Clavennæ*; *Silver-leaved Milfoil*. Leaves jagged, flat, obtuse, tomentose. This plant scarcely rises six inches in height; its flowers are white, and grow in flat corymbs, and appear in June and July. The leaves are

very hoary, something like those of the common Wormwood, growing close to the ground, and decaying in autumn.—It is a native of the Alps of Switzerland, Austria, Pannonia, and Carinthia. As it never perfects its seeds in England, it is propagated by slips; which should be planted in a dry soil, because much wet in winter will cause it to rot.

12. *Achillea Ptarmica*; *Sneezewort Milfoil*. Leaves lanceolate, acuminate, finely serrate. It is found wild in all the temperate parts of Europe, and in England in meadows, by the sides of ditches, on the balks of corn-fields, in moist woods and shady places. It grows two feet high, has daisy-like flowers, and narrow dentated leaves, from the form of which it is sometimes called *Goose-tongue*. The roots have a biting acrid taste, and so likewise have the young leaves; these, powdered, and snuffed up the nose, excite sneezing, and are excellent in inveterate head-aches. A piece of the dried root held in the mouth soon fills it with rheum, and removes the tooth-ache, in the same manner as Pellitory of Spain. The young tops are pleasant in the spring, when they are eaten as a salad, and reckoned wholesome. In Siberia a decoction of the whole herb is said to be used with success in internal hemorrhages. When planted in pots so as to confine the roots from creeping, the stalks will grow closer together, and then it makes a tolerable appearance when flowering, which takes place in July and August.

13. *Achillea Alpina*; *Alpine Milfoil*. Leaves lanceolate, tooth-serrate, toothlets very finely serrate. It is very nearly allied to the preceding species, which it somewhat resembles, but it has longer leaves, more deeply cut on their edges, and of a darker green.—It is very hardy, and a native of Switzerland, Savoy, and Siberia.

14. *Achillea Serrata*; *Notch-leaved Milfoil*. Leaves linear-lanceolate, sessile, tomentose, deeply serrate, jagged at the base.—The flowers resemble those of Sneezewort: they appear in August and September.

15. *Achillea Cristata*; *Slender-branched Milfoil*. Leaves linear, serrate; serratures transverse crested; stem branched, weak.—It is a native of the East; and flowers here in July and August.

16. *Achillea Atrata*; *Camomile-leaved, or Black Milfoil*. Pinnules comb-like, almost entire; peduncles villous.—This plant is found on the mountains of Switzerland, the Valais, and Austria. It was introduced by Drs. Pitcairn and Fothergill in 1774, but will not admit of cultivation, nor can be reconciled to a garden, whatever pains you take with it.

17. *Achillea Moschata*; *Musk Milfoil, or Swiss Genipi*. Leaves pinnate, dotted; pinnas remote, linear subulate, almost entire, rays the length of the calix. This can only be distinguished from the preceding species by its aromatic smell. It is the true *Genipi* of the Swiss, though called *Genipi bâtard* in Savoy. This plant promises to be of essential efficacy in disorders arising from a debility of the solids; it is an excellent sudorific, though hot, and frequently injurious in the pleurisy when the fever is high; and it is also a grateful food to all sorts of cattle. Hill says, “the seed is the only part used, and that very rarely.” It is said to be good against the head-ache, but we seldom meet with it fresh enough to have any virtue.—It is found wild in Switzerland, on the high Alps, and in Savoy, Piedmont, and Austria.

18. *Achillea Nana*; *Dwarf Milfoil*. Leaves pinnate, toothed, extremely hirsute; flowers glomerate-umbelled. It is a very small plant, and has a fainter smell than the preceding species, for which it is often sold.—It grows on the high Alps of Switzerland, the Valais, and Savoy; and Allione observes, that the higher and colder the situation in which it is found, the thicker is the *tomentum* or flock which covers

it. It is hardy, will thrive with us in almost any soil, and deserves a place in gardens.

19. *Achillea Magna*; *Great Milfoil, or Yarrow*. Leaves bipinnate, rather hairy, the divisions linear and toothed; earlets decussated.—It is a native of Italy, hardy, and requires little culture.

20. *Achillea Millefolium*; *Common Milfoil, or Yarrow*. Leaves bipinnate-naked; divisions linear-toothed; stems furrowed towards the top. This plant has been generally execrated as a noxious weed in pastures; sheep, however, are found to eat it; and Anderson has even recommended it for cultivation. It is frequently found in our meadows, pastures, and by road-sides; flowering in June, and the following summer months, until September. It creeps greatly by its roots, and multiplies by seeds, so that it is a troublesome weed in gardens. There is a variety with purple flowers, which are apt to lose their colour by cultivation. The whole plant is used fresh-gathered, but the best part is the tops of the shoots; these are to be boiled in water, and the decoction sweetened with fine sugar: though generally neglected, it is an excellent medicine in the overflowing of the menses, bloody fluxes, and bleeding of the piles. It increases the urinary discharges, and removes ulcers of the kidneys or urethra. Sir John Hill says, “the best way of taking it, is in strong decoctions of the whole plant.” Linneus recommends the bruised herb fresh, as an excellent vulnerary and styptic, and many foreign physicians still esteem it in hemorrhages. An ointment is made of it for the piles, and it is reckoned good against the scab in sheep. An essential oil is extracted from the flowers, but the plant is excluded from the present medical practice.

21. *Achillea Nobilis*; *Noble Milfoil*. Leaves bipinnate; the lower one naked, flat; the upper obtuse, tomentose; the flowers in convex and very crowded corymbs. This strongly resembles the Common Milfoil, but its leaves are not so long or so much cut, they have a pale green colour, and a strong sweet scent when bruised. This scent, as well as its other qualities, are stronger than those of the preceding species.—It is a native of Italy, Germany, Switzerland, Narbonne, and Tartary.

22. *Achillea Odorata*; *Scented Milfoil*. Leaves bipinnate, oval, almost naked; corymbs fastigiate, crowded.—Its stem is scarcely a palm in height: it is a native of Spain, Narbonne, Switzerland, &c.

23. *Achillea Cretica*; *Cretan Milfoil*. Leaves linear; pinnas roundish, imbricate backwards; stem tomentose.—It is, as its name imports, a native of the island of Crete.

24. *Achillea Squarrosa*; *Rough-headed Milfoil*. Leaves lanceolate-linear, pinnatifid; pinnas ovate, wedge-shaped, gash acuminate, vertical; stem somewhat villose.—It was introduced into England in the year 1755.

25. *Achillea Herbarota*; *Herbarota Milfoil*. Leaves wedge-shaped, entire, toothed at the top. The whole plant is green, and has a strong smell, like Maudlin. It is in general esteemed among the peasants of the Alps, and is recommended as a sudorific, against worms, flatulencies, and intermittent fevers.

26. *Achillea Ligustica*; *Marjoram-scented Milfoil*. Leaves pinnate; pinnas sharply-toothed, flat, smooth.—The stems are eighteen inches high, the leaves rather thick and juicy; and, like the preceding species, it has a very strong smell, like Maudlin.

27. *Achillea Tanacetifolia*; *Tansy-leaved Milfoil*. Leaves pinnate; pinnas laciniate, flat, gashed, and entire: the stem of this plant is eighteen inches high. It is a native of the Grisons, and not uncommon in the pastures and valleys of the Alps.

Achras; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth six-leaved; leaflets ovate, concave, erect; outer broader, shorter; inner coloured. *Corolla*: one petalled, ovate, of the same height with the calix: border cut into six subovate flat divisions; scales at the jaw of the corolla equal in length to the divisions, narrower, spreading, emarginate. *Stamina*: filamenta short, awl-shaped, at the jaws of the corolla, alternate with the divisions, bent inwards; antheræ sharp. *Pistil*: germen roundish, flattened; style awl-shaped, longer than the corolla; stigma obtuse. *Pericarp*: a globose very succulent pome, with twelve cells. *Seeds*: solitary, ovate, shining, scarred on one side, and pointed at the base. **ESSENTIAL CHARACTER.** *Calix*: six-leaved. *Corolla*: ovate, sixfid, with six scales alternate, more within. *Pome*: ten-celled. *Seeds*: solitary, with a scar on the edge, and a tail or a process at the top.—The trees of this genus are natives of very warm countries, and cannot be preserved in England unless they are placed in the warmest stoves, and managed with great care.—The species are,

1. *Achras Mammosa*; *Mamme Sapota*. This has a sixth part less in the parts of fructification than the other species of this genus. It is also called *nippled Sapota*, or American Marmalade; it grows in America, to the height of thirty-five or forty feet, having a straight trunk covered with an ash-coloured bark. The flowers are cream-coloured, and are succeeded by large oval or top-shaped fruit, covered with a brownish skin, under which is a thick pulp of a russet-colour, very luscious, called natural marmalade, from its resemblance to marmalade of quinces. This tree is commonly planted in gardens for the fruit, in Jamaica, Barbadoes, Cuba, and most of the West India islands. It is esteemed one of the best timber trees in Jamaica. The bark of this and the following species is called *Cortex Jamaicensis*, or Jamaica bark. It is an excellent astringent, but very different from the Jesuits' bark, for which it was mistaken, and given to the negroes, with very ill effect, and has been also tried in England. There is a wild Mammee, which bears a fruit of no value; but the tree is straight, tall, and tough, and therefore principally used for masts.

2. *Achras Sapota*; *Common Sapota*. Flowers solitary; leaves lanceolate-ovate. A large, tall, straight tree, without knots or branches for sixty or seventy feet or more. The fruit is bigger than a quince, round, and covered with a thick grey rind: it tastes and smells well: the flesh is yellow as a carrot, with two large rough stones, each bigger than an almond, in the middle; the kernels of which are bitter, and may be used in strengthening emulsions. This tree is larger and taller than the preceding species.

3. *Achras Dissecta*; *Cloven-flowered Sapota*. Flowers crowded; corollas cloven into eight parts; leaves obovate, bluntly notched at the end. This is a lofty tree, with a thick upright trunk. The flowers are white; and all its herbaceous parts milky. In Malabar it is cultivated for the fruit, which is succulent, and of a sweetish acid flavour. The leaves bruised, and boiled with the root of Curcuma and the leaves of ginger, are used for cataplasms to tumors.—It is supposed to be a native of the Philippine Islands, and also to grow in China; Forster found it flowering in September upon the island of Tongatabu.

4. *Achras Salicifolia*; *Willow-leaved Sapota*. Flowers crowded; leaves lanceolate-ovate, acuminate.—This species is called the White Bully-tree, or Galimeta-wood, in Jamaica, where it grows to a considerable height, commonly straight and tapering, and most frequently found in the lower lands. The wood is pale yellow, and reckoned good

timber, but is mostly used in such parts of the building as are least exposed to the weather.

Achyranthes; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth, outer three-leaved, lanceolate, acute, permanent; inner five-leaved, permanent. *Corolla*: none; nectary of five valves, surrounding the germen, bearded at the top, concave, caducous. *Stamina*: filamenta filiform, the length of the corolla; antheræ ovate, incumbent. *Pistil*: germen superior, turbinate; style filiform, the length of the stamina; stigma bifid, villous. *Pericarp*: capsule roundish, one-celled, not gaping. *Seed*: single, oblong. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: none. *Stigma*: bifid. *Seeds*: solitary.—These plants have not much beauty to recommend them; they are preserved in botanic gardens, and the greater number must be placed in a stove, to preserve them through the winter.—The species are,

1. *Achyranthes Aspera*; *Rough Achyranthes*. Stem shrubby, erect; calices reflex, pressed to the spike.—It is found in Sicily, Malabar, Ceylon, Jamaica, and almost every where within the tropics. It has been long known in England, and may be raised on a hot-bed from the seeds; and when the plants have acquired strength, they may be removed into the full ground, where the flowers will appear in July, and the fruit ripen in September. * If kept in pots, set into a warm green-house in winter, they will live two or three years.

2. *Achyranthes Lappacea*; *Burry Achyranthes*. Stem shrubby, diffused, prostrate; spikes interrupted; lateral flowers having a bundle of hooked bristles on each side.—It is a lofty plant, native of Malabar and Ceylon.

3. *Achyranthes Muricata*; *Prickly Achyranthes*. Stem shrubby, patulous; leaves alternate; flowers in remote ovate spikes; calices squarrose.—It is a native of India.

4. *Achyranthes Patula*; *Spreading Achyranthes*. Stem shrubby, patulous, pubescent; flowers in orbicular spikes, hedgehog-hooked. This plant is three feet high. In a state of sleep, the opposite leaves are bent down under the branch, and approximate to the under surface.—Native of the East Indies.

5. *Achyranthes Alternifolia*; *Alternate-leaved Achyranthes*. Stem herbaceous, erect; flowers in subglobular burrs. The flowers have two stigmas; the germen is globose; and the style purple. Native of the East Indies.

6. *Achyranthes Corymbosa*; *Corymbed Achyranthes*. Leaves fourfold, linear; panicle dichotomous, corymbed. This herb is a foot in height; its stem is round and jointed.—A native of Ceylon.

7. *Achyranthes Dichotoma*; *Dichotomous Achyranthes*. Stems suffruticose; leaves opposite, linear, flat, acute; cyme dichotomous.—It resembles the preceding species; and is a native of Virginia.

8. *Achyranthes Prostrata*; *Prostrate Achyranthes*. Stems prostrate, shrubby; spikes oblong; floscules in pairs, with a hooked fascicle on each side. The stems of this species are often creeping.—It is a native of India.

9. *Achyranthes Nivea*; *White, or Snowy Achyranthes*. Leaves verticillated, ovate, tomentose; corymbs compact, dichotomous; flowers corolled.—This species, which will live in a green-house, was introduced into England in 1780, from the Canary Islands. It flowers from May to July.

10. *Achyranthes Altissima*; *Tall Achyranthes*. Stem suffruticose, scandent; panicles terminating and axillary, branched. The stalks of this species climb up trees to the height of twenty feet. Browne calls it Bastard Hoop-withe. It is common among low bushes about Spanish Town and Kingston in Jamaica, and in the woods of St. Domingo.

11. *Achyranthes Polygonoides*; *Many-cornered Achy-*

ranthes. Stem decumbent, four-cornered; leaves ovate-cordate; spikes lax, short. The stems are frequently eighteen inches high.—It is a native of Arabia.

Acia; a genus of the class Monadelphia, order Dodecandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, turbinate, curved; border five-parted; parts roundish, spreading; the uppermost and two lowest larger; the two middle ones smaller. *Corolla*: petals five, oblong, rounded; the three upper longer, ascending; the two lower shorter. *Stamina*: filamenta twelve, unequal, uniting at the bottom in a linear fleshy membrane, inserted into the calix between the two smaller petals; antheræ roundish, small. *Pistil*: germen ovate, above the base adhering by the membrane of the stamina, to a rib internally prominent from the bottom of the calix: style filiform, curved; stigma acute. *Pericarp*: drupe ovate, fibrous, chinked, large. *Seed*: nut, ovate, with a brittle shell. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Corolla*: five petalled, unequal. *Drupe*: full of chinks.—The only known species is,

1. *Acia Guianensis*; the *Guiana Acia*. A tree with a trunk sixty feet in height, and three or four feet in diameter, covered with a smooth gray bark. The fruit is of the size of a walnut, covered with a thick, woody, fibrous, coriaceous skin, of a brown colour, cracking irregularly, and adhering to the stone, which is thin, and easily breaks. It encloses a large kernel of an irregular form, dividing into two parts. The Creoles at Cayenne eat it when brought to market in August; they reckon it good fruit, and extract an oil as sweet as that of almonds from it: they call the tree *Coupi*. The wood is hard and heavy, of a white colour inclining to yellow.

Acidoton; a genus of the class Monœcia, order Polyandria.—**GENERIC CHARACTER.** *Male flowers.* *Calix*: perianth five-leaved; leaflets ovate-lanceolate, reflex. *Corolla*: none. *Stamina*: filamenta numerous, thirty-five to forty, placed on a globular receptacle; the outer shorter, the inner longer; antheræ cordate-ovate, upright, small. *Females on the same or a different tree.* *Calix*: perianth six-leaved: leaflets linear-lanceolate, spreading. *Corolla*: none. *Pistil*: germen three-cornered; style short, acute, thick, trifid at the top; stigmas tomentose, reflex. *Pericarp*: capsule three-grained, hirsute, three-celled. *Seeds*: solitary, ovate. **ESSENTIAL CHARACTER.** *Male.* *Calix*: five-leaved. *Corolla*: none. *Stamina*: fixed to a globular receptacle. *Female.* *Calix*: six-leaved. *Corolla*: none. *Style*: trifid. *Capsule*: three-grained.—The only known species is,

1. *Acidoton Urens*. It is eight or nine feet high; trunk round, straight, and woody, the size of the little finger; covered with a smooth brownish bark. This plant, described by Sloane, seems to have been young, as he never saw either flower or fruit.—A native of Jamaica.

Acnida; a genus of the class Diœcia, order Pentandria.—**GENERIC CHARACTER.** *Male.* *Calix*: perianth five-leaved; leaflets ovate, concave, acute, membranaceous on the edge. *Corolla*: none. *Stamina*: filamenta five, capillary, very short; antheræ versatile, bilocular, forked each way. *Female.* *Calix*: involucre many-leaved, linear, deciduous; perianth two-leaved, linear, very small, permanent. *Corolla*: none. *Pistil*: germen superior, ovate; styles five, long, reflex, pubescent; stigmas simple. *Pericarp*: fruit ovate, compressed, many-angled, furrowed, covered with a succulent calix. *Seeds*: solitary, round, compressed. **ESSENTIAL CHARACTER.** *Male.* *Calix*: five-leaved. *Corolla*: none. *Female.* *Calix*: two-leaved. *Corolla*: none. *Styles*: five. *Seed*: one, covered with the succulent calix.—The only known species is,

1. *Acnida Cannabina*; *Virginian Hemp*. This plant grows

naturally in Virginia, and in some other parts of North America, but is rarely cultivated in Europe, except in some few botanic gardens. It is near of kin to Hemp, but there is little beauty in it, and hitherto no use has been made of it.

Aconite, Winter. See *Helleborus*.

Aconitum; a genus of the class Polyandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals five, unequal, opposite, in pairs. 1. The highest helmet-tubed, inverted, the back upwards, obtuse; the top reflected to the base, acuminate, to which top the connecting base is opposite. 2, 3. The two lateral ones broad, roundish, opposite, converging. 4, 5. The two lowest oblong, pointing downwards. Nectaries two, concealed under the first petal, fistulous, nodding; mouth oblique; tail recurved; sitting on long subulate peduncles; six little very short coloured scales, in the same circle as the nectaries. *Stamina*: filamenta subulate, very small, broader at the base, inclining towards the first petal; antheræ erect, small. *Pistil*: germina three, (five) oblong, ending in styles the length of the stamina; stigmas simple, reflex. *Pericarp*: capsules as many as the styles, ovate-subulate, straight, one-valved, gaping inward. *Seeds*: very many, angular, wrinkled. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: five, the highest arched, shaped like a hood or helmet. *Nectaries*: two. *Peduncle* recurved; *Capsules*: three or five.—All the species of this genus may be propagated by seeds, which, if sown in a shady situation during autumn, will appear in the following spring. The ground must be kept free from weeds, and the plants watered in dry weather, for the first year, when they may be transplanted to where they are intended to remain; all the attention they will there require, is, to cut down the stalks in autumn, after they have done flowering. They are all hardy perennials, require little care or culture, and, having most handsome spikes of spacious flowers, are very desirable plants for shrubberies and wilderness quarters.—The species are,

* *With three Capsules*

1. *Aconitum Lycoctonum*; *Great Yellow Monk's Hood*, or *Wolf's bane*. Leaves palmate, multifid, villose. The stem is eighteen inches high or more, very little branched, and leafy. It is reckoned among the earliest spring flowers of Sweden; where a decoction of the powder of the root is used for destroying flies and other insects. Linneus says, it is eaten in Medelpadia, a province of Sweden, without injury. It seems, indeed, to be milder than some of the other species, and hence goats and horses are said to eat it. It was cultivated here by Gerarde, in 1596.—The mountains of Switzerland, Germany, Austria, Carniola, Italy, and Siberia, produce it in a wild state.

2. *Aconitum Japonicum*; *Japanese Monk's Hood*. Leaves trifid, palmate; divisions gashed, blunt. The stem is round and smooth, and the spike of flowers short.—It is a native of Japan, and is there called *Soo Huso*.

3. *Aconitum Napellus*; *Common Monk's Hood*, or *Wolf's-bane*. Divisions of the leaves linear, broader above, and scored with a line. The species has the root simple, woody, tuberous, unequal; stem erect, firm, covered with leaves eighteen inches high. This plant is allowed on all hands to be a most deadly poison, a criminal having been put to death by taking one drachm of the root. It has nevertheless been so subdued as to become a powerful remedy in some of the most troublesome disorders incident to the human frame. Baron Stoerck began by administering it in violent pains of the side and joints, in glandulous schirrh, tumors, ulcerous tubercles of the breast, &c. to the quantity of from ten to thirty grains in a dose, of an extract made with the juice of this plant by a gentle evaporation, and then

adding two drachms of lump sugar, in powder, to two grains of the extract. Its principal sensible effect was in exciting a copious perspiration. A much larger dose has also been safely administered, but it is recommended to begin with a small quantity. Dr. Murray asserts its chief virtue to be in rheumatic and other chronic disorders, for which the above extract is the best preparation. It is said to have been serviceable in confirmed venereal cases, and even to have discussed nodes, and cured obstinate ulcers. Its efficacy in the *gutta serena* has been commended, but probably not with such certainty as in the forementioned disorders.—Those which have blue flowers are said to be more potent than those which are yellow or white. The variety of this species, is the most common in our English gardens, being cultivated for the specious appearance of its long spikes of blue flowers. It grows nearly four feet in height, the spikes are above two feet long; and being very hardy, growing in any soil or situation, and multiplying greatly by its roots, it has been allowed a place in most gardens and plantations of shrubs. It ought, however, to be admitted with great caution where children and ignorant persons frequent. It flowers in May and June, and the seeds ripen in September.

4. *Aconitum Pyrenaicum*; *Pyrenean* or *Fennel-leaved Monk's Hood*, or *Wolf's-bane*. Leaves many-parted; divisions linear, incumbent, and squarrose.—This plant grows wild on the Pyrenees, in Tartary, and Siberia. The spike nods before the time of flowering, which in our gardens is in July: it attains to four feet high, and has a long spike of yellow flowers of a middling size. It may be allowed a place among shrubs, or such parts of a garden as are not frequented by children.

** *With five Capsules.*

5. *Aconitum Anthora*; *Salutary Monk's Hood*. Flowers with five pistils; divisions of the leaves, linear. The flowers are not so large as those of the common sort; they are of a sulphur colour, and make a pretty appearance in the borders of a flower-garden. This plant, though absurdly called *Salutary Monk's Hood*, is only poisonous in a less degree than the rest of the same genus. It was supposed to be a remedy against poison, particularly that of the other *Aconites*; but that dangerous error is now happily exploded. The taste of the root is sweet, with a mixture of bitterness and acrimony. The smell is pleasant. It purges vehemently when fresh, but loses its qualities when dried; it is not used in modern practice.—Its native places are, the Alps of Switzerland, Savoy, Piedmont, Dauphiny, Austria, Carniola, Siberia, &c.; flowering from August to September.

6. *Aconitum Variegatum*; *Variiegated*, or *Small Blue Monk's Hood*. Flowers with five pistils; divisions of the leaves parted half way, broader above. This species seldom grows more than two feet high. The corollas will change from variegated to plain: it flowers at the end of June.—Native of Italy and Bohemia.

7. *Aconitum Album*; *White Wolf's-bane*, or *Monk's Hood*. Flowers with five pistils; leaves smooth, three-parted; segments acutely gashed; the claw of the upper petal longer than the side ones.—It is rare in Europe, was brought from the Levant; and is characterized by Mr. Miller as having a tall stem upwards of six feet high, palmate leaves, and large white flowers.

8. *Aconitum Cammarum*; *Purple Monk's Hood*, or *Wolf's-bane*. Flowers mostly with five styles; divisions of the leaves wedge-shaped, gashed, acute.—It is found wild in Switzerland, Austria, Stiria, Piedmont, &c.; and generally has a stem six feet high. Flowers white, or pale blue.

9. *Aconitum Uncinatum*; *American Monk's Hood*, or *Wolf's-*

VOL. I.—5.

bane. Flowers mostly with five styles; leaves many-lobed; helmet extended very far.—It is a native of Pennsylvania.

Acorus; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: spadix cylindric, entirely simple, covered with floscules; spathe none; perianth none, unless the calix be so named. *Corolla*: petals six, obtuse, concave, loose, thicker at the top, and in a manner truncate. *Stamina*: filaments thickish, a little longer than the corolla; antheræ thickish, twin, terminal, adnate. *Pistilla*: germen gibbous, rather oblong, the length of the stamina; style none; stigma a prominent point. *Pericarp*: a short triangular capsule, attenuated to both ends, obtuse, three-celled. Seeds many, ovate, oblong. **ESSENTIAL CHARACTER.** Spadix cylindric, covered with floscules. *Corollas*: five-petalled, naked. *Style*: none. *Capsule*: three-celled.—The species are,

1. *Acorus Calamus*; *Common Sweet Rush*. The point of the scape very long and leafy. This species is distinguished by its long sword-shaped leaves, resembling those of the flag, but narrower, and of a brighter green. The root has a strong aromatic smell, and a warm, pungent, bitterish taste: the flavour is greatly improved by drying them. The roots are said to have cured agues when the Peruvian bark has failed. No cattle whatever will eat this plant, which grows naturally on the banks of rivers, and in shallow standing waters.—It is found wild in many parts of England, grows plentifully in the dykes of Holland, and is common in many other parts of Europe. This plant will succeed very well in a garden, if the ground be moist; but never produces its spikes unless it grows in the water. It continues flowering from June till August, and multiplies itself fast by creeping roots.

2. *Acorus Gramineus*; *Grass-leaved Sweet Rush*, or *Chinese Sweet Grass*. The point of the stalk scarcely extending beyond the top of the spadix. The whole of this herb has an aromatic smell when bruised, much resembling our English sweet-flag; for the sake of which it is cultivated.—It is probably a native of China, as the Chinese frequently have it in pots about their habitations. It flowers in the spring, must be kept in a dry-stove, and does not require a great degree of heat.

Acrostichum; a genus of the class Cryptogamia, order Filices.—**GENERIC CHARACTER.** The fructifications cover the whole under surface of the frond.—Few of these species have yet been introduced into gardens. Those of Europe may be either preserved in pots filled with gravel and lime rubbish, or planted on walls and artificial rocks: but most of them being natives of very hot climates, must be planted in pots, and plunged into the bark pit.

**Frond simple, undivided.*

1. *Acrostichum Lanceolatum*. Fronds linear-lanceolate. acute; shoot climbing.—It is a native of the East Indies and Cochin-china, adhering to trees.

2. *Acrostichum Citrifolium*. Fronds lanceolate-ovate, quite entire; shoot-climbing.—A native of America.

3. *Acrostichum Heterophyllum*. Fronds quite entire, smooth, petiolate; barren ones roundish, fertile linear.—It is found in the woods of the East Indies, Cochin-china, and Africa.

4. *Acrostichum Crinitum*. Fronds ovate, obtuse, hirsute, crinite above.

5. *Acrostichum Punctatum*. Fronds heart-tongued, acuminate, quite entire, dotted above. This species very much resembles Hart's-tongue.—It is a native of China, where it is used medicinally.

6. *Acrostichum Spicatum*. Frond simple, petiolate, lanceolate, attenuated to both ends, quite entire; spike terminal, linear.—Found on the island of Mauritius.

7. *Acrostichum Lingua*. Fronds oblong, obtuse, entire, petiolate; shoot creeping; stipe three-cornered, villous, erect.—A native of Japan.

8. *Acrostichum Hastatum*. Frond simple, hastate.—Also a native of Japan.

** *Frond simple, divided.*

9. *Acrostichum Septentrionale*. Fronds naked, linear-laciniate.—This species grows in tufts, at first sight resembling rushy grass, on clefts of rocks and old walls, in Yorkshire, Westmoreland, Wales, and Scotland.

10. *Acrostichum Australe*. Stipes naked, quite smooth, dichotomous at top, with five or six subulate rays, and flowering from the sides.—This much resembles the preceding species, but is silvery and more regularly divided. Found in the isles of France and Bourbon.

11. *Acrostichum Pectinatum*. Naked, perfectly simple: spike crescent-shaped on one side, ascending, compressed.—A native of the Cape.

12. *Acrostichum Dichotomum*. Naked dichotomous spikes on one side, ascending, reflex, compressed.—It is a native of China and the Society Islands.

13. *Acrostichum Digitatum*. Stipes naked, three-sided; frond digitate, linear, quite entire, equal. The stipe is linear, a foot high, smooth, contracted at top.—Native of Ceylon.

14. *Acrostichum Ferrugineum*. Fronds pinnatifid; pinnae linear, acute, spreading, quite entire, connate; stipe smooth.—This strongly resembles the following species.

15. *Acrostichum Polypodioides*. Fronds pinnatifid; pinnae linear, obtuse, quite entire, spreading, crowned; stipe scaly. This species has the appearance of Common Polypody.—Native of Jamaica and Virginia.

*** *Frond pinnate.*

16. *Acrostichum Aureum*. Pinnae alternate, tongue-shaped, quite entire, smooth. The stipes of this plant grow in bundles of a very dark rufous colour, smooth, about the thickness of the little finger, and nine feet in height.—It is a native of Jamaica, Dominica, and the Society Isles.

17. *Acrostichum Rufum*. Pinnae oblong, ovate, quite entire, pubescent. It is eighteen or twenty inches high, leafy almost from the root.—A native of Jamaica.

18. *Acrostichum Punctatum*. Leaflets alternate, lanceolate, quite entire, the lowest eared, the upper ones decurrent, the upper surface dotted, smooth.—It is a native of the island of Bourbon, and strongly resembles the preceding species.

19. *Acrostichum Sorbifolium*. Pinnae oblong-ovate, entire serrate, acute; stipes scaly.—It is found in Jamaica and St. Domingo.

20. *Acrostichum Areolatum*. Pinnae alternate, linear, serrate at top. The little floriferous buds in this species are divided with two phalanxes by the longitudinal nerves of the leaf; and are disposed in several parts transversely on each side.—A native of Virginia and Maryland.

21. *Acrostichum Marginatum*. Pinnae oblong, quite entire, waved, acuminate; stipes naked. This is said to be only a barren frond of *Pteris Grandifolia*.

22. *Acrostichum Sanctum*. Fronds lanceolate; pinnae linear-lanceolate, gash-serrate, the lower serratures largest. This species is a Polypodium.

23. *Acrostichum Platyneuron*. Pinnae alternate-ovate, crenate, sessile, bowed, upwards about a palm in height.—This species, which is a native of Virginia, has the appearance of Common Polypody.

24. *Acrostichum Trifoliatum*. Leaflets ternate-lanceolate.—This species is about a foot high, and is a native of Jamaica.

**** *Frond subpinnate.*

25. *Acrostichum Siliquosum*. Pinnae alternate, pinnulate upwards, linear, the lower ones two-parted.—A native of Ceylon.

26. *Acrostichum Thaliotroides*. Pinnae alternate, on each side pinnatifid, the barren ones broader.—Supposed to be the same with the preceding species; and is a native of Ceylon.

27. *Acrostichum Marantæ*. Fronds subbipinnate; pinnae oppositely coadunate, very hirsute underneath, a little toothed at the base. Its stipes are about seven inches in height, sometimes they reach a foot; they are hairy, and of a blood-red colour. Its fronds are like those of Common Spleenwort.—Native of the southern countries of Europe.

28. *Acrostichum Ilvense*. Fronds subbipinnate; pinnae oppositely coadunate, obtuse, hirsute underneath, quite entire at the base. This has a great resemblance to the foregoing, but it is scarcely longer than the finger, and never so high as seven inches. The stipe is green and not red. It is allied to the Polypodies, by having the fructifications in dots, but they are closely crowded.—It is found growing upon rocks in the northern counties of England, in Scotland, and in Wales; and is said to be found also in Jamaica.

29. *Acrostichum Ebeneum*. Pinnae sessile, oblong, sinuate, the uppermost shortest and quite entire. This is only a young plant of the *Acrostichum Calomelanos*. See the thirty-fourth species.—Native of Jamaica.

30. *Acrostichum Furcatum*. Dichotomous; leaflets pinnate; pinnae parallel-lanceolate, approximating, quite entire. This species is a Polypodium, and is seldom found in flower.—Native of Jamaica.

***** *Frond bipinnate.*

31. *Acrostichum Aculeatum*. Fronds super-decompound; pinnae bifid; stipes prickly.—This is a species of *Trichomanes*; and a native of Jamaica.

32. *Acrostichum Cruciatum*. Leaflets opposite, lanceolate, the lowest appendaged, crosswise.—A native of Dominica.

33. *Acrostichum Barbarum*. Leaflets opposite; pinnae lanceolate, obtuse, serrate, sessile, alternate; stipes smooth, upright, and two or three feet high.—Native of Africa.

34. *Acrostichum Calomelanos*. Pinnae alternate-lanceolate, acuminate, pinnatifid. The stipe is black, but the leaves silvery white underneath.—It is a native of South America and Jamaica.

35. *Acrostichum Viviparum*. Fronds viviparous; pinnae in pairs, one-sided; pinnules pinnatifid, forked, subulate, bearing the fructifications on the inner margin.—This species is a native of the isles of France and Bourbon.

36. *Acrostichum Velleum*; *Woolly Acrostichum*. Fronds bipinnate; all the pinnae ovate, cordate, gashed on the side, and very hirsute underneath.—A native of Madeira.

37. *Acrostichum Simplex*. Fronds entire, smooth, petiolated; the barren ones lanceolate acuminate, the fertile ones linear lanceolate.—This species is a native of Jamaica.

38. *Acrostichum Petiolatum*. Fronds entire, smooth, petiolated; the barren ones linear-lanceolate, the fertile ones linear.—Also a native of Jamaica.

39. *Acrostichum Latifolium*. Fronds petioled, broad lanceolate, very smooth, entire, margined; the fruit-bearing ones ovate lanceolate; shoots creeping.—Native of Jamaica.

40. *Acrostichum Villosum*. Fronds broad-lanceolate, somewhat crenulate, villous on both sides.—Native of Jamaica.

41. *Acrostichum Muscosum*. Fronds petioled, entire, scaly; the barren ones oblong-lanceolate, blunt; the fertile ones linear-lanceolate.—This species is also a native of Jamaica.

42. *Acrostichum Serrulatum*. Fronds linear, toothed, fruit-bearing at the tip; shoots very short, rooting.

43. *Acrostichum Graminoides*. Fronds naked, linear, subdichotomous, and fruit-bearing at the tip.

44. *Acrostichum Sulphureum*. Pinnas alternate-ovate, pinnatifid; leaflets retuse, serrate.—This and the two foregoing, are natives of Jamaica.

Actæa, a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, leaflets roundish, obtuse, concave, caducous. *Corolla*: petals four, acuminate to both ends, larger than the calix, caducous. *Stamina*: filamenta usually about thirty, capillary, broader at top; antheræ roundish, twin, erect. *Pistilla*: germen superior, ovate; style none; stigma thickish, obliquely depressed. *Pericarp*: a berry, oval-globose, smooth, one-furrowed, one-celled. *Seeds*: very many, semi-orbicular, lying over each other in two rows. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: four-petalled. *Berry*: one-celled. *Seeds*: semi-orbicular in two rows.—These plants may be propagated by seeds, which should be sown on a shady border soon after they are ripe, where they can be obtained fresh; for if they are kept out of the ground till spring, the plants will not appear till the year after. As they seldom come all up at the same time, the border should not be disturbed till the following autumn, when they should be transplanted to another shady border, where they may remain to flower.—The species are,

1. *Actæa Spicata*; *Common Black-berried Herb Christopher*, or *Bane berry*. Raceme ovate; fruits berried. This species grows naturally in several places in the north of England. It grows two feet and a half high. The footstalks of the leaves arise from the root; these divide into three smaller footstalks, and are so divided again that each leaf is composed of twenty-seven lobes, or small leaves. The flower-stem which arises from the root, has leaves of the same form, but smaller. The flowers grow in ramose spikes, and are of a pure white. It flowers in June, and in autumn ripens its fruits, which are black and shining, about the size of pease, and very poisonous. Indeed the whole plant is of an acrid and poisonous nature, and therefore, though a powerful repellent, and having a root useful in some nervous cases, must be administered with caution. The juice of the berries, mixed with alum, yields a black dye. Toads seem to be allured by the smell of this plant; but Dr. Withering observes, that this may be owing to its fondness for the same damp shady situations as the toad.—There are two varieties of this species, one an American plant with white berries; the other of British origin, and being only distinguished from the rest of the same species by its berries being red instead of black.

2. *Actæa Racemosa*; *American Black or Wild Snake-root*. Racemes very long; fruits dry. The root of this plant is much used in America in many disorders, and is supposed to be an antidote against poison, and the bite of the rattlesnake.—It is a native of North America, where it is called Black Snake-root, to distinguish it from Common Snake-root. The Seeds are annually sent to Europe, and should be sown as soon as the season will permit. It flowers in June, or early in July, but does not perfect seed in England. During the flowering time it makes a good appearance; and therefore deserves a place in shady borders, or among shrubs, where if it be not overhung by them, it thrives well, and, being hardy, will only require the same care as the shrubs themselves.

3. *Actæa Japonica*; *Japanese Herb Christopher*. Spikes very long; leaflets gashed, palmate, undivided.

4. *Actæa Aspera*; *Rough-leaved Herb Christopher*. Stem

climbing; leaves lanceolate, rough; spikes interrupted.—This species is a native of Canton, near China; and its leaves being extremely rough, the Chinese use them for polishing, particularly tin-ware.

Adam's Needle. See *Yucca*.

Adansonia; a genus of the class Monadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved; semiquinquefid, cyathiform; divisions revolute, deciduous. *Corolla*: petals five, roundish, nerved, revolute, connected by the claws with each other and the stamina. *Stamina*: filamenta united at bottom into a tube, which they crown; expanding horizontally; antheræ kidney-shaped. *Pistilla*: germen ovate; style very long, tubulous, variously intortéd; stigmas many, (ten,) prismatic, villous, radiate-expanded. *Pericarp*: capsule ovate, woody, not gaping, ten-celled, with farinaceous pulp, the partitions membranaceous. *Seeds*: numerous, kidney-shaped, rather bony, involved in a friable pulp. *Observe*. This genus is very nearly allied to *Bombax*; the fructification differing only in the seeds being covered with meal instead of wool or cotton. **ESSENTIAL CHARACTER.** *Calix*: simple, deciduous. *Style*: very long. *Stigmas*: many. *Capsule*: woody, ten-celled, with farinaceous pulp, and many seeds.—The only species is,

1. *Adansonia Digitata*; *Ethiopian Sour Gourd*, or *Monkies' Bread*.—This tree was found in Africa of the amazing size of from sixty-five to seventy-eight feet in circumference, but their usual height was not extraordinary, only from twelve to fifteen feet. The fresh fruit is very pleasant, of an acid flavour, and is eaten with sugar. The pulp or juice mixed with sugar, or a syrup made of it, is used in putrid and pestilential fevers. At Cairo they reduce this pulp to a powder; and use it in the lientery, dysentery, and all sorts of fluxes.—It is propagated by seeds, which it does not produce in Europe. They must be sown in pots, and plunged into a hot-bed, where they will appear in about six weeks; and soon after be fit to transplant, which should be done, and each removed into a separate pot filled with light sandy earth, and put into a fresh hot-bed, observing to shade them until they have taken root; after which they should have free air every day in warm weather. They reach to the height of six feet, and some have even attained to twelve and fifteen feet; but they cannot with us endure the open air.

Adder's Tongue. See *Ophioglossum*.

Adelia; a genus of the class Dicoecia, order Monadelphia.—**GENERIC CHARACTER.** *Male. Calix*: perianth one-leaved, three-parted; leaflets oblong, curved back. *Corolla*: none. *Stamina*: filamenta many, capillary, the length of the calix, united into a cylinder at the base; antheræ roundish. *Female. Calix*: perianth five-parted; parts oblong, permanent. *Corolla*: none. *Pistil*: germen roundish; styles three, very short, divaricate; stigmas torn. *Pericarp*: capsule tricocous, roundish, three-celled. *Seeds*: solitary, roundish. **ESSENTIAL CHARACTER.** *Male. Calix*: three-parted. *Corolla*: none. *Stamina*: many, united at the base. *Female. Calix*: five-parted. *Corolla*: none. *Styles*: three, torn. *Capsule*: tricocous.—These plants are propagated by seeds, which they do not produce of good quality in England: they must be sown upon a hot-bed in the spring. As the flowers are of little beauty, the plants are seldom found except in botanic gardens.—The species are,

1. *Adelia Bernardia*; *Villous-leaved Bernardia*. Leaves oblong, tomentose, serrate.—It grows naturally in the island of Jamaica, and is near of kin to the Croton.

2. *Adelia Ricinella*; *Smooth-leaved Bernardia*. Leaves obovate, quite entire. It grows to the height of eight or ten feet, and has slender flower-stalks.—Native of Jamaica.

3. *Adelia Acidoton*; *Box-leaved Adelia*. Branches flexuose; spines gemmaceous. It seldom rises above four feet in height, and has much the appearance of a young Ebony.—It flowers in June with us; and in Jamaica, of which it is a native, early in April and May.

Adenanthera; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved; five-toothed, very small. *Corolla*: five-petalled, bell-shaped; petals lanceolate, sessile, convex inwards, concave underneath. *Stamina*: filamenta subulate, erect, a little shorter than the corolla; antheræ roundish, incumbent, bearing a globose gland at the outer tip. *Pistil*: germen oblong, gibbous downwards; style subulate, the length of the stamina; stigma simple. *Pericarp*: a legume, long, compressed, membranaceous. *Seeds*: very many, roundish, remote. ESSENTIAL CHARACTER. *Calix*: five-toothed. *Petals*: five; globose glands, affixed to the outer tip of the antheræ. *Legume* membranaceous.—The species are,

1. *Adenanthera Pavonina*. Leaves smooth on both sides.—This is one of the largest trees in the East Indies, and the timber is in common use on account of its solidity. It flowers in September, bears fruit at the beginning and end of the year, and is never without leaves. Its duration is two hundred years. The natives use the powder of the leaf in their ceremonies; and of the bruised leaves they make a drink, which they esteem good against pains in the loins. The seeds, besides being eaten by the common people, are of great use to the jewellers and goldsmiths, on account of their equality for weights, each of them weighing four grains; they also make a cement by beating them up with water and borax.—In England it must be raised from the seeds on a hot-bed, and afterwards placed in the bark-stove, where the fine branching leaves will make a handsome appearance. It has never been known to flower in Great Britain.

2. *Adenanthera Falcata*. Leaves tomentose underneath.—This species is little known, never having been cultivated in England:—Native of the East Indies.

3. *Adenanthera Scandens*. Leaves pinnate, two paired; leaflets ovate, oblique, smooth; claspers terminal, bifid.—It has never been cultivated in England, and is therefore little known.—Native of Mallicollo, in the S. Seas.

Adiantum; a genus of the class Cryptogamia, order Filices.—GENERIC CHARACTER. Fructifications assembled in oval spots at the end of the fronds which are turned back; or at the reflex tip of the frond underneath.—A large genus of Ferns, chiefly the growth of hot climates.

* *Fronde simple*.

1. *Adiantum Reniforme*; *Kidney-leaved Maiden-hair*. Fronds kidney-shaped, stalked, many-flowered.—It is a native of the island of Madeira; has been cultivated in England, and must be confined to the green house.

2. *Adiantum Philippense*; *Philippine Maiden-hair*. Fronds kidney-shaped, alternate, petiolate, lobate, many flowered. Native of the Philippine Islands.

3. *Adiantum Repens*; *Creeping Maiden-hair*. Fronds trapezium-shaped, cordate, pinnatifid; divisions lance-shaped, serrate at the tip, the lower ones gashed.—A native of the Isle of France.

** *Fronde compound*.

4. *Adiantum Radiatum*; *Rayed Maiden-hair*. Frond digitate; leaflets pinnate; pinnae one-flowered.—This elegant little plant rises by a simple stalk to the height of six or eight inches, and then divides in five or more simple branches, disposed in a radiated expanded form; and sustained by a few simple leaves placed in the manner of an umbrella, under their insertions. It is a native of Jamaica and St. Domingo.

5. *Adiantum Pedatum*; *Canadian Maiden-hair*. Fronds pedate; leaflets pinnate; pinnae gibbous before, gashed, fruit-bearing. The leaves of this plant resemble the comb of a cock. It has been cultivated in England, and will live through the winter in the open air, if the season be moderate.—It grows naturally in Canada in such quantities, that when the French were in possession of that country, they sent it to France as a package for goods, and the Parisian apothecaries used it instead of the true Maiden hair. It is also found in Japan and the Society Isles, and flowers in August and September.

6. *Adiantum Lanceum*; *Surinam Maiden-hair*. Fronds pinnate; pinnae opposite, oblong, the end ones triangularly hastate.—It is a native of Surinam.

7. *Adiantum Hastatum*; *Hastate-leaved Maiden-hair*. Fronds pinnate; pinnae hastate-trilobate, straight. This plant seldom exceeds six inches in height.—Native of the Cape.

8. *Adiantum Trilobum*; *Three-lobed Maiden-hair*. Pinnae three-parted, obtuse, gashed, many-flowered.—A native of America.

9. *Adiantum Serrulatum*; *Serrate-leaved Maiden-hair*. Fronds bipinnate; pinnules deltoid-oblong serrate; fructifications solitary, superior.—This species is about six inches high; and a native of Jamaica.

10. *Adiantum Caudatum*; *Tail-leaved Maiden-hair*. Fronds pinnate, sickle-tailed at the top.—Native of the East Indies and Japan.

*** *Fronde decomposee*.

11. *Adiantum Flabellulatum*; *Fan-leaved Maiden-hair*. Fronds decomposee; pinnae alternate, rhombed, rounded, many-flowered; stipes pubescent above.—Native of China.

12. *Adiantum Trifoliatum*; *Ternate-leaved Maiden-hair*. Fronds decomposee; leaflets alternate, ternate, linear, one-flowered.—Native of America.

13. *Adiantum Chusanum*; *Chinese Maiden-hair*. Fronds decomposee; pinnae alternate, pinnatifid; lobes unequal.—Native of China.

14. *Adiantum Capillus Veneris*; *True Maiden-hair*. Fronds decomposee; leaflets alternate; pinnae wedge-shaped, lobed, pedicelled. It is a very succulent plant, yielding almost its whole weight of juice; but neither its taste nor smell promise any efficacy, although a decoction of the fresh plant is recommended as a gentle diuretic, which removes obstructions of the lungs and other viscera; and, made into a syrup, as an excellent medicine for coughs, hoarsenesses, and other disorders of the breast. Haller says, that if the syrup of Capillaire made from this plant be good for any thing, it is from the orange-flower water which they put into it; though Sir John Hill asserts, that as we cannot easily have the plant fresh, and that it loses a great deal of the virtue in drying, the best expedient is to use the fine syrup of Capillaire, which is made of an infusion of the plant when in its perfection, with pure Narbonne honey. We, continues he, suppose this is a trifle; but barley-water sweetened with it, is one of the best remedies for a violent cold.—This is a native of the south of Europe, and of the Levant, and is found, though but rarely, in Wales and Scotland, growing wild on rocks; but that which is met with at the druggists is procured from France. The plant is in perfection in the latter end of summer. It may be preserved in pots filled with gravel, lime, and rubbish, in which it will thrive much better than in good earth.

15. *Adiantum Villosum*; *Hairy-stalked Maiden-hair*. Fronds bipinnate; pinnae rhombed, fructifying before and without; stipe villous.—It is two feet in height; a native of Jamaica; and requires a stove in England

GOMPHRENA. *Globe Amaranth.*

AGRIMONIA. *Sweet scented Agrimony.*

ALOE. *Barbadoes Aloe.*

ADONIS. *The Common Adonis or Pheasant's Eye.*

16. *Adiantum Pulverulentum*; *Dusty Maiden-hair*. Fronds bipinnate; pinnae oval, truncate, before one-flowered, stipe shaggy.—Native of South America.

17. *Adiantum Cristatum*; *Crested Maiden-hair*. Fronds bipinnate; lowest leaflets two-parted; pinnae crescent-shaped, many-flowered above.—A native also of South America.

18. *Adiantum Furcatum*; *Forked Maiden-hair*. Frond bipinnate; pinnae generally two-parted, linear; line of fructification single. Stem smooth, and two feet high.—Native of the West Indies.

19. *Adiantum Caffrorum*; *Caffrarian Maiden-hair*. Fronds bipinnate; pinnae ovate, gash-toothletted, chaffy underneath.—Native of Jamaica.

20. *Adiantum Fragrans*; *Sweet-scented Maiden-hair*. Fronds bipinnate; pinnae ovate, sublobed, obtuse, naked underneath.—This species is a native of Madeira. It may be kept with us in a green-house, where alone it has been found able to endure our climate.

21. *Adiantum Truncatum*; *Truncate-leaved Maiden-hair*. Fronds decomposed, with pinnate leaflets; pinnae alternate, wedge-shaped, rather sickle-shaped, truncate, quite entire.—Native of the West Indies.

**** *Fronde super-decomposita.*

22. *Adiantum Clavatum*; *Clubbed Maiden-hair*. Leaflets alternate; pinnae wedge-shaped, quite entire, alternate, one-flowered.—A native of Dominica.

23. *Adiantum Aculeatum*; *Prickly-stiped Maiden-hair*. Pinnae palmate, many-flowered, stipe-prickly.—It is a native of Jamaica and Dominica.

24. *Adiantum Trapeziforme*; *Rhomb-leaved Maiden-hair*. Leaves alternate; pinnae rhombed, gashed, fruit-bearing on each side.—It is a native of New Zealand, and of the countries between the tropics. It has been introduced into England, but cannot be preserved except by a stove; its shining black stalks and oddly-shaped leaves, will there afford an agreeable variety among other exotic plants.

25. *Adiantum Hexagonum*; *Hexagon-leaved Maiden-hair*. Pinnae hexangular, emarginate, quite entire, one-flowered on both sides.—It is said to be *Pteris heterophylla*.

26. *Adiantum Pteroides*; *Heart-leaved Maiden-hair*. Pinnae ovate entire, crenulate; stipe polished, seven inches high, purple and smooth.—Native of the Cape.

27. *Adiantum Æthiopicum*; *Cape Maiden-hair*. Pinnae rounded, entire crenulate, petioles capillary.—It is a native of the Cape, and of Japan.

New Species.—* *Fronde compound.*

28. *Adiantum Triphyllum*; *Three-leaved Maiden-hair*. Frond three-leaved; leaflets sessile, lanceolate, pinnatifid, crenate.—This is a very beautiful little fern, tender, entirely smooth, a span high; and was found by Commerson at Buenos Ayres in South America.

29. *Adiantum Cunneatum*; *Wedge-leaved Maiden-hair*. Fronds pinnate; leaflets opposite; subpinnate pinnae wedge-shaped, retuse, alternate.—This species seems to be little known.

30. *Adiantum Pumilum*; *Dwarf Maiden-hair*. Frond pinnate; stipe capillary; pinnae alternate, roundish, serrulate, the uppermost larger trapezium-shaped, fructifications interrupted.—This plant seldom rises above two or three inches from the root; its leaves and stalks are very delicate, and the fructifications but few.—Found in dry and rocky places in Jamaica, of which it is a native.

31. *Adiantum Deltoideum*; *Deltoid-leaved Maiden-hair*. Frond pinnate; pinnae alternate, deltoid, obtuse; the uppermost triangular; fructifications continued above and in front.—This species is a native of Jamaica.

32. *Adiantum Macrophyllum*; *Large-leaved Maiden-hair*. Frond pinnate; pinnae opposite, rhomboid acute, the lower larger, the lowest sub-hastate, reflex fructifications continue in front and below.—It is a native of Jamaica, in moist and shady places.

** *Fronde decomposita.*

33. *Adiantum Scandens*; *Climbing Maiden-hair*. Leaflets wedge-shaped, equally gashed; stem climbing.—A native of Cochin-China.

34. *Adiantum Striatum*; *Striated Maiden-hair*. Frond bipinnate; pinnules rigid, sickle-ovate; fructifications superior, interrupted; stipe round, rough.—Native of Jamaica.

35. *Adiantum Strictum*; *Stiff Maiden-hair*. Frond bipinnate; pinnae four-cornered, fastigiate, erect; pinnules alternate, polished, entire; fructifications superior continued.—Also a native of Jamaica.

36. *Adiantum Microphyllum*; *Small-leaved Maiden-hair*. Frond bipinnate; leaflets alternate, oblong, obtuse, crenate, the lowest pinnatifid. It attains to the height of nine inches. Native of Jamaica; and is found among the rocks by the river near St. Jago de la Vega.

37. *Adiantum Denticulatum*; *Tooth-leaved Maiden-hair*. Pinnae alternate, trapezoid, acuminate, crenate, notches tooth-letted; fructifications superior, interrupted.—This species is a native of Jamaica.

*** *Fronde super-decomposita.*

38. *Adiantum Fragile*; *Brittle Maiden-hair*. Frond bipinnate, at top; pinnae obovate wedge-shaped, entire; fructifications interrupted.—Native of Jamaica.

39. *Adiantum Tenerum*; *Tender Maiden-hair*. Pinnules alternate, rhomb wedge-shaped, blunted, gashed; fructifications interrupted.—It is a native of Jamaica, has a black, shining, branched stipe, from fourteen to eighteen inches high, and is found in shady places.

Adiantum Nigrum. See *Asplenium*.

Adonis; a genus of the class Polyandria, order Polygynia. —GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets obtuse, concave, a little coloured, deciduous. *Corolla*: petals five to fifteen, oblong, obtuse, shining. *Stamina*: filaments very short, subulate; antheræ oblong, inflex. *Pistilla*, germs numerous, in a head; styles none; stigma, acute, reflex. *Pericarp*, none. Receptacle oblong, spiked. *Seeds* numerous, irregular, angular, gibbous at the base, reflex at the top, a little prominent, naked. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five or more, without a nectary. *Seeds*: naked.—The leaves are multifid in some species, in others biternate. The flowers are terminating, varying in the number of petals, from five to twelve or more: these are long, narrow, red or yellow, without any nectary, as in *Anemone*, which genus the *Adonis*-flower resembles, though its fruit approaches more to the *Ranunculus*; having the seeds on a receptacle, more or less lengthened out, forming a bunch, pretty much as in that genus.—The species are,

1. *Adonis Æstivalis*; *Tall Adonis*. Corollas five-petalled, heads of seeds ovate.—This species is a native of the southern counties of Europe, and is found among corn. It flowers in May and June, is an annual plant, and if sown in autumn, will appear in the following spring. They thrive best in a light soil, and the seed should be sown where they are intended to remain, as the plant will not bear transplanting.

2. *Adonis Autumnalis*; *Common Adonis*, *Bird's Eye*, *Pheasant's Eye*, *Red Maithes*, or *Red Morocco*. Its stalks is about a foot high.—It is a native of the southern parts of Europe, but grows in Kent by the side of the Medway, between Rochester and Maidstone, where it is met with in great plenty. Among spring corn, there is rarely a plant of

it to be found; which shows the propriety of sowing the seeds in gardens in autumn; for those fields of spring corn, if suffered to remain undisturbed after the harvest, will abound with this plant in the following year. It is supposed to have been conveyed from the gardens to the fields by means of the dung-heap, as it is not probably of long standing, not being recorded as indigenous by our old botanical writers. Great quantities of the flowers are annually sold in London by the name of *Red Morocco*. They flower in the beginning of June, and the seeds ripen in August and September. For the mode of propagating them, see the preceding species.

3. *Adonis Vernalis*; *Perennial*, or *Spring Adonis*. Flower twelve-petalled; heads of seeds ovate.—This species is a native of Oeland, Switzerland, Austria, Carniola, Silesia, Prussia, Bohemia, the Palatinate, and other parts of Germany, where the root is often used for the true Black Hellebore. Its large yellow flowers are produced at the end of March or the beginning of April, and the seeds ripen in August, and should be sown soon after, otherwise they seldom succeed. The plants must be kept free from weeds, and if refreshed with water in dry weather, it will promote their growth. They should remain where sown till the second year, for they make but slow progress when young. The best time to transplant them is in autumn, when they ought to be planted where they are to remain, for if often removed, they will not produce many flowers, and even those will be much the weaker for it. They may be increased by parting the roots, either in autumn or spring. Being hardy and easily cultivated, and producing their showy flowers early in the season, they are desirable plants for the garden.

4. *Adonis Apennina*: *Apennine Adonis*. Flowers fifteen petalled. The stem is about a foot and a half in height.—It is found wild in the Apennines, and in Siberia. For its culture and propagation, see the preceding species.

5. *Adonis Capensis*; *Cape Adonis*. Flowers ten-petalled, heads depressed, leaves biternate, leaflets serrate, heart-shaped. Found wild near the Cape.

6. *Adonis Vesicatoria*; *Blister Adonis*. Flowers ten-petalled; leaves biternate; leaflets serrate, smooth.—This plant is perfectly smooth, and has hard firm leaves. It is also a Cape plant, and receives its name from the Africans using it for raising blisters.

Adoxa; a genus of the class Octandria, order Tetragynia.—**GENERIC CHARACTER.** *Calix*: perianth inferior, bifid, flat, permanent. *Corolla*: monopetalous, flat, quadrifid; clefts ovate, acute, longer than the calix. *Stamina*: filaments subulate, the length of the calix; antheræ roundish. *Pistilla*: germ below the receptacle of the corolla; styles simple, erect, the length of the stamina, permanent; stigmas simple. *Pericarp*: a globose berry, between the calix and the corolla, the calix being united below with the berry umbilicate, four-celled. *Seeds* solitary, compressed.—Observe, such is the terminal fructification, but all the lateral ones add a fifth part of the whole number. **ESSENTIAL CHARACTER.** *Calix*: bifid, inferior. *Corolla*: four or five cleft, superior. *Berry*: four or five celled, united with the calix.—The roots of plants of this genus may be transplanted any time after the leaves are decayed, till winter. They must be planted in the shade under shrubs; for if they are exposed to the open sun, they will not thrive.—The following species only has been discovered.

1. *Adoxa Moschatellina*; *Bulbous Fumitory*, or *Hollow Root*, and *Tuberous Moschatell.* It has a perennial root, and grows naturally in shady places, and woods; as in Hampstead and Charlton woods, &c. The flowers appear at the

end of March, or beginning of April, and the berries ripen in May, soon after which the leaves decay. These and the flowers smell like musk, from whence some have called it *Musk Crowfoot*.

Ægiceras; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-shaped, half five-cleft, coriaceous, permanent. *Corolla*: petals five. *Stamina*: filaments five. *Pistil*: germ oblong; style single. *Pericarp*: capsule bowed, coriaceous, one-celled, one-valved, gaping on the convex side. *Seed*: single. **ESSENTIAL CHARACTER.** *Calix*: bell-shaped, half five-cleft. *Capsule*: bow-shaped, one-celled, gaping on the convex side. *Seed*: inverted.—The following are the species:—

1. *Ægiceras Majus*; *the Greater Ægiceras*. Leaves ovate, quite entire; legumes long, sickle-shaped. This is a shrub about twelve feet high, with several stems a foot in thickness, putting out many twigs and suckers. Its flowers have an agreeable smell.—Native of the Molucca Islands.

2. *Ægiceras Minus*; *the Lesser Ægiceras*. Leaves ovate, sometimes notched; legumes short, crescent-shaped.—A native of Ceylon.

Ægilops, a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** Two lateral flowers hermaphrodite. *Calix*: a large bivalvular glume, sustaining three flowers; valves ovate, truncate, streaked, with various awns. *Corolla*: a bivalvular glume; the outer valve ovate, terminated by a double or triple awn; the inner lanceolate, erect, awnless, with the edge bent in longitudinally; nectary two-leaved; leaflets ovate, flat, transparent, very small. *Stamina*: filaments three, capillary, with oblong antheræ. *Pistil*: germ turbinate; styles two, reflex, with hairy stigmas. *Pericarp*: none. *Seeds*: oblong, convex on one side, grooved on the other, with the inner valve of the corolla adhering to it, and not opening. One male flower between the two former. **ESSENTIAL CHARACTER.** *Calix*: a glume, subtriflorous, cartilaginous. *Corolla*: a glume, terminating in a three-fold awn. *Stamina*: three. *Styles*: two. *Seed*: one.—All the species of this genus of Grasses appear to be annual: they are,

1. *Ægilops Ovata*. Spike-awned, all the calices with three awns.—This grass grows wild in the southern countries of Europe.

2. *Ægilops Caudata*. Spike-awned, all the calices with two awns.—This grass is a native of Crete.

3. *Ægilops Truncialis*. Spike-awned, the lower calices with two awns.—This species of grass grows about Montpellier, Marseilles, Nice, and Smyrna.

4. *Ægilops Squarrosa*. Spike awl-shaped, longer than the awns.—This species of grass has been found in the Levant by Tournefort, and by Cavanilles in Spain.

Ægilops. See *Quercus*.

Æginetia. See *Orobanche*.

Ægiphila, a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-shaped, four-toothed, loose, very short, permanent. *Corolla*: one-petalled, salver-shaped; tube cylindrical, narrower and longer than the calix, border quadrifid, flat, equal; clefts oblong. *Stamina*: filaments capillary, inserted into the mouth of the tube, erect; antheræ roundish. *Pistil*: germ roundish, superior; style capillary, deeply bifid; stigmas simple. *Pericarp*: a roundish two-celled berry, surrounded with the permanent calix. *Seed*: either in pairs or solitary. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Corolla*: quadrifid. *Style*: semi-bifid. *Berry*: four-seeded.—The species are,

1. *Ægiphila Martinicensis*. Leaves ovate-lanceolate, acuminate, smooth; branches diffused; panicles terminating or

axillary, calices smooth.—This is a shrub six feet high, with panicles terminating and axillary, leafy, compound, and stiff; the flowers white.—Found on the edges of woods in the island of Martinico. It flowers in November.

2. *Ægiphila Elata*. Leaves elliptic, acuminate, membranaceous, panicles terminating; calices pubescent. This plant is a climber, and frequently rises to the height of six or seven feet or more. It is a native of Jamaica.

There are two other species, *Fætida* and *Trifida*, with leaves ovate-lanceolate, the first having them hirsute beneath, the last smooth.

Ægopodium; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal manifold, convex: partial, similar, but flat. *Involucre*, none. Proper perianth scarcely observable. *Corolla*: universal uniform, with every floscule fertile; particular with five petals, obovate, concave, inflex. at the tip, and equal. *Stamina*: filaments simple, twice as long as the corolla, with roundish antheræ. *Pistilla*: germ inferior; styles simple, erect, the length of the corollas, with headed stigmas. *Pericarp*: none. *Fruit*: ovate-oblong, streaked, bipartite. *Seeds*: two, ovate-oblong, convex and streaked on one side, flat on the other. ESSENTIAL CHARACTER. *Fruit*: ovate-oblong, streaked.—One species only is known, viz.

1. *Ægopodium Podagraria*; *Herb Gerard*, *Gout-weed*, *Ash-weed*, or *Ground-ash*, and *Wild Masterwort*. This weed is not uncommon in hedges, orchards, &c. It is a perennial plant; and, as it is a great creeper, cannot be admitted into gardens without great caution. It requires no care, but to plant it in the shade, and confine the roots. The stem grows two or three feet high. The flowers are white, and appear from May to July. Although it is aromatic, like most umbellate plants, it is not admitted into medical use; nor has it any title to its name of *Goutweed*, though formerly used by the Germans to assuage the pains of the gout and piles. Linneus says it is eaten in Sweden, boiled for greens, when tender in the spring. Culpeper says, "It is not to be supposed that Goutwood hath its name for nothing, but upon experiment to heal the gout and sciatica; as also joint-aches, and other cold griefs. *The very bearing of it about one easeth the pains of the gout, and defends him that bears it from disease!*" Meyrick and Hill, are, however, more reasonable: the former calls the roots and leaves "a good external application for the sciatica and other pains, whether they are employed as a fomentation or a poultice; and though many extol their efficacy in the gout, he says they are well omitted in that complaint, as they are seldom productive of any lasting good effects, and may sometimes be the occasion of much distress and mischief." The latter, (Hill) recommends the root, and fresh buds of the leaves, as excellent fomentations and poultices for pains, and says he has seen a good effect from a quantity of the leaves and roots boiled soft together, and applied to the hip in the sciatica, keeping a fresh quantity hot to renew the other as it grew cold, but he advises not to make any use of it for the gout.

Ægopicon; a genus of the class Monœcia, order Monandria.—GENERIC CHARACTER. Male flowers small, in an ovate ament. *Calix*: one-leafed, tubulous, trifiid. *Corolla*: none. *Stamina*: filament one, longer than the calix, erect; with an ovate anthera. Female flowers upon the same plant, solitary. *Calix* and *Corolla*: same as above in the male. *Pistil*: germ ovate, superior; styles three, divaricate; with simple permanent stigmas. *Pericarp*: a globular berry, tricocous and trilocular within, with a bifid point. (Capsule tricocous elastic.) *Seeds*: solitary, angular on one side. ESSENTIAL CHARACTER. *Male*, an ament. *Calix*: common trifid; partial tubulous. *Anthera*: four-lobed. *Female flowers*, solitary.

Calix: as in the male. *Corolla*: none. *Styles*: three, coadunate at the base. *Capsule*: tricocous.—One species only is known.

1. *Ægopicon Betulinum*. A tree, is very much branched. Branchlets alternate, bent different ways, leafy, flowering at the ends. Bark somewhat wrinkled, except in the younger shoots.—Dalberg noticed it at Surinam; and Aublet in Guiana.

Æschynomene, a genus of the Diadelphia class, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leafed, bell-shaped, sub-bilabiate; lips equal, upper bifid, lower three-toothed. *Corolla*: papilionaceous; banner subordinate, scarcely gaping, large; wings subovate, obtuse, shorter than the banner; keel lunate, acuminate, the length of the wings. *Stamina*: filaments ten, (single and nine-cleft;) antheræ small. *Pistil*: germ oblong, villous, columnar; style subulate, rising; stigmas simple; rather obtuse. *Pericarp*: legume, long, flat, jointed, rough, one-celled, opening at the truncate joints. *Seeds*: solitary between the joints, kidney-shaped. ESSENTIAL CHARACTER. *Calix*: bilabiate. *Legume*: with truncate one-seeded joints.—All the plants of this genus are propagated by seeds, which should be sown on a hot-bed early in the spring; and when the plants have strength enough to be removed, they should be put each into a separate small pot, filled with light earth, and plunged into a fresh hot-bed, from whence, as they advance in growth, they should be shifted into larger pots, but not be too large, otherwise the plants will not thrive.—The species are,

1. *Æschynomene Grandiflora*; *Great-flowered Æschynomene*. Stem arborescent, flowers very large, legumes filiform. It is a shrub from ten to fifteen feet in height. It is a native of the East Indies; and called *Pois du Duc de Choiseul* by the French. It has been cultivated in England, and is frequent in the gardens at Jamaica; domestic fowls are partial to the seeds. It is difficult to preserve this plant through the winter in this country. The seedling plants should be brought forward on a hot-bed, and then plunged into the bark-bed in the stove, where, if they be tenderly treated, they will survive the winter, and flower in the summer following.

2. *Æschynomene Arborea*; *Arborescent Æschynomene*.—Stem aborescent, smooth; joints of the legumes semi-cordate, smooth. This plant attains the height of six or seven feet. It requires the same treatment as the preceding species, flowers early in the summer, and ripens its seeds in the autumn. As their stalks are succulent, they must be kept dry in winter, otherwise they are very apt to rot.

3. *Æschynomene Coccinea*; *Scarlet-flowered Æschynomene*. Stem arborescent; leaves pinnate; leaflets numerous, linear, obtuse, dusty; legumes compressed, equal. This species is smaller and lower than the first, but the head and leaves are more dense.—Native of the East Indies; and of the islands Otaheite and Huaheine in the South Seas.

4. *Æschynomene Aspera*; *Rough-stalked Æschynomene*. Stem herbaceous, rugged; joints of the legumes rugged in the middle. This species reaches the height of four or five feet, with a single herbaceous stem, which is in some parts rough.—It is a native of the East Indies.

5. *Æschynomene Americana*; *Hairy Æschynomene*. Stem herbaceous, hispid; joints of the legumes semicordate; leaflets acuminate, bractes, ciliate. The root of this species is annual, its stem one, two, and sometimes even three feet high. It is somewhat sensitive, folding its leaves together during the night, and at the approach of rain.—It is found in dry pastures, on the south side of the island of Jamaica, of which it is a native. Propagated in England in the same manner as the first species.

6. *Æschynomene Indica*; *Indian Æschynomene*. Stem herbaceous, smooth; legumes smooth, swelling on one

side, obtuse; leaflets obtuse.—It is a native of the East Indies, and may be propagated in the same manner as the first species.

7. *Æschynomene* Sesban; *Egyptian Æschynomene*. Stem herbaceous, smooth; legumes cylindric, equal; leaflets obtuse.—It is a native of Egypt, flowers in July and August.

8. *Æschynomene* Pumila; *Dwarf Æschynomene*. Stem herbaceous, smooth; legumes serrate on one side, rough in the middle; leaflets acuminate. This is an annual plant, a foot and half high, branching at bottom, and a native of the East Indies. For the method of propagating it with us, see the first species.

9. *Æschynomene* Sensitiva. Stem shrubby, smooth; leaflets obtuse; legumes smooth and even, obtuse; stipules acute, deciduous.—Native of the West Indies; it flowers in July, and the seeds ripen in October.

10. *Æschynomene* Heterophylla. Stem shrubby, lower leaves ternate-ovate, upper pinnate, roundish.—The stem of this species is arboreous, weak, with spreading tomentose branches.—A native of northern Cochin China.

11. *Æschynomene* Lagenaria. Stem herbaceous, leaflets obtuse, in several pairs; legumes mucronate. The stem of this plant, which is a native of marshy places in Cochin China, is there used for stopping bottles, where are no corks. It is herbaceous, three feet high, upright, thick, round, spongy, and elastic.

12. *Æschynomene* Cannabina. Stem herbaceous; leaflets obtuse, acuminate; peduncles solitary; legumes compressed, smooth, and even.—In the East Indies, where it is indigenous. If treated as hemp, as its name signifies, it may be applied to the same purposes.

Æseulus; a genus of the class Heptandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, ventricose, small, five-toothed. *Corolla*: petals five, roundish, plaited, and waving about the edge, flat, spreading claws narrow, inserted into the calix, irregularly coloured. *Stamina*: filaments subulate, the length of the corolla, declining; antheræ ascending. *Pistil*: germ roundish, ending in a subulate style; stigma acuminate. *Pericarp*: capsule leathery, roundish, three-celled, three-valved. *Seeds*: two, subglobular. *Observe*, one seed only commonly occurs in the capsule, but, on inspection of the embryos, it is evident that the natural number is two. ESSENTIAL CHARACTER. *Calix*: one-leaved, five-toothed, ventricose. *Corolla*: five-petalled, irregularly coloured, inserted into the calix. *Capsule*: three-celled.—The species are,

1. *Æseulus* Hippocastanum; *Common Horse Chesnut*. The flowers with seven stamina; leaves digitate, with seven entire leaflets; capsules prickly.—This tree is well known, and was formerly in greater esteem for walks and avenues than at present, which is owing to the litter made by its leaves when falling; it affords, notwithstanding, a noble shade very early in the year, and no tree has more beauty during the time of its flowering, for the extremities of the branches are terminated by fine spikes of flowers, so that every part of the tree seems covered with them, and being intermixed with the large digitate leaves, they make a noble appearance, continuing in beauty for nearly a month. In Turkey the nuts are ground, and mixed with the provender of those horses which have coughs or are broken-winded. Some assert that swine will fatten on them; and Haller says that sheep have been fed with them whole, and poultry with them boiled, and that both have done well; but this is disputed by others. They may be used to save soap in washing, having a saponaceous quality; and the bark has been successfully used in Italy as a medicine for intermittent fevers; and has answered very

well in dyeing several sorts of yellow colours. Notwithstanding the bad character Mr. Miller gives of the timber of this tree, it is said to be useful in making pipes to convey water under ground, as it will last longer than harder woods. Dr. Hunter says it is used for turnery, and is worth sixpence per foot in the north of England. Mr. Hanbury confirms Hunter's account, and adds, that the tree grows speedily to a great magnitude, and sells at such a price as to make it well worth planting for the sake of the timber, and that it ought to be felled in November or December. This species was brought from the northern parts of Asia nearly three centuries ago, and is more common now than it was an hundred years since.—These trees are propagated by sowing the nuts early in the spring, but they must be preserved in sand during the winter, otherwise they will mould and rot. They will shoot nearly a foot the first summer, and if they stand close, should be transplanted the next autumn into the nursery, and remain there two years; they should then be removed where they are intended to remain, and well secured by a fence of good stakes against young cattle and violent winds. It requires little care in the management, is never injured by the cold of this climate, and will thrive in most soils and situations, but in a sandy loam makes the greatest progress.

2. *Æseulus* Flava; *Yellow-flowered Horse Chesnut*. Leaves digitate, with five leaflets; the lamina of the corolla cordate, roundish; the claws twice the length of the calix.—This species flowers in May and June; and is a native of North Carolina.

3. *Æseulus* Pavia; *Scarlet Horse Chesnut*. Flowers with eight stamina; leaves digitate, with five or six serrate leaflets; capsules smooth; laminas of the corolla obovate; claws the length of the calix. This species rises to the height of twenty feet, but does not spread its branches to any extent. The flowers appear in June, and are sometimes succeeded by fruit, but the seeds rarely ripen in England.—It grows naturally in Brazil, Carolina, Japan, and several parts of the East; from which countries those who wish to propagate it must procure the nuts, and plant them early in the spring, in pots which must be plunged into a moderate hotbed. The nursery-men, who propagate this tree for sale, commonly graft or bud it upon common Horse-chesnut stocks; but as the stock greatly outgrows the bud or graft, the trees make a bad appearance, and do not last long.

Æthiopsis. See *Salvia*.

Æthusa; a genus of the Pentandria class, order Digenia.—GENERIC CHARACTER. *Calix*: umbel universal spreading, the rays gradually shortening towards the middle; partial also spreading, but small. Involucre universal, none; partial placed on the outside, only consisting of three very long, linear, pendulous leaflets. Proper, perianth scarcely observable. *Corolla*: universal nearly uniform, with all the floscules fertile; partial has the petals bent in, heart-shaped, and unequal. *Stamina*: filaments simple, with roundish antheræ. *Pistil*: germ inferior; styles reflex, with obtuse stigmas. *Pericarp*: none. *Fruit*: roundish, streaked, bipartite. *Seeds*: two, roundish, streaked, except on a third part of the surface, which is plane. ESSENTIAL CHARACTER. *Partial involucre*: halved, three-leaved, pendulous. *Fruit*: streaked.—The species are,

1. *Æthusa* Cynapium; *Common Fool's Parsley*. Leaves conform.—This species has a stem from one to two feet high, and is a common weed in kitchen gardens, and in a slight degree poisonous. It is easily mistaken for true Parsley and Chervil when young. The leaves emit, in a slight degree, a disagreeable smell. The safest way to avoid all doubt is to cul-

tivate the *curled Parsley*, for which this cannot be mistaken. Most cattle eat it; but it is said to be noxious to geese. This is an annual plant, and may be easily restrained in gardens by not suffering it to seed, which it does abundantly.

2. *Æthusa Buniis*; *Coriander-leaved Fool's Parsley*. Radical leaves pinnate, cauline manifold-setaceous.—This is a perennial plant, native of the Pyrenees. It flowers in July.

3. *Æthusa Meum*; *Spicknel*, *Mew*, or *Bawd Money*. All the leaves manifold setaceous.—This is a perennial plant, rising a foot and a half high, with channelled stalks, terminated by an umbel of flowers that are white with a tincture of green, and are succeeded by oblong smooth seeds. It grows wild in the mountains of Switzerland, Germany, Austria, Carniola, Italy, and Spain: also in the high pastures of Westmoreland, Cumberland, Lancashire, and Merionethshire. It blossoms in May. The roots and seeds are aromatic and acrid; they are recommended as carminatives and stomachics; in the stone, stoppage of urine, and all uterine disorders; sometimes they are given to cure tertians. Spicknel is an ingredient in theriaca and mithridate; and appears to be of the same nature as lovage. It is a powerful diuretic, and remover of obstructions in the viscera, consequently good against the gravel, jaundice, obstructions of the menses, &c. The root is the part to be made use of for these purposes, and an infusion of it is the best preparative; dried and given in powder, it strengthens the stomach, creates an appetite, and is good against the colic. This is a hardy plant, and may be increased by parting the roots at Michaelmas, or sowing the seeds soon after they are ripe, which is in July and August. They should have a shady situation and a moist soil.

4. *Æthusa Fatua*; *Fine-leaved Fool's Parsley*. All the leaves many-parted, setaceous; leaflets subverticillate; stem many-leaved; sheaths of the petioles narrow; universal involucre many-leaved. This species flowers in August and September: it is not known of what country it is a native.

African Bladder Nut. See *Royena*.

African Flea-Bane. See *Tarhonanthus*.

African Marygold. See *Tagetes*.

African Ragwort. See *Othonna*.

Agallocha. See *Excoecaria*.

Agapanthus, a genus of the Hexandria class, Monogynia order.—GENERIC CHARACTER. *Calix*: Spathe common gaping at the side. *Corolla*: one-petalled, funnel-shaped, regular; tube cornered, as if composed of six claws; border six-parted; parts oblong spreading. *Stamina*: filaments six, inserted into the throat, shorter than the corolla, declinate, antheræ kidney-shaped, incumbent. *Pistil*: germ superior, oblong, three-cornered; style filiform, length of the stamina, declinate; stigma simple. *Pericarp*: capsule oblong, three-sided, three-celled, three-valved; valves navicular, with contrary dissepiment. *Seeds*: numerous, oblong, compressed, enlarged with a membrane. ESSENTIAL CHARACTER. *Corolla*: inferior, funnel-shaped, hexapetaloid, regular.—Of this genus the following species only is known,

1. *Agapanthus Umbellatus*; *African Blue Lily*.—It is a native of the Cape; and is propagated by offsets, which come out of the sides of the old plants; and may be taken off at the latter end of June, planted each in a separate pot, and placed in a shady situation, where they can have the morning sun and free air, and be watered twice a week. They only require protection from frost and wet, and as they flower at the end of August, or in the beginning of September, they will frequently continue in beauty till spring.

Agaricus, a genus of the class Cryptogamia, order Fungi.—GENERIC CHARACTER. *Pilcus* or *cap*; with gills underneath.

Gills: differing in substance from the rest of the plant, composed of two laminas. *Seeds*: in the gills. In order to cultivate *Agarici* or *Mushrooms*, the small white knobs which are always found near their roots, in August or September, and are the offsets, or young mushrooms, should be carefully gathered with the earth about them; and as this spawn cannot be found in the pastures except during the mushroom season, you will probably find it in old dunghills where there has been much litter and little wet, also in old hot-beds, shooting out in long strings. The beds for these spawn should be made of dung, with good store of litter, on dry ground, three feet wide at bottom, and long in proportion to the quantity desired. The dung must be laid a foot thick, covered with four inches of strong earth, and upon this two more layers of dung ten inches thick, succeeded by another layer of earth, contracting the sides of the bed like the roof of a house. When finished, the bed should be covered with litter or old thatch, to keep out the wet, and prevent the bed from drying. In eight or ten days the bed will be moderately warm, and fit to receive the spawn; then the thatch or litter being removed, a covering of rich light earth, about an inch deep, should be laid all over the bed, placing the lumps of spawn upon it, four or five inches asunder, which must be covered with the same light earth, half an inch deep; and the old thatch or litter then replaced, to keep out the wet, as before. In warm weather the mushrooms will probably appear in a month; but if the weather be cold it will be much longer. The great skill is, to keep up a due degree of moisture in these beds; in warm weather showers of rain may be admitted, in winter they must be kept as dry as possible. A bed thus managed, if the spawn take kindly, will remain good for several months, and produce better mushrooms than can be gathered in the fields. When destroyed, the spawn for a new bed may be taken out of it, and plenty of mushrooms may thus be ensured throughout the year.—In many parts of Europe several sorts are eaten, which we deem poisonous. Even *Agpipperatus*, the most acrid and suspicious species of this genus, is eaten in large quantities by the Russians. They season or pickle them with salt in autumn, and eat them in Lent. Caution is nevertheless very indispensable, as several species would be highly injurious, if taken in any considerable quantity. See *Fungi*.—Authors differ exceedingly in their enumerations of the species of this genus: the following are the most worthy of notice, viz:

Agaricus Campestris; *Common Mushroom*, or *Champignon*. Gills crowded, irregular, pink changing to liver colour; cap convex, white to brown; stem white, cylindrical; cut: in white. The stem of this species is solid, from two to three inches high, and half an inch in diameter. It is esteemed the best and most savoury of the genus; and is in much request for the table in England. It is eaten fresh, either stewed or broiled, and preserved either as a pickle or in powder: the sauce vulgarly called *Catchup*, is made from its juice with salt and spices. The wild mushrooms, fresh from undunged pastures, are more delicate than those raised on artificial beds, the flesh of the latter being less tender; and those who are much accustomed to them, can distinguish them from each other by the smell. Those artificially raised are certainly more sightly, and more easily procured in a proper state for eating; they are also firmer, and better for pickling.

Agaricus Georgii, of Linnaeus, resembles this, but is far inferior to it in flavour, though not poisonous, as it is generally supposed. It is very common; and the caps turn yellow, but the gills are always white.

Agaricus Procerus, or *Tall Mushroom*, which is common

in woods and dry hilly pastures, is sometimes exposed to sale in Covent Garden market. It may be easily distinguished from the genuine sort by the sponginess of its flesh, and from all others by its tallness, bulbous base, and large volva or ruffle, and the scaly texture of its spongy cap.

Agaricus Cæsareus, or *Imperial Agaric*, is the most splendid of all the species. It is common in Italy, where it is exposed in the markets for sale. The ancient Romans esteemed it one of the greatest luxuries; and Juvenal and Martial have celebrated it as the vehicle whereby Claudius Cæsar was poisoned by his wife Agrippina. It was first found wild in this country in the year 1791.

Agaricus Orcades; a small pale-brown, or rather buff-coloured mushroom, very frequent in dry pastures, and particularly in fairy rings; which Dr. Withering is satisfied are entirely produced by their growth. It is found in woods and hedges, but is then inferior in flavour. Those from dry pastures are the best, have a pleasant smell, and a most luscious flavour, either stewed alone, or in hashes and ragouts. They make excellent *Catchup*, and are admirable in the form of a powder. The *cap* is of a pale brown buff colour; and the *stem* solid and white, an inch and half high, and about the thickness of a crow-quill. It is in season during September and October, but may be so dried as to be in use for the table all the winter. They should be gathered young, and early in the morning.

Agathopyllum; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth very small, truncate, entire, permanent. *Corolla*: petals six, ovate, somewhat villose within, inserted into the calix. *Stamina*: filaments twelve, broadish, very short, alternately placed at the base of the petals, and alternately on the calix; antheræ roundish. *Pistil*: germ superior, very small; style very short; stigma pubescent. *Pericarp*: drupe somewhat globose, crowned with the calix. *Seed*: nut somewhat globose, terminated by a truncate point, half six-celled kernel convex, beneath six-lobed, with coriaceous partitions separating the lobes. **ESSENTIAL CHARACTER.** *Calix*: superior, very short, toothless. *Corolla*: six-petalled, somewhat villose. *Stamina*: alternately inserted into the calix and petals. *Drupe*: juiceless, with a half six-celled nut, and one seed.—The only species known is,

1. *Agathopyllum Aromaticum*. This is a large bushy tree, with a pyramidal head like the Clove-tree, and a reddish odorous bark; the wood is hard, heavy, white, with some reddish fibres, and has no smell. Its fruit, which is the size of a large cherry, is shaped like a pear; it consists of a nut divided into six parts, as a walnut is divided into four, covered with a hard coriaceous shell, and that with a green thin bark very closely adhering to it, both of which are aromatic; but the nut has an acrid biting taste, which is almost caustic. The tree bears at five or six years of age, flowers in January and February, and is ten months in ripening its fruit. The natives of Madagascar, who call it *raventsara*, gather it before it is ripe, as a spice for the purpose of seasoning their meat. When fresh, it has a fine aromatic smell; and the caustic taste may be diminished by keeping it some months, then throwing it into boiling water for four or five minutes, and afterwards drying it in the sun. The leaves may be prepared as a spice in the same manner.

Agave; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: one-petalled, funnel-shaped; border six-parted, equal; parts lanceolate erect. *Stamina*: filaments filiform, erect, longer than the corolla; antheræ linear, shorter than the filaments, versatile. *Pistil*: germ oblong, growing thinner towards both

ends, inferior; style, filiform, the length of the stamina, three-cornered; stigma-headed. *Pericarp*: capsule oblong, three-cornered, three-celled, three-valved. *Seeds*: numerous. **ESSENTIAL CHARACTER.** *Corolla*: erect, superior. *Filaments*: longer than the corolla, erect.—The species are,

1. *Agave Americana*; *Common American Agave*. Stemless; leaves tooth-thorny. When vigorous the stems generally rise twenty feet high, and branch out so as to form a kind of pyramid, composed of greenish-yellow flowers, which stand erect, and come out in thick clusters at every joint. This plant has been long known in England, where it will flower in gardens, but not ripen seed. When they flower they make a fine appearance, and continue a long time in beauty; and if protected from the cold in autumn, will continue to flower for three months in favourable seasons. It has been erroneously said, not to flower until it is an hundred years old; but this is a mistake, as it flowers in a few years in warm countries, but in colder climates, where the growth is slow, it will be much longer before it shoots up a stem. In Portugal and Spain there are hedges of this plant: it also flourishes about Naples, and in other parts of Italy. The leaves are very useful as a succedaneum for soap; they are cut and passed (points foremost) between the rollers of a mill, the expressed juice being conducted into wide shallow receivers through a coarse cloth or strainer; it is then placed in a hot sun until reduced to a thick consistence by the exhalation of the aqueous part, after which it is made up into balls with lye-ashes, and will then lather with salt water as well as fresh. This soap may be made by pounding the leaves in a wooden mortar, and reducing them to a consistence by the sun or by boiling. A gallon of juice yields a pound of soft extract: the juice must always be carefully strained, and never combined with tallow or other unctuous materials. The leaves are also used for scouring pewter, and other kitchen utensils and floors. The inward spongy substance of the decayed stalk is used for tinder. The fibres of the leaves, separated by bruising and steeping in water, and afterwards beating them, make a strong thread for common uses. It is a hardy plant. This, and the third species, should be planted in pots or tubs filled with light sandy earth, and housed in winter with Oranges, Myrtles, &c.; and during that season should have but little wet. They may remain abroad during summer, and until the end of October.

2. *Agave Vivipara*; *Viviparous* or *Childing Agave*. Stemless, leaves toothed. This never grows to a large size; it is so tender that it will not thrive out of the stove even in summer: and as it never produces off-sets or suckers from the roots, it cannot be propagated that way except when in flower, when there will be an abundance of them. They require a light sandy earth, and should have little wet in winter, but may be gently watered twice a week in summer, and be allowed a great share of free air. Every summer they must be shifted, but not have large pots, and have fresh earth: unless the roots are confined, the plants will not thrive.

3. *Agave Virginica*; *Virginian Agave*. Stemless, herbaceous; leaves tooth-thorny. This is very like the first sort, but does not rise so high: both sorts have lived in the open air for some years in mild seasons; but in severe winters they are always killed if not sheltered. The third species seldom puts out so many suckers as the first, though it generally produces sufficient for propagation.

4. *Agave Lurida*. Subcaulescent; leaves tooth-thorny.—This also greatly resembles the first species, but the leaves are thinner, and their spines blacker. This is propagated like the second species; which see.

AGAVE LURIDA — Vera Cruz Agave.

H. Frederick del.

5. *Agave Tuberosa*; *Tuberous-rooted Agave*. Caulescent, leaves tooth-thorny. For the mode of propagating it, see the second species.

6. *Agave Fœtida*; *Fetid Agave*. Caulescent leaves, quite entire.—This is propagated in the same manner as the second species; which see.

Ageratum; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common oblong; with many lanceolate subequal scales. *Corolla*: compound uniform; corollets hermaphrodite, tubulous, numerous, equal, scarcely longer than the calix. Proper monopetalous, funnel-shaped; border quadrifid, spreading. *Stamina*: filaments capillary, very short; anthera cylindrical, tubular. *Pistil*: germ oblong; style filiform, the length of the stamina; stigmas two, very slender, erect. *Pericarp*: none. *Calix*: unchanged. *Seeds*: solitary, oblong, angular, crowned with a chaffy, five-leaved; upright, awned culicle. *Receptacle*: naked, convex, very small. ESSENTIAL CHARACTER. *Receptacle*: naked. *Down*: five-awned. *Calix*: oblong, subequal. *Corollets*: quadrifid.—The species are,

1. *Ageratum Conyzoides*; *Hairy Ageratum*. Leaves ovate, stem hairy. This has an annual root; and its leaf resembles that of the Nettle. It flowers in July and August; is a native of Africa, the islands of America, and the isle of Tanna in the South Seas.—The seeds must be sown on a hot-bed in the spring, and should be transplanted after they have taken root. In June they may be inured to the open air. They will begin to flower in July, and continue till the frosts of autumn destroy them.

2. *Ageratum Ciliare*. Leaves ovate, crenate, obtuse; stem smooth, two feet high.—A native of the East Indies, and of China, near Canton.

Ageratum. See *Achillea*.

Agnus Castus. See *Vitæ*.

Agrimonia; a genus of the class Dodecandria, order Digenia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, acute, small, superior, permanent, fenced with an outer calix. *Corolla*: petals five, flat, emarginate; claws narrow, inserted into the calix. *Stamina*: filaments capillary, shorter than the corolla, inserted into the calix; antheræ small, twin, compressed. *Pistil*: germ inferior, styles simple, the length of the stamina; stigmas obtuse. *Pericarp*: none; calix contracted at the neck, and hardened. *Seeds*: two, roundish. Observe, the number of stamina is very uncertain, 12, 10, 7. ESSENTIAL CHARACTER. *Calix*: five-cleft, fenced with another. *Petals*: five. *Seeds*: two, at the bottom of the calix. This is a genus of hardy perennial plants, which if kept free from weeds will thrive in any soil or situation. They are propagated by parting their roots in autumn, when their leaves begin to decay, that the young plants may be well established by the spring; and they should be kept two feet asunder. The seeds sown in autumn will appear in the following spring.—The species are,

1. *Agrimonia Eupatoria*; *Common Agrimonia*. Stem-leaves pinnate; the end-lobe petiolate; fruits hispid.—This plant is only a foot and a half in height; it is a native of woods, shady places, hedges and borders of corn-fields in Great Britain, and most parts of Europe. It is perennial, and flowers in June and July. The root in spring is sweet-scented; and the fresh-gathered flowers smell like apricots. Kalm informs us that the Canadians use an infusion of the root in burning fevers with great success. Dr. Hill affirms, that an infusion of six ounces of the crown of the root, in a quart of boiling water, sweetened with honey, and half a pint of it drank three times a day, is an effectual cure for the jaundice. He advises to begin with a vomit, afterwards to keep the bowels soluble, and to continue the medicine as long as any symp-

toms of the disease remain. The leaves, which make a pleasant tea, are said to be serviceable in hemorrhages, and in obstructions of the liver and spleen: they may be used either fresh or dried. They are found by experience to be salutary in the diabetes, and incontinence of urine. This plant is also one of the famous vulnerary herbs, and an ingredient in the genuine arquebusad-water. It is frequent, according to Meyrick, in dry pastures; and is a mild corroborant, of great efficacy in all such disorders as arise from a lax habit of body: its roots appear to possess the properties of the Peruvian bark in a very considerable degree, without manifesting any of its inconvenient qualities; and if taken in pretty large doses, either in decoction or powder, seldom fails to cure the ague. The leaves, digested in whey, afford an useful diet-drink for the spring, particularly for such as are troubled with scorbutic complaints. The country people also use them by way of cataplasm in contusions and fresh wounds. If gathered when it is coming into flower, this plant will dye wool of a good bright full nankeen colour; but if gathered in September, the yellow colour will be darker. As it gives a good dye at all times, and is a common plant easily cultivated, it deserves the notice of the dyers: in the Berlin Acts it is recommended for dressing leather. Sheep and goats eat it; but kine, horses, and swine, refuse it.—There are two varieties of this species, the *White Agrimonia*, and the *Sweet-scented Agrimonia*, both natives of Italy. The leaves of the latter emit an agreeable odour, and also make a pleasant cooling tea, which is an excellent beverage for persons in a fever.

2. *Agrimonia Repens*; *Creeping Agrimonia*. Leaves pinnate; the end-lobe sessile; fruits hispid. This plant seldom rises above two feet in height, and it multiplies faster than the common sort, which it strongly resembles.

3. *Agrimonia Decumbens*. Leaves pinnate, hirsute; stem procumbent; fruits every way hispid-hooked. This species is usually monogynous.—Native of the Cape.

4. *Agrimonia Agrimonioides*; *Three-leaved Agrimonia*. Stem-leaves ternate; fruits smooth.—It is found in moist woods and among bushes in Italy and Carniola, where it is a native.

5. *Agrimonia Parviflora*; *Small-flowered Agrimonia*. Stem-leaves pinnate; leaflets many, lanceolate; petals half as long again as the calix; fruits hispid.—It flowers in July; and is a native of North America.

Agrimonioides. See *Agrimonia*.

Agrimonia, Hemp. See *Eupatorium*.

Agrimonia, Water Hemp. See *Bidens*.

Agrostemma; a genus of the class Decandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, coriaceous, tubulous, five-toothed, permanent. *Corolla*: petals five; claws the length of the tube of the calix; border spreading, obtuse. *Stamina*: filaments awl-shaped, five alternately later than the other five, inserted into each claw of the petals; anthera simple. *Pistil*: germ ovate; styles filiform, erect, the length of the stamina; stigmas simple. *Pericarp*: capsule oblong, ovate, covered, one-celled, five-valved. *Seeds*: very many, kidney-shaped, dotted. *Receptacles*: free, as many as seeds, the interior ones gradually longer. ESSENTIAL CHARACTER. *Calix*: one-leaved, coriaceous. *Petals*: five, clawed; border obtuse, undivided. *Capsule*: one-celled.—The species are,

1. *Agrostemma Githago*; *Corn Champion*, or *Cockle*. Hirsute, calix longer than the corolla, which is not crowned as in the other species; petals entire, or slightly emarginate, and naked. The stem is two feet high, and the root annual; it is a common weed in corn-fields, enlivening them at the expense of the careless husbandman, along with Poppy and

Blue-bottle; it flowers in June and July. The seeds are diuretic; they promote the menses, and are serviceable in the dropsy and jaundice, but the use of them must be continued for a considerable length of time. Hill says, the seeds are used; they work by urine, and open all obstructions, promote the menses, and are good in dropsy and jaundice: the best way of giving them is powdered, and put into an electuary, to be taken for a continuance of time; for those medicines whose virtues are against chronic diseases, do not take effect at once.

2. *Agrostemma Coronaria*; *Rose Campion*. Tomentose, leaves ovate-lanceolate; petals slightly emarginate, crowned, serrate.—This is a native of Italy, the Valais, and Siberia, and is a biennial plant. It has long been an inhabitant of the English gardens, whereby its seed having scattered, it is become a kind of weed. There are three varieties of this plant, one with a deep red, another with a flesh-coloured, and the third with a white flower; but all little esteemed, as the double rose *Campion*, being a fine flower, has turned the others out of most gardens. The single rose *Campions* propagate themselves best by their seeds; but the variety with double flowers is propagated by parting the roots in autumn, after the flowers are past.

3. *Agrostemma Flos Jovis*; *Umbellate Rose Campion*, or *Flower of Jove*. Tomentose; petals emarginate; flowers in a corymb. The flowers, which are of a bright red, appear in July, and the seeds ripen in September.—It grows naturally on the Swiss and Piedmontese mountains, and in the Palatinate. This requires a shady situation and moist soil.

4. *Agrostemma Coeli Rosa*; *Smooth Campion*. Smooth; leaves linear-lanceolate; petals emarginate, crowned.—An annual plant, the stem a foot or eighteen inches high; native of Italy, Sicily, and the Levant; and having little beauty is only preserved in botanic gardens.

Agrostis; a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: a one-flowered, bivalve, acuminate glume. *Corolla*: bivalve, acuminate, one valve larger than the other. *Stamina*: filaments longer than the corolla, with forked antheræ. *Pistil*: germ roundish; styles reflex, villous, with stigmas longitudinally hispid. *Pericarp*: corolla growing to the seed, not gaping. *Seed*: roundish, pointed at both ends, the corolla adhering closely to it. **ESSENTIAL CHARACTER.** *Calix*: bivalve, one-flowered, a little less than the corolla. *Stigmas*: longitudinally hispid.—This is said to be an artificial genus, the species of which are in general very ill ascertained. For the method of propagating and cultivating these grasses, see the article *Grass*.—The species are.

* *Awned*.

1. *Agrostis Spica Venti*; *Silky Bent Grass*. The outer petal has a very long stiff awn; the panicle is spreading.—This is from three to four feet high, annual, frequent in sandy corn-fields, and flowering from June to August.

2. *Agrostis Interrupta*; *Interrupted Spike Bent Grass*. The outer petal awned; the panicle attenuated, contracted, interrupted.—It is an annual; and native of France, Italy, Switzerland, Carniola, and Germany.

3. *Agrostis Miliacea*; *Millet Bent Grass*. The outer petal terminating in a straight stiff awn of a moderate length.—This resembles the first species; and is a native of Montpellier, Spain and Siberia.

4. *Agrostis Bromoides*; *Brome-like Bent Grass*. Panicle simple, narrowed; corolla pubescent; awn straight, longer than the calix; culm a foot and half high.—A perennial; growing wild about Montpellier.

5. *Agrostis Australis*; *Southern Bent Grass*. The panicle approaching to a spike; the seed ovate, pubescent; awn

the length of the calix.—This species is three feet high; and a native of Portugal.

6. *Agrostis Arundinacea*; *Reedy Bent Grass*. Panicle oblong; outer petal villous at the base, and furnished with a writhed awn, longer than the calix. Very erect, height sometimes two and sometimes four feet.—It is perennial, and native of many parts of Europe. The *Calmuc Tartars* weave mats, and thatch their huts, with it. Goats will almost starve rather than eat this species of grass.

7. *Agrostis Calamagrostis*; *Branching Bent Grass*. Panicle thickened; whole of the outer petal woolly, awned at the tip; culm branching.—Reaches three feet in height, is a perennial, and native of Germany, Switzerland, and about Verona. It resembles the preceding.

8. *Agrostis Serotina*; *Late Bent Grass*. Floscules oblong mucronate; culm covered with very short leaves.—This species is about a foot high; and was observed by Seguier near Verona.

9. *Agrostis Rubra*; *Red Bent Grass*. Flowering part of the panicles very spreading; outer petal smooth; awn terminal, spiral, recurved.—This species is common in Sweden and Scotland.

10. *Agrostis Spiciformis*; *Spiky Bent Grass*. Panicle resembling a spike; flowers two-awned; one awn inserted into the receptacle, jointed and longer than the other, which is straight, and inserted below the tip of the corolla, which is rough. This species is nine inches in height, erect, very smooth, and the culms perfectly simple.—It has been observed in the island of Teneriffe.

11. *Agrostis Hirsuta*; *Hairy Bent Grass*. Panicle approaching to a spike; culm and leaves hirsute; glumes of the corolla awned on the back, and bifid at the tip. This species is easily distinguished by its shagginess.—Native of the island of Teneriffe.

12. *Agrostis Matrella*. The flowers in racemes; outer valve of the calix bent in, the tip of the keel only gaping.—This differs somewhat from the other species in character, and is found in the sandy lands of Malabar.

13. *Agrostis Canina*; *Brown Bent Grass*. Calix elongate; a recurved awn on the back of the petals; culms prostrate, a little branching. This species is perennial.

** *Naked*, or *Awnless*.

14. *Agrostis Stolonifera*; *Creeping Bent Grass*. Branches of the panicle spreading, naked; culm creeping; calices equal. This is known by its creeping stems, putting out roots, and producing new plants.—It is a native of most parts of Europe, flowering from June to August, and is found in moist meadows.

15. *Agrostis Capillaris*; *Fine Bent Grass*. Panicle capillary, spreading, flexuose; calices subulate, equal, smooth, coloured.—Native of Lapland, common in pastures and by road-sides. Perennial.

16. *Agrostis Sylvatica*; *Wood Bent Grass*. Panicle contracted; calices equal, those of the barren flower shorter than the corolla, those of the fertile ones twice as long.—It is perennial; and is found in moist woods, as in Bishop's Wood, and Hornsey Wood, near London.

17. *Agrostis Alba*; *White Bent Grass*. Panicle loose; calices equal; culm creeping; it has purple antheræ.—Grows in ditches, marshes, and moist meadows; and is perennial.

18. *Agrostis Pumila*; *Dwarf Bent Grass*. Panicle on one side; culms erect in bunches.—It is a perennial plant, native of Iceland, Sweden, Germany, Switzerland, of dry places in England, and of Wales and Scotland.

19. *Agrostis Minima*; *Least Bent Grass*. Panicle filiform. This is an annual spring plant, which flowers early, and ripens its seeds in May.—Native of France and Germany, and has been seen in Wales.

20. *Agrostis Tenacissima*; *Tough Bent Grass*. Panicle contracted, filiform; flowers linear, valves parallel.—A perennial, and native of the East Indies.

21. *Agrostis Virginica*; *Virginian Bent Grass*. Panicle contracted; leaves rolled inwards, subulate, rigid, standing out.—An elegant little plant, the stalk somewhat compressed, and seldom rising above four or five inches from the root.

22. *Agrostis Mexicana*; *Mexican Bent Grass*. Panicle oblong, heaped; calix and corolla acuminate, and nearly equal. Culms numerous, a foot high, smooth, erect. This species is difficult to determine.—It is a native of South America, flowers the second year, and has the appearance of *Cinna*.

23. *Agrostis Purpurascens*; *Purple Bent Grass*. Panicle contracted, elongate; branches pressed close, upright; florets unequal, acuminate.—A native of Jamaica.

24. *Agrostis Indica*; *Indian Bent Grass*. Panicle contracted; racemes lateral, erect, alternate.—A native of India.

25. *Agrostis Ciliata*; *Ciliate Bent Grass*. Glume of the calix angular, and ciliate.—A native of Japan.

26. *Agrostis Panicea*; *Bearded Bent Grass*. Panicle subspiked; branches and branchlets fascicled; valves of the calix, and one of the corolla, awned; that of the corolla very short.—This grows in marshes and wet pastures.

27. *Agrostis Lenta*; *Forked Bent Grass*. Spikes subtern, umbellate; floscules awnless, oblong, acute; calycine valves subequal; leaves and sheaths smooth.—It is annual, a native of the East Indies, and flowers in July and August.

28. *Agrostis Complanata*; *Flat-stalked Bent Grass*. Spikes umbelled, smooth; outer calycine valves awned; flattened leaves, and sheaths smooth.—This species is perennial, flowers in July and August, and is a native of Jamaica.

29. *Agrostis Pungens*; *Prickly Bent Grass*. Panicle contracted; leaves involute, stiff, pungent; the upper ones obliquely opposite; culm branching.—Perennial; and a native of Arabia, Barbary, and the dry countries near the coast of the country of Nice. The Arabs use it as a medicine for the piles.

30. *Agrostis Vinealis*; *Short-awned Bent Grass*. Culms ascending; calix coloured; awn nearly straight, from below the middle of the back, about as long as the calix.—Native of Switzerland, and the north of England.

31. *Agrostis Ovata*; *Ovate-panicked Bent Grass*. Outer petal awned below the tip; panicle ovate, contracted, spike-form.—A native of New Zealand.

32. *Agrostis Odorata*; *Sweet Bent Grass*. Spikes with the florets pointing one way, heaped together; culm six inches high.—A native of Cochin-China, near the coast. This grass is highly esteemed by the Cochin-Chinese for the permanency of its odour; they dry it to perfume their clothes with.

33. *Agrostis Plicata*; *Plaited-leaved Bent Grass*. Leaves plaited; spike linear, awnless. Culm a foot and half high.—Native of the suburbs of Canton.

34. *Agrostis Cinna*. Panicle contracted, awnless; flowers acuminate, with one, two, or three stamina; leaves flat, scabrous.

35. *Agrostis Diandra*. Panicle elongate, contracted; flowers subulate, two-stamined; leaves convolute.—Native of the East Indies, whence it was sent by Koenig under the name of *Cinna*.

Aglyneia; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. Male flowers below the female. *Calix*: six-leaved; leaflets oblong, obtuse, equal, permanent. *Corolla*: none. In the male, instead of filaments, a column shorter than the calix; three or four antheræ, oblong, growing to the column below the top. In the female flowers, germ of the size of the calix, subovate, obtuse, perforated at top with a six-notched hole; neither style nor stigma.

Pericarp: supposed to be a tricocous capsule. ESSENTIAL CHARACTER. *Calix*: six-leaved. *Corolla*: none. *Male*: three antheræ, growing to the rudiment of a style. *Female*: germ perforated at top; without style or stigma.—Species.

1. *Aglyneia Impubes*.—Leaves smooth on both sides.—An erect shrub, a native of China.

2. *Aglyneia Pubera*. Leaves down underneath. Also a native of China.

Ailanthus; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, five-parted, very small. *Corolla*: petals five, lanceolate, acute, convolute at the base, spreading. *Stamina*: filaments ten, compressed, the length of the corolla; antheræ oblong, versatile. *Female*. *Calix*: as in the male, permanent. *Corolla*: as in the male. *Pistil*: germs three to five, curved inwards; styles lateral; stigmas capitate. *Pericarp*, capsules as many as there are germs, compressed, membranaceous, sabre-shaped, acute, on one of the edges emarginate. *Seeds*: solitary, lens-shaped, bony, close to the emarginature. *Hermaphrodite*. *Calix*: as in the male and female. *Corolla*: as in the male. *Stamina*: filaments two or three, as in the male. *Pistil*: pericarp and seed as in the female.

ESSENTIAL CHARACTER. *Male*. *Calix*: five-parted. *Corolla*: five-petalled. *Stamina*: ten. *Female*. *Calix* and *Corolla*: as in the male. *Germs*: three to five. *Styles*: lateral. *Pericarp*: membranaceous, one-seeded. *Hermaphrodite*. *Calix* and *Corolla*: as in the male. *Stamina*: two to three.—One species only is known, viz.

1. *Ailanthus Glandulosa*; *Tall Ailanthus*. This tree rises with a straight trunk to the height of forty or fifty feet; the bark is grey, slightly furrowed, and has white marks on it; the young twigs are covered with a fine velvet down. The flowers are numerous, and exhale a disagreeable odour.—It is a native of China, grows very fast in our climate, and being a handsome and lofty tree, is proper for ornamental plantations. If the bark be wounded, a resinous juice flows out, which hardens in a few days. The wood is hard, heavy, glossy, like satin, and susceptible of a very fine polish.

Aira; a genus of the class Triandria, order Digynia. GENERIC CHARACTER. *Calix*: a two-flowered, two-valved glume; valves ovate-lanceolate, acute, equal. *Corolla*: bivalve; valves like those of the calix; nectary two-leaved; leaflets acute, gibbous at the base. *Stamina*: filaments capillary, the length of the flower, with oblong antheræ, forked at each end. *Pistil*: germ ovate, styles setaceous, spreading, with pubescent stigmas. *Pericarp*: none. *Seed*: subovate, covered by the corolla. ESSENTIAL CHARACTER. *Calix*: two-valved, two-flowered, without any rudiment of a third.—For the method of propagation and culture, see *Grass*.—The species are,

* *Naked, or awnless.*

1. *Aira Arundinacea*; *Reedy Aira-grass*. Panicle oblong, on one side, imbricate; leaves flat.—It is found in the Levant, and in Cochin-China.

2. *Aira Minuta*; *Minute Aira-grass*. Panicle loose, almost level-topped, very branching.—This is an annual grass, scarcely an inch high, and a native of Spain.

3. *Aira Aquatica*; *Water Aira-grass*. Panicle spreading; flowers smooth, longer than the calix; leaves flat. The root of this species is perennial; it runs to a considerable distance in the water, throwing off roots and young shoots as it passes along. It flowers in June and July, but is not worthy of cultivation.—The sandy lands near Exmouth, about Northfleet in Kent, and in Yorkshire and Lancashire, produce it.

** *Awned.*

4. *Aira Subspicata*; *Spiked Aira-grass*. Leaves flat; pa-

nicle spiked; flowers awned on the middle; awn reflex, loose.—It is a perennial, and is found upon the mountains of Switzerland, Savoy, Denmark, and Lapland.

5. *Aira Cæspitosa*; *Turfy Aira-grass*. Leaves flat; panicle spreading; petals villous, and awned at the base; awn straight, short. The culm of this grass is about a yard high. In marshes it is frequently viviparous, and growing in tufts it occasions irregularities, tussocks, or hassocks, as they are vulgarly called, in meadows. Cows, goats, and swine, eat it, but horses are not fond of it.—It is perennial; and found in meadows, fields, and woods.

6. *Aira Flexuosa*; *Heath Aira-grass*. Awned; leaves setaceous; culms almost naked; panicle divaricated; peduncles flexuose.—Perennial; and a native of heaths, barren pastures, and rocky moors. Horses, kine, and sheep, eat it.

7. *Aira Montana*; *Mountain Aira-grass*. Leaves setaceous; panicle narrowed; flowers hairy at the base, and awned; awn twisted, and very long.—This is a native of high heaths and barren pastures: it is perennial, and sheep are very fond of it. Supposed to be a variety of the foregoing.

8. *Aira Alpina*; *Alpine Aira-grass*. Leaves subulate; panicle dense; flowers hairy at the base, and awned; awn short.—This species grows on the mountains of Germany, Savoy, and Lapland.

9. *Aira Villosa*; *Villose Aira-grass*. Leaves subulate; panicle long and narrow; flowers sesquialteral, shaggy, awned; awn straight, short.—Native of the Cape.

10. *Aira Canescens*; *Gray Aira-grass*. Leave setaceous, the upper one involving the panicle at bottom like a spathe. This may be known at first sight from most other grasses by its paleness.—It is a native of sandy shores, the walls of Basil, and the sandy fields of Germany and Piedmont.

11. *Aira Præcox*; *Early Aira-grass*. Leaves setaceous; sheaths angled; flowers panicle-spiked, and awned at the base. This species has a sweet taste; horses and sheep eat it, and cows are very fond of it.—It grows in ditches, in wet meadows, and on the banks of streams; it flowers in June and July.

12. *Aira Caryophyllæa*; *Silver Aira-grass*. Leaves setaceous; panicle divaricated; flowers awned, distant.—This is an annual plant; and is a native of the sandy pastures and heaths of England, France, Switzerland, Piedmont, Germany, and Denmark.

13. *Aira Antartica*; *South Sea Aira-grass*. Leaves flat; panicle compound, spreading; calices three-flowered; floscules awned in the middle; awn elongated, straightish.—A native of New Zealand.

14. *Aira Involucrata*; *Involucrated Aira-grass*. Panicle spreading, involucrated, with bristles at the base; floscules awnless.—Native of Spain, on the barren hills near Madrid; it is annual, and flowers in June and July.

Aitonia; a genus of the class Monadelphia, order Octandria.—GENERIC CHARACTER. *Calix*: perianth one-leafed, erect, four-parted, short, divided into four ovate sharp segments. *Corolla*: has four, erect, equal, broadly-ovate, concave, very obtuse, petals. *Stamina*: filaments joined as far as the middle; divided above into eight; awl-shaped, furrowed, standing out of the corolla; and having ovate furrowed antheræ. *Pistil*: germ superior, ovate, smooth, subangular; style one, filiform, of the same length with the stamina; stigma obtuse, undivided. *Pericarp*: an ovate, dry, membranaceous, four-cornered, one-celled, brittle berry; the corners are produced and sharp. *Seeds*: many, fixed to a column, globular, and smooth. *Observe*. It varies with five cleft, ten-stamined flowers. ESSENTIAL CHARACTER. *Style*: one. *Calix*: four-parted. *Corolla*: four-petalled. Berry

dry, quadrangular, one-celled, many-seeded.—Only one species is known, viz.

1. *Aitonia Capensis*. This shrub is slow of growth with us, and seldom exceeds three feet in height. It is raised only from seeds, which are sparingly produced in this country; and it must be kept in the greenhouse or cape-stove. When it is of sufficient age, it produces flowers and fruit, which is large, and of a fine red colour through most of the year.

Ajuga; a genus of the class Didymamia, and order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, short, cut half way into the five-clefts, with the segments nearly equal. *Corolla*: monopetalous, ringent; tube cylindrical, bent in; upper lip very small, erect, bifid, obtuse; middle division very large and obovate; side ones small. *Stamina*: filaments subulate, erect, longer than the upper lip; antheræ twin. *Pistil*: germ four-parted; style filiform, situation and length as in the stamina; stigmas two, slender, the lowest shorter. *Pericarp*: none; the calix, which is converging, fosters the seeds. *Seeds*: somewhat oblong. ESSENTIAL CHARACTER. *Corolla*: upper lip very small. *Stamina*: longer than the upper lip.—The species are,

1. *Ajuga Orientalis*; *Eastern Bugle*. Flowers inverted. The stem is a foot and half high: there are several varieties, differing only in the colour of their flowers.—It is found in the Levant, Japan, and Cochin-China; and requires a little protection in winter, and as much free air as possible, except in hard frosts. They are propagated by seeds, and also by offsets; but the latter is a very slow method.

2. *Ajuga Pyramidalis*; *Pyramidal Bugle*. Spike a quadrangular, villous pyramid; leaves approximating; root-leaves very large; bracts nearly entire. The stem is four or five inches high. The plant is biennial, and flowers in April.—It is a native of Italy, France, Germany, Switzerland, Sweden, Denmark, Wales, and Scotland.

3. *Ajuga Alpina*; *Alpine Bugle*. Stem simple; stem-leaves equalling the radical ones.—This plant requires a moist and shady situation; it grows naturally on the Alps, and is admitted into some gardens for the sake of variety, where it propagates plentifully by its trailing stalks.

4. *Ajuga Genevensis*; *Geneva Bugle*. Leaves downy, streaked with lines, lowermost narrower; calices shaggy; bracts generally three-lobed. This species nearly resembles the common Bugle. There are two varieties, one with a white, the other with a red flower.—It grows wild about Geneva, and in many of the southern countries of Europe.

5. *Ajuga Reptans*; *Common Bugle*. Smooth, and creeping by runners. This species is so plentiful in a wild state, that it is seldom admitted into gardens. Its stalk is six inches high, upright, hairy, and purple. The corolla is blue, coloured with white veins. It flowers from May to June, and grows naturally in woods and moist meadows, in most parts of England, and of the south of Europe. There are two varieties, one with a white, the other with a pale purple flower, growing in different parts of Westmoreland, but they only differ in mere colour from the blue sort.—It is numbered among cooling and gently astringent vegetables, and is recommended both as an internal and external vulnerary. The leaves, when first chewed, have a sweetish taste, which soon changes into an austere and bitter one. An infusion of them, or their expressed juice, is good for wounds and bruises, whether internal or external, and is also esteemed a good diuretic. The leaves are of a wild astringent corroborating nature, and may be advantageously used in fluxes and all disorders of that kind, as they do not, like many other plants of the same nature, produce costiveness, but rather operate as gentle laxatives. The roots of this plant appear to be more astringent than

any other part by their striking a black colour with vitriol of iron. Some foreign physicians of eminence have recommended a decoction of this herb in the quinsy; it is not employed among us, but is constantly found mixed with the vulnerary herbs imported from Switzerland.

6. *Ajuga Decumbens*; *Japanese Bugle*. Decumbent and villous; leaves obovate, toothed. The flowers in whorls, small, and blue.—This plant sends up many stems: it may be propagated in the same manner as the first species.

Aizoon; a genus of the class Icosandria, order Pentagynia. —GENERIC CHARACTER. *Calix*: perianth one-leaved, divided into five lanceolate permanent segments. *Corolla*: none. *Stamina*: filaments very many, capillary, inserted by bunches into the sinuses of the calix; antheræ simple. *Pistil*: germ five-cornered, superior; styles five, simple; stigmas simple. *Pericarp*: capsule five-celled, five-valved, swelling, and retuse. *Seeds*: several, roundish, or kidney-shaped. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: none. *Capsule*: superior, five-celled, five-valved.—The species are,

1. *Aizoon Canariense*; *Purslane-leaved Aizoon*. Leaves wedge-ovate; flowers sessile.—This species is an annual plant, and a native of the Canary islands; it must be raised on a moderate hot-bed in the spring, and when fit to remove, should be carefully planted in a small pot filled with light fresh earth, and plunged into another bed, shaded from the sun, until they have again taken root; after this they must be gradually hardened to the open air, into which they should be removed in June, placing them in a sheltered situation, where they will flower and ripen seed in September, soon after which they die.

2. *Aizoon Hispanicum*; *Spanish Aizoon*. Leaves lanceolate; flowers sessile.—An annual plant, whose branches trail on the ground, growing naturally in Spain and Africa; and which, as the flowers have no beauty, is only preserved by those who are curious in collecting rare plants. It is propagated like the preceding, in which they produce better flowers, requiring a poor sandy soil.

3. *Aizoon Lanceolatum*; *Panicled Aizoon*. Leaves lanceolate; flowers panicled.—This is of humble growth, and perishes soon after the seeds are ripe; grows naturally at the Cape; and may be propagated in the same manner as the two preceding species.

4. *Aizoon Sarmentosum*. Leaves linear, filiform; panicle dichotomous; flowers solitary, peduncled.—Native of the Cape.

5. *Aizoon Paniculatum*; *Panicled Aizoon*. Shaggy; leaves lanceolate; flowers sessile; branches erect.—Native of the Cape.

6. *Aizoon Perfoliatum*; *Perfoliate Aizoon*. Downy; leaves inversely ovate, conjoined, crystalline dotted; flowers peduncled.—Native of the Cape.

7. *Aizoon Glinoides*; *Hairy Aizoon*. Shaggy, herbaceous, procumbent; leaves ovate; flowers sessile, distinct.—Native of the Cape.

8. *Aizoon Secundum*. Shag-hoary, herbaceous, procumbent; leaves ovate; flowers sessile, imbricate, one-ranked.—This species also is a native of the Cape.

9. *Aizoon Fruticosum*; *Shrubby Aizoon*. Shrubby, erect, smooth; leaves lanceolate; flowers sessile.—A native of the Cape.

10. *Aizoon Rigidum*; *Stiff Aizoon*. Shrubby, procumbent, downy; leaves ovate; flowers sessile, remote.—A native of the Cape.

Aizoon. See *Sedum*.

Alaternoides. See *Cluytia*.

Alaternus. See *Rhamnus*:

Albica; a genus of the class Hexandria, order Monogynia. —GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong-oval, permanent; the three outer spreading, the three inner converging. *Stamina*: filaments shorter than the corolla, three opposite to the inner petals, linear-subulate; complicate a little about the base, then flat; three opposite to the outer petals thicker; antheræ on the former oblong, fixed to the inflexed tip of the filament below the middle, upright; on the latter, similar but barren, or none. *Pistil*: germ oblong, triangular; style three-sided; stigma a triangular pyramid. *Pericarp*: an oblong, obtuse, triangular, three-celled, three-valved capsule. *Seeds*: numerous, flat, lying over each other, and widening outwards. ESSENTIAL CHARACTER. *Corolla*: six-petalled; the inner ones difform. *Stamina*: three of the six castrated. *Stigma*: surrounded by three cusps.—The roots of these plants are kept in pots filled with light earth, and sheltered under a hot-bed frame in winter; but thrive best in a border in front of the greenhouse.—The species are,

* *Three Stamina only fertile*.

1. *Albica Altissima*; *Tall Albica*. Interior petals glandulose, and bent in at the tip; leaves subulate, channelled, convolute.—This species flowers in April and May.

2. *Albica Major*; *Great Albica*. Interior petals glandulose, and bent in at the tip; leaves linear-lanceolate, flattish.—It is a native of the Cape, and flowers in May.

3. *Albica Minor*; *Small Albica*. Interior petals glandulose, and bent in at the tip; leaves linear-subulate, channelled. It flowers in May and June.

4. *Albica Coarctata*; *Channel-leaved Albica*. Interior petals vaulted at the tip; leaves smooth, linear-subulate, channelled; peduncles the length of the bractes. The flowers are yellow, and appear in May.

5. *Albica Spiralis*; *Spiral-leaved Albica*. Interior petals vaulted at the tip; leaves spiral.—Native of the Cape.

** *All the Stamina fertile*.

6. *Albica Fastigiata*; *Upright-flowered Albica*. Interior petals vaulted at the tip; leaves smooth; peduncles very long. This species flowers in May.

7. *Albica Viscosa*; *Viscose Albica*. Interior petals vaulted at the tip; leaves hairy-glandulose. This species flowers in May and June.

8. *Albica Abyssinica*; *Abyssinian Albica*. Leaves linear, channelled, smooth.

Alcea; a genus of the class Monadelphia, order Polyandria. —GENERIC CHARACTER. *Calix*: double, each one-leaved; the outer cut half way into six parts, permanent, and very spreading; the inner cut half way into five parts, larger and permanent. *Corolla*: five orbiculate, emarginate, spreading petals, coalescing at their bases. *Stamina*: filaments uniting into a sort of five-angled cylinder at bottom, loose at top, and inserted into the corolla; antheræ almost kidney-shaped. *Pistil*: germ orbiculate; style cylindrical, short; stigmas about twenty, setaceous, the length of the style. *Pericarp*: many jointed arils in a ring round a columnar flatted receptacle, parting and opening on the inside. *Seed*: one, flat, kidney-shaped, in each aril. ESSENTIAL CHARACTER. *Calix*: double; outer six-cleft. *Arils*: many, one-seeded.—Plants of this genus are propagated by seeds, which should be selected from those plants whose flowers are the most double, and of the best colours: They must be gathered dry, kept from damp in winter, and sown an inch deep in a bed of light earth in the middle of April. When the young plants have six or eight leaves, they should be transplanted to nursery beds, and placed a foot asunder, observing to water them

until they have taken root; after which they require no further care, except to weed them until October, when they may be planted out wherever they are intended to remain.—The species are,

1. *Alcea Rosea*; *Common Hollyhock*. Leaves sinuate-angular.—This species grows naturally in China, whence its seeds are frequently imported, so that they are become very common. They flower from July until September, and often rise to nine feet high in good ground, six feet of which is garnished with flowers, which when *double*, and of a good colour, make a beautiful appearance, especially if the various colours be properly intermixed. Meyrick says, that a decoction of the roots operates by urine, and is serviceable in the stone, gravel, and all other disorders of the urinary vessels, such as the strangury, heat of urine, &c. It is a good ingredient in poultices, fomentations, and clysters, for any of the aforesaid purposes, and appears to possess nearly the same virtues with the Marshmallow.

2. *Alcea Ficifolia*; *Fig-leaved Hollyhock*. Leaves palmate.—The seeds of this species were received from Istria, by Mr. Miller: like the common Hollyhock, though a native of warm countries, it is hardy enough to bear the open air of England: and is one of the greatest ornaments of our gardens towards the latter end of summer. Both this and the first species require tall stakes to secure them from violent winds, and produce a succession of flowers for two months.

3. *Alcea Africana*; *African Hollyhock*. Leaves three-lobed, crenate; flowers solitary, axillary; both calices six-parted. The stem of this species rises upright four feet high.—It is a native of the eastern shore of Africa.

Alcea. See *Malva*.

Alchemilla; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubulous, permanent; edge flat, divided into eight segments. *Corolla*: none. *Stamina*: filaments erect, awl-shaped, very small, on the edge of the calix; antheræ roundish. *Pistil*: germ ovate; style filiform, length of the stamina, inserted at the base of the germ; stigma globular. *Pericarp*: none; the neck of the calix closes and never opens. *Seeds*: solitary, elliptic, compressed. ESSENTIAL CHARACTER. *Calix*: eight-cleft. *Corolla*: none. *Seed*: one.—The best way to propagate this genus of plants, is by parting their roots in autumn, that they may be established before the drying winds of spring come on. They require a moist soil and shady situation, or they will not thrive in the southern parts of England.—The species are,

1. *Alchemilla Vulgaris*; *Common Ladies-Mantle*, or *Bears-foot*. Leaves lobed.—This plant grows naturally in high pastures of several parts of England, but is not very common near London; it rises about a foot high, and its leaves are scalloped round the edges, resembling the scalloped mantles of the ladies, from which it has its name. Cows are not partial to it; but horses, goats, and sheep eat it. In Sweden, a tincture of the leaves is given in spasmodic or convulsive diseases: they are also esteemed to be vulnerary, drying, and binding, and are of great force to stop inward bleeding. The root is the most valuable part of the plant; and a strong decoction of it fresh taken up is excellent for immoderate discharges of the menses, the bloody flux, and all other bleedings. Dried and reduced to powder, it answers the same purposes, and is also good for common purges when they continue too long. Some say it has its name from its being used by the women in the north of England, to reduce their breasts to form after they have been swelled with milk, which is effected by an external application of the leaves. It is a perennial plant.

2. *Alchemilla Alpina*; *Cinquefoil*, or *Alpine Ladies-Mantle*. Leaves digitate, serrate.—This is found growing naturally on the mountains of Yorkshire, Westmorland, and Cumberland, generally upon moist boggy places. It is also a native of Sweden, Denmark, the Alps, and other cold parts of Europe; and is admitted into gardens for its elegance. The leaves are of a fine white, consisting of from five to nine folioles, and the stem seldom exceeds six inches in height.

3. *Alchemilla Aphanoides*. Leaves many-parted; stem erect.—This is a small plant, resembling the *Aphanes Arvensis* or Parsley Piert, and was found in South America by Meutis.

4. *Alchemilla Pentaphyllea*; *Five-leaved Ladies-Mantle*. Leaves quinate, multifid, smooth.—This species grows naturally on the high Alps, as Gothard, Furca, Speluga, Pilat, &c.; and is only to be found in some few curious botanic gardens in this country.

Alchornea; a genus of the class Diœcia, order Monadelphia.—GENERIC CHARACTER. *Male*. *Calix*: perianth three or five leaved; leaflets ovate, concave, equal, coloured, deciduous. *Corolla*: none. *Stamina*: filaments eight, equal, scarce longer than the calix, slightly connate at the base; antheræ ovate, upright. *Pistil*: a rudiment. *Female*. *Calix*: perianth one-leaved, four or five toothed; teeth equal, small. *Corolla*: none. *Pistil*: germ twin, superior; styles two, very long, filiform; stigmas simple, acute. *Pericarp*: capsule berried, two-seeded, two-celled, two-valved. *Seeds*: solitary, large, oblong. ESSENTIAL CHARACTER. *Male*. *Calix*: three or five leaved. *Corolla*: none. *Female*. *Calix*: five-toothed. *Corolla*: none. *Style*: two-parted. *Capsule*: berried, dicoecous.—One species only is known, viz.

1. *Alchornea Latifolia*. *Note*, This genus was named after Mr. Stainsby Alchorne, apothecary, of London; but there are no particulars of its qualities or use, in Miller's Gardener's Dictionary, edited by Professor Martyn, Lond. 1807.

Alder-Tree. See *Betula Alnus*.

Aldrovanda; a genus of the Pentandria class, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, erect, equal, permanent. *Corolla*: petals five, oblong, acuminate, length of the calix, permanent. *Stamina*: filaments length of the flowers; antheræ simple. *Pistil*: germ globose; styles very short; stigmas obtuse. *Pericarp*: a globose capsule, with five blunt angles; five-valved, one-celled. *Seeds*: ten, longish, fixed to the inner wall of the pericarp. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Capsule*: five-valved, one-celled, ten-seeded.—There is but one species.

1. *Aldrovanda Vesiculosa*. Root perennial, flowers solitary, and the stem seeming to terminate in a peduncle, whilst that continues the stem, or produces a branch from the side. *Stamina* between the petals. *Antheræ* yellow, twin.—This plant is found in marshes, both in Italy and India.

Ale-cost. See *Tanacetum*.

Alectra; a genus of the class Didynamia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth one-leaved, two-lipped, upper lip two-cleft, lower three-cleft; clefts ovate, obtuse, shorter than the tube. *Corolla*: one-petalled, tubular; tube by degrees widened a little; border expanding, five-parted; parts broad-lanceolate, obtuse. *Stamina*: filaments four, inserted into the tube, filiform, bearded, length of the tube; two of them are a little shorter; antheræ twin. *Pistil*: germ ovate; style filiform, length of the filaments; stigma incurved, a little thicker than the style, and of the same length, striated on both sides. *Pericarp*: capsule ovate-obtuse, twin, smooth, two-celled, two-valved. *Seeds*: solitary, ovate. ESSENTIAL CHARACTER. *Corolla*:

20. *Agrostis Tenacissima*; *Tough Bent Grass*. Panicle contracted, filiform; flowers linear, valves parallel.—A perennial, and native of the East Indies.

21. *Agrostis Virginica*; *Virginian Bent Grass*. Panicle contracted; leaves rolled inwards, subulate, rigid, standing out.—An elegant little plant, the stalk somewhat compressed, and seldom rising above four or five inches from the root.

22. *Agrostis Mexicana*; *Mexican Bent Grass*. Panicle oblong, heaped; calix and corolla acuminate, and nearly equal. Culms numerous, a foot high, smooth, erect. This species is difficult to determine.—It is a native of South America, flowers the second year, and has the appearance of *Cinna*.

23. *Agrostis Purpurascens*; *Purple Bent Grass*. Panicle contracted, elongate; branches pressed close, upright; florets unequal, acuminate.—A native of Jamaica.

24. *Agrostis Indica*; *Indian Bent Grass*. Panicle contracted; racemes lateral, erect, alternate.—A native of India.

25. *Agrostis Ciliata*; *Ciliate Bent Grass*. Glume of the calix angular, and ciliate.—A native of Japan.

26. *Agrostis Panicea*; *Bearded Bent Grass*. Panicle subspiked; branches and branchlets fascicled; valves of the calix, and one of the corolla, awned; that of the corolla very short.—This grows in marshes and wet pastures.

27. *Agrostis Lenta*; *Forked Bent Grass*. Spikes subtern, umbellate; floscules awnless, oblong, acute; calycine valves subequal; leaves and sheaths smooth.—It is annual, a native of the East Indies, and flowers in July and August.

28. *Agrostis Compladata*; *Flat-stalked Bent Grass*. Spikes umbelled, smooth; outer calycine valves awned; flattened leaves, and sheaths smooth.—This species is perennial, flowers in July and August, and is a native of Jamaica.

29. *Agrostis Pungens*; *Prickly Bent Grass*. Panicle contracted; leaves involute, stiff, pungent; the upper ones obliquely opposite; culm branching.—Perennial; and a native of Arabia, Barbary, and the dry countries near the coast of the country of Nice. The Arabs use it as a medicine for the piles.

30. *Agrostis Vinealis*; *Short-awned Bent Grass*. Culms ascending; calix coloured; awn nearly straight, from below the middle of the back, about as long as the calix.—Native of Switzerland, and the north of England.

31. *Agrostis Ovata*; *Ovate-panicked Bent Grass*. Outer petal awned below the tip; panicle ovate, contracted, spike-form.—A native of New Zealand.

32. *Agrostis Odorata*; *Sweet Bent Grass*. Spikes with the florets pointing one way, heaped together; culm six inches high.—A native of Cochin-China, near the coast. This grass is highly esteemed by the Cochin-Chinese for the permanency of its odour; they dry it to perfume their clothes with.

33. *Agrostis Plicata*; *Plaited-leaved Bent Grass*. Leaves plaited; spike linear, awnless. Culm a foot and half high.—Native of the suburbs of Canton.

34. *Agrostis Cinna*. Panicle contracted, awnless; flowers acuminate, with one, two, or three stamina; leaves flat, scabrous.

35. *Agrostis Diandra*. Panicle elongate, contracted; flowers subulate, two-stamined; leaves convolute.—Native of the East Indies, whence it was sent by Koenig under the name of *Cinna*.

Agyneia; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. Male flowers below the female. *Calix*: six-leaved; leaflets oblong, obtuse, equal, permanent. *Corolla*: none. In the male, instead of filaments, a column shorter than the calix; three or four antheræ, oblong, growing to the column below the top. In the female flowers, germ of the size of the calix, subovate, obtuse, perforated at top with a six-notched hole; neither style nor stigma.

Pericarp: supposed to be a tricoccus capsule. ESSENTIAL CHARACTER. *Calix*: six-leaved. *Corolla*: none. *Male*: three antheræ, growing to the rudiment of a style. *Female*: germ perforated at top; without style or stigma.—Species.

1. *Agyneia Impubes*.—Leaves smooth on both sides.—An erect shrub, a native of China.

2. *Agyneia Pubera*. Leaves down underneath. Also a native of China.

Ailanthus; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, five-parted, very small. *Corolla*: petals five, lanceolate, acute, convolute at the base, spreading. *Stamina*: filaments ten, compressed, the length of the corolla; antheræ oblong, versatile. *Female*. *Calix*: as in the male, permanent. *Corolla*: as in the male. *Pistil*: germs three to five, curved inwards; styles lateral; stigmas capitate. *Pericarp*, capsules as many as there are germs, compressed, membranaceous, sabre-shaped, acute, on one of the edges emarginate. *Seeds*: solitary, lens-shaped, bony, close to the emargination. *Hermaphrodite*. *Calix*: as in the male and female. *Corolla*: as in the male. *Stamina*: filaments two or three, as in the male. *Pistil*: pericarp and seed as in the female.

ESSENTIAL CHARACTER. *Male*. *Calix*: five-parted. *Corolla*: five-petalled. *Stamina*: ten. *Female*. *Calix* and *Corolla*: as in the male. *Germ*: three to five. *Styles*: lateral. *Pericarp*: membranaceous, one-seeded. *Hermaphrodite*. *Calix* and *Corolla*: as in the male. *Stamina*: two to three.—One species only is known, viz.

1. *Ailanthus Glandulosa*; *Tall Ailanthus*. This tree rises with a straight trunk to the height of forty or fifty feet; the bark is grey, slightly furrowed, and has white marks on it; the young twigs are covered with a fine velvet down. The flowers are numerous, and exhale a disagreeable odour.—It is a native of China, grows very fast in our climate, and being a handsome and lofty tree, is proper for ornamental plantations. If the bark be wounded, a resinous juice flows out, which hardens in a few days. The wood is hard, heavy, glossy, like satin, and susceptible of a very fine polish.

Aira; a genus of the class Triandria, order Digynia. GENERIC CHARACTER. *Calix*: a two-flowered, two-valved glume; valves ovate-lanceolate, acute, equal. *Corolla*: bivalve; valves like those of the calix; nectary two-leaved; leaflets acute, gibbous at the base. *Stamina*: filaments capillary, the length of the flower, with oblong antheræ, forked at each end. *Pistil*: germ ovate, styles setaceous, spreading, with pubescent stigmas. *Pericarp*: none. *Seed*: subovate, covered by the corolla. ESSENTIAL CHARACTER. *Calix*: two-valved, two-flowered, without any rudiment of a third.—For the method of propagation and culture, see *Grass*.—The species are,

* *Naked, or awnless.*

1. *Aira Arundinacea*; *Reedy Aira-grass*. Panicle oblong, on one side, imbricate; leaves flat.—It is found in the Levant, and in Cochin-China.

2. *Aira Minuta*; *Minute Aira-grass*. Panicle loose, almost level-topped, very branching.—This is an annual grass, scarcely an inch high, and a native of Spain.

3. *Aira Aquatica*; *Water Aira-grass*. Panicle spreading; flowers smooth, longer than the calix; leaves flat. The root of this species is perennial; it runs to a considerable distance in the water, throwing off roots and young shoots as it passes along. It flowers in June and July, but is not worthy of cultivation.—The sandy lands near Exmouth, about Northfleet in Kent, and in Yorkshire and Lancashire, produce it.

** *Awned.*

4. *Aira Subspicata*; *Spike Aira-grass*. Leaves flat; pa-

flowers twelve-stamined; capsules hook-pointed.—A native both of North and South America.

5. *Alisma Natans*; *Creeping Water Plantain*. Leaves ovate, obtuse; peduncles solitary.—This is found in ditches in France, Sweden, Germany, and Siberia; also in a lake or two in Wales; and flowers in July and August.

6. *Alisma Ranunculoides*; *Small Water Plantain*. Leaves linear-lanceolate; capsules globose and squarrose. The corolla of this plant is bluish, and opens about noon.—It is found on marshes and moors, as on Giggleswick Farm, Yorkshire; between Burton and Derby; Bungay, Suffolk; Ellingham-fen, Norfolk; and also in Sweden, Holland, France, Germany, and Italy.

7. *Alisma Subulata*. Leaves awl-shaped.—This is a Virginian plant; with a very tender white corolla, and subulate leaves.

8. *Alisma Parnassifolia*. Leaves heart-shaped, acute; petioles jointed. The seeds are awned.—It is a native of Italy, in the marshes under the Apennines.

9. *Alisma Repens*. Stems creeping; leaves lanceolate, petioled, acute. It flowers in August.—Native of Spain, on the sandy backs of the river Manzanares.

Alisma. See *Arnica*, *Primula*, and *Senecio*.

Alkænda. See *Myrtus*.

Alkanet. See *Anchusa*.

Alkekengi. See *Physalis*.

Allamanda; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, five-parted; parts ovate, acute. *Corolla*: one-petalled, funnel-shaped; tube cylindrical; border semi-quinquefid, swelling; divisions spreading, obtuse. *Stamina*: filaments scarcely any; antheræ five, sagittate, converging in the throat of the tube. *Pistil*: germ oval, surrounded with a ring; style filiform, the length of the tube; stigma headed, contracted in the middle. *Pericarp*: an orbicular, lens shaped, echinate, one-celled, two-valved capsule. *Seeds*: very many, imbricate, orbiculate, flat, edged with a membranous wing. **ESSENTIAL CHARACTER.** *Corolla*: contorted. *Capsule*: lens-shaped, erect, echinate, one-celled, two-valved, many-seeded.—The only species known is,

1. *Allamanda Cathartica*. A milky shrub, the stem twining, and climbing on trees. The leaves are cathartic; and an infusion of them is used at Surinam in the colic.—Found wild there, at Cayenne, and in Guiana, by the sea-side.

All-heal. See *Stachys*.

Alliaria. See *Erysimum*.

Alligator Pear. See *Laurus*.

Allionia; a genus of the class Tetrandia, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth common to three flowers, simple, oblong, five-parted; parts ovate, acute, permanent; proper obsolete, superior. *Corolla*: proper one-petalled, funnel-shaped, edge quinquefid, erect. *Stamina*: filaments setaceous, longer than the corolla, bending to one side; antheræ roundish. *Pistil*: germ inferior, oblong; style setaceous, longer than the stamina; stigma multifid, linear. *Pericarp*: none. *Seeds*: solitary, oblong five-cornered, naked. *Receptacle*: naked. **ESSENTIAL CHARACTER.** *Calix*: common, oblong, simple, three-flowered; proper obsolete, superior. *Corollules*: irregular. *Receptacle*: naked.—The species are,

1. *Allionia Violacea*. Leaves heart-shaped; calices quinquefid.—A native of South America.

2. *Allionia Incarnata*. Leaves obliquely ovate; calices triphyllous. An annual glaucous plant, native of Peru, and grows on rocks and in sandy soils.

Allium; a genus of the class Hexandria, order Monogynia.

—**GENERIC CHARACTER.** *Calix*: spathe common roundish; withering, many-flowered. *Corolla*: petals six, oblong. *Stamina*: filaments six, subulate, often the length of the corolla; antheræ oblong, upright. *Pistil*: germ superior, short, bluntly three-cornered, the corners marked with a line; style simple; stigma sharp. *Pericarp*: capsule very short, broad, three-lobed, three-celled, three-valved. *Seeds*: few, roundish. **ESSENTIAL CHARACTER.** *Corolla*: six-parted, spreading. *Spathe*: many-flowered. *Umbel*: heaped. *Capsule*: superior.—All the flowering sorts are very hardy, thriving in any soil and situation; they may be propagated by roots or seeds: if from roots, should be planted in autumn; the seeds must be sown either in autumn or spring, on a border of common earth, and should be well weeded; in the following autumn, they may be transplanted into borders where they are intended to remain. They flower in May, June, and July.—The species are,

* *Stem-leaves flat; umbel capsule-bearing.*

1. *Allium Ampeloprasum*; *Great Round-headed Garlic*. Umbel globose; stamina three-cusped; petals with a rough keel. The stem is a foot high or more.—It grows naturally in the East, in Switzerland, in a small island in the Bristol Channel, &c. flowering in July and August.

2. *Allium Porrum*; *Common Leek*. Umbel globose; stamina three-cusped; petals with a rough keel; root coated.—This flowers in April or May. For the cultivation of Leeks, see that of the Onion species, No. 36. of this genus. Hill recommends an infusion of the roots of the Leek, boiled into syrup with honey, as a good medicine in coughs, asthmas, and other disorders of the breast and lungs. He says it answers, the same purpose with syrup of Garlic, but being milder it may be taken by many who cannot bear that medicine. The juice of Leeks is a good diuretic, and will frequently afford relief in the stone and gravel, when most of the usual remedies fail.

3. *Allium Lineare*; *Linear-leaved Garlic*. Umbel globose; stamina three-cusped, twice as long as the corolla.—Flowers purple: its leaves are narrower than the common Leeks, nor does it rise so high.—Native of Siberia.

4. *Allium Rotundum*. *Great Round-headed Garlic*. Umbel subglobose; stamina three-cusped; side-flowers nodding. The root of this species consists of many purple and black bulbs, crowded between white common sheaths.—It is a native of the southern parts of Europe.

5. *Allium Victorialis*; *Long-rooted Garlic*. Umbel rounded; stamina lanceolate, larger than the corolla; leaves elliptic.—This species grows on the mountains of Switzerland, Austria, Silesia, and Savoy. The stem is from a foot to eighteen inches in height. The petals are of a dirty white, with a tincture of green.

6. *Allium Subhirsutum*; *Hairy Garlic*, or *Dioscorides's Moly*. Stamina awl-shaped; lower leaves hirsute. The flowers are white, and the stem from a foot to eighteen inches high, round, smooth, and solid.—Native of the Levant, Italy, Spain, and Africa. It flowers in May.

7. *Allium Magicum*; *Homer's Garlic*, or *Moly*. Stamina simple; branches bulb-bearing.—This species grows a foot high, and is preserved by many persons in their gardens for variety's sake, although it has a very strong scent.

8. *Allium Obliquum*; *Oblique-leaved Garlic*. Stamina filiform, thrice as long as the flower; leaves oblique.—This is a native of Siberia; it attains to two feet in height, with a cylindrical stalk.

9. *Allium Ramosum*; *Branched Garlic*. Umbel globose; stamina awl-shaped; longer leaves linear-subconvex. The

petals of this species are purplish.—It grows naturally in Siberia, whence the seeds have been obtained with which most botanic gardens are supplied. They are solely preserved for the sake of variety.

10. *Allium Roseum*; *Rose Garlic*. Umbel flat-topped; petals emarginate; stamina very short, simple. Flowers large, and of a dark purple colour, with white and very short stamina.—It grows naturally about Montpellier and in Piedmont, in the fields, olive-grounds, and vineyards.

11. *Allium Tartaricum*; *Tartarian Garlic*. Umbel flat; stamina simple; leaves semi-cylindrical. This species rises half a foot high, has a flat and white corolla, with filaments shorter than the petals, and brown antheræ.—Native of Siberia.

***Stem-leaves flat; Umbel bulb-bearing.*

12. *Allium Sativum*; *Common Garlic*. Bulb compound; stamina three-cusped.—It is said to be found wild in the island of Sicily. It has many bulbs, commonly called *cloves*, invested with a white skin; the leaves are linear, long, and narrow, like those of grass. This species is very heating and penetrating, and should not be too freely used. A clove or two of garlic, pounded with honey, and taken two or three nights successively, is good in rheumatic cases. A quart of water, poured boiling hot upon a pound of the fresh root, cut into slices, and suffered to stand upon it in a close vessel for twelve hours, will be strongly impregnated with the smell of garlic, and it is this infusion, with a proper quantity of sugar, which makes the Syrup of Garlic of the shops. Vinegar and honey greatly improves this medicine as a detergent and remover of obstructions in the breast: this composition is prepared by infusing an ounce and half of the fresh root in half a pint of vinegar, and dissolving in the strained liquor, when at the heat of a water-bath, ten ounces of clarified honey; to cover the ill smell of the garlic, a little caraway and sweet-fennel seed bruised, of each two drachms, are boiled for a short time in the vinegar, before the garlic is put in. The garlic itself must on no account be boiled, as its essential oil, in which its whole virtue consists, exhales during that process. Besides the above syrup, which is an invaluable medicine for asthmas, hoarseness, coughs, difficulty of breathing, and most other disorders of the breast and lungs, it is sometimes externally applied in ointments and lotions, to prevent or stop putrefaction, and disperse hard swellings. When bruised, and applied to the soles of the feet, in the low stages of acute disorders, it raises the pulse and gives relief to the head. The principal effects of garlic are, to warm and stimulate the solids of the body, attenuate thick humours, and prevent putrefaction, as above specified. Hence the use of it appears very improper in hot bilious constitutions, where there is already too great a degree of irritation, or where the juices are thin and acrimonious, and the viscera unsound, in which cases it is almost certain to occasion head-aches, flatulence, thirst, and a variety of feverish symptoms. But on the other hand, where the constitution is cold and phlegmatic, its use is frequently attended with happy effects: when people of this last description find themselves troubled with loss of appetite, or with asthmatic complaints, or their stomach and lungs oppressed with tough viscid phlegm, they will generally find relief from the use of this plant. It is a powerful strengthener, and promotes expectoration, removes obstructions of the viscera, increases the urinary evacuation, destroys worms, and is serviceable in dropsies, by removing the water which may be already collected, and preventing its future accumulation.—This species is a native of the East, but very common in our gardens; where it flowers in the summer months. Garlic is easily propagated by planting the cloves or

small bulbs of the root in the spring, with a dibber or in drills, in beds four feet wide, in rows six inches from each other, and four or five inches distant in the rows, taking care to weed them. The leaves should be tied in knots, in the beginning of June, to prevent their spindling or running to seed, which will greatly enlarge the bulb. Towards the end of July, the leaves will begin to wither and decay; when the roots should be taken up, cleaned, dried in the sun, tied in bunches, and hung up in a dry room, where they will be preserved from rotting, for winter use.

13. *Allium Scorodoprasum*; *Rocamble*. Stamina three-cusped; leaves crenulate; sheaths two-edged.—Found wild in Sweden, Denmark, and Hungary. It has compound bulbs, but the cloves are smaller than those of garlic. The stem rises from two to three feet high, and bears many small bulbs at top, which may be used as well as those of the root. Rocamble may be propagated either by the roots or the bulbs produced on the stalks: they should be planted in autumn, especially on dry ground, otherwise their bulbs will not be large. They are to be planted and prepared for use in the same manner as garlic.

14. *Allium Arenarium*; *Sandy Garlic*. Stamina three-cusped; sheaths columnar; spathe awnless.—This species grows wild in Thuringia, Scania, Denmark, Switzerland, Italy, and Westmoreland. It always grows in a sandy soil; the bulbs and flowers are blue, few in number, and the stamina a little longer than the corolla.

15. *Allium Carinatum*; *Mountain Garlic*. Stamina awl-shaped; spathe very long. The stem is four feet high; the outer petals are darker in colour than the inner ones, which are yellow, with a line of green, but sometimes purple. The bulb is simple, with very little of the garlic smell or taste.—It is found wild in Scania, Germany, Italy, and Switzerland: also in Westmoreland, about Ramsgate, in the isle of Thanet, and between Sandwich and Deal.

****Stem-leaves columnar; Umbel capsule-bearing.*

16. *Allium Sphærocephalon*; *Small Round-headed Garlic*. Stamina three-cusped, longer than the corolla; leaves semi-columnar. Petals red with a darker keel; filaments purple towards the top.—Native of Italy, Germany, Switzerland, and Siberia.

17. *Allium Parviflorum*; *Small-flowered Garlic*. Umbel globose; stamina simple, longer than the corolla; spathe awl-shaped. Native of the south of Europe.

18. *Allium Descendens*; *Purple-headed Garlic*. Stamina three-cusped, outer peduncles shorter. Two bulbs at the origin of the stalk; leaves fistulous, channelled above; stalk two feet high; sheath quadrifid.—It is a native of Italy and Switzerland.

19. *Allium Moschatum*; *Musk-smelling Garlic*. Umbel flat topped, mostly six-flowered; petals acute; stamina simple; leaves setaceous. It seldom attains to a foot in height, has a slender stem, and a dusky white corolla, with brown lines, smelling like musk or civet.—It grows wild in Provence, Narbonne, and Spain.

20. *Allium Flavium*; *Sulphur-coloured Garlic*. Flowers pendulous; petals ovate; stamina longer than the corolla.—A native of the south of France, Italy, and Austria.

21. *Allium Pallens*; *Pale-flowered Garlic*. Flowers pendulous, truncated; stamina simple, equalling the corolla. This species is two feet high, with a white bell-shaped corolla. It is a native of Italy, Spain, Montpellier, and Hungary.

22. *Allium Paniculatum*; *Panicled Garlic*. Peduncles capillary, spread out; stamina awl-shaped; spathe very long. The leaves are awl-shaped and channelled; the flowers hang on very long, loose, slender peduncles; the petals are purple,

obovate, the length of the stamina; the spathe has a very long awl-shaped point.—Native of Italy, Austria, Switzerland, Carniola, Siberia, and the Levant.

23. *Allium Vineale*; *Crow Garlic*. Stamina three-cusped. The stem is two feet high.—It is a native of Germany, Switzerland, Italy, &c. With us it is frequent in pastures, and communicates its rank taste to the milk and butter. In other countries, it grows in vineyards and among corn.

24. *Allium Oleraceum*; *Purple-striped Garlic*. Stamina simple; leaves rough, semi-columnar, furrowed underneath. The stem rises two or three feet high: very minute white dots, scarcely visible to the naked eye, are scattered over the whole plant. The smell and taste of the bulb is not strong, the flowers are true bell-shaped; the outer petals more acute, with a green nerve and a blush of purple: inner broader, more obtuse, whiter, and the nerve less prominent.—Native of Sweden, Germany, Switzerland, and Italy. In England it is found among the corn, in Westmoreland, Yorkshire, near Bristol; and in Essex, near Notley.

25. *Allium Pallasii*; *Pallas's Garlic*. Umbel difform; stamina simple, equalling the corolla; style very short. The stem is round, a foot and half high, slender, and leafy,—Supposed to be a native of Sweden.

****Leaves radical; Stem naked:

26. *Allium Nutans*; *Flat-stalked Garlic*. Scape two-edged: leaves linear, flat; stamina three-cusped. This species varies so much in different ages and soils, as scarcely to be known. The cusps of the stamina are obliterated in old plants.—Native of Siberia.

27. *Allium Ascalonicum*; *Shallot* or *Eschallote*. Scape columnar; leaves awl-shaped; umbel globose; stamina three cusped. This species rises from about seven to eight inches high; the petals are blue, with a dark keel; and the antheræ yellow.—Hasselquist found it native in Palestine. The *Eschallote*, *Chalott*, or *Shallot*, is propagated by the smaller roots or offsets, planted in November or February, on beds four feet wide, six inches apart, and two or three deep, requiring no culture, except weeding. At the end of July or beginning of August they will be full grown, but should not be taken up till the leaves begin to wither, in dry weather; then spread them in the sun, and when they are properly dried, clean and tie them up in bunches for use.

28. *Allium Senescens*; *Narcissus-leaved Onion*, or *Garlic*. Scape two-edged; leaves linear, convex beneath, smooth; umbel roundish; stamina awl-shaped.—It is a native of Siberia, the Alps, Silesia, and the island of Sicily.

29. *Allium Odorum*; *Sweet-smelling Garlic*. Scape nearly columnar; leaves linear, channelled, angular, beneath; umbel flat-topped. Corolla white, sweet-smelling; scape a foot high, round, or with one obscure angle, erect.—Native of the south of Europe, China, Japan, &c.

30. *Allium Inodorum*; *Carolina Garlic*. Scape naked, subtriquetrous; leaves linear, flat-keeled beneath; umbel fastigiate, floriferous; stamina simple.—It flowers in March and April, and is a native of Carolina.

31. *Allium Angulosum*; *Angular-scaped Garlic*. Scape two-edged; leaves linear, channelled, somewhat angular beneath; umbel flat-topped.—It grows in the moist parts of meadows; and is a native of Siberia, Italy, Austria, Switzerland, and Germany.

32. *Allium Nigrum*; *Black Garlic*. Scape columnar; leaves linear; umbel hemispherical; petals erect; spathe pointed, bifid.—It is a native of Provence, Italy, Austria, and the neighbourhood of Algiers.

33. *Allium Canadense*; *Canada Tree-Onion*. Scape columnar; leaves linear; head bulb-bearing. Root perennial;

flowers few, pedicelled, whitish; petals oval; filaments simple, the length of the corolla, with brownish red antheræ.—Native of North America.

34. *Allium Ursinum*; *Ramsons*. Scape three-sided; leaves lanceolate, petiolate; umbel flat-topped. Stem a foot high and leafy; corolla white; smell and taste very acrid.—Native of Sweden, Denmark, Germany, Switzerland, Italy, in woods and moist shady places; and with us in England not uncommon.

35. *Allium Triquetrum*; *Three-cornered Moly*. Scape and leaves three-sided; stamina simple. Leaves resembling those of the burr reed, very much keeled; petals lanceolate acuminate, white, with a green keel; stamina and pistil half the length of the petals; antheræ yellow; stigma acute.—A native of Italy and Spain.

36. *Allium Cepa*; *Common Onion*. Scape swelling out below, and longer than the columnar leaves. The varieties of the common Onion, are, 1. The Strasburgh or Common Oval; 2. the Spanish Silver-skinned and Red-skinned; 3. the Portuguese great Oval Onion; and, 4. the Tripoli. All these vary from seeds, and there are several intermediate differences not worth enumerating. The virtues of this species are considerable. The common onion has been prescribed in malignant and epidemical distempers: They are very diuretic, and powerful in cleansing and breaking away any obstructions in the urinary passages. They are likewise very efficacious in removing all oppression from the lungs, greatly promoting expectoration, and relieving asthmas and difficulty of breathing. They are externally employed in cataplasms for suppurating hard tumours. They are excellent to be taken by those who abound in cold watery humours, but very injurious to those of a bilious habit, affecting their heads, eyes, and stomachs. Onions, when eaten plentifully, procure sleep, help digestion, cure acid belchings, remove obstructions of the viscera, increase the urinary secretions, and promote insensible perspiration. Steeped all night in spring water, and the infusion given to children to drink in the morning fasting, kills worms. Onions bruised, with the addition of a little salt, and laid on fresh burns, draws out the fire, and prevents the part from blistering. They are best suited for the use of old phlegmatic people, in cold weather, when their lungs are stuffed, and their breath short. A syrup made of the juice of onions and honey is an excellent medicine in asthmatic complaints. Care should be taken not to eat *peeled onions*, or *pieces of onions*, that have been exposed in that state for any considerable time, as very bad effects have followed, though the exact cause is not known.—*Culture*. The cultivation of Onions and Leeks is exactly the same: many persons sow their Leeks very thick in beds in the spring; and in June, after some of their early crops are taken off, they dig up the ground, and plant the Leeks out thereon, in rows a foot apart, and six inches asunder in the rows, observing to water them until they have taken root; after which they only require to be weeded: and in good ground, the Leeks thus planted, will grow to a large size. To save the Leek seed, take the largest and best Leeks you have, let them grow in their original place till February, then transplant them in a row against a warm hedge, paling, or wall, eight inches asunder; and when their stems advance, which will be in May or June, support them with a string, as they are very liable to be broken down, especially when in head; and the closer they are drawn to the fence in autumn, the better the seeds will ripen. They are known to be ripe by the heads turning brown, which should then be cut off, with about a foot or more of the stalk to each, and tie them up in bundles, three or four heads in each, and hang them up in a dry place, where

they may remain until Christmas or after, when you may thresh out the seeds for use. The husk is very tough, and makes it difficult to get out the seeds; the best way for those who have but a small quantity, is to rub it hard against a rough tile, which will break the husks, and extract the seeds with great dispatch.—The Onion is propagated by seeds, which should be sown on good, rich, light ground, well dug, levelled and cleared from weeds, in a dry time, about the latter end of February or beginning of March, when the surface of the ground is not moist, and must not be sown too thick, if intended for a winter crop. In cold wet land, it is best to defer sowing till the middle of March; and in very moist rich soils, it may be done any time before the middle of April; but the early-sown crops bulb or apple best, and grow to the largest size. Nothing should be sown with Onions except a little *Cos Lettuce*. The seed should be fresh; if above one year old, not one plant in fifty will grow. Six pounds of seed to an acre, or an ounce to a pole, is generally allowed, though most gardeners sow more, because they allow for cuttings or young Onions, which they draw out for the market; but this injures the main crop. Six or seven weeks after sowing, they should be gently hoed and weeded, and separated where they grow too close, leaving them at least two inches apart. A month or five weeks after, this must be repeated, cutting out all the weeds, and removing the Onions to three or four inches asunder. A month or six weeks afterwards, they must be again hoed and weeded for the third and last time, taking care to cut up all the weeds, and single out the Onions to near six inches square, by which means they will grow much larger than if left too close; and this, if well performed, will keep the ground clean till the Onions are fit to pull up, but if weeds re-appear, they must be pulled up by the hand, as the Onions will now have begun to bulb, and must not be disturbed by the hoe. Towards the middle of August, the Onions will have arrived at their full growth, which is known by their blades falling to the ground and shrinking; they should then, before their necks or blades are withered off, be drawn out of the ground, the extreme part of the blade being cropped off, and laid upon a dry spot of ground, and turned every day to prevent their striking fresh root, which they will very suddenly do in moist weather. In a fortnight they will be dry enough to house, which must be done in perfectly dry weather, after all the earth has been rubbed from their roots, and taking care to mix no faulty ones among them, as that would spoil great numbers. They must not lie too thick, which would bring on sweating and the rot, nor be put in a lower room or ground floor, but in a loft or garret; and the closer they are kept from the air, the better they will keep. Once a month they should be examined, and all the decayed removed; for after all the care you can possibly take in the drying and housing your Onions, many, especially in mild winters, will grow; therefore, those who preserve them late in the season, should select a parcel of the firmest, and most likely to keep, from the others, and with a hot iron slightly singe their beards or roots, which will effectually prevent their sprouting; but great care must be taken not to scorch the pulp of the Onions, for that will cause them to perish soon after. The best-keeping Onions are the Strasburg kind, which have an oval-shaped bulb, but seldom grow so large as the Spanish, which are flatter; the white sort is esteemed the sweetest, but varieties of this sort are not lasting, because they always degenerate. To save Onion seed in the spring choose the firmest, largest, and best-shaped Onions, plant them in rows six inches deep, and nine inches asunder, in a piece of good well dug ground. In a month's time they will appear above ground, and must be well weeded; and about

the beginning of June, when the heads of the flowers begin to appear, stakes about four feet long must be provided, and driven into the ground, at about six or eight feet apart; to which you should fasten some packthread, rope yarn, or small cord, which should be run on each side the stems of the onions, a little below their heads, to support them against the wind and rain, which, as they are also apt to fall by their own weight, often beat them down, when the seeds are formed, and the heads heavy; and if the stalks be broken before the seeds have arrived at maturity, they will not be near so good, nor keep so long, as those that are perfectly ripened. The seed is known to be ripe by its changing brown about the end of August; and if not soon cut, the seed will then fall to the ground. When cut, the heads should be spread abroad upon coarse cloths in the sun, sheltering them in the night and in wet weather, and beating out the seeds, which are very easily discharged from their cells, when quite dry. The seeds must be exposed one day more to the sun, and then preserved in bags for use. The directions above given are for a general crop of winter Onions; but there are two other crops of this common sort of Onion cultivated for the London market, one called the *Michaelmas Onion*, which are sown about the middle of August, in beds, pretty close; from the thinnings of which they carry young green Onions to market in March, for salads, &c. and in the spring they sow more beds in the same manner and for the same purpose, after the *Michaelmas Onions* have grown too large for salads. To have Onions for pickling, some seed should be sown in light poor land in the middle of April. It should be thickly sown, and not thinned, except they rise in clusters. They will be fit to take up in August. The Scallion or Escallion is a sort of onion which never forms any bulbs at the roots, and was chiefly used in the spring for green onions, but is now scarce, and known to few people. It is propagated by parting the roots in spring or autumn, but the latter season is preferable. They are hardy enough to withstand our severest winters, and well deserve a place in all good kitchen gardens.

37. *Allium Moly*; *Yellow Moly*. Scape sub-cylindric; leaves-lanceolate, sessile; umbel level-topped.—Native of Hungary, or Monte Baldo, about Montpellier, and on the Pyrenees. This was formerly preserved in gardens for the sake of its yellow flowers, but, having a very strong garlic scent, most people have rooted it out. It increases plentifully, both by roots and seed. The whole plant smells like garlic, and is, like it, a good remedy in asthmatic complaints, the chincough, and other disorders of the breast. It is also of an opening nature, and removes most obstructions of the viscera.

38. *Allium Tricoccum*; *Three-seeded Garlic*. Scape naked, semi-columnar; leaves lanceolate-oblong, flat, smooth; umbel globular, seeds solitary.—Native of North America.

39. *Allium Fistulosum*; *Welch Onion*, or *Ciboule*. Scape equalling the columnar swelling leaves.—This species is perennial, and does not form bulbs like the common Onion, and therefore only fit for salads. They are sown about the end of July, in beds of about three feet and a half wide, and appear above ground in a fortnight; they must then be weeded. About the middle of October their blades will die away; but will come up again very strong in January, growing vigorously, and resisting all weathers; by March they will be fit to draw for young onions, and are more valued in the market than any other sort at that time in season, as they are extremely green and fine, though they are more like the Garlic than the common Onion in taste. The roots of these onions, if planted out at six or eight inches distance in March, will produce ripe seeds in autumn, but it will be in small

quantities the first year ; therefore the same roots should remain unremoved, which in the second and third year will produce many stems, and afford a good supply of seeds ; these roots will continue good for many years, but should be transplanted and parted every second or third year, which will cause them to produce strong seeds.

40. *Allium Schœnoprassum* ; *Cives* or *Chives*. Scape equaling the columnar awl-filiform leaves. The petals of this species are of a faint purple colour ; it has a very strong smell.—Native of Italy, Switzerland, Sweden, and Siberia. This is a very small sort of Onion, which never produces any bulbs, and seldom grows above six inches high in the blade, which is also very small and slender, and in round bunches ; this was formerly in great request for salads in the spring, as being milder than those Onions which had stood through the winter. They are propagated by parting their roots, and are also very hardy, and will be fit for use early in the spring.

41. *Allium Sibiricum* ; *Siberian Garlic*. Scape columnar : leaves semi-cylindric ; stamina awl-shaped. It has white petals, with a greenish keel. Native of Siberia.

42. *Allium Tenuissimum* ; *Slender-leaved Garlic*. Scape columnar, empty ; leaves awl-filiform ; heads loose, few-flowered.—A native of Siberia ; much eaten by the field-mice, who lay up the roots for their winter food.

43. *Allium Chamæ-Moly* ; *Bastard Garlic*. Scape scarcely any, naked ; capsules drooping ; leaves flat, ciliate. Flowers seven to ten, white, with the outside purplish or greenish.—It flowers in January ; and is a native of Italy.

44. *Allium Gracile* ; *Jamaica Garlic*. Scape naked ; columnar very long ; leaves linear, channelled ; stamina subulate, connate at the base. Petals erect, white, the claws uniting below with the stamina, and forming a green tube.—A native of Jamaica ; flowering in February.

45. *Allium Neapolitanum* ; *Naples Garlic*. Scape naked, ancipital ; leaves lanceolate, channelled ; umbel scattered. Corolla white, and spreading ; stamina shorter than the corolla.—It is cultivated in gardens in the neighbourhood of Naples, and begins to grow spontaneously about the city ; it flowers in March.

Allophylus ; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix* : perianth four-leaved ; leaflets orbiculate ; two exterior, opposite, smaller by half. *Corolla* : of four petals, less than the calix, orbiculate, equal ; claws broad, length of the two smaller leaves of the calix. *Stamina* : filaments filiform, the length of the corolla ; antheræ roundish. *Pistil* : germ superior, roundish, twin ; style filiform, longer than the stamina ; stigma bifid, with the divisions rolled back. **ESSENTIAL CHARACTER.** *Calix* : four-leaved ; leaflets orbiculate, two opposite smaller. *Petals* : four, less than the calix. *Germs* : twin. *Stamina* : quadrifid.—The species are,

1. *Allophylus Zeylanicus*. Leaves oval, acuminate, quite entire ; racemes axillary, very short.—A native of the island of Ceylon.

2. *Allophylus Rigidus*. Leaves simple, toothletted, and spiny ; flowers in racemes.—Native of Hispaniola.

3. *Allophylus Racemosus*. Leaves ternate ; flowers in racemes.—A native of Hispaniola.

4. *Allophylus Cominia*. Leaves ternate ; flowers in panicles. The stem is the thickness of the human thigh, rising thirty feet in height, with a smooth ash-coloured bark. Flowers very numerous, whitish yellow, to which succeed small orange-coloured smooth berries, the size of a small pin's head, having a single stone in them, with a thin brittle shell, and a large kernel in proportion to the fruit.—It grows abundantly in Jamaica.

5. *Allophylus Ternatus*. Leaves ternate serrate ; racemes long, terminating. This is only a shrub five feet in height, with spreading branches. Flowers small, white, with hairy petals, and a nectary of four glands.—It is a native of Cochinchina, by the banks of rivers. The inhabitants use the leaves as a cataplasma in contusions.

Aloe ; a genus of the class Hexandria, order Monogynia.—

GENERIC CHARACTER. *Calix* : none. *Corolla* : one-petalled, erect, sexfid, oblong ; tube gibbous ; border spreading, small, nectareous at bottom. *Stamina* : filaments awl-shaped, as long as the corolla, or longer, inserted into the receptacle ; antheræ oblong, incumbent. *Pistil* : germ ovate ; style simple, the length of the stamina ; stigma obtuse, trifid. *Pericarp* : an oblong capsule, three-furrowed, three-celled, and three-valved. *Seeds* : several, angular. **ESSENTIAL**

CHARACTER. *Corolla* : erect, with an expanded mouth, and a nectareous base. *Filaments* : inserted into the receptacle.—The roots of this genus are perennial and stoloniferous.

Stem none, or else formed from the bases of the leaves ; round, generally single, seldom branched. Leaves succulent, embracing the stem, in some smooth and even, in others spotted or painted, in others warted ; variously disposed. Scape or peduncle braeted, erect, frequently single, seldom branched.

Native place of growth, principally the Cape of Good Hope, and all hot climates.—The inspissated juice of the various species of Aloe is a hot and irritating purgative. The Socotorine Aloe is gentler and purer than the others, and is generally the only kind used in medicine. As the drossy resinous part of the Aloe is not soluble in water, it has been found, when combined with other mixtures, an excellent preservative against the worm which is so injurious to ships trading to the East or West Indies : one ounce of aloes is sufficient for two superficial feet of plank ; about twelve pounds for a vessel of fifty tons' burthen ; and three hundred pounds for a first-rate man of war. It may be incorporated with six pounds of pitch, one pound of Spanish brown, or whiting, and a quart of oil ; or with the same proportion of turpentine, Spanish brown, and tallow. Such a coat will preserve a ship's bottom eight months, and the expense for a first-rate ship will be about eighteen pounds. The same composition may be used in hot countries for preserving rafters, &c. from the wood ant.—The soil in which this genus of plants thrive best, is one-half fresh light earth from a common, and if the turf be taken with it and rotted, it is much better ; the rest should be white sea-sand, or road-sand, and sifted lime-rubbish, of each of these two a fourth part ; mix them together six or eight months at least before the compost is used, observing to turn it over often during that time. The middle of July is the time to shift these plants, which must be done by taking them out of the pots, and opening the roots with the fingers, shake out as much of the earth as possible, and remove all dead or mouldy roots, then fill the pot three parts full with the above-mentioned earth, putting a few stones at the bottom to drain off the moisture, and replacing the roots of the plant so as to prevent their interfering with each other, fill the pot almost to the rim with the same earth, observing to shake the plant, that the earth may settle among the roots, and keep it steady in the pot, and water it gently, especially in hot dry weather, setting it abroad in a shady place. Towards the end of Sep-

tember, in a dry day, remove them into the house again, water them once a week in winter, and give them fresh air when the weather is warm. The hardier Aloes thrive best abroad in summer, and secured from cold and rain in winter. The tender sorts should always remain in the stove, or be removed to an airy glass-case during summer. Most Aloes are increased by offsets, which should be taken from the mother plants at the time they are shifted, and must be planted in very small pots, filled with the same earth as was before directed for the old plants. After planting, let them remain in a shady place for a fortnight, then remove the tender kinds to a very moderate hot-bed, and plunge the pots therein, which will greatly facilitate their taking new root; but observe to shade the glasses in the middle of the day, and to give them a great share of air. Towards the middle of August begin to harden these young plants by taking off the glasses in good weather, and giving them plenty of air, which is absolutely necessary for their growth, and to prepare them to be removed into the house, which must be done towards the end of September; and they will afterwards require the same management as the old plants.—The species are,

1. Aloe Dichotoma; *Smooth-stemmed Tree Aloe*. Branches dichotomous; leaves sword-shaped, serrate. Trunk round, upright, very stiff, ash-coloured, twelve feet high, about the thickness of a man's thigh.—Native of the Cape; where the natives hollow out the trunk to make quivers for their arrows.

2. Aloe Perfoliata; *Perfoliate Aloe*. Stem-leaves toothed, embracing, sheathing; flowers in corymbs, drooping, peduncled, subcylindrical.—Of this species there are the following varieties.—

a. Aloe Arborescens; *Narrow-leaved Sword Aloe*. Leaves embracing, reflex, toothed; flowers cylindrical; stem shrubby. Has a strong naked stem, ten or twelve feet high, with leaves of a sea-green colour, and very succulent; the flowers of a bright red, which grow in pyramidal spikes, and are in beauty in November and December.

β. Aloe Africana; *Broad-leaved Sword Aloe*. Leaves broader, embracing, thorny on the edge and back; flowers in spikes; stem shrubby. This resembles the preceding species, but has broader leaves, and the flowers grow in looser spikes.

γ. Aloe Barbadosis; *Barbadoes Aloe*. Leaves toothed, upright, succulent, subulate; flowers yellow, hanging down in a thyse. The flower-stem rises nearly three feet high.—This species, though generally known by the name of Barbadoes Aloe, is very common in the other islands of America, where the plants are propagated on the poorest land to obtain the hepatic aloes, which are brought to England, and used chiefly for horses. At Barbadoes, in the month of March, when the plants are a year old, they are cut just above the surface of the earth, and placed in a tub, until their juice is drained off, when they are thrown upon the land by way of manure. The juice will keep several weeks without injury. It is put into boilers, and thickened by a regular fire till of a proper consistency to be ladled out into gourds, or other small vessels fitted for its final reception. As to the sun-dried aloes, which are most approved for medicinal purposes, very little is made in Barbadoes. The process is, to suspend bladders filled with the raw juice, and open at the top in the sun every dry day until the fluid parts are exhaled, and a perfect resin formed; which is then packed up for use or exportation. Those lands in the islands of Barbadoes, which lie near to the sea, are subject to drought, and are too stony and shallow to plant sugar canes, answer best for the Aloe plant. The larger stones are removed, and

frequently formed into a surrounding fence. The land is then lightly ploughed, carefully weeded, and the young plants set like Cabbages, at about six inches from each other. They are thus planted to be weeded by hand, and will bear being planted in any season of the year, as they will live on the surface of the earth for many weeks without a drop of rain.

δ. Aloe Socotorina; *Socotorine Aloe*. Leaves very long and narrow; thorny at the edge; flowers in spikes.—This is the true Socotorine Aloe, which is named from the island of Socotra or Socotora in the straits of Babelmandel, formerly famous for the extract of this plant. It is of a yellowish brown colour, approaching to purple: and when reduced to powder, is a sort of gold colour. Socotorine Aloes may be given in considerable doses, as a scruple, or half a drachm at a time; and is a very good purge, particularly as an aperient, and remover of obstructions in phlegmatic habits. The tincture, called *Tinctura Sacra*, or *Hiera Picra*, is a solution of it in wine: it may be given as a purgative from one to two ounces or more, or may be taken as an alterant in smaller doses, and continued until it has produced a lax habit or soluble state of the bowels. It is an excellent medicine for languid and phlegmatic constitutions; warming the solids, cleansing the intestines, and attenuating viscid juices in the remoter parts. Spanish liquorice is said to be the most efficacious ingredient of all others, in covering the unpleasant taste of Aloes. Equal parts of Aloes and Spanish juice dissolved in water, is said to be the most pleasant and useful of all the aloetic purges. Indeed the purgative properties of Socotorine aloes are universally known; and the different preparations of it purify the blood, help digestion, dissipate gross humours, and are friendly to the nervous system in general. They likewise powerfully resist putrefaction, remove obstructions of the viscera, kill worms in the stomach and intestines, cure the jaundice and green sickness, provoke the menses and piles, and prove serviceable in the ague, and all cold watery disorders; but should be forborne by such as have hot bilious constitutions or gravelly complaints. It should not be given to pregnant women, nor to those who spit blood, as in those cases it might prove fatal.

ε. Aloe Purpurascens; *White-spined Glaucous Aloe*. Leaves purplish beneath, with small roundish spots at bottom.

ζ. Aloe Glauca; *Red-spined Glaucous Aloe*. Stem short; leaves embracing, standing two ways; spines on the edges erect; flowers growing in a head.

θ. Aloe Ferox; *Great Hedge-hog Aloe*. Leaves embracing, very dark green, beset with spines on every side. It rises to the height of eight or ten feet, with a strong stem. It has not yet flowered in England, nor does it put out suckers, so that it is difficult to propagate.

ι. Aloe Saponaria; *Great Soap Aloe*; and,

κ. Aloe Obscura; *Common Soap Aloe*. Leaves broader, spotted, thorny at the edge; flowers in spikes. The first seldom rises above two feet in height; the leaves are very broad at their base, where they closely embrace the stalk, and gradually decrease to a point. The underleaves are of a dark green colour spotted with white, resembling the colour of soft soap. The flowers grow in umbels on the tops of the stalks, are of a beautiful red colour, and appear in August and September. The second has broader leaves, of a lighter green; the edges and spines are copper-coloured, and the flowers grow in loose spikes.

λ. Aloe Serrulata; *Hollow-leaved Perfoliate Aloe*. Leaves spotted, finely serrate at the edge and the tip of the keel. It seldom rises above a foot high; the leaves, which grow near

the ground, are of a sea-green colour, with some white spots; the flowers grow in loose spikes the tubulous part being red, and the brim of a light green colour.

μ. Aloe Suberecta; *Upright Perfoliate Aloe*. Leaves flat, almost upright, thorny at the edge and on the lower surface.

ν. Aloe Depressa; *Short-leaved Perfoliate Aloe*. Leaves embracing, thorny on both sides; flowers in spikes.

ξ. Aloe Humilis; *Dwarf Hedge-hog Aloe*. Leaves upright, subulate, radicate, with weak spines all round. This is a very low plant, never rising into a stem. The flowers, which shew that it belongs to this species, grow on a loose head at the top of the stalk, which is very thick, but seldom a foot high; below their colour is a fine red, but a pale green above.

ο. Aloe Mitriformis; *Great Mitre Aloe*. Grows with an upright stalk to the height of five or six feet; the leaves are of a dark green colour; the tube of the corolla is of a fine red, the brim of a pale green.

π. Aloe Brevifolia; *Small Mitre Aloe*.

3. Aloe Arachnoides; *Cobweb Aloe*. Stemless; leaves three-cornered, cusped, ciliate; flowers in a sort of spike, upright, cylindrical. There are two varieties,

α. Aloe Arachnoides Communis; *Common Cobweb Aloe*. Leaves short, plain, fleshy, triangular at the end; the borders set with soft spines. Cobweb Aloe never rises from the ground, but the leaves spread flat on the surface; these are plain, succulent, and triangular toward the end; the borders and keel are closely set with soft white spines. The flower-stem rises about a foot high, is very slender, and has three or four small distant herbaceous flowers.

β. Aloe Arachnoides Pumila; *Small Cobweb Aloe*. Leaves ovate-lanceolate, fleshy, triangular at the end, with numerous soft spines. A small plant near the ground.

4. Aloe Margaritifera; *Pearl Aloe*. Stemless: leaves three-cornered, cusped, papillose; flowers in racemes, drooping, cylindrical. It is of humble growth, and flowers in several seasons of the year. There is a smaller sort, which has been long preserved in the English gardens.

5. Aloe Verrucosa; *Warted, or Pearl-tongued Aloe*. Stemless; leaves sword-shaped, sharp, papillose, distich; flowers in racemes, reflex, club-shaped. This species produces offsets in plenty, and flowers in several seasons of the year. The flowers are of a beautiful red colour, tipped with green.

6. Aloe Carinata; *Keel-leaved Aloe*. Stemless: leaves acinaciform, papillose; flowers in racemes, drooping, curved. The flowers are of a paler colour, and the spikes shorter than those of the preceding species.

7. Aloe Maculata; *Spotted Aloe*. Leaves blunt with a point. Almost stemless; leaves acinaciform, smooth, painted; flowers in racemes, drooping, curved. It varies with large, oblong, white confluent spots; and with small ones.—Native of the Cape; flowering in August.

8. Aloe Lingua; *Tongue Aloe*. Almost stemless; leaves tooth-letted, smooth distich; flowers in racemes, upright, cylindrical. The flowers are in slender loose spikes, each hanging downwards, of a red colour at bottom, and green at top. There is a variety of this with leaves much more spotted.

9. Aloe Plicatilis; *Fan Aloe*. Almost stemless; leaves tongue-shaped, even, distich; flowers in racemes, pendulous, cylindrical. This grows to the height of six or seven feet, with a strong stem; the flowers, which are of a red colour, are produced in short loose spikes, and appear at different times of the year.

10. Aloe Variegata *Partridge-breasted Aloe*. Almost stemless; leaves in three ranks, painted channelled; angles

cartilaginous; flowers in racemes, cylindrical. It is a low plant, seldom rising above eight inches high. The leaves are triangular, fleshy, and serrated; they are curiously veined, and spotted like the feathers of a partridge's breast. The flowers are in loose spikes, of a fine red colour, tipped with green.

11. Aloe Viscosa; *Upright Triangular Aloe*. Subcaulescent; leaves imbricate in three ranks, ovate; flowers in racemes, drooping, cylindrical.—Grows near a foot high, and has triangular leaves of a dark green colour; the flowers grow thinly on very slender peduncles, they are of a herbaceous colour, and their upper part turns backward.

12. Aloe Spiralis; *Spiral Aloe*. Subcaulescent; leaves imbricate in eight ranks, ovate; flowers in racemes, curved back. This somewhat resembles the preceding species.

13. Aloe Retusa; *Cushion Aloe*. Stemless; leaves in five ranks, deltoid. This species receives its name from its very short thick succulent leaves, which are compressed on the upper side like a cushion; the flowers are of a herbaceous colour. It grows very close to the ground.

14. Aloe Spicata; *Spiked Aloe*; flowers in spikes, horizontal, bell-shaped; stem-leaves flat, embracing, toothed. This very much resembles the second species. It was observed by Thunberg at the Cape. The flower is full of a purple honey-juice. The best and purest Hepatic Aloe is obtained from this species; that obtained from Barbadoes is of different degrees of purity, darker, and more bitter and nauseous than the Socotorine kind.

Alopecuros. See *Betonica*.

Alopecurus; a genus of the class Triandria, order Digynia.—GENERIC CHARACTER. *Calix*: glume, one-flowered, two-valved; valves ovate-lanceolate, concave, compressed, equal, connate at the base. *Corolla*: one-valved; valve ovate-lanceolate, concave, the edges united at the base, a little shorter than the calix; awn twice as long, with a bent joint, inserted into the back of the valve near the base. *Stamina*: filaments three, capillary, flattish at the base, longer than the calix; antheræ forked at each end. *Pistil*: germ roundish; styles two, capillary, united at the base, longer than the calix; stigmas villous. *Pericarp*: none; corolla investing the seed. *Seed*: ovate, covered. ESSENTIAL CHARACTER. *Calix*; two-valved. *Corolla*: one-valved.—For the culture and propagation of this genus see GRASS.—The species are,

1. *Alopecurus Indicus*; *Indian Fox-tail Grass*. Spike cylindrical; involucre setaceous, fasciculate, two-flowered; peduncles villous.—Native of the East Indies.

2. *Alopecurus Bulbosus*; *Bulbous Fox-tail Grass*. Culm erect; spike cylindrical; root bulbous.—It rises about a foot high; and has been found in great plenty in a wet salt-marsh near Yarmouth in Norfolk.

3. *Alopecurus Pratensis*; *Meadow Fox-tail Grass*. Culm spiked, erect; glumes villous; corollas awnless. Roots perennial; stalks from a foot to eighteen inches, two, and even three feet high; the antheræ are frequently purple when in full vigour.—It is a native of most parts of Europe. It is common in the best pastures about London; and produces the spike in April or May, being one of the earliest grasses. It frequently flowers twice in one season, and the seed may be collected without much difficulty, for it does not quit the chaff, and the spikes are very prolific. This grass is highly worth cultivation on the lands that are proper for it, as it possesses the three great requisites of quantity, quality, and earliness, in a superior degree to any other.

4. *Alopecurus Agrestis*; *Field Fox-tail Grass*. Culm spiked, erect; glume smooth; calix surrounded at bottom by a ring. It resembles the preceding, but is distinguished from

P. 80.

L. M. (Chrys.)

ALOE LINGUA — Tongue Aloe.

P. 80.

ALOE VARIEGATA — Partridge-breasted Aloe.

it by the great length and slenderness of its spikes, tapering to a point, and usually of a purple colour. The stalk is a foot or eighteen inches high, and it has obtained the name of Mouse-tail in English from the great length and slenderness of the spike, resembling the tail of the mouse. It is every way inferior to Fox-tail Grass, and therefore not worth cultivation. It flowers early, continues flowering till autumn, and comes very quickly into bloom after it is sown.

5. *Alopecurus Geniculatus*; *Flute Fox-tail Grass*. Culm spiked, infracted; corollas awnless; (awns concealed within the calix.) Stalk from twelve to eighteen inches high; root perennial. It is called Black Grass in some places, from the deep purple colour of the spikes; cattle eat it readily, but it is not a profitable grass. It flowers in June.

6. *Alopecurus Hordeiformis*; *Barley-like Fox-tail Grass*. Raceme simple; flowers intrinched with awns. This is an Indian grass, about a foot high, with the pistil longer than the flower; and it has the appearance of Barley-grass.

7. *Alopecurus Mospeliensis*; *Bearded Fox-tail Grass*. Panicle subspiked; calices rugged; corollas awned. This is an annual, which grows wild in marshes and wet pastures, and flowers in June and July.

8. *Alopecurus Panicus*; *Hairy Fox-tail Grass*. Panicle subspiked; glumes villous; corollas awned. This plant only reaches to five or six inches high; it grows on dry soils, and is annual, flowering in July.

Alpinia; a genus of the class Monandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubulose, three-toothed; leaflets equal, erect, acute. *Corolla*: monopetalous, tubulose; tube cylindraceous, short; border three-parted; parts nearly equal, oblong. Nectary connate with the tube of the corolla, two-parted; the lower part forming the lower lip is larger and longer than the parts of the corolla, broadish, spreading, often divided. *Stamina*: filament proper, none; but along the upper division of the nectary, forming the upper lip, which is flattish, and the length of the corolla, grows a large anthera; either deeply bifid or entire. *Pistil*: germ inferior, oblong, style filiform, often inserted into the fissure of the anthera, stigma incrassate, obtuse. *Pericarp*: capsule oval, three-celled three-valved, crowned with the permanent calix. *Seeds*: some ovate, angular, covered with a sort of berried aril. ESSENTIAL CHARACTER. *Calix*: three-toothed, equal, tubulose. *Corolla*: three-parted, equal. *Nectary*: two-lipped, the lower lip spreading.—The species are,

1. *Alpinia Racemosa*. Raceme terminating, spiked; flowers alternate; lip of the nectary trifid; leaves oblong, acuminate. Root fleshy, branched, and having the taste and smell of ginger; the stem from two to five feet high.—It is a native of the West Indies; and must be preserved in a stove, with the pot plunged into a tub of water. When the leaves decay, which is every winter, it may be propagated by parting the roots.

2. *Alpinia Occidentalis*. Raceme radical, compound, erect; nectary emarginate; capsules three-celled; leaves lanceolate-ovate, very smooth.—It is a native of Jamaica and St. Domingo.

Alsine; a genus of the class Pentandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets concave, oblong, acuminate. *Corolla*: of five equal petals longer than the calix. *Stamina*: filaments capillary; anthera roundish. *Pistil*: germ subovate; styles filiform; stigmas obtuse. *Pericarp*: an ovate, one-celled, three-valved; capsule, covered with the calix. *Seeds*: many, roundish. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five, equal. *Capsule*: one-celled, three-valved.—The species are,

1. *Alsine Media*; *Common Chickweed*. Petals bipartite; leaves ovate-cordate. This plant is very generally known; it assumes a diversity of appearances, according to the soil in which it grows. It is commonly given as food to chickens and small birds, and when boiled it exactly resembles spinach: swine, and also many insects, are very fond of it. As a medicine, it contains no active principle, but is frequently applied to swellings, either alone or in poultices. The whole plant, or the juice of it, boiled in a sufficient quantity of hog's lard, makes an excellent cooling ointment. Taken inwardly, it is said this plant is good against the scurvy, and promotes the urinary evacuation. A poultice made of the bruised herb is recommended to remove inflammations arising from blows. Chickweed flowers upright, and open from nine to noon; but if it rains, the flowers do not open; after rain they become pendant, but in a few days rise again. Chickweed is also a remarkable instance of the sleep of plants: at night the leaves approach in pairs, so as to enclose between their upper surfaces the tender buds; and the two upper leaves but one, at the end of the stalk, are furnished with longer petioles than the others, so that they can close upon the terminating pair, and protect the end of the branch.—It is found wild in most parts of the world.

2. *Alsine Segetalis*. Petals entire; leaves awl-shaped.—It is an annual, and grows in France about Paris, and in Piedmont.

3. *Alsine Mucronata*. Petals entire, short; leaves setaceous; calices awned; stems erect, a foot high, many together, branching, a little hairy. Petals ovate, white.—It is a native of France and Switzerland.

Alstonia; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth inferior, imbricate; scales ovate, very obtuse, concave; the inner ones gradually larger, forming as it were a quadripartite or quinquepartite calix. *Corolla*: one-petalled, shorter than the calix; tube short; border spreading, divided into eight or ten parts; divisions equal, in a double row, alternately interior and exterior; obovate, obtuse, quite entire. *Stamina*: filaments very many, inserted into the tube very short, imbricate, very smooth; the outer ones longer, linear, attenuated at the tip; anthera orbiculate, furrowed. *Pistil*: germ superior, ovate, small; style simple, length of the corolla, filiform, erect; stigma capitate-obovate. ESSENTIAL CHARACTER. *Corolla*: one-petalled, eight or ten cleft; clefts alternated.—There is only one species, viz.

1. *Alstonia Theaeformis*. This shrub was found by Mutis in South America. It is very smooth, and resembles Bohea tea; its dried leaves also give a greenish colour to the saliva when chewed, and have the same taste as the Chinese tea. The flowers are axillary, three or four together, and sessile; the calix is very smooth, the scales rounded and green, with a membranaceous edge; the corollas white and spreading.

Astroemeria; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: six-petalled, sub-bilabiate; the three outer petals wedge-shaped, retuse, mucronate; the inner, which are alternate with the others, lanceolate; the two lower ones, tubulose at the base. *Stamina*: filaments awl-shaped, bending down, unequal; anthera oblong. *Pistil*: germ inferior, hexangular, truncate; style bending down, filiform, the length of the stamina; stigmas three, oblong, bifid. *Pericarp*: a roundish six-ribbed mucronate capsule, three-celled, three-valved, valves concave, contrary to the dissepiment. *Seeds*: very many, globose, covered with raised points, subumbilicate at the tip. ESSENTIAL CHARACTER. *Corolla*: of six petals, sub-bilabiate; the two lower petals tubulose at the

base. *Stamina*: bending down.—These plants are all found in South America, and must be kept in a stove in England, (except the first species) where they may be propagated by parting their roots in autumn.—The species are,

1. *Alstroemeria Pelegrina*; *Spotted-flowered Alstroemeria*. Stem erect; corollas bell-shaped, straight; leaves linear-lanceolate, sessile. The flowers are whitish, most beautifully stained, and veined with purple and red; they flower from June until October.—This species may be treated as a greenhouse plant; it will however flower and ripen its seeds better under the glass of a hot-bed frame, where air is freely admitted. It is generally raised from seeds, sown in a pot of light earth in the spring, on a gentle hot-bed, either of dung or tan.

2. *Alstroemeria Pulchella*. Stem erect; corollas reflex, spreading, acute; leaves sessile; pedicles shorter than the involucre. This much resembles the first species: its petals spread from the base, recurved, acute, alternately less, whitish, red at the tip, streaked or dotted with red at the base; filaments yellow, equal; pistil red, rising; stigma trifid.

3. *Alstroemeria Ligtu*; *Stripe-flowered Alstroemeria*. Stem erect; leaves spatulate-oblong; peduncles of the umbel longer than the involucre; corolla two-lipped.—This species is remarkable for the largeness and fragrant of the flowers, which are scarcely inferior to Mignonette. It flowers in February and March.

4. *Alstroemeria Salsilla*. Stem twining; leaves petiolate, lanceolate, acuminate; umbel branching; peduncles longer than the involucre, bracted and loose. Leaves nervous; petioles naked; the outer petals red, the inner greenish.

5. *Alstroemeria Multiflora*. Stem twining; leaves petiolate, lanceolate, acuminate; umbel simple; peduncles shorter than the bractes; petals alternate, truncate. This species is very distinct from the rest.

6. *Alstroemeria Ovata*. Stem twining; leaves lanceolate, lanuginose on the upper surface, lucid on the lower; corollas tubular. Stem twining, contrary to the sun, slender, hardish and rising three feet high. Flowers terminating in umbels. Petals approximating into a tube; the three outer scarlet and green at the tip, the three inner green, flattish towards the top, and variegated with black dots.—A native of Peru.

Althæa; a genus of the class Monadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth double; outer smaller, one-leaved, unequally novemfid; divisions very narrow: inner semiquinquefid; divisions broader, sharper. *Corolla*: five-petalled, united at the base, obovate, præmorse, flat. *Stamina*: filaments many, inserted in the corolla; antheræ subreniform. *Pistil*: germ orbiculate; style cylindrical, short; stigmas many, setaceous, the length of the style. *Pericarp*: consists of arils not jointed, forming a flat ring about a columnar receptacle; they are deciduous, and open on the inside. *Seed*: one, flat kidney-shaped in each aril. **ESSENTIAL CHARACTER.** *Calix*: double; outer nine-cleft. *Arils*: many, one-seeded.—The species belonging to this genus are the following.

1. *Althæa Officinalis*; *Common Marshmallow*. Leaves simple, downy. This species grows naturally on the banks of rivers, and in salt marshes and ditches, in Cambridgeshire, Norfolk, and Suffolk; on the sea-shores of Cornwall; and in Holland, France, Italy, and Siberia. The root is perennial; the stalk annual, growing erect to the height of four or five feet, putting out a few lateral branches; the flowers are axillary, shaped like those of the Mallow, but smaller, and of a pale colour: they appear in July, and the seeds ripen in September. The whole plant, particularly the root, abounds with a mild mucilage, which is emollient in a much greater

degree than common Mallow. The boiled root is much used as an emollient cataplasm, and an infusion of it is very generally prescribed in all cases wherein mild mucilaginous substances are useful as a pectoral, and in complaints of a gravelly nature. It is kept in most gardens on account of its medicinal qualities. An infusion of it is excellent for blunting and sheathing those sharp and acrimonious humours which occasion tickling coughs, hoarseness, erosions of the stomach and intestines, difficulty and heat of urine, and for lubricating and relaxing the passages, and for the stone and gravelly complaints. A syrup and ointment of it are kept in the shops; but, a strong infusion has far more virtues than the syrup; and a poultice made of the fresh root, with the addition of a little white bread and milk, will prove more serviceable, when applied externally, than the ointment.—The common Marshmallow may be propagated by sowing the seeds in the spring, or parting the roots in autumn when the stalks decay. The plant should be placed two feet asunder, and will thrive in any soil or situation, but grow larger in moist than in dry land.

2. *Althæa Cannabina*; *Hemp-leaved Marshmallow*. Lower leaves palmate, upper digitate. This species has a woody stem, which rises to the height of four or five feet, and puts out many side-branches; the leaves are alternate. The flowers are axillary, not so large as those of the common Marshmallow, but of a deeper red colour, with a larger calix. It seldom flowers the first year, unless the summer prove warm; but when the plants survive the winter, they will flower early in the succeeding summer, and produce good seeds; which should be sown in the spring where they are intended to remain, in a sheltered situation and dry soil, or they will not bear an English winter, and transplanting is hurtful to them. In a stony soil, or in lime rubbish, their growth is stunted, but they become more hardy. They seldom continue longer than two years in England, and are by no means scarce.—It grows naturally in Hungary, Istria, Carniola, Italy, and by wood-sides in the south of France.

3. *Althæa Hirsuta*; *Hairy Marshmallow*. Leaves trifid, hairy-hispid, smooth above; peduncles solitary, one-flowered. This is a low plant, with its branches trailing on the ground. The leaves and stalks are beset with strong hairs; the flowers have purplish bottoms. If the seeds be sown in April, the plants will flower in July, and the seeds ripen in September.—It grows wild in Spain, Portugal, Italy, &c.

4. *Althæa Ludwigii*; *Ludwig's Marshmallow*. Leaves lobed, naked on both sides; peduncles collected, one-flowered.

5. *Althæa Narbonensis*; *Narbonne Marshmallow*. Leaves tomentose on both sides; the lower five-lobed, the upper three-lobed; peduncles solitary, one-flowered. Roots perennial, stems annual, from four to six feet high. Corolla purple rose-coloured, twice as long as the calix.—First discovered near Narbonne; found also in Spain; and flowers in August and September.

6. *Althæa Corymbosa*. Leaves simple, cordate or angular, smooth; peduncles and calices hairy; flowers in corymbs.—A native of Jamaica.

7. *Althæa Racemosa*. Leaves simple, cordate-ovate, serrate, scabrous on the upper surface, raceme terminating erect. Stems thick, stiff, five feet high, with many branches; corolla yellow; the fruit composed of five bivalve capsules.—A native of Jamaica.

Althæa Frutex. See *Hibiscus*.

Alyssum; a genus of the class Tetradynamia, order Siliculosa.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, oblong; leaflets ovate-oblong, obtuse, convergent, deciduous. *Corolla*: four-petalled, cruciform; petals flat, shorter than the

calix, very spreading; claws the length of the calix. *Stamina*: filaments six, the length of the calix; two opposite, a little shorter marked with a toothlet; antheræ from erect, spreading. *Pistil*: germ subovate; style simple, the length of the stamina, longer than the germ; stigma obtuse. *Pericarp*: a subglobose, emarginate *silicle*, with a style the length of the silicle, two-celled; partitions elliptic, valves elliptical, hemispherical. *Seeds*: fixed to filiform receptacles, issuing forth at the end of the silicle, few, orbicular. **ESSENTIAL CHARACTER.** The shorter filaments marked with a toothlet; *silicle* emarginate.—Every species of this genus may be propagated by seed, and most of them by slips and cuttings. The seeds should be sown in a border of light earth in April; cuttings or slips should be planted in April or May, shaded in the heat of the day, and gently refreshed with water. They seldom survive an English winter, when planted in rich ground; but in a poor, dry, rubbishy soil, or on old walls, they will abide the cold, and last much longer.—The species are,

* *Undershrubs.*

1. *Alyssum Spinosum*; *Thorny Madwort*. The old racemes thorny, naked. It has woody branches rising two feet high, and armed with small spines; the leaves are hoary, lanceolate, and thinly placed on the stalks without any order; the flowers grow in small clusters at the extremity of the branches.—It grows naturally in Italy, Spain, and the south of France; seldom remains more than two or three years with us, and must be often sown to preserve it; but if the seeds be suffered to remain, and fall upon the ground, the plants will rise without any trouble.

2. *Alyssum Halimifolium*; *Sweet Madwort*. Stems procumbent, perennial; leaves lance-linear, acute, quite entire. It spreads itself upon the ground, and never rises to any height; at the extremities of its branches it produces very pretty tufts of small white flowers, of which the plant is seldom destitute for six or seven successive months.—It is a native of the southern countries of Europe.

3. *Alyssum Saxatile*; *Yellow Madwort*. Stems shrubby, panicled; leaves lanceolate, very soft, repand; petals entire. This plant has a fleshy stalk, seldom more than a foot high; the flowers are of a bright yellow colour.—It is a showy and hardy plant, very suitable to embellish rock-work. The seeds ripen in July, but it is only from young plants that seeds can be expected; for the old plants, or those which are raised from slips or cuttings, rarely produce seeds in England.

4. *Alyssum Alpestre*; *Italian Madwort*. Stems undershrubby, diffused; leaves roundish, hoary; calices coloured. The flower is yellow; the plant perennial. Found on Mount Cenis, and the mountains of Provence towards Italy.

** *Herbaceous.*

5. *Alyssum Hyperboreum*; *Northern Madwort*. Leaves hoary, toothed; stamina four-forked.—Native of North America.

6. *Alyssum Incanum*; *Hoary Madwort*. Stem erect; leaves lanceolate, hoary, quite entire; flowers in corymbs; petals bifid. Grows to two feet in height, with small white flowers. The silicle is entire, oval, and full of brown seeds. It grows naturally in the south of France, in Spain, Italy, Germany, Austria, and Sweden. Chiefly on rocky or gravelly soils. It flowers from June to September, and the seeds ripen soon after; if these be permitted to scatter, the plants will come up, and require little care.

7. *Alyssum Minimum*; *Least Madwort*. Stems diffused; leaves linear, downy; silicles compressed. The petals are yellow and submarginate.—It is an annual plant, and grows well in Spain.

8. *Alyssum Calycinium*; *Calycine Madwort*. Stamina awl-toothed; calices permanent.—Annual, found wild in Austria, Carniola, France, Germany, and Switzerland. The petals are yellow, but turn white with age. It should be sown where it is intended to remain; if thinned, and kept clean from weeds, they will flower in July, and perfect their seeds in autumn.

9. *Alyssum Montanum*; *Mountain Madwort*. Stems diffused; leaves sublanceolate, dotted, and echinate. This is a perennial, and has dark yellow flowers.—It grows naturally upon the rocks of Burgundy and other parts of France and is also found in Germany.

10. *Alyssum Campestre*; *Field Madwort*. Stamina guarded with a pair of bristles; calices deciduous.—This much resembles the eighth species; but is more decumbent, and has lance-ovate leaves. It is a native of the same countries, and requires the same treatment.

11. *Alyssum Clypeatum*; *Buckler-podded Madwort*. Stem erect; silicles sessile, oval, compressed-flat; petals pointed, linear.—A biennial plant, growing naturally in Spain and Portugal.

*** *Silicles inflated, or Calices oblong, closed.*

12. *Alyssum Sinuatum*; *Sinuate-leaved Madwort*. Stem herbaceous; leaves lance-deltoid; silicles inflated. A low spreading plant, with flowers of a bright yellow colour.—It is annual or biennial, grows by way-sides in Spain, and in the islands of the Archipelago, but will bear the open air of England, in a dry soil and warm situation.

13. *Alyssum Creticum*; *Cretan Madwort*. Stem shrubby; leaves lanceolate, a little toothed, downy; silicles globular. This species seldom continues more than two years in England, and in a warm dry situation will live in the open air. The seeds should be sown in August soon after they are ripe; and if a few of the plants be potted in October, and sheltered under a frame in winter, they will flower in the following June, and produce good seeds in the same year.—Found in Spain and Candia.

14. *Alyssum Gemonense*; *Gemona Madwort*. Stem herbaceous; branches divaricated; root-leaves obovate, rather downy. Root perennial; flowers of a deep yellow colour; stem four or five inches long.—It has its name from being discovered on the mountain Della Fontana, near Gemona in Italy, in the clefts of rocks. It flowers in May and June.

15. *Alyssum Utriculatum*; *Bottle Madwort*. Stem herbaceous, erect; leaves smooth, lanceolate, quite entire.—This species is well adapted to decorating walls, or rock-work; it grows in the vineyards of Savoy; and is a hardy and beautiful perennial, flowering from April to June, at which time it begins to form its curiously inflated pods.

16. *Alyssum Vesicaria*; *Bladder Madwort*. Leaves linear, toothed; silicles inflated, angular, acute. This has a trailing stalk, and produces its flowers in loose spikes towards the extremity.—Found in the Levant.

17. *Alyssum Deltoideum*; *Deltoid-leaved Madwort*. Stems under-shrubby, prostrate; leaves lance-deltoid; silicles shaggy. Flowers of a purple colour.—Native of the Levant. It rarely producing seed in this country, may be propagated from its trailing branches; which if planted in April will take root and become good plants by the following autumn. It is properly a rock plant, being hardy, forming with very little care a neat tuft of flowers; and is very valuable from its beginning to flower in March, and continuing through the summer.

Amaranth, Globe. See *Gomphrena*.

Amaranthus; a genus of the class *Monœcia*, order *Pentandria*. **GENERIC CHARACTER.** Male flowers on the same plants with the females. *Calix*: perianth five or three-leaved,

upright, coloured, permanent; leaflets lanceolate, acute. *Corolla*: none, (unless the calix be so termed.) *Stamina*: filaments five or three, capillary, from upright patulous, the length of the calix; antheræ oblong, versatile. *Female flowers in the same racemes with the males.* *Calix*: perianth as in the male. *Corolla*: none. *Pistil*: germ ovate; styles three, short, subulate; stigmas simple, permanent. *Pericarp*: capsule ovate, somewhat compressed, as is the calix, on which it is placed; coloured, and of the same size, three-beaked, one-celled, cut open transversely. *Seed*: single, globular, compressed, large. **ESSENTIAL CHARACTER.** *Male.* *Calix*: three or five-leaved. *Corolla*: none. *Stamina*: three or five. *Female.* *Calix*: three or five-leaved. *Corolla*: none. *Styles*: three. *Capsule*: one-celled, opening horizontally. *Seed*: one.—These plants are generally disposed in pots with Cockscombs, and other showy plants, to adorn court-yards, and other immediate environs of the house. They are tender, and require much care to bring to perfection in England. They are annual herbaceous plants; the leaves simple, alternate ending in a little bristle; the flowers loosely disposed in glomerules or spikes; and are almost all natives of North America; although some are found in the tropical countries of Asia and Africa, and only two in Europe.—The species are,

*With three Stamina.

1. *Amaranthus Græcizans*; *Pellitory-leaved Amaranth*. Glomerules axillary; leaves lanceolate, repand, obtuse; the stem a span high.—It flowers from July to September, and is a native of North America.

2. *Amaranthus Albus*; *White Amaranth*. Glomerules axillary; leaves roundish, ovate, emarginate; stem four-cornered, simple. The stem is greenish white, a span high. A native of the coast of Pennsylvania, from whence it has migrated in Italy; it flowers in July and August.

3. *Amaranthus Deflexus*. Spike very short, with few flowers; leaves rhomb-lanceolate; capsules not gaping.—Its native place is unknown.

4. *Amaranthus Polygonoides*: *Spotted-leaved Amaranth*. Glomerules three-leaved; female flowers funnel-shaped; leaves rhomb-ovate, emarginate. This species varies in different situations; in a hot-bed, the stems were a foot high, and the whole plant green except the calicés; and in the open air the stem was red, and six inches high. It is found wild by the way-side, and among rubbish, in the tropical countries of Asia, Africa, and America; as in Jamaica, Guiana, Senegal, Guinea, Ceylon, &c. It was brought to England in 1778, and flowers in August.

5. *Amaranthus Polygamus*; *Hermaphrodite Amaranth*. Glomerules two-stamined, subspliked, ovate; flowers hermaphrodite and female; leaves lanceolate. Stem upright, eighteen inches high.—It is a native of Guiana, China, and Amboyna, where the inhabitants boil and eat the leaves and stalks. It flowers in July.

6. *Amaranthus Mangostanus*, Glomerules subspliked, axillary, solitary; leaves rhomb-roundish.—Native of the East Indies.

7. *Amaranthus Inamænus*. Glomerules subspliked, three-leaved, axillary, geminate; leaves rhomb-lanceolate. Stem a foot and half high. Supposed to be a native of Japan.

8. *Amaranthus Melancholicus*; *Two-coloured Amaranth*. Glomerules axillary, peduncles roundish; leaves ovate-lanceolate, coloured. Stem upright, half a foot high. In the open air, the leaves are of a dirty purple on their upper surface, and the younger ones are green; in a stove, the whole plant is of a fine purple colour. It is well worth a place in a pleasure garden, but is very tender, and requires some art and

care to bring them to perfection in England.—It is a native of the East Indies and of Guiana. The leaves have two colours, an obscure purple, and a bright crimson, so blended as to set off each other, and making a fine appearance when the plant is vigorous. See the twenty-third species, for its propagation, cultivation, &c.

9. *Amaranthus Gangeticus*; *Oval-spiked Amaranth*. Glomerules in very short spikes, ovate; leaves ovate-lanceolate, emarginate. Stem a foot high.—A native of Bengal, and the Society Isles, and flowers from July to September.

10. *Amaranthus Oleraceus*; *Eatable Amaranth*. Glomerules axillary, branching; leaves wrinkled, oblong, very obtuse, emarginate. Stem upright, a foot or a foot and half high, even, smooth, round, and white; leaves pale green.—It is a native of Guiana, the East Indies, and Egypt, but is not entitled to a place in gardens on account of its beauty. This and the next species are gathered in India when young, and dressed as we dress spinach: it flowers in July.

11. *Amaranthus Viridis*; *Green Amaranth*. Glomerules axillary, geminate; male flowers trifid; leaves ovate, emarginate. Stem erect, a foot or a foot and half high; leaves a bright green in open situations, but dusky in the shade.—Native of Brazil; flowering in August and September.

12. *Amaranthus Tricolor*; *Three-coloured Amaranth*. Glomerules sessile, roundish, stem-clasping; leaves lanceolate-ovate, coloured. Stem upright, a foot and half or two feet in height; leaves blue, with a red point. It has long been celebrated for the beauty of its variegated leaves, in which the colours are elegantly mixed.—Native of Guiana, Persia, Ceylon, China, Japan, the Society Isles, &c.

13. *Amaranthus Lividus*; *Livid Amaranth*. Glomerules subspliked, rounded; leaves elliptic, retuse; stem upright, two feet high, hollow, dark red, smooth, round, deeply streaked or grooved. Leaves dusky green, with pale purple veins; flowers green.—Native of Virginia and Guiana.

14. *Amaranthus Tristis*; *Round-headed Amaranth*. Glomerules in loose spikes; leaves subcordate, ovate, emarginate, shorter than the petioles; stem upright, a foot and half high, leaves and flowers green.—Native of China, Cochin, Amboyna and Brazil; where the young plant is eaten by the natives, as the spinach is with us. It flowers from June till August.

15. *Amaranthus Blitum*; *Least Amaranth*, or *Blite*. Glomerules subspliked; flowers three-leaved; leaves ovate, retuse. Stem diffused, a span high, upright, streaked, smooth; leaves smooth, green, emarginate, with a very short white point.—Native of all Europe, except the very cold parts, Japan, &c. in cultivated grounds, on dunghills, banks, among rubbish, &c. Culpeper recommends this plant as excellent to restrain the fluxes of blood in either sex; and states, that there is a sort of wild Blites, resembling the other wild kinds, but having long and spiky heads of greenish seeds, appearing by their thick setting together, to be all seed, at which fish will bite with great avidity; and adds that it is much sought after by anglers.

16. *Amaranthus Scandens*; *Climbing Amaranth*. Spikes interrupted, compound; spikelets bent; in leaves ovate; stem weak, two feet high.—It resembles the preceding species; and is a native of America.

**With five Stamina.

17. *Amaranthus Hecticus*. Flowers in simple spikes, axillary, glomerate; leaves ovate, acute. Stem red, nearly a foot high.—Its native place is unknown.

18. *Amaranthus Hybridus*; *Clustered Amaranth*. Racemes decomposed, heaped, erect; leaves ovate-lanceolate. Stem two feet high, and double that height in gardens, green or red, upright, smooth, streaked. There are several

AMARANTHUS. *Bloody Amaranth.*

varieties.—It is found wild in Virginia, and Arabia Felix : it flowers from June to September.

19. *Amaranthus Strictus*. Racemes compound, erect strict ; leaves ovate, concave. Stem two feet high or more, obscurely angular.—Place of growth unknown.

20. *Amaranthus Lætus*. Racemes compound, erect ; leaves ovate, obtuse, mucronate. Stem never exceeding a foot in height ; leaves green, smooth ; the point herbaceous.

21. *Amaranthus Cruentus* ; *Various-leaved Amaranth*. Racemes decomposed, naked, patulous ; leaves lanceolate-ovate. Stem a foot and half or two feet in height, grooved ; green, with red streaks, smooth, slightly pubescent among the flowers.—Native of the East Indies and China ; flowering from June to August. Propagated as the 23d species.

22. *Amaranthus Hypochondriacus* ; *Prince's-feather Amaranth*. Racemes compound, crowded, erect ; leaves oblong-lanceolate, mucronate. Stem erect, a foot and half, or two feet high.—It is a native of Virginia, and flowers from July to September. It is now become a common weed, growing upon dunghills.

23. *Amaranthus Sanguineus* ; *Spreading or Bloody Amaranth*. Racemes compound, erect ; branches spreading, smooth ; leaves oblong, acute. Stem four feet high ; flowers of a bright purple colour, turning darker as the seeds ripen. It flowers from the middle of June until September.—To propagate this species, the seeds should be sown in a moderate hot-bed, towards the end of March. The plants must be transplanted, when large enough, to another moderate hot-bed, where they must be watered, and shaded from the sun, till they have taken new root ; and then should have free air always during mild weather. At the beginning of June, they may be taken up, with large balls of earth to their roots, and planted, some in pots, and others into the borders of the pleasure garden, observing to shade them until they have taken good root ; after which they must be frequently watered in dry weather, especially those in pots, which will require it every evening in warm dry-weather. These plants are a great ornament to good gardens during the latter part of summer.

24. *Amaranthus Paniculatus*. Racemes compound ; branches spreading, pubescent ; leaves ovate-lanceolate. Stem upright, firm, a fathom in height, grooved.—Native of America.

25. *Amaranthus Retroflexus* ; *Hairy Amaranth*. Racemes super-decompound, erect ; branches pubescent ; leaves ovate. Stem three-feet high.—A native of Pennsylvania ; and now a common weed in gardens near London.

26. *Amaranthus Chlorostachys*. Racemes compound, nodding ; leaves lanceolate. Stem four feet high.—Its native place of growth unknown.

27. *Amaranthus Flavus* ; *Pale Amaranth*. Racemes compound, nodding ; leaves ovate-lanceolate. Stem sometimes exceeding four feet high ; flowers green. The Portuguese cultivate it as a culinary herb.—Native of the East Indies.

28. *Amaranthus Caudatus* ; *Pendulous Amaranth*, or *Loves-bleeding*. Stem generally two feet high ; leaves a bright green colour.—Native of Persia, Ceylon, Guiana, Peru, &c.

29. *Amaranthus Spinosis* ; *Prickly Amaranth*. Racemes terminating, compound ; axils thorny. Stem upright, from twelve to eighteen inches high. In the East and West Indies it is eaten as a green, boiled with *Basella Cordifolia*. Native of Guiana and Guinea, and flowering from July to September.

Amaryllis ; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix* : spathe oblong, obtuse, compressed, emarginate, gaping on the flat side, and withering. *Corolla* : petals six, lanceolate ; nectary six very short scales, without the base of the filamenta. *Stamina* :

filamenta six, awl-shaped, with oblong, incumbent, rising antheræ. *Pistil* : germen roundish, furrowed, inferior ; style filiform, almost of the length, and in the situation, of the stamina ; stigma trifid, slender. *Pericarp* : a subovate, three-celled, three-valved capsule. *Seeds* : several. ESSENTIAL CHARACTER.—*Corolla* : six-petalled, irregular ; filamenta inserted into the throat of the tube, bending down, unequal in proportion or direction.—These plants are of the liliaceous or bulbous tribe ; most of them have flowers of singular beauty, highly deserving the care and attention of the curious botanist and florist. The best time to transplant the roots of all the species is about the beginning of August, when their leaves are decayed : they delight in a loose sandy soil, mixed with good kitchen mould. There should be little water given when their leaves are decaying ; but when putting out their flowering stems, they should frequently be refreshed with water.—The species are,

1. *Amaryllis Lutea* ; *Yellow Amaryllis*, or *Autumnal Narcissus*. Spathe undivided, obtuse ; flower sessile ; corolla bell-shaped, erect, shortly tubular at the base ; stamina erect, alternately shorter. Its flowers seldom rise above three or four inches high ; they are shaped somewhat like those of the large yellow *Crocus*.—It flowers in September, and is a native of the south of France, Spain, Italy, and Thrace. It is very hardy, and increases fast by offsets ; is a pretty plant ; and continues flowering until November, if the frost do not destroy the flowers. It will grow in any soil or situation, but thrives best in a fresh, light, dry soil, and open situation.

2. *Amaryllis Pumilio* ; *Dwarf Amaryllis*. Spathe two-leaved, one-flowered ; corolla funnel-shaped, equal ; segments revolute ; stamina bent in, alternately shorter.—Native of the Cape ; flowering in November.

3. *Amaryllis Atamasco* ; *Atamasco Lily*. Spathe bifid, acute ; flower pedicelled ; corolla bell-shaped, nearly equal, erect, shortly tubular at the base ; stamina bent down, equal. The flowers are of a fine carnation colour on the outside at their first appearance, but fade till they become almost white ; they are nearly as large as those of the Orange Lily, but do not grow above six or eight inches high, appearing at the end of May, or beginning of June, and sometimes in August.—It is a native of Virginia and Carolina, where it grows plentifully in the fields and woods, making a beautiful appearance when in flower. It may be propagated by offsets from the bulbs ; and, if planted in a warm situation, will bear the open air of England.

4. *Amaryllis Formosissima* ; *Jacobæa Lily*. Spathe undivided ; flower pedicelled ; corolla two lipped, nodding, deeply six-parted ; stamina and pistil bent down. The flowers are large, of a deep red ; the under petals very large ; and as the whole flower stands nodding on one side of the stalk, it makes a most beautiful appearance. It is a native of South America. It is propagated by offsets, which may be taken off every year in August ; and planted in pots of a middling size, having a moderate degree of warmth, will produce flowers plentifully, especially from March to September.

5. *Amaryllis Reginæ* ; *Mexican Lily*. Spathe with about two flowers ; pedicels divaricating ; corollas bell-shaped, shortly tubular, nodding ; throat of the tube hirsute ; leaves lanceolate, patulous. Corolla scarlet, with a bottom of a whitish green, the flower-stems seldom rising more than one foot high. It is in beauty in February ; and, in a moderate temperature of air, will flower in March or April. It requires a warm stove.

6. *Amaryllis Purpurea* ; *Purple-flowered Amaryllis*. Spathe with about two flowers ; corollas somewhat erect, tubular at the base ; throat of the tube smooth ; leaves linear-lanceolate.

The corolla is large, and of a blood-red purple colour.—It is a native of the Cape.

7. *Amaryllis Equestris*; *Barbadoes Lily*. Spathe with about two flowers; pedicels erect, shorter than the spathe; tube filiform, horizontal; border spreading open obliquely, and curved upwards; throat hairy.—Native of the West Indies.

8. *Amaryllis Reticulata*; *Flat-stalked Amaryllis*. Spathe with about two flowers; corollas tubular at the base and nodding; throat of the tube smooth; scape compressed; leaves oblong, attenuated at the base.—It flowers in April; and is a native of Brazil.

9. *Amaryllis Belladonna*; *Belladonna Lily*. Corollas somewhat erect, six-petalled; petals flat; scape compressed; leaves sharply channelled, bluntly keeled, very smooth.—It is a very ornamental plant in a garden: the stem rises upwards of two feet high, the flowers are of a soft purple colour appearing about the end of September, or beginning of October, in England; and will continue in beauty a month or longer, in a favourable season.—It was originally imported from Portugal; but is a native of shady hills, by the side of streams, in the West Indies. To cultivate this species, remove all the earth to the depth of three feet, from a border close to a wall, with a south-west aspect; put six inches depth of very rotten dung at the bottom, then replace the original mould to the depth of twenty inches. Plant the roots every way six inches apart, then cover them to the former height of the border, with light sandy earth, and cover the whole three inches deep with rotten tanner's bark, to keep out the frost. This process has been very successful, producing a great many flowers, and making a fine appearance in October.

10. *Amaryllis Vittata*; *Superb or Ribband Amaryllis*. Flowers pedicelled; corollas wedge-funnel-shaped, the rachis of the outer fastened to the edge of the inner petals; scape round; stigmas grooved. This species rarely puts forth off-sets from the roots, but readily produces seeds, by which it is propagated without difficulty. The stem rises to three feet or more, producing from two to five beautiful flowers. It usually blossoms from April to May, but may be forwarded by artificial heat.—Native country unknown.

11. *Amaryllis Falcata*; *Sickle-leaved Amaryllis*, or *Crinum*. Corollas peduncled, erect, six-petalled; scape compressed, length of the umbel; leaves flat, pressed to the ground, about the edge sickle-shaped, white-cartilaginous, crenate. Flowers sweet-scented; corolla white.—Native of the Cape.

12. *Amaryllis Oranata*; *Cape Coast Lily*, or *Amaryllis*. Flowers sessile; corollas tubular at the base; tube longer than the spathe, and border curved; segments of the border oblong, awned, lowest segments divaricate, concave.—Native of Guinea, flowering in June and July.

13. *Amaryllis Longifolia*; *Long-leaved Amaryllis*. Flowers pedicelled, from twelve to twenty in a spathe; corollas tubular at the base; tube curved, short; segments of the border lanceolate, obtuse; leaves broad, subulate, channelled, flaccid at the tip. Flower-stem rarely rising more than three or four inches high; flowers of a deep purple colour, appearing in December.—Native of the Cape; and may be propagated and cultivated in the same manner as the fourth species.

14. *Amaryllis Revoluta*; *Revolute Amaryllis*. Flowers pedicelled; corollas tubular at the base; tube filiform, short, curved; leaves linear-narrow, channelled, long, flaccid from their origin. Scape a foot high; flowers sweet-scented, and of a pale red colour, appearing in Sept.—Native of the Cape.

15. *Amaryllis Aurea*; *Golden Amaryllis*. Flowers pedicelled, somewhat erect; corollas funnel-form club-shaped, almost six-petalled; segments linear-lanceolate; stamina and

style straight; leaves linear, erect, channelled, with a reflex smooth margin. Corolla yellow; scape scarcely two feet high.—A native of China; flowering in August and September.

16. *Amaryllis Orientalis*; *Broad-leaved African Amaryllis*. Spathe many-flowered; flowers pedicelled, six-parted, considerably shorter than the peduncles, irregular; germina wedge-shaped, angular.—Native of the Cape.

17. *Amaryllis Sarniensis*; *Guernsey Lily*. Petals linear, flat, stamina and pistilla straightish, longer than the corolla; stigmas parted, revolute; leaves dark willow green. Scape flattened, twelve or fourteen inches high; corolla, when in its prime, has the colour of a fine gold tissue, wrought on a rose-coloured ground; and, when it begins to fade, it is a pink; when beheld in full sunshine, it seems to be studded with diamonds, but by candle-light, the specks or spangles look more like fine gold dust; when the petals begin to wither, they assume a deep crimson colour. The flowers begin to come out at the end of August, and the head is usually three weeks in expanding gradually.—This beautiful plant is a native of Japan, and has been long naturalized in Guernsey, where it is reputed to owe its introduction to the shipwreck of a vessel returning from Japan, probably before the middle of the last century. The roots are sent over from Guernsey to England, and should be planted in pots filled with fresh, light, sandy earth, mixed with a little very rotten dung, placed in a warm situation, where they must be occasionally watered. The bud will appear about the middle of September, and must then have the full benefit of the sun, being sheltered from strong winds. When the flowers begin to open, the pots should be removed under shelter, to prevent the flowers being injured by too much wet, but not kept in too close and warm a place, as that will weaken their colour, and hasten their decay. They will continue in beauty a full month, if properly managed; and, though they have no scent, they are justly placed in the first rank of the flowery tribe. After the flowers decay, the leaves will continue growing all the winter, and should have fresh air every day in fine weather. The roots should be transplanted every fourth or fifth year, at the latter end of June or beginning of July, and ought to be replanted into fresh earth.

18. *Amaryllis Undulata*; *Waved-flower African Amaryllis*. Petals linear, channelled, waved; stamina and pistil bent down, shorter than the corolla; stigma obsolete. Petals rose-coloured. The flowers have no scent, and expand from November to the beginning of January.—Native of the Cape; flowering in England from April till June.

19. *Amaryllis Radiata*; *Snowdrop-leaved Amaryllis*. Petals lanceolate, waved; stamina and pistil bent down, diverging, twice as long as the corolla; stigma obsolete.—This species flowers in June; its native country not known.

20. *Amaryllis Montana*. Spathe many-flowered; leaves linear, subulate; petals alternate, mucronate; stamina and style erect. Stem upright; petals blue; seeds ovate oblong, black.—Native of the higher parts of Mount Lebanon.

21. *Amaryllis Tubispatha*. Spathe one-leaved, tubular, bifid, one-flowered; peduncle twice as long as the spathe. Scape erect, four inches high.—Native of Buenos Ayres.

22. *Amaryllis Tubiflora*. Spathe one-flowered, two-leaved; corolla funnel-shaped, with a very long tube.—Found in Peru.

23. *Amaryllis Spiralis*. Spathe two-leaved, few-flowered; peduncles filiform, very long; leaves subulate. Corolla six-parted; scape twisted at the base.—Native of the Cape.

24. *Amaryllis Maculata*. Spathe one-flowered, two-leaved, linear; flower peduncled; stamina and style bent down. Scape variegated with linear spots; corolla bell-shaped.—It was found in China by Dombey.

25. *Amaryllis Chilensis*. Spathe one or two flowered, one or two leaved, lanceolate; flowers peduncled; leaves linear.—Has purple flowers; and was found in Chili by Dombey.

26. *Amaryllis Clavata*. Spathe one-flowered, two-leaved, subulate; corolla club-shaped.—Native of the southern part of Africa.

27. *Amaryllis Zeylanica*; *Ceylon Lily*. Spathe many-flowered; corollas reclining; tube filiform, very long; segments uncinatè. Tube of the corolla of the same rufous colour as the scape; oorder white, with lanceolate recurved petals, with a red keel underneath; filamenta and style blood-red; pericarps viviparous.—Native of the East Indies.

28. *Amaryllis Latifolia*. Spathe many-flowered; flowers pedicelled, somewhat reclining, tubular at the base; leaves oblong-lanceolate. Scapes, tube of the flower, and stamina, purple coloured.—It is a native of the East Indies. This plant may be increased by offsets from its roots, or by the bulbs which succeed the flowers.

29. *Amaryllis Cinnamomea*. Spathe many-flowered; corollas subhexapetalous, lanceolate, waved; stamina and pistil erect, shorter than the corolla.—Found at the Cape.

Amasonia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, semiquinquefid, acute, equal, permanent. *Corolla*: one-petalled, tubulous, longer than the calix; border quinquefid, subequal, spreading, small. *Stamina*: filamenta four, at the upper side of the corolla, and longer than it, bending in at the end, two of them shorter; antheræ oval, incumbent. *Pistil*: germen ovate; style in the situation and form of the stamina; stigmas two, sharp. *Pericarp*: none. *Seed*: an ovate one-celled nut, of the same length with the calix. ESSENTIAL CHARACTER. *Corolla*: tubulous; limb small, quinquefid. *Nut*: ovate, one-celled.—There is only one species, viz.

1. *Amasonia Erecta*.—A native of Surinam; the stem herbaceous, three feet in height, round, and quite simple. The flowers in a simple terminal raceme, a foot long, with about three upon a pedicel; bractes ovate, sessile, a little longer than the flowers, which are yellow, nodding, and grow on one side of the stalk.

Amber-tree. See *Anthospermum*.

Ambrosia; a genus of the class Monœcia, order Pentandria.—GENERIC CHARACTER. *Male Flowers compound*. *Calix*: perianth common one-leaved, flat, of the same length as the floscules. *Corolla*: compound, uniform, tubulous, equal, hemispherical; proper one-petalled, tubulous, funnel-shaped, erect, quinquefid. *Stamina*: filamenta very small; antheræ erect, parallel, acuminate. *Pistil*: style filiform, length of the stamina; stigma orbiculate, membranaceous. *Receptacle*: common scarcely any, naked. *Female flowers below the male, doubled*. *Calix*: perianth one-leaved, acuminate, entire, permanent, the belly five-toothed, one-flowered. *Corolla*: none. *Pistil*: germen ovate, in the bottom of the calix; style filiform, of the same length with the calix; stigmas two, setaceous, long, divaricate. *Pericarp*: a subovate nut, formed from the calix, hardened, one-celled, not opening, crowned with the five acuminate teeth of the calix. *Seed*: single, roundish. ESSENTIAL CHARACTER. *Male*. *Calix*: common, one-leaved. *Corolla*: one-petalled, trifid, funnel-shaped. *Receptacle*: naked. *Female*. *Calix*: one-leaved, entire, the belly five-toothed, one-flowered. *Corolla*: none. *Nut*: of the hardened calix, one-seeded.—The species are,

1. *Ambrosia Trifida*; *Trifid-leaved Ambrosia*. Leaves three-lobed, serrate.—Grows eight or ten feet high; it is a common weed in North America, and is only preserved by the curious in botany. The seeds, though sown in spring,

seldom come up till the second year, when they may be transplanted into a moist rich soil, every way four or five feet apart. If suffed to scatter their seeds, they will vegetate in the following spring.

2. *Ambrosia Elatior*; *Tall Ambrosia*. Leaves pinnatifid, racemes panicled, terminal, smooth. It is an annual herbaceous plant.—Native of Jamaica, where it is found in barren, sandy, and rocky situations, by the sides of rivers, in the southern parts of the island. It flowers there from February till June, but with us from July to the end of August. This plant has the appearance and taste of Wormwood; and will thrive, but not produce good seed, in our open air.

3. *Ambrosia Artemisifolia*; *Mugwort-leaved Ambrosia*. Leaves bipinnatifid; the first leaves at the origin of the smaller branches undivided, and quite entire. The primary stem is scarcely more than a foot high.—Native of America.

4. *Ambrosia Maritima*; *Sea Ambrosia*. Leaves multifid; spikes solitary, hairy, subsessile. Rises about two feet and a half high; the leaves emit a strong odour upon being handled; the spikes of flowers are axillary. It is not remarkable for beauty, and seldom perfects its seeds in England.—Found in Cappadocia, Tuscany, &c., on sandy shores.

5. *Ambrosia Arborescens*; *Tree Ambrosia*. Leaves pinnatifid, hirsute; racemes solitary, terminating; stem shrubby. This species grows to the height of ten or twelve feet, with a woody stem dividing into several branches. Perennial.—Native of Peru. It may be propagated by cuttings or seeds; the former planted in a shady border during any of the summer months, and well watered. The seeds when sown in the spring seldom appear till the spring following.

Ambrosinia; a genus of the class Gynandria, order Polyandria.—GENERIC CHARACTER. *Male*. *Calix*: spathe one-leaved, cowlèd, convolute at the base, converging at the tip; partition membranaceous, divided into two cells, communicating at top. *Corolla*: none. *Stamina*: filamenta none; antheræ very many, solitary, within the hinder cell of the spathe, in the upper part of the partition, digested in a distinct order; nectaries two, roundish, concave, at the base of the antheræ. *Female*. *Calix*: spathe common with the males. *Pistil*: germen in the interior cell of the spathe, and the lower part of the partition, solitary, roundish; style cylindrical, shorter than the spathe; stigma obtuse. *Pericarp*: capsule roundish, one-celled. *Seeds*: very many, ovate, nestling. ESSENTIAL CHARACTER. *Spathe*: one-leaved, separated by a partition. *Stamina*: on the inner, *Pistilla*, on the outer side of it. The only species is,

1. *Ambrosinia Bassii*. Roots perennial, tuberous, acrid. Leaves radical, petiolate, ovate, shining; they appear at the beginning of autumn, and decay in spring.—It is a native of Sicily, near Palermo. May be propagated by the root, and requires the protection of a green-house.

Amellus; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common imbricate, roundish. *Corolla*: compound radiate; corollets hermaphrodite, very many in the disk, females very many in the ray. Proper of the hermaphrodites, tubulous, five-cleft; female, ligulate, lax two or three toothed. *Stamina*: in the hermaphrodites; filaments five, capillary, short; antheræ cylindrical, tubulous. *Pistil*: in the hermaphrodites; germen obovate; style filiform, the length of the stamina; stigmas two, filiform. Females very like the hermaphrodites. *Pericarp*: none; calix unchanged. *Seeds*: to the hermaphrodites, solitary, obovate. *Down*: capillary, to the females, very like the others. *Receptacle*: chaffy. ESSENTIAL CHARACTER. *Calix*: imbricate. *Corollets*: of the ray, undivided. *Down*: simple. *Receptacle*: chaffy.—The species are,

1. *Amellus Lychnitis*; *Trailing Amellus*. Leaves opposite, lanceolate, obtuse, downy; peduncles one-flowered. This plant rises from two to three feet high, sending out branches on every side, terminated by flower-stalks, each supporting one violet-coloured flower, with a yellow disk, which appears in July or August.—It grows naturally at the Cape; and is a perennial plant, easily propagated by cuttings planted in the shade during any of the summer months, and duly watered. They must be sheltered in winter.

2. *Amellus Umbellatus*; *Umbelled Amellus*. Leaves opposite, three-nerved, downy underneath; flowers umbelled. Stem from two, to two and a half feet high; flower yellow.—Native of the cooler woods and mountains of Jamaica, where it flowers in summer. It may be propagated by seeds sown in a hot-bed in the spring.

American Earth-nut. See *Arachis*.

Amerimum; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved; tube bell-shaped, five-toothed; teeth sharp. *Corolla*: papilionaceous; standard with an oblong claw, roundish, heart-shaped, expanding, convex; wings lanceolate, shorter than the standard; keel short. *Stamina*: filamenta ten, conjoined; antheræ roundish. *Pistil*: germen pedicelled, oblong, compressed, leafy, varicose, with lateral veins, within woody, not gaping; cells disposed longitudinally within. *Seeds*: solitary, kidney-shaped, thicker at the base, appendicled at the tip. ESSENTIAL CHARACTER. *Calix*: two-lipped. *Legume*: compressed, leafy, two-valved, gaping. *Seeds*: few, solitary.—The species are,

1. *Amerimum Brownei*. Unarmed: leaves petioled, alternate, subcordate-ovate; racemes compound, axillary, and lateral. The shrub rises to the height of ten feet; the flowers, which are white, and have a very sweet scent, come out in great abundance after the rainy season.—Native of Carthage, Jamaica, and Domingo.

2. *Amerimum Ebenus*; *Prickly Amerimum*, or *Jamaica Ebony*. Spiny; leaves subsessile, aggregate, obovate, oblong; peduncles two-flowered.—This is common in Jamaica, and is sent to England under the name of Ebony; though it is not the true ebony, but a plant of a very different genus. The wood being of a fine greenish brown colour, and polishing well, is much coveted by instrument makers, and is of a very hard and durable nature. It is propagated by seed, which must be procured from its native climate, and sown in pots of light earth early in the spring. They will not bear the open air of this country.

Amethystea; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved; tube bell-shaped, angular, semiquinquefid, subequal, acuminate, permanent. *Corolla*: one-petalled, ringent, little longer than the calix; border five-parted, subequal; upper lip erect, rounded, concave, two-parted, gaping; lower three-parted, the sides rounded, erect, shorter; the middle quite entire, concave, the length of the upper lip. *Stamina*: filamenta filiform, approximating, under the upper lip, and longer than it; antheræ simple, roundish. *Pistil*: germen quadrifid; style size of the stamina; stigma two, acute. *Pericarp*: none, but the calix becomes more bell-shaped and spreading. *Seeds*: four, shorter than the calix, obtuse, angular within. ESSENTIAL CHARACTER. *Corolla*: quinquefid, the lower division more spreading. *Stamina*: approximated. *Calix*: subcampanulate. *Seeds*: four, gibbous.—Only one species has yet been discovered, viz.

1. *Amethystea Cœrulea*. An annual plant, with an upright stalk, about a foot high. Flowers small, but of a fine blue colour, making a pretty appearance while they continue. The

seeds should be sown in autumn; they will appear in the spring, and only require to be well weeded, and kept from growing too close together.—It is a native of the mountains of Siberia.

Ammannia; a genus of the class Tetrandia, and order Monogynia.—GENERIC CHARACTER. *Calix*: perianth bell-shaped, oblong, erect, with eight streaks and folds, quadrangular, eight-toothed; teeth alternate, bent in, permanent. *Corolla*: none, or four-petalled; petals, vertically ovate, spreading, inserted into the calix. *Stamina*: filamenta (from four to eight) bristly, the length of the calix, into which they are inserted; antheræ twin. *Pistil*: germen subovate, large, superior; style simple, very short; stigma headed. *Pericarp*: a roundish, four-celled capsule, covered with the calix. *Seed*: numerous, small. ESSENTIAL CHARACTER. *Corolla*: four-petalled, inserted into the calix. *Calix*: one-leaved, plaited, eight-toothed, inferior. *Capsule*: four-celled.—The species are,

1. *Ammannia Latifolia*; *Broad-leaved Ammannia*. Leaves half stem-clasping; stalk square; branches erect. Root annual. The plant grows about a foot high, with an upright square stalk; the leaves are of a pale green; the flowers come out in whorls, and the petals white.—It is a native of moist places in Jamaica.

2. *Ammannia Ramosior*; *Branching Ammannia*. Leaves half stem-clasping; stalk square; branches very spreading.—This is an annual plant, a native of Virginia and Carolina, rising about a foot high, with red succulent stalks.

3. *Ammannia Baccifera*; *Berry-bearing Ammannia*. Leaves subpetiolate; capsules larger than the calix, and coloured. A tender, erect, low plant, without branches.—Native of China, and now naturalized in Italy.

4. *Ammannia Octandria*; *Eight-stamined Ammannia*. Flowers petaloid, and eight-stamined. Stem erect; peduncles axillary, very short, three or one flowered; petals blood-red.—Found in the East Indies.

5. *Ammannia Pinnatifida*; *Pinnatifid-leaved Ammannia*. Stalks procumbent, rooting, compressed; leaves linear, pinnatifid. *Corolla* red.—Found in the isle of Java.

6. *Ammannia Debilis*; *Cluster-flowered Ammannia*. Leaves lanceolate, attenuated at the base; stem branching; flowers in bundles from the axils; capsules two-celled. An annual plant; petals pale purple.—It flowers in July and August; and is a native of the East Indies.

7. *Ammannia Sanguinolenta*. Leaves half stem-clasping, cordate at the base; flowers subpeduncled, eight-stamined; perial bearing.—A native of Jamaica and Domingo.

Ammi; a genus of the class Pentandria, and order Digynia.—GENERIC CHARACTER. *Calix*: universal umbel, manifold, frequently of fifty rays; partial short, crowded. Universal involucre of many linear, pinnatifid, acute leaflets, scarcely the length of the umbel; partial many-leaved; leaflets linear, acute, simple, shorter than its umbellet; proper perianth scarcely apparent. *Corolla*: universal uniform, all the floscules fertile; proper of five inflex heart-shaped petals, of unequal size in the ray, almost in the middle of the disk. *Stamina*: filamenta capillary; antheræ roundish. *Pistil*: germen inferior; styles reflex; stigmas obtuse. *Pericarp*: none; fruit roundish, smooth, small, streaked, bipartite. *Seeds*: two, convex, and streaked on one side, flat on the other. ESSENTIAL CHARACTER. *Involucre*: pinnatifid. *Corolla*: radiate, all hermaphrodite. *Fruit*: smooth.—The species are,

1. *Ammi Majus*; *Common Bishop's Weed*. Lower leaves pinnate, lanceolate, serrate; upper ones multifid, linear.—It is an annual, and grows in the vineyards and fields in the southern parts of Europe, and in the East. It is propagated by seeds sown in autumn where they are to remain. In the

spring they must be hoed and thinned like Carrots, leaving them four or five inches asunder, and will afterwards require no further care. It flowers in July, and is common in our gardens. The seeds are the only part of the plant used in medicine; like all other carminatives, they are good against the colic, and are diuretic also; so that they are particularly efficacious in colics arising from the stone in the kidneys and urethra; they also promote the menses.

2. *Ammi Copticum*. Leaves super-decompound, linear; seeds muricate. Stem smooth, and streaked; corollas white, equal, five-angular; seeds aromatic.—Found in Egypt.

3. *Ammi Glaucifolium*; *Perennial Bishops' Weed*. Subdivisions of all the leaves lanceolate. The stem is from one to two feet high; the plant is an annual.—Native of the south of France. It is hardy, thrives best on a moist soil, and will grow in any open situation.

Amomum; a genus of the class Monandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, cylindraceous, unequally trifid. *Corolla*: monopetalous, funnel-shaped; tube cylindraceous; border three parted; parts oblong, spreading, nectary two-leaved, or two-lipped; lower lip inserted under the upper segment of the corolla, spreading, almost erect, entire, or three-lobed. *Stamina*: filamentum none, except the upper lip of the nectary, smaller than the lower, and opposite to it, acuminate or three-lobed at the tip; along the middle, or at the end of which, grows longitudinally a large oblong antheræ, germinate, or divided by a longitudinal furrow into two, which are one-valved. *Pistil*: germen inferior, oblong; style filiform, drawn through the suture of the antheræ; stigma turbinate, obtuse, ciliate. *Pericarp*: capsule fleshy, ovate, three-cornered, three-celled, three-valved. *Seeds*: several, covered with a sort of berried aril. **ESSENTIAL CHARACTER.** *Calix*: trifid, unequal, cylindrical. *Corolla*: three-parted, unequal, spreading. *Nectary*: two-lipped, almost erect.—All the species of this genus are tender, and require a warm stove to preserve them in this country; and are propagated by parting their roots, early in the spring. In the West Indies, ginger thrives best in a rich cool soil; in a more clayey soil, the roots shrink less in scalding. The land laid out for the culture of it, is first well cleared and hoed, then slightly trenched, and planted in March or April; it flowers about September: when the stalks are wholly withered, the roots are fit to take up, which is generally done in January and February.—The species belonging to this genus are,

1. *Amomum Zinziber*; *Narrow-leaved Ginger*. Scape middle-sized; spike ovate; leaves linear-lanceolate. The corolla is a yellowish green.—It is a native of the East Indies, and largely cultivated both there and in the West Indies. The root is less liable to heat the constitution, than might be expected. A syrup, made from an infusion of three or four ounces of the root in three pints of boiling water, is kept in the shops. The cases in which it is more immediately serviceable are flatulent colics, debility and laxity of the system, and in torpid and phlegmatic constitutions, to excite a brisker action of the vessels. Ginger is a warm and grateful aromatic; it strengthens the stomach, disperses wind, helps digestion, prevents or cures the colic, and is useful in all cold flatulent disorders and weaknesses of the intestines. It is one of the best additions that can be made to rough purging medicines, in order to prevent them from griping in the operation.

2. *Amomum Zerumbet*; *Broad-leaved Ginger*, or *Zerumbet*. Scape naked; spike oblong, obtuse. Culm four feet high, perennial, straight, and quite simple; corolla pale.—It is a native of the East Indies, Cochin-china, Otaheite, and the other Society Isles. It flowers with us from September to

November; and is used in the East externally in cataplasms and fomentations. The root is used as warm and good in all nervous cases, its virtues nearly resembling those of Zedoary, which is often sold under its name, though in reality it is a much longer and larger root than the Zedoary itself.

3. *Amomum Sylvestre*; *Great Wild Ginger*. Scape naked; spike elongate, with oblong ventricose bractes; leaves broad lanceolate. This resembles the foregoing species, but grows higher.—It is a native of Jamaica, where it is common in the woods. The root is warm, and gently stimulant; it may be properly administered as a stomachic and alexipharmic.

4. *Amomum Mioga*; *Japanese Ginger*. Scape very short; capsule ovate; leaves ensiform, acute. Root fusiform, fibrose, aromatic.—A native of Japan, where it flowers in September.

5. *Amomum Cardamomum*; *Cardamom*. Scape very simple, and short; bractes alternate, loose. It has thick fleshy roots, which in the spring send forth many green reed-like stalks, which rise to the height of seven or eight feet, garnished with very long narrow leaves; but it has not yet flowered in England. The seeds are the only parts used in medicine, and when freed from their husks are a grateful aromatic, warm, but not fiery; not heating and inflaming, like many other seeds of this nature. The seeds should never be separated from their husks till wanted for use, for in that case they lose much of their flavour and virtue. They are an excellent cordial, and peculiarly grateful to the stomach, dispersing wind, creating an appetite, and strengthening the digestive faculties. There is a spirituous distilled water and tincture of them kept in the shops, either of which are more agreeable than the seeds themselves, and equally efficacious. A glass taken after eating flatulent food, is serviceable in preventing or removing that disagreeable eructation or rising which frequently succeeds. The tincture is also occasionally used as a pleasant warm cordial, as well as for flavouring other medicines. The Lesser Cardamom seeds are said to be excellent for colics and disorders of the head, when chewed singly in the mouth; and their taste is not at all disagreeable.

6. *Amomum Villosum*. Scape short, reclining; bractes linear; fruit villose. Culm six feet high; corolla pale. The smell of the whole plant is aromatic, mild, and slightly sharp. The root has a sweetish and pleasant taste when fresh.—It is a native of China; where the seeds are in much request as a medicine.

7. *Amomum Medium*. Spine cauline, branched; fruit oblong, streaked, valveless. Culm straight, single, eight feet high.—Native of Yunan, in China: where the seeds are used in agues; for culinary purposes; and to increase the strength of any odours whatever.

8. *Amomum Globosum*. Spike cauline, branched; fruit globose, with an even surface. Culm four feet high.—A native of China and Cochin-china; and used medicinally in both countries, in disorders of the bowels, &c.

9. *Amomum Hirsutum*. Spike cauline, simple, reclining; fruit roundish, hirsute. Culm six feet high; the smell and taste very weak.—A native of Cochin-china, in woods.

10. *Amomum Granum Paradisi*; *Grains of Paradise*. Scape branching, very short.—It is a native of Guinea, and of the islands of Ceylon and Madagascar, from whence we receive the seeds, which are of a warm aromatic nature, much resembling pepper, for which they are frequently substituted in many places. They are but little used in medicine, but might prove useful in cold flatulent disorders, the colic, &c.

11. *Amomum Galanga*; *Galangale*. Spike cauline, erect; spathes nearly three-flowered; capsule three-cornered-ovate, smooth. The culm is perennial, entirely simple, upright, smooth, and six feet high. The smell of the whole plant is

aromatic, and it has a biting taste.—It is a native of China and Cochin-china, where it is cultivated, and the roots and seeds, used medicinally. The plant was formerly used as a warm stomachic bitter, and generally made an ingredient in bitter infusions; but it is now almost wholly laid aside, on account of its unpleasant flavour. The spirituous extract is excessively fiery, and the watery extract very hot and pungent. The essential oil has little smell, and no great pungency. An infusion of the root in boiling water, or a tincture made with brandy, is a good medicine in windy complaints, and other disorders of the stomach, as well as for head-achs which arise from some debility or evil affection in that organ. The same root is usually given in the shops for Galangale and for Zedoary.

12. *Amomum Arboreum*. Stem arboreous; fruit calicine. This tree is ten feet high, with many twisted spreading branches; with a pale red flower. It has scarcely any taste or smell, and its use unknown. The wood is very light, not even fit for the fire.—Native of the eastern coast of Sumatra.

Amorpha; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, tubulous, cylindrical, turbinate; mouth erect, five-toothed, obtuse, the two upper teeth larger than the others, permanent. *Corolla*: of one ovate concave petal, scarcely larger than the calix, erect, inserted into the calix, between the two larger and upper teeth, and placed at the upper side of it. *Stamina*: filamenta very slightly united at the base, erect, unequal in length, longer than the corolla; antheræ simple. *Pistil*: germen roundish; style subulate, the length of the stamina; stigma simple. *Pericarp*: legume lunulate, reflex, larger than the calix, compressed, more reflex at the tip, one-celled, tubercled. *Seeds*: two, oblong kidney-shaped. **ESSENTIAL CHARACTER.** *Standard of the Corolla*: ovate, concave. *Wings*: none. *Keel*: none.—The only species yet discovered is,

1. *Amorpha Fruticosa*; *Bastard Indigo*. It rises with many irregular stems to the height of twelve or fourteen feet: with very long winged leaves; at the extremity of the same year's shoots branch out long spikes of purple flowers in July; but it does not ripen seed in England, although it is become very common in all gardens and nurseries. It is propagated by seeds from abroad, and also by laying down young branches in sheltered situations.—Native of Carolina.

Amygdalus; a genus of the class Icosandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, tubulous, inferior, quinquefid, deciduous; divisions spreading, obtuse. *Corolla*: of five petals, oblong-ovate, obtuse, concave, inserted into the calix. *Stamina*: filaments about thirty, filiform, erect, shorter by half than the corolla, inserted into the calix; antheræ simple. *Pistil*: germen roundish, villose; style simple, length of the stamina; stigma headed. *Pericarp*: a drupe, roundish, villose, large, with a longitudinal furrow. *Seed*: a nut, ovate, compressed, acute, with prominent sutures on each side, reticulated with furrows, and dotted with small holes. **ESSENTIAL CHARACTER.** *Calix*: quinquefid, inferior. *Petals*: five. *Drupe*: having a shell perforated with pores; skin pubescent.—The species are,

1. *Amygdalus Persica*. The *Peach* and *Nectarine*. All the serratures of the leaves acute; the flowers sessile and solitary.—The wood of the Peach-tree is of a reddish brown colour, darker toward the middle, and fit for the use of the turner. It is of quick growth, and not of very long duration. There are many varieties, the best of which are,—the early Purple Peach, which is ripe before the middle of August; the large or French Mignon (*Grosse Mignon*;) the Chev-

reuse, or Belle Cheveruse, ripe towards the end of August; the Red Magdalen; Chancellor; Bellegrade; Bourdine; Rossanna; Rambouillet; and Nivette. Others recommend the Small Migaon, Early Newington, Noblesse, Admirable, Royal, Monstrous Pavy, and Swalch. These are the best sorts for planting; but in warm situations one or two trees of the Catharine Peach should be admitted, as it is an excellent fruit in warm seasons. The *Nectarine* is only a variety of the Peach-tree, somewhat smaller: there are twelve sorts, the best of which are Fairchild's Early Nectarine, the Elruge Nectarine, the Newington Roman Red, and Temple's Nectarine.—All the species of *Peaches* have been originally obtained from the stones, which is the best method of propagating them. The best sorts are those whose flesh is firm, and cleaves to the stone; they should be planted in autumn, on a bed of light dry earth, three inches deep and four inches asunder, carefully weeded and watered when they come up, until the following spring, when they must be transplanted into a nursery, and placed one foot apart, in rows three feet asunder, observing to lay a little mulch upon the ground to prevent it drying too fast; and if the spring prove dry, watering them once a-week. Here they may continue two years, and may be afterwards transplanted where they are intended to remain, to produce fruit. In removing these trees, observe to prune their downright roots, cutting off all bruised parts and small fibres. All the pruning they require is the lopping off of decayed or irregular branches, which are very detrimental.—The common method of propagation, is by inoculating them upon other stocks, such as those of the Muscle and White-Pear Plums, which are most esteemed, also upon Almond and Apricot stocks, for some tender sorts of Peaches will not grow upon Plum stocks. These stocks should be planted three feet asunder, and one foot apart in the rows, and after two years will be strong enough to bud, which takes place generally about Midsummer, or any time in July, when you should make choice of some good cuttings from healthy trees of the sort of fruit you wish to propagate. These cuttings should be taken from the trees in a morning or evening, or in a cloudy day, otherwise they are apt to perspire and miscarry. Much depends upon the choice of trees: the stock should be of the size of a man's finger, free from moss or canker; the bud of one year's growth only, not such as have been cut down in the spring, and made a second shoot. The best soil for planting is such as is taken from a pasture ground, neither too stiff and moist, nor over dry, but of a middling nature, such as is termed hazel-loam. It should be dug from the surface of the ground ten inches deep, taking the turf with it; and should be laid in heaps eight or ten months at least; but if one year before it is used, it will be still better, that it may have a summer's heat and winter's frost to mellow it, during which time it should be often turned, to rot the turf, and break the clods. The trees should never be planted less than twelve feet asunder, and in good ground fourteen feet: this to be done in October. First make a hole wide enough to receive the roots of the tree, then place it down, observing to turn the bud outwards, that the wounded part of the stock may be hid from sight; and let the stem of the tree be placed about four or five inches from the wall, with its head inclining thereto; then fill in the earth with your hands, observing to break the clods, that the earth may fall in between the roots, and gently shaking the tree with your hand, the better to settle, but do not tread it down. In May the shoots should be nailed to the wall, observing to train them horizontally, and cutting off all weak and downright shoots. In October they must be pruned in proportion to the strength of the tree. Blights are oftener pro-

duced by weakness, and want of nourishment, and distempers in the trees themselves, than by the inclemency of the season, to which they may have been exposed only by being planted in an improper situation. The best method, when the fault is not in the tree itself, is to sprinkle the branches gently with water, which should always be done before noon, in dry weather, and when little dew falls, soon after the blossoming season, when the young-set fruit is tender. When it is grown to the size of a small nut, it will require thinning. The quantity of fruit left on large full-grown trees, ought not to exceed five dozen, and four dozen is sufficient for those of a middling size. In hot and dry seasons, the earth round the stem of each tree may be formed into a hollow basin, six feet in diameter, and covered with mulch; into which once a week or fortnight, according to the heat of the season, eight or ten gallons of water may be poured down round the root of the tree. But the best method is, to sprinkle the same or a larger quantity of water all over the tree like rain, by means of an engine; which will prevent the fruit from falling off.—The culture of the *Nectarine* is the same as that of the *Peach*, only the buds of the former should be taken from bearing trees, and not from young nursery trees, as is too often done. For further information, as to the propagation and culture of these trees, see the articles *Inoculation* and *Nursery*.

2. *Amygdalus Communis*; *The Almond Tree*. The lower serratures of the leaves glandulous; the flowers sessile, and in couplets. This tree grows to the height of twenty feet, with spreading branches; but it is scarcely worth considering in England, for the sake of the fruit it produces. It is common in the East Indies, China, and Barbary, where it is a native; and it is a great object in some parts of Italy, and the south of France, as in Provence and Dauphiny, where there are vast plantations of Almonds. An Almond-tree, covered with its blossoms, is one of the most elegant objects in nature. There are several species and varieties not satisfactorily ascertained. Sweet almonds used in food are difficult of digestion, and afford very little nutriment, unless well masticated. As medicines, they contribute, by their soft unctuous quality, to blunt acrimonious humours in the first passages, and thus sometimes give present relief in the heartburn. On expression, they yield nearly half their weight in oil, which is more agreeable than most of the common expressed oils, and is therefore employed medicinally for allaying acrid juices, softening and relaxing the solids, in tickling coughs, hoarseness, costiveness, nephritic pains, &c. When pounded in water, it unites with the fluid, forming a milky liquor, which is prescribed as a diluent in acute diseases; and for supplying, in some degree, the place of animal milk, with which it has a great analogy: an ounce of almonds is sufficient for a quart of water, to which gum-arabic is in most cases an useful addition. The pure oil, mixed with a thick mucilage of gum-arabic, forms a more permanent emulsion; one part of gum, with an equal quantity of water, being enough for four parts of oil. Almonds are also useful medicines for uniting substances with water which will not of themselves mix with it. Camphor, and the purgative and other resins, pounded with about six times their quantity of almonds, dissolved in water into a milky liquor, and are thus fit for being taken in a liquid form. Bitter almonds, and emulsions made from them, have been recommended as aperients, resolvents, diuretics, and anthelmintics. These almonds, taken freely in substance, occasion sickness and vomiting: to dogs, and some other animals, they are poisonous. A simple water, strongly impregnated by distillation with their volatile parts, has been found also poisonous to brutes, and there are instances of cordial spirits flavoured by them being poisonous to man. It is remarkable that the kernels of other fruits, that

have any bitterness or particular flavour, appear to be impregnated with a substance of a similar nature to this poisonous principle of bitter almonds. Almonds are distinguished into sweet and bitter, but there is no perceptible difference in the trees which produce them. Six or eight sweet almonds, peeled and eaten, frequently cure the heartburn. Notwithstanding the noxious qualities of the bitter kind, they are said to destroy worms, and operate as diuretics. Sweet almonds blanched, and beaten into an emulsion with barley-water, are of great use in the stone, gravel, strangury, and other disorders of the kidneys, bladder, and biliary ducts.—The common and dwarf Almonds are propagated by inoculating a bud of these trees into a Plum, Almond, or Peach stock, in July. The next spring, when the buds shoot, they may be trained up either for standards or suffered to grow to half-standards; and the second year they may be removed to the places where they are to remain.

3. *Amygdalus Pumila*; *Double-flowered Dwarf Almond*. Leaves veined, wrinkled. Branches smooth, two or three feet high; flowers red. These shrubs make a very agreeable variety among low flowering trees, in small wilderness quarters.—Native of Africa: flowering time, April.

4. *Amygdalus Nata*; *Common Dwarf Almond*. Leaves attenuated at the base. It blossoms in April, at which time all the young shoots are covered with flowers, which are of a peach-blossom colour, and make a fine appearance when intermixed with shrubs of the same growth.—It is a native of the northern parts of Asia, particularly abundant in Calmuc Tartary, and very frequent on the banks of the Volga.

5. *Amygdalus Incana*; *Hoary Dwarf Almond*. Leaves lanceolate, serrate, wrinkled, subsessile, white-tomentose beneath.—It is doubted whether this be any thing more than a variety of the preceding species.

6. *Amygdalus Orientalis*; *Silvery-leaved Almond*. Leaves lanceolate, quite entire, silvery, perennial; petiole shorter.—The leaves are silvery, and continue most of the year; the flowers are very small.—It was found growing near Aleppo.

7. *Amygdalus Cochinchinensis*. Leaves ovate, quite entire; racemes small, subterminal.—This is a large tree; native of the vast woods of Cochinchina.

Amyris; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, four-toothed, acute, erect, small, permanent. *Corolla*: of four, oblong, concave, spreading petals. *Stamina*: filamenta awl-shaped, erect; antheræ oblong, erect, the length of the corolla. *Pistil*: germen superior, ovate; style thickish, the length of the stamina; stigma four-cornered. *Pericarp*: a drupaceous, roundish berry. *Seed*: a round shining nut. ESSENTIAL CHARACTER. *Calix*: four-toothed. *Petals*: four, oblong. *Stigma*: four-cornered. *Berry*: drupaceous.—The species are,

1. *Amyris Elemifera*; *Gum Elemi Tree*. Leaves ternate and pinnate, with five lobes, downy underneath. This is described as a lofty tree with a small trunk, covered with a smooth grey bark. A resin, called *gum-elemi*, is from this tree.—It is a native of Carolina and Brazil.

2. *Amyris Sylvatica*. Leaves ternate, crenate, acute. A leafy branching shrub, from two to fifteen feet high.—Found about Carthage, in woods near the sea. Flowering in August; and abounding in turpentine of a strong disagreeable smell.

3. *Amyris Maritima*; *Small Shrubby Sweetwood*. Leaves ternate, crenulate, obtuse. A dwarf shrub, branching, with a juice like that of the former species, but pleasanter, and smelling like Rue.—It grows in very barren coppices, in a calcareous rocky soil, both near the sea and on the interior mountains of Jamaica, Hispaniola, and Cuba, flowering from June to September.

4. *Amyris Gileadensis*; *Balsam of Gilead Tree*. Leaves ternate, quite entire; peduncles one-flowered, lateral.—This is a shrub with purple branches, striated a little, having protuberant buds loaded with balsamic resin; it is, however, doubtful whether it is not the same with the following species:—

5. *Amyris Opobalsamum*; *Balsam of Mecca Tree*. Leaves pinnate, leaflets sessile. The true opobalsamum is said to be produced from this tree; it is at first turbid and white, of a very strong pungent smell, like that of turpentine, but sweeter, and more fragrant, like Mint, varying according to its goodness, and of a bitter, acrid, astringent taste; by age it becomes thin, light, limpid, and of a greenish hue, and then of a gold colour; after which it grows thick like turpentine, and loses much of its fragrance. Its scarcity has prevented its coming into use among us; nor are its virtues, probably, superior to those of some of the resinous juices more common in the shops; all these substances being alike in substance and general qualities, though differing in the degree of their pungency, gratefulness, and warmth. It has always been esteemed as a cosmetic: the Eastern women in particular make great use of it. Lady Mary Wortley Montague informs us, that the balm of Mecca, when applied to her face, caused it to become swelled and red during three days, but that her complexion was much mended by the operation. She says, that of the best quality is not easily procured, even at Constantinople, where the women all use it, and have the loveliest bloom in the world!

6. *Amyris Toxicifera*; *Poison Ash*. Leaflets pinnate; leaflets petiolate, plain. A liquor as black as ink distils from the trunk of this tree, which the Americans say is poison. Birds feed upon the fruit. Native of America.

7. *Amyris Protium*. Leaves pinnate; leaflets petiolate, waved; perennial.—Native of the East Indies.

8. *Amyris Ambrosiaca*. Leaves pinnate, petiolate; panicles crowded, axillary. The trunk of this tree is thirty feet high, branching at the top; the flowers yellowish-white. It is extremely sweet-scented, and pours out a very odorous balsam from the wounded trunk or branches, which is used in the dysentery: the dose is one drachm in red wine; it is also used in houses and churches, to burn as a perfume. It grows in the woods of Guiana and by the sea-shore, flowering and fruiting in September.

9. *Amyris Balsamifera*; *Sweet Amyris*, *White Candle Wood*, or *Rosewood*. Leaves two-paired. This species grows to a considerable size, and is one of the most valuable timber-trees in the island of Jamaica; the wood grows of a dirty clouded ash-colour, has a pleasant smell, and, bearing a fine polish, is in great repute among cabinet-makers. All the parts of this tree are full of warm aromatic particles, and may be used in baths and fomentations. An infusion of the leaves has a pleasant flavour, is highly cephalic, strengthens the nerves, and is peculiarly restorative to weak eyes.

Anabasis; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets roundish, concave, obtuse, spreading. *Corolla*: five-petalled; petals ovate, equal, less than the calix, permanent. *Stamina*: filamenta filiform, longer than the corolla; antheræ roundish. *Pistil*: germen roundish, acuminate, ending in two styles; stigmas obtuse. *Pericarp*: a berry; roundish, surrounded by the calix, dilated. *Seeds*: single, screw-shaped. ESSENTIAL CHARACTER. *Calix*: three-leaved. *Corolla*: five-petalled. *Berry*: one-seeded, surrounded by the calix.—The species are,

1. *Anabasis Aphylla*; *Leafless Anabasis*. Without leaves, the joints emarginate. The stem short and roundish; the berry dyes a yellow colour.—It is perennial, and has been found wild on the shores of the Caspian sea.

2. *Anabasis Foliosa*; *Leafy Anabasis*. Leaves subclavate. This is seldom more than a foot and half high. Annual, also found on the shores of the Caspian sea.

3. *Anabasis Tamariscifolia*; *Tamarisk-leaved Anabasis*. Leaves awl-shaped; pericarps juiceless.—A shrub with white branches: native of Spain.

4. *Anabasis Spinosissima*; *Thorny Anabasis*. Shrubby: branches without leaves, but full of spines.—A shrub; its native place unknown.

Anacardium; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite flower*. *Calix*: perianth five-leaved; leaflets ovate, concave, coloured, erect, deciduous. *Corolla*: petals five, lanceolate, acute, three times as long as the calix, upright at the bottom, reflex at the end. *Stamina*: filamenta ten, united at the base, upright; nine of them capillary, shorter than the calix; one thicker, double the length of the others, lying on the germen in front; antheræ roundish; in the longer filamentum large and fertile, in the rest small. *Pistil*: germen kidney-shaped, obliquely emarginate in front; style subulate, bent in, the length of the corolla; stigma small, roundish, depressed, concave. *Pericarp*: none. *Receptacle*: fleshy, very large, obovate. *Seed*: nut kidney-shaped, large, at the top of the receptacle; with a thick shell, cellular within, and abounding in oil. *Male flowers*, either mixed with the hermaphrodites, or on a distinct tree. *Calix*, *Corolla*, and *Stamina*, as above. *Pistil*: germen none, or abortive. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five, reflex. *Antheræ*: ten, one only fertile. *Nut*: kidney-shaped, on the top of a fleshy receptacle.—One species only is yet known, viz.

1. *Anacardium Occidentale*; *Cashew Nut*, *Cassu*, or *Acajou*. This is an elegant tree, twenty feet high. The fruit or apple has an agreeable subacid flavour; the juice expressed from it, and fermented, yield a pleasant wine; and when distilled, produces a spirit far surpassing arrack or rum, making admirable punch, and powerfully promoting urine. The nut springs from one end of the apple, and contains, between it and the kernel, an inflammable caustic oil, which will raise blisters on the skin, and has been used with great success in eating off ring-worms, cancerous ulcers, and corns; but should be cautiously employed. When fresh, the kernel has a most delicious taste, abounding with a sweet milky juice. When it is old, and ground with cocoa, it makes excellent chocolate. The body of the tree, when tapped, produces a milky juice, which will stain linen indelibly with black; the thick oil of the shell also tinges it of a rusty iron colour, which can hardly be got out, and if rubbed over wood, will preserve it from decaying, and might therefore prove an excellent preservative to house-timber and ship's bottoms. The tree yields annually five, ten, or even twelve pounds weight of a fine semitransparent gum, similar to gum-arabic, and not inferior in virtue or quality, except that it has a slight astringency, which perhaps renders it in some respects more valuable. The inside of the fleshy receptacle, which is commonly called the cherry, is stringy, but full of an austere acrid but pleasant juice, which the Americans employ in making punch, as we do that of lemons. When the West India ladies imagine their beauty too much impaired by the scorching rays of the sun, they scrape off the outside skin, and then rub their faces and hands all over with the stone, which soon after swell and grow black; and in five or six days after the skin has been thus poisoned, it comes off the face and other parts in large flakes. This operation prevents their appearance in public for the full space of a fortnight; at the end of which time the new skin looks as fair as that of a young child. The slaves and negroes in Brazil cure themselves of disorders in

the stomach, to which they are very subject, by eating the fleshy parts of the fruit, the acidity of which dissolves the tough humour which prevents the free circulation of the blood and juices, and thus removes the complaint by destroying its cause. It is however necessity, not choice, which leads the negroes to the use of this fruit, which they are far from being fond of; but their masters, the Portuguese, deny them every other kind of sustenance. Being constrained to use this food, in a few days they recover from their indisposition, and return to their masters with health and vigour sufficient to perform the labour usually allotted to them. These trees are easily raised from the nuts, sown in small pots, and plunged into a hot-bed: they generally appear in a month; but are with difficulty preserved in England.

Anacyclus; a genus belonging to the class Syngenesia, order Polygamia Superflua.—**GENERIC CHARACTER.** *Calix*: common hemispherical, imbricate, with many ovate, flat, sharp scales. *Corolla*: compound radiate, with numerous hermaphrodite corollets in the disk; from five to ten females in the ray, scarcely higher than the disk. Hermaphrodites funnel-shaped, with a quinquefid spreading border; females with a flattened tube, and an ovate entire border. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; antheræ cylindric. *Pistil*: germen flattened, stigma bifid, in the hermaphrodites, with a membrane on each side; style filiform, the length of the corollet; and two slender reflex stigmas in the floscules. *Pericarp*: none; calix unchanged. *Seed*: in the hermaphrodites, solitary, oblong, compressed, naked, or without down; in the females, with a very broad membranaceous wing on each side, and emarginate at top, but without down. *Receptacle*: chaffy; chaffs obtuse with a point. **ESSENTIAL CHARACTER.** *Receptacle*: chaffy. *Down*: emarginate. *Seeds*: in the ray, membranaceous.—All the plants of this genus are annual.—The species are,

1. *Anacyclus Creticus*; *Trailing Anacyclus*. Leaves decomposed, linear; divisions subdivided, flat. Flowers small, white.—Native of the islands of the Archipelago.

2. *Anacyclus Orientalis*; *Eastern Anacyclus*. Leaves compound, bristly, acute, straight. This plant has white flowers resembling the chamomile.—Native of the islands of the Archipelago; first discovered by Tournefort.

3. *Anacyclus Aureus*; *Golden-flowered Anacyclus*. Leaves bipinnate, roundish, hoary, hollow-dotted; stems many, seven inches high, and erect.—It is a native of the south of Europe, and the Levant.

4. *Anacyclus Valentinus*: *Fine leaved Anacyclus*. Leaves decomposed, linear; divisions subdivided, roundish, acute; flowers flosculose. Grows a foot and half high, with flowers of a bright yellow colour, and a silvery scaly calix.—It is a native of Spain, flowering in June and July.

Anagallis; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, sharp, permanent; division keeled. *Corolla*: wheel-shaped, border five-parted; divisions ovate-orbiculate, with the claws connected. *Stamina*: filamenta erect, shorter than the corolla, shaggy below; antheræ simple. *Pistil*: germen globose; style filiform, slightly bending; stigma capitate. *Pericarp*: a globose one-celled capsule, opening transversely. *Seeds*: very many, angular. *Receptacle*: globose, very large. **ESSENTIAL CHARACTER.** *Corolla*: rotate. *Capsule*: opening horizontally.—The four first species are annuals, propagated from seed, which must be sown after they are ripe, and sheltered from extreme cold.—The species are,

1. *Anagallis Arvensis*; *Common Pimpernel*. It is an annual plant, with a quadrangular stem and scarlet corollas, with purple bottoms; the blossoms open about eight in the

morning and close in the afternoon, except it rain, in which case they neither open nor close; hence it is called the *Shepherd's* or *Poor Man's Weather-glass*. Cows and goats feed upon it, but sheep reject it. It is common in corn-fields, and in other cultivated places, and blossoms from May till August. It is of a cordial sudorific nature, and a strong infusion of it is an excellent medicine in feverish complaints, which it relieves by promoting a gentle perspiration. The same simple preparation is much used among country people in the first stages of consumptions; and is often the happy means of checking the disorder, and preventing its fatal consequences. The whole plant, dried and powdered, is good for the falling sickness; and there are, says Hill, many well-authenticated accounts of that dreadful disorder being absolutely cured by it. A decoction of it in wine, drank in bed, causes sweating, and is a preservative in pestilential and contagious diseases; a water distilled from it is excellent for sore eyes. The expressed juice is serviceable in the beginning of dropsies, and in obstructions of the liver, spleen, and reins. It brings away stony and gravelly concretions from the bladder and urinary passages, and is good in consumptive cases, ulcerated lungs, and other disorders of the breast. The infusion is best made by pouring boiling water upon it fresh gathered. The dried leaves may be given in powder, or an infusion made of the whole dried plant, but nothing equals the infusion of the fresh plant.—This species grows wild in Sweden, Germany, and Switzerland; and with us between Stockwell and Camberwell; near Mitcham in Surry; near Histon in Cambridge-shire; and Bredon-Hill in Worcestershire.

2. *Anagallis Monelli*; *Upright Pimpernel*. Leaves undivided; stem erect. This is a very beautiful small plant, producing great numbers of fine blue flowers in April and May.—It is a native of Verona.

3. *Anagallis Latifolia*; *Broad-leaved Pimpernel*. Leaves heart-shaped, stem-clasping; stem compressed. This is very nearly allied to the preceding species; corolla blue; filamenta purple; antheræ oblong, yellow. It is a trailing annual plant; and was imported from Spain.

4. *Anagallis Linifolia*; *Flax-leaved Pimpernel*. Leaves linear; stem erect, three or four inches high.—It grows wild in Spain and Portugal.

5. *Anagallis Tenella*; *Bog Pimpernel*, *Purple Loosestrife*, or *Moneywort*. Leaves ovate, sharpish; stem creeping. Roots perennial, numerous; corolla large, of a pale-red colour, with deeper veins. Not uncommon on bogs, flowering from June to August.—Moneywort is cooling and astringent, and a good antiscorbutic; excellent against spitting of blood, and in bloody fluxes, for which purposes it is best to give the leaves in powder. The juice of it is a well-known remedy among country people, for overflowings of the menses; and the roots dried and powdered are good in purgings; and the leaves, bruised, and applied to green wounds, speedily heal them.

6. *Anagallis Verticillata*; *Verticilled Pimpernel*. Stem-leaves verticilled; stem erect, a foot high; corolla a bright blue: has not yet been cultivated in England.

7. *Anagallis Pumila*; *Dwarf Pimpernel*. Stem erect; leaves roundish, acute, sessile.—Annual; and a native of Jamaica.

Anagyris; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth bell-shaped; mouth five-toothed, the upper pair of teeth more deeply divided. *Corolla*: papilionaceous; standard obcordate, straight, emarginate, broader than the other petals twice as long as the calix; wings ovate-oblong, flat, longer than the standard; keel straight, very long. *Stamina*: filamenta parallel, distinct, rising; antheræ simple. *Pistil*: germen ob-

long; style simple, rising; sigma villose. *Pericarp*: an oblong, large, roundish, obtuse legume, a little reflex. *Seeds*: six or more, kidney-form. **ESSENTIAL CHARACTER.** *Standard* and *Wings*; shorter than the *keel*, in a papilionaceous corolla. *Fruit*: a legume.—These plants may be propagated by laying down their tender branches in the spring: if seeds be used, they must be sown on a moderate hot-bed at the beginning of March. The fourth year from sowing, they will begin to produce their flowers, and will flower every year after.—The species are,

1. *Anagyris Fœtida*; *Stinking Bean Trefoil*. Leaves ovate; flowers axillary.—It is a shrub eight or ten feet high, with bright yellow flowers, appearing in April and May; and grows wild in France, Spain, Italy, Sicily, and about Smyrna.

2. *Anagyris Cœtica*: Leaves oblong; racemes longer.—A native of Candia; very rare in England.

3. *Anagyris Inodora*. Leaves pinnate; calices inflated, coloured; legumes compressed, straight; racemes terminating, oblong.—An upright shrub, with a white flower; and native of the woods of Cochinchina.

Anastatica; a genus of the class Tetradymania, order Siliculosa.—**GENERIC CHARACTER.** *Calix*: Perianth four-leaved, deciduous; leaflets ovate-oblong, concave, erect, deciduous. *Corolla*: tetrapetalous, cruciform; petals roundish, flat, spreading; with claws nearly the length of the calix, but more spreading. *Stamina*: filamenta six, subulate, the length of the calix, from erect spreading; antheræ roundish. *Pistil*: germen bifid, very small; style subulate, the length of the stamina, permanent; stigma capitate. *Pericarp*: a very short silicle; partition ending in a subulate point, oblique, and longer than the silicle itself; the valves parallel, making a cell of the lower half, but standing out from the upper, rounded, concave, gaping, oblique, hence having the form of a sheep's hoof. *Seeds*: solitary, roundish. **ESSENTIAL CHARACTER.** *Silicle*: retuse, crowned at the edge with valves twice as long as the partition. *Style*: intermediate, pointed, oblique. *Cells*: one-seeded.—These plants are annual, and can only be propagated by seeds, which rarely ripen in England, they must be sown on a hot-bed in the spring.—The species are,

1. *Anastatica Hierochuntica*. *Common Anastatica*, or *Rose of Jericho*. Leaves obtuse; spikes axillary, very short; silicles hooped, thorny.—This curious plant if taken up before it is withered, and kept entire, may be preserved many years in a dry room; and afterwards, if the root be placed a few hours in a glass of water, the buds of flowers will swell, open, and appear as if newly taken out of the ground.—It grows naturally on the coasts of the Red Sea, in the sandy parts of Palestine, and near Cairo.

2. *Anastatica Syriaca*; *Syrian Anastatica*. Leaves acute; spikes longer than the leaf; silicles ovate, beaked.—It flowers in May and June; and is a native of Austria, Stiria, Carniola, Syria, and Sumatra.

Anchovy Pear. See *Grias*.

Anchusa; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, oblong, round, acute, permanent. *Corolla*: monopetalous; funnel-shaped; tube cylindrical, the length of the calix; limb semi-quinquefid, from erect expanding, obtuse; throat closed with five small scales, convex, prominent, oblong, converging. *Stamina*: filamenta very short, in the throat of the corolla; antheræ oblong, incumbent, covered. *Pistil*: germen four; style filiform, the length of the stamina; stigma obtuse, emarginate. *Pericarp*: none; but the calix enlarged, and erect, contains the seeds in its bosom. *Seeds*: four oblongish, obtuse, gibbose. **ESSENTIAL CHARACTER.** *Corolla*: funnel-shaped, the throat closed with an arch of scales

Seeds: engraved at the base. All the species of this genus may be propagated by seeds, sown in the autumn upon a bed of light sandy earth, and removed from thence in the spring to beds planted at two feet distance, watering them till they have taken root; after which they will require no further care. If the seeds of the common sorts be permitted to scatter themselves, the plants will rise in plenty.—The species are,

1. *Anchusa Officinalis*; *Official* or *Garden Alkanet*, or *Bugloss*. Leaves lanceolate; spikes imbricate, pointing one way. Stems from a foot to eighteen inches high; leaves seven inches long, and about an inch broad, which, with the stems, are hairy and rough; corolla purple, and sometimes white. It flowers in June, July, and August.—Bees are very fond of the tube of the corolla. This is not the *Anchusa*, but the *Bugloss*, of official writers: it appears to be nearly similar to *Borage*; the leaves being less juicy, and the roots more mucilaginous: these, with the leaves and flowers, are ranked among the articles of the materia medica.—It is in great esteem in China, for gently promoting the eruption in the small-pox.

2. *Anchusa Angustifolia*; *Narrow-leaved Alkanet*. Racemes almost naked, in pairs. Grows two feet high in gardens, but seldom more than one when wild. The flowers are small, and of a red colour.—It is found wild in Germany and Switzerland, flowering in July and August, by way-sides, and the borders of ploughed fields. The great Boerhaave recommended the juice of this plant in the pleurisy and in maniacal cases.

3. *Anchusa Italica*; *Italian Alkanet*. Leaves lucid, strigose; racemes two-parted, two-leaved; flowers somewhat unequal, bearded at the throat. Roots biennial: stem erect, four feet high or more.

4. *Anchusa Undulata*; *Waved Alkanet*. Strigose: leaves linear, toothed; pedicles less than the bracte; fruit-bearing calices inflated. Height three feet; leaves stiff, rough, six or seven inches long, and half an inch broad; corollas a fine blue colour.—A native of Spain and Portugal.

5. *Anchusa Tinctoria*; *Dyer's Alkanet*. Downy: leaves lanceolate, obtuse; stamina shorter than the corollas. This greatly resembles the *Garden Alkanet*, and is cultivated in the south of France for the deep purplish red colour of the roots. It gives a fine deep red to oils, wax, and all unctuous substances, as well as to spirit of wine.—It grows about Montpellier, in Silesia, Spain and Italy.

6. *Anchusa Virginica*; *Virginian Alkanet*. Flowers scattered; stem smooth. Seldom rises a foot high; and where it abounds, the ground seems covered with bright yellow flowers.—Native of North America; and called there *Puccoon*.

7. *Anchusa Lanata*; *Woolly Alkanet*. Leaves villose; calices shaggy; stamina longer than the corollas. Stem single, a foot high; corolla blue.—Found near Algiers.

8. *Anchusa Sempervirens*; *Evergreen Alkanet*. Leaves ovate; peduncles two-leaved, racemed. Corollas blue; stems at the sides of the crown of the root hispid.—Found wild in Spain and Italy, and in various parts of England, by roadsides, among rubbish, and from the joints of old walls. It flowers from May through a great part of the summer, and is perennial. Cows, horses, sheep, and goats, are said to eat it.

9. *Anchusa Barrelieri*; *Barrelier's Alkanet*. Leaves ovate lanceolate; stem erect; peduncles racemed, pointing one way. Root pale red; stalk angular; corolla azure.—Found in Piedmont.

10. *Anchusa Paniculata*; *Panicled Alkanet*, or *Bugloss*. Leaves lanceolate, strigose, quite entire; panicle dichotomous divaricate; flowers peduncled; calices five-parted, with subulate segments. It is biennial; flowers in May and June; and is a native of Madeira.

Ancistrum; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, turbinate, truncate, four-toothed; teeth cylindric, awned, erect, terminating in four reversed hooks. *Corolla*: superior, one-petalled, funnel-shaped, with a very short tube, and a spreading quadrid border; the divisions nearly equal, obtuse, the length of the tube. *Stamina*: filamenta, fastened to the base of the tube, longer than the corolla, capillary; antheræ roundish. *Pistil*: germen oblong; style filiform, the length of the corolla: stigma pencil-shaped. *Pericarp*: none, but the calix, in the bottom of which is the fruit. *Seed*: single, oblong. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Corolla*: none. *Stigma*: many-parted. *Drupe*: dry, hispid, one-celled.—The species are,

1. *Ancistrum Decumbens*. Stems decumbent; peduncle scape-form, solitary; flowers in a globular head; leaflets wedge-form, deeply serrate, hairy beneath; seed covered with the thickened calix.—Native of New Zealand.

2. *Ancistrum Lucidum*; *Shining Ancistrum*. Stems submerged; peduncles scape-form; spikes ovate; leaflets oblong, quite entire, acute, subfascicled.—It flowers in May and June; and is a native of the Falkland Isles.

3. *Ancistrum Latebrosum*; *Hairy Ancistrum*. Stems demerged; peduncles scape-form; spikes elongate; leaflets oblong, gashed, villose; fruits armed on every side.

Andrachne, a genus of the class Monœcia, order Gynandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth five-leaved, equal, marcescent. *Corolla*: petals five, emarginate, slender, shorter than the calix; nectary, leaflets five, semibifid, herbaceous, one within each petal, and less than it. *Stamina*: filamenta five, small, inserted into the rudiment of each style; antheræ simple. *Female*. *Calix*: perianth five-leaved, equal, permanent. *Corolla*: petals none; nectary as in the male. *Pistil*: germen superior, globose; styles three, filiform, two-parted; stigmas globose. *Pericarp*: capsule globose, trilobate, three-celled; cells bivalved, the size of the calix. *Seeds*: in pairs, rounded on one side, triangular and obtuse on the other. ESSENTIAL CHARACTER. *Male*. *Calix*: five-leaved. *Corolla*: five-petalled. *Stamina*: five, inserted into the rudiment of the style. *Female*. *Calix*: five-leaved. *Corolla*: none. *Styles*: three. *Capsule*: three-celled. *Seeds*: two.—The plants of this genus are propagated in England by seeds sown upon a hot-bed in March. The second and third sorts are very tender. They ripen their seeds in August or September, and decay soon after.—The species are,

1. *Andrachne Telephoides*. Procumbent and herbaceous.—It grows wild in Italy and the Archipelago, and is a low trailing plant.

2. *Andrachne Fruticosa*. Erect, shrubby. Fourteen feet high, with small herbaceous-white flowers.—A native of the East Indies, China, and of Vera Cruz, in New Spain.

3. *Andrachne Arborea*. Stem arborescent; leaves ovate, obtuse, hoary underneath. This species has a strong woody stem rising more than twenty feet high.—Native of Campeachy.

Andromeda, a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Perianth*: five-parted, acute, very small, coloured, permanent. *Corolla*: monopetalous, campanulate, quinquefid; clefts reflex. *Stamina*: filamenta subulate, shorter than the corolla, and scarcely fixed to it; antheræ two-horned, nodding. *Pistil*: germen roundish; style cylindric, longer than the stamina, permanent; stigma obtuse. *Pericarp*: capsule roundish, five-cornered, five-celled, five-valved, opening at the corners; partitions contrary. *Seeds*: very many, roundish, shining. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*:

ovate, or campanulate, quinquefid at the edge. *Capsule*: superior, five-celled, with the partitions from the middle of the valves.—Most of the plants of this genus are hardy deciduous shrubs, delighting in moist ground. They are propagated by their creeping roots, which putting up suckers at a distance, may be taken off with roots, and transplanted where they are designed to remain; for they will not bear frequent removals.—The species are,

1. *Andromeda Tetragona*. Peduncles solitary, lateral; corollas bell-shaped; leaves opposite, imbricate, obtuse, revolute.—Grows in Siberia and Lapland.

2. *Andromeda Hypnoides*. Peduncles solitary, terminal; corollas bell-shaped; leaves crowded, awl-shaped.—This little plant is found in Denmark, Siberia, and in the Lapland Alps; where it covers great tracts of ground, adorning them with its beautiful red flowers.

3. *Andromeda Cerea*. Peduncles axillary, two-leaved, one-flowered; leaves alternate, ovate, serrate.—Native of Otaheite.

4. *Andromeda Cœrulea*. Peduncles aggregate; corollas ovate; leaves scattered, linear, obtuse, flat.—Found in Sweden, Denmark, Lapland, and Siberia.

5. *Andromeda Mariana*; *Maryland Andromeda*. Peduncles aggregate, branched; corollas ovate cylindrical; leaves oblong-ovate, quite entire, deciduous.—Native of North America. There are two varieties belonging to this species.

6. *Andromeda Ferruginea*; *Rusty Andromeda*. Peduncles aggregate, axillary; corolla subglobose; leaves elliptic, quite entire, beneath scaly scariose.—Native of North America.

7. *Andromeda Polifolia*; *Marsh Andromeda*. Peduncles aggregate; corollas ovate, leaves alternate, lanceolate, revolute.—This elegant little shrub is from six to eight inches and a foot high, with a red calix and pink-coloured corolla. It flowers about the end of May; and is a native of America; of turf-bogs in the northern countries of Europe; and of Cheshire, Lancashire, Cumberland, Yorkshire, &c. It is called *Moor-wort*, *Wild Rosemary*, *Marsh Holy Rose*, &c.

8. *Andromeda Bryantha*. Flowers corymbed; leaves elliptic; stem prostrate.—It comes up in thick clumps, like Wild Thyme, on the rocks of Kamtschatka.

9. *Andromeda Daboecia*; *Irish Whorts*, *Cantabrian Heath*, or *Trailing Andromeda*. Racemes pointing one way; flowers quadrid-ovate; leaves alternate, lanceolate, revolute. Found only in the Irish bogs, and flowers in June and July.

10. *Andromeda Droseroides*; *Clammy Andromeda*. Racemes pointing one way; leaves linear, hairy, viscid.—A native of the Cape.

11. *Andromeda Paniculata*; *Panicled Andromeda*. Racemes terminal, panicled; corollas roundish; leaves ovate, rather entire. Stem four feet high.—Native of Virginia.

12. *Andromeda Japonica*. Racemes panicled, cylindric, bracted; leaves elliptic, reflex, serrate at the tip. This is a tree, flowering in December.—Native of Japan.

13. *Andromeda Arborea*; *Tree Andromeda*, or *Sorrel Tree*. Racemes terminal; corollas rather downy; leaves elliptic, pointed, toothletted.—A shrub from ten to twenty feet high; native of Virginia and Carolina.

14. *Andromeda Racemosa*; *Branching or Pennsylvania Andromeda*. Racemes terminal, simple, bracted; corollas cylindric; leaves oblong-lanceolate, serrate.—It flowers in July, and is a native of Pennsylvania.

15. *Andromeda Axillaris*; *Notch-leaved Andromeda*. Racemes axillary, simple; corollas oblong; leaves ovate, acute, serrulate.—Native of Carolina; flowering from May to August.

16. *Andromeda Coriacea*; *Thick-leaved Andromeda*. Racemes axillary, simple; leaves ovate, very entire, very shin-

ing ; branchlets three-cornered. Flowers in July and August.—Native of North America.

17. *Andromeda Acuminata*; *Acute-leaved Andromeda*. Racemes axillary, simple; leaves ovate-lanceolate, acuminate serrate. A shrub four feet high, flowering in July and August.—Native of North America.

18. *Andromeda Calyculata*; *Calicled Andromeda*. Peduncles solitary, axillary, pointing one way; bractes two; leaves oval, scaly, dotted, obsoletely serrulate.—A low shrub, with leaves like those of the Box; growing upon mossy land in Sweden, Ingria, Siberia, and North America.

19. *Andromeda Anastomozans*. Racemes crowded, leafy; leaves ovate, slightly serrate, anastomosing underneath, and dotted.—Native of New Granada.

20. *Andromeda Rupestris*. Leaves oblong, alternate, serrulate.—Native of New Zealand.

21. *Andromeda Salicifolia*; *Willow-leaved Andromeda*. Racemes pointing one way, naked; corollas subcylindrical; leaves lanceolate, acute, quite entire.—Found in the island of Mauritius.

22. *Andromeda Buxifolia*; *Box-leaved Andromeda*. Racemes pointing one way, naked; corollas subcylindrical; leaves cordate-ovate, quite entire, with a little dagger-point.—Native of the Isle of Bourbon.

23. *Andromeda Fasciculata*. Peduncles aggregate; leaves alternate, ovate-lanceolate, obtuse, slightly crenulate, coriaceous.—24. *Andromeda Jamaicensis*. Peduncles aggregate; corollas ovate, transparent; leaves alternate, broad lanceolate, obtuse, entire, beneath ash-coloured, membranaceous.—25. *Andromeda Octandra*. Peduncles aggregate; corollas cylindrical quadrifid; leaves alternate, ovate-lanceolate, entire, membranaceous.—All natives of Jamaica.

Andropogon; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite*. *Flowers sessile*. *Calix*: a glume, one-flowered, two valved, oblong, obtuse, cartilaginous, awnless; the outer valve concave, flattish at the back, embracing the inner, which is narrower, with its edges. *Corolla*: a two-valved glume, less and more slender than the calix; outer valve smaller, frequently very small, within the inner valve of the calix, sharp or bifid at the end, in most of the species awned; awn terminating, or from the cleft of the glume, long, with a bent joint and twisted at bottom; the inner valve lanceolate, doubled at the edges. Nectary two-leaved; leaflets thickish, diaphanous. *Stamina*: filamenta three, capillary, very tender; antheræ oblong; forked at both ends, incumbent. *Pistil*: germen oblong; styles two, capillary; stigmas oblong, feathered. *Pericarp*: none; glumes of the corolla and calix involving and inclosing the seed. *Seed*: solitary, oblong, covered, armed with the awn of the corolla, which easily falls off. *Male Flowers peduncled, single, or in-pairs to each Hermaphrodite*. *Calix*: *Corolla*, and *Stamina*: as in the others, only that the corolla has no awn. ESSENTIAL CHARACTER. *Hermaphrodite*. *Calix*: glume one-flowered. *Corolla*: glume awned at the base. *Stamina*: three. *Styles*: two. *Seeds*: one. *Male*. *Calix* and *Corolla*: the same. *Stamina*: three.—Few of these grasses have been cultivated in England; the greater part of them would require a stove, since they are natives of the East and West Indies.—The species are,

1. *Andropogon Caricosum*. Spike solitary, imbricate; seeds shaggy; awns naked, contorted.—Native of Amboyna and Japan.

2. *Andropogon Cantortum*. Spike solitary; male flowers awnless on the back of the spike; female flowers on the belly of it, twice as long as the males, with twisted approximating awns longer than the whole spike.—Native of the East Indies.

3. *Andropogon Crinitum*. Spike solitary, shaggy; awns naked, jointed, very long.—A native of Japan.

4. *Andropogon Divaricatum*. Spike oblong; flowers woolly, remote, divaricate; awn flexuose, naked.—Native of Virginia.

5. *Andropogon Gryllus*. Peduncles of the panicle entirely simple: three-flowered: the hermaphrodite floscule sessile, awned, ciliate, bearded at the base. Culm three feet high.—Native of Piedmont, Switzerland, &c.

6. *Andropogon Saccharoides*. Branches of the panicle single: florets in pairs; hermaphrodite awned, sessile, the other awnless, pedicled, withering; pedicle and rachis woolly.—Native of Jamaica.

7. *Andropogon Nutans*. Panicle nodding; awns twisted, polished; glumes of the calix shaggy.—Found in Virginia and Jamaica.

8. *Andropogon Ciliatum*. Panicle nodding; outer calix many-flowered, ciliate; awns contorted, hairy.—It flowers in September; and is a native of the mountains of Japan.

9. *Andropogon Serratum*. Panicle loose; one floscule sessile, villose at the base; the other pedicled, with the pedicle villose, and shorter than the calix.—Native of Japan.

10. *Andropogon Cotuliferum*. Panicle spreading, villose; awn twisted, naked; pedicles clubbed or swelling at top, and hollowed like a saucer or dish.—Found in Japan.

11. *Andropogon Cymbarum*. Panicles scattered; bractes boat-form; flowers transverse, awned, three-fold. Culms three feet high.—A native of the East Indies.

12. *Andropogon Squarrosus*. Panicle crowded; glumes awl-shaped, rugged. Culms smooth; leaves rugged.—A native of Ceylon; where the natives make fans of it, and esteem it for its pleasant smell.

13. *Andropogon Prostratum*. Peduncles in five-flowered umbels without calicles; the hermaphrodite floscule awned.—Native of the East Indies.

14. *Andropogon Fastigiatum*. Spikes of the panicle solitary; peduncles elongate, subfastigate; rachis woolly; floscules awned; male fertile.—Native of Jamaica.

15. *Andropogon Alopeuroides*. Panicle loose; rachis woolly; a twisted awn to each floscule.—Native of Virginia and Jamaica.

16. *Andropogon Distachyum*. Spikes two, terminal; culm undivided.—A foot high; said to grow wild in Switzerland.

17. *Andropogon Schœnanthus*; *Sweet Rush*, or *Camel's Hay*. Spike of the panicle conjugate, ovate-oblong; rachis pubescent; floscules sessile, with a twisted awn. This species is cultivated in the gardens of China and Cochin-china, where the inhabitants employ it to season their meat. We receive it in bundles from Turkey. When in perfection, it has a warm, bitterish, and not unpleasent taste, with an agreeable smell. It was once employed as a warm stomachic and remover of obstructions, but has been superseded by more common aromatics. Perennial.—Native of Arabia and India.

18. *Andropogon Virginicum*. Spikes of the panicle conjugate; peduncles simple; rachis woolly; floscules awnless, the male one wanting.—About six feet high; and a native of America.

19. *Andropogon Bicoorne*. Spikes of the panicle conjugate; peduncles branching very much; rachis woolly; awn caducous; male floscule wanting.—This is found upon dry hills in the East Indies; and there called *Fortail Grass*.

20. *Andropogon Hirtum*. Spikes of the panicle conjugate; calices shaggy.—Native of Portugal, Italy, Sicily, and Smyrna.

21. *Andropogon Insulare*. Panicle loose, smooth; floscules double, awnless; one pedicle shorter; calices woolly.—Native of Jamaica.

22. *Andropogon Barbatum*. Spikes digitate: calices permanent; corollas ciliate. Culm a foot high.—Found in the East Indies.

23. *Andropogon Pubescens*. Spikes digitate; calices subtriflorous; outer petals awned; keel and hedge of the hermaphrodite flower ciliate.—This species is perennial; flowers from July to September; and is a native of Jamaica.

24. *Andropogon Nardus*; *Indian Nard*, or *Spikenard*. Branches of the panicle superdecompound, proliferous. This is said to be used as a spice among the Orientals: as brought to us, it is a congeries of small tough reddish-brown fibres, forming a bunch about the size of a finger, and is moderately warm and pungent, accompanied with a flavour which is not disagreeable. The whole plant has a strong aromatic odour; but both the smell and the virtues reside principally in the husky roots, or lower part of the stalks, which in chewing have a bitter, warm, biting taste, accompanied with a slight degree of that glow in the mouth which cardamoms occasion, and possesses a pungency to the taste little inferior to the *Serpentaria*, and much more considerable than the *Contrayerva*. The Hindoos call it *terankus*, (fever-restrainer) from the virtues they attribute to it in that disease. They infuse about a drachm of it in half a pint of hot water, with a small quantity of black pepper. This serves for one dose, which they repeat three times a day. It is esteemed a powerful medicine in all kinds of fevers, whether continued or intermitting; and a work attributed to Galen, informs us, that a medicine, composed of this and some other aromatics, was found useful in long-protracted fevers, which are the cases in which modern practitioners employ medicines of this class. The ancients highly valued it as a luxury, as well as a medicine, it being the favourite perfume which they used at their baths and feasts; and, from the following words of Horace, it appears that it was so valuable, that as much of it as could be contained in a small box of precious stone was considered as a sort of equivalent for a large vessel of wine; and, according to the custom of antiquity, a handsome quota for a guest to contribute towards an entertainment:—

“ — *Nardo vina merebere,*

“ *Nardi parvus onyx elicet cadum.*”

HOR. LIB. IV. CAR. XII. V. 16, 17.

“ To purchase wine with spikenard dost thou ask?

“ A tiny box will bring a teeming cask.”

25. *Andropogon Muticum*, Spikes digitate, mostly three; floscules alternate, sessile, awnless. Culms seven inches high.—A native of the Cape.

26. *Andropogon Ischæmum*. Many digitate spikes; floscules sessile, awned and awnless; pedicles woolly.—This species is found upon mountains and hills, and in dry situations, in the southern parts of Europe.

27. *Andropogon Fasciculatum*; *Many-spiked Andropogon*. Spikes fascicled, very many, smooth; calices two flowered; valves acute, smooth, and even, the outer like petals and awned, the inner floscule barren.—Native of Jamaica, flowering from July to September.

28. *Andropogon Polydactylon*. Spikes fascicled; outer petals awned; those of the lower floscule ciliate-bearded.—Native of Jamaica.

29. *Andropogon Glaucum*. Panicle leafy; involuclers and calices two-flowered; calices of the sessile flowers three-valved, of the peduncled ones two-valved. Culm filiform, a foot high, leafy.—It is a native of the East Indies.

30. *Andropogon Serratum*. Spike simple, imbricate, with two rows of awned sessile flowers, and two of awnless pedicelled ones; calices one-valved.—Native of Bengal.

31. *Andropogon Incurvatum*. Spikes filiform, subdigitate;

flowers twin, the female pedicelled and awned, the male sessile and awnless; calices one-valved.—Found near rivers in Tranquebar.

32. *Andropogon Binatum*. Spikes twin, woolly; one valve of the calices acuminate, the other truncate, three-toothed; the larger petal awned.—Found in the East Indies.

33. *Andropogon Aciculatum*. Panicle contracted, upright; peduncles three-flowered; male flowers two-pedicelled, acuminate, female sessile, awned.—Native of the East Indies.

34. *Andropogon Bladhii*. Spikes about eight; hermaphrodite floscule sessile, awned; neuter, peduncled, ciliate, awnless.—Native of China.

35. *Andropogon Provinciale*. Spikes fascicled, smooth; floscules alternate, subsessile, directed one way, awned. Root annual; culms a foot high, leafy, branched at the base. A native of the south of France.

Androsace; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre many-leaved, many-flowered, very small; perianth one-leaved, five-cornered, semiquinquefid, acute, erect, permanent. *Corolla*: monopetalous, salver-shaped; tube ovate, involved in the calix; border flat, five-parted; divisions ovate-oblong, obtuse, entire; throat beset with glands. *Stamina*: filamenta very short, within the tube; antheræ oblong, erect, included. *Pistil*: germen globose; style filiform, very short; stigma globose, included. *Pericarp*: capsule globose, sitting on a flat calix, one-celled, opening into five parts at the top. *Seeds*: very many, roundish, gibbous on one side, flat on the other. *Receptacle*: erect, free. ESSENTIAL CHARACTER. An involucre to the umbel; tube of the corolla ovate, with a glandulous mouth; capsule one-celled, globose.—These are low plants with small flowers, and make no great appearance. They only require to be kept free from weeds, and to be sown in a shady situation. They seldom appear the first year, but if permitted to scatter themselves, often succeed better than when sown. The annual sorts perish as soon as the seeds are ripe; but the others will live in an open border for several years.—The species are,

1. *Androsace Maxima*; *Oval-leaved Androsace*. Perianths of the fruit very large. Root annual, slender. It flowers in April or the beginning of May, the seeds ripen in June, and the plants perish soon after. It grows naturally among the corn in various parts of Germany and Italy.

2. *Androsace Elongata*; *Cluster-flowered Androsace*. Leaves lanceolate-toothed; fruiting umbel elongate; corollas shorter than the angular calix.—Native of Austria, near Vienna, growing up to the very suburbs. Its flowers, which are white, appear in May, and the seeds are perfected in June.

3. *Androsace Septentrionalis*; *Tooth-leaved Androsace*. Leaves lanceolate-toothed, smooth; perianths angular, shorter than the corollas, annual.—Native of mountainous situations on all the northern parts of the Continent.

4. *Androsace Villosa*; *Hairy Androsace*. Leaves hairy: perianths shaggy. Tube of the corolla yellow, spreading into a white border, which at length becomes purple.—Common in the Swiss Alps, the mountains of Austria and Carniola, the Pyrenees, &c. Perennial. Flowers in July and August.

5. *Androsace Lactea*; *Grass-leaved Androsace*. Leaves lanceolate, smooth; umbel many times larger than the involuclers. Root perennial. Tube of the corolla yellow, with yellow glands at the throat; segments orbiculate; large, emarginate, snow-white.—Place of growth, and time of flowering, the same as the fourth, or preceding species.

6. *Androsace Carneæ*; *Awl-leaved Androsace*. Leaves awl-shaped, smooth; umbel equalling the involuclers. Corollas flesh-coloured.—Native of the Alps and Pyrenees.

7. *Androsace Filiformis*. Leaves ovate-toothed, petioled; rays of the umbel capillary; corollas exceeding the bell-shaped calix. Corolla white.—A native of Siberia.

Androsæmum. See *Hypericum*.

Andryala; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common, many-parted, short, rounded, villous: scales very many, subequal, subulate. *Corolla*: compound imbricate, uniform; corollules hermaphrodite, numerous, equal; each ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical tubulose. *Pistil*: germen ovate; style filiform, the length of the stamina; stigmas two, reflex. *Pericarp*: none. *Calix*: converging, globose. *Seeds*: solitary, ovate; down capillary, the length of the calix. *Receptacle*: villose, flattish. ESSENTIAL CHARACTER. *Receptacle*: villose. *Calix*: many-parted, subequal, rounded. *Down*: simple, sessile.—Every species in this genus may be propagated from seeds; those of the hardy sorts should be sown in spring, wherever they are to remain. These plants require no culture, but occasional thinning and weeding. The second, third, fourth, and fifth species, require the protection of a green-house, where they will flower all the summer and frequently produce seeds fit for propagation. The perennials are increased by their creeping roots.—The species are,

1. *Andryala Integrifolia*; *Hoary Andryala*. Lower leaves runcinate; upper ovate-oblong, tomentose. The flowers are yellow, like Sowthistle. It flowers in July, and the seeds ripen in September.—There is a variety of this species; both are annuals, and natives of the southern parts of Europe.

2. *Andryala Cheiranthifolia*; *Various-leaved Andryala*. Leaves runcinate; upper ones lanceolate, entire; down glanduliferous. Perennial; three feet high, full of milk; flowers yellow, scarce, nodding.—Native of the island of Madeira.

3. *Andryala Pinnatifida*; *Pinnatifid-leaved Andryala*. Leaves tomentose, pinnatifid; calices tomentose, hairy; hairs rather stiff.—Biennial: flowering in July and August.—Native of the Canary Islands, where, and in Madeira, it and two varieties of the same species are found.

4. *Andryala Crithmifolia*; *Samphire-leaved Andryala*. Leaves pinnate, linear, tomentose.—Native of Madeira.

5. *Andryala Ragusina*; *Downy Andryala*. Leaves lanceolate, undivided, denticulate, acute, tomentose; flowers solitary. This plant has a yellow flower, terminating every branch in June and July, and being very hoary, makes a pretty appearance among others whose leaves are green. It will not bear the open air, except in a dry soil and warm situation.—Found in Spain, in Algiers, as well as at the Cape.

6. *Andryala Lanata*; *Woolly Andryala*. Leaves oblong-ovate, slightly toothed, woolly; peduncles branching. A biennial; with a large yellow flower, which appears in June, and is followed by the seeds in August. The whole plant is white.—Native of the south of Europe.

Anemone; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals in two or three rows, three in a row, somewhat oblong. *Stamina*: filamenta numerous, capillary, half the length of the corolla: antheræ twin, erect. *Pistil*: germina numerous, in a head; styles acuminate; stigmas obtuse. *Pericarp*: none; receptacle globular or oblong, hollowed and dotted. *Seeds*: very many, acuminate, retaining the style. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: six or nine. *Seeds*: many.—The plants of this genus are mostly hardy perennials, and may be propagated both by seeds and by the roots.—The species are,

1. *Anemone Hepatica*; *Hepatica*. Leaves three-lobed,

quite entire. Flower subcaliculate, lying a year complete in all its parts within the bud, and is one of the most eminent beauties of the spring. The flowers appear plentifully in February and March, before the green leaves appear; and the double sorts, which have fairer and more durable flowers than the single ones, make a beautiful appearance upon the borders of a pleasure-garden. The single sorts produce seed annually, which should be sown in pots or boxes of light earth at the beginning of August, placed so as to have only the morning sun upon them till October, and then removed into the full sun for the winter season. In March they must be replaced in a shady situation, and frequently be watered in dry weather. In the following August they must be transplanted into a border of good fresh loamy earth, facing the east, where they must be placed six inches asunder each way, and have the earth pressed closely to their roots, otherwise the worms will draw them out of the ground. They will shew their flowers in the following spring; but it will be three years before they flower strongly.

You may then venture to judge of their quality; and if you find any double flowers, or any of a different colour from the common sorts, they should be taken up and transplanted into borders of the flower-garden, where they should continue two years at least before they are taken up or parted; for when they are often removed and parted, they are very subject to die, but if undisturbed for many years, they thrive exceedingly and produce large roots. The double flowers are therefore propagated by parting their roots in March, placing them where they can enjoy the morning sun, in a strong loamy soil. They will grow any where, except in very hot places, and are not injured by cold.—There are many varieties of this *Hepatica* species, as 1. Single and double blue. 2. Single and double red or peach-coloured. 3. Single and double white. 4. Single and double variegated red and white. 5. Single and double violet-coloured. 6. With striped leaves. This is an astringent plant, but is seldom used.—It is found wild in Sweden, Denmark, Switzerland, France, Spain, Italy, and other parts of Europe, in woods and among bushes with blue, red, and white flowers.

2. *Anemone Patens*; *Woolly-leaved Anemone*. Peduncles involucred; leaves digitate, multifid; seeds tailed. Corolla white.—A native of Siberia and Lower Lusatia. This and the following eight species are propagated by seeds in nearly the same manner as the *Hepatica*, No. 1. which see. They must not be exposed to the forenoon sun in the spring, and they require a loamy soil, as they are apt to decay in light ground during summer.

3. *Anemone Sulphurea*. Peduncle involucred; leaves tri-pinnate, hairy, flat, acutely gashed: seeds tailed. Petals yellow within.—See the preceding species.

4. *Anemone Baldensis*. Peduncle involucred; seeds tailed; leaves biternate, shaggy. The corolla has eight or ten white petals, shaggy on the outside and reddish.—It grows wild in Switzerland, Monte Baldo, Mont Cenis, &c.

5. *Anemone Vernalis*. Peduncle involucred; leaves pinnate; flowers erect; seeds tailed. Flower red without, white within.—Found growing in woods bordering on the mountains, and barren sands, in Sweden, Germany, and on the high Alps of Switzerland.

6. *Anemone Cernua*. Peduncle involucred; leaves pinnate; flowers nodding; seeds tailed.—Found flowering early in the spring near Jeddo, in the island of Japan.

7. *Anemone Pulsatilla*; *Pasque-flower*. Peduncle involucred; petals straight; leaves bipinnate; seeds tailed. The corolla is a specious purple.—It grows wild in the dry soils of almost every country upon the European continent, and upon

the chalky downs of England; as Gog-magog hills, Barnack-heath, near Stamford; about Leadstone-hall, near Pontefract; near Charlbury, in Oxfordshire; Hexam, Bury, Newmarket, &c. It flowers in April, and derives its Italian name, *pulsatilla*, from the downy seed being beaten about by the wind. There is one variety with double, and another with white flowers. It is an acrid plant, and will raise blisters; the distilled waters produce vomiting: it cannot therefore be safely given in disorders of the lungs.

8. *Anemone Pratensis*; *Meadow Anemone*. Peduncle involucred; petals reflex at the tip; leaves bipinnate. The flower of this is less than that of the former, and of a darker colour.—This species is common in barren stony fields of Oeland and Scania; also in Denmark, Germany, and Piedmont.

9. *Anemone Alpina*; *Alpine Anemone*. Peduncle involucred; stem leaves ternate, connate, super-decompound, multifid; seeds shaggy, tailed. Flower almost the size of the Tulip, white, with a tinge of purple, and pubescent on the outside.—It grows wild on the Alps, Jura, and in Austria.

10. *Anemone Apiifolia*. Peduncle involucred; stem-leaves ternate, connate, super-decompound, multifid, very slender, extremely hairy underneath. Stem simple, about a span high; flower large, and of a sulphureous colour, without any smell.—A native of the Leontine Alps.

11. *Anemone Coronaria*; *Narrow-leaved Garden Anemone*. Radical leaves ternate, decompound; involucre leafy. It has a leafy stem, and tailed seeds.—This species is a native of the Levant, particularly in the islands of the Archipelago, where the borders of the fields are covered with it of all colours; but the flowers are single, and have been doubled only by culture. Modern seeds-men reckon from one hundred and fifty to two hundred sorts of this flower; the principal colours of which are white, red, blue, and purple, and these in some are curiously intermixed. The prevailing colours of English-raised Anemones are white and red; though we have received from France great variety of blues and purples, which are exceedingly fine flowers, and make a beautiful variety, when intermixed with those of English growth. A Double Anemone, in order to be a fine one, should have a strong upright stem, about nine inches high; the flower two or three inches in diameter, the outer petals firm and horizontal, except a little turning up at the end; while the smaller petals within these should lie gracefully over each other so as to form an elegant whole. The plain colours ought to be brilliant and striking, the variegated tints clear and distinct.

—*Directions for their culture*. Twelve months before you want to use it, mix a quantity of light sandy loam, or hazel mould, taken with the turf to the depth of ten inches, but no more; add a third part of rotten cow-dung, and lay the whole in a heap, turning it once a month, taking out all the stones, and breaking every clod, but on no account sift it. After the year has expired, at the beginning of September prepare your bed by laying this earth six or eight inches above the surface of wet ground, but if a dry soil, three inches will do, whereon you have previously laid the rakings of your heap to drain off the moisture, and upon that four or five inches deep of rotten cow-dung, putting your prepared earth upon the top to the depth of about two feet. If the soil be wet, lay the bed a little round, to shoot off the water; but if dry, bring it nearly to a level. Plant the forward flowers at the latter end of September, those of a middle season any time in October, at the time of some gentle showers, and cover them from the winter frosts by arching the beds over with hoops, and laying mats and garden cloths upon them. They will flower in the beginning of April, and continue for three weeks or more, according to the mildness of the weather, and the care taken to screen them from the sun.

The leaves will begin to decay in June; they must soon after be taken up, cleared from decayed stalks, washed clean, and spread upon a mat in a shady place until they are perfectly dried, and should then be hung up out of the reach of vermin in bags. Observe, in planting the roots, to distribute the different colours, which will greatly increase their beautiful appearance by the contrast with each other. No good florist, however, who has garden room, should omit to sow the seeds; he should provide himself with a quantity of good single or *Poppy Anemones* of the best colours, having more leaves than common, with other good qualities, and plant them early in the beginning of August, either in pots, beds, or tubs of light earth, taking care to rub the seeds between his hands with a slight mixture of dry sand, to separate and prevent them from adhering together; and after sowing them as equally as possible over the bed, taking a strong hair-brush and sweeping it gently over the whole bed, observing not to brush off the seeds, by which he will leave no lumps, and make the distribution complete. Light earth, to the depth of one quarter of an inch, may then be sifted over the seeds; and mats laid over the whole, if the weather be hot and dry. They may be occasionally but sparingly watered, and should always be exposed to gentle showers. In ten weeks the plants will appear; they will be very liable to suffer, if not protected from the frosts of the first winter, and from too much wet, together with the piercing winds of February and March: a low reed-fence on the north and east sides of the bed will be very useful. As the spring advances, they may be thinned if necessary; and as soon as their green leaves decay, you must sift the earth of the bed with a very fine sieve, till you have taken out all the roots you can find; and then level the bed, and let it remain till the next year, when you will again find a plentiful crop from those roots which will unavoidably have escaped you in the sifting. The before-mentioned young roots must be cleaned and dried, as above prescribed for the older plants; but when replanted, the former should be put into the ground three weeks before the latter, that they may gather strength, and flower abundantly in the succeeding year. The single or poppy Anemones, in favourable seasons and warm situations, will flower through most part of the winter and spring, and from their peculiar beauty well deserve admittance into every flower-garden. They need little culture; it will be often enough to take them up every other year, and when they are taken up, they should be replanted very early in the autumn, otherwise they will not flower till the spring. The seeds of these flowers must be gathered daily as they ripen, otherwise they will soon be dispersed by the winds.—This species was cultivated in France, long before it was known in England or Holland.

12. *Anemone Hortensis*; *Broad-leaved Garden Anemone*. Leaves digitate; seeds woolly; leafy stem, and tailed seeds.—This was formerly called *Hard-leaved Anemone* by the Walloons, who imported the roots. It is found wild with single flowers in Italy, Provence, and Germany. It was discovered with red and with purple flowers near the Rhine, and in many parts of Italy and Switzerland; and with white flowers in Germany and in Austria. There are many varieties of this species, to enumerate which would be as tedious as useless. For the culture and propagation of this species, see the preceding species, No. 11. the detail respecting which, is equally applicable to the proper management of both.

13. *Anemone Palmata*. Leaves heart-shaped, sublobate; calix six-leaved, coloured; stem leafy; seeds tailed. The petals, ten or more, are yellow without and orange within.—Found near the Tagus in Portugal.

14. *Anemone Sibirica*. Stem one-flowered; involucre leafy, obtuse; flower naked; seeds tailless.—Found in Siberia.

15. *Anemone Silvestris*; *Large White-flowered Wood Anemone*. Peduncle naked; seeds rounded, shaggy, awnless; flower naked; seeds tailless. The flower is large, and white, with but little beauty; yet there is in the flowers, especially before they expand, a simple elegance, resembling the Snow-drow, which forms a pleasing contrast to the more showy ones of the garden. They appear in May, and produce seeds in June, standing on the tops of the flower-stalks, which sometimes grow two together, but generally single. It is a native of many parts of Germany, and has been seen in Sweden, Alsace, and Siberia.

16. *Anemone Fragifera*. Peduncle naked; seeds roundish, woolly, awnless, tailless. Flowers naked, without smell, pale purple, solitary, deciduous, hirsute.—Native of Corinthia.

17. *Anemone Virginiana*; *Virginian Anemone*. Peduncles alternate, very long; fruit cylindrical; seeds shaggy, awnless, tailless; flowers naked, and green like the calix, appearing in May and June.—Native of N. America.

18. *Anemone Decapetala*; *Ten-petalled Anemone*. Stem one-flowered; flower ten-petalled; leaves ternate, lobate, radical. Flower naked, small, and white; seed tailless.—It is found in Brazil.

19. *Anemone Pennsylvanica*; *Pennsylvanian Anemone*. Stem dichotomous; leaves sessile, stem-clasping, the lowest ternate, trifid, gashed. Flower naked; seed tailless.—Native of Canada and Pennsylvania.

20. *Anemone Dichotoma*. Stem dichotomous, a foot high; leaves sessile, all opposite, stem-clasping, trifid, gashed. Flower naked; seed tailless; root creeping far and wide; corollas purplish underneath.—Native of Canada and Siberia.

21. *Anemone Trifolia*. Leaves ternate, ovate, entire, serrate; stem one-flowered. Flower naked; seed tailless; corolla six-petalled, and white. It flowers at the end of April.—Grows in the woods of France, Carniola, and Siberia.

22. *Anemone Quinquifolia*. Leaves quinate, oval, serrate; stem one-flowered; flower naked; seed tailless.—Native of Virginia and Canada.

23. *Anemone Nemorosa*; *Wood Anemone*. Seeds acute, tailless; leaflets gashed; stem one-flowered; flower naked. Root perennial, creeping; height of the plant five to ten inches; the usual colour of the flower white. It grows in woods among bushes, in hedges, sometimes in pastures, of most parts of Europe. It almost covers the ground with its flowers in some of the woods of England during March, April, and May. In fine clear weather the blossoms are expanded, and become so erect as to face the sun; but in wet weather, and in the evening, they are closed and hang down. As the paper in which dried specimens of this plant had been preserved was stained brown, it might probably be useful as a dye. It is acrid, and slightly poisonous. Linneus informs us, that cattle brought from open to woody pastures, and eating of this plant, have afterwards had the bloody flux, and voided bloody urine. When the flowers become double, the Wood Anemone is cultivated by the gardeners; and, were the same pains taken with it as with the foreign Anemones, it would in all probability be much improved in the eye of the florist. This plant is also called the *Wind Flower*. The juice snuffed up the nose, or the root held in the mouth, excites a discharge of cold watery humours from the head and parts adjacent. The leaves bruised, and applied to ulcers and running sores, cleanse, and dispose them to heal. Some authors recommend it in suppressions of the menses; but it is too acrid in its nature for internal use, and might prove fatal in unskilful hands.—The roots may be taken up when the leaves decay, and transplanted into wildernesses, where they will greatly increase if not disturbed; and in the spring, before the leafing of the trees, the ground will be covered with their flowers.

24. *Anemone Apennina*; *Mountain Wood Anemone*. Seeds acute, tailless; leaflets gashed; petals lanceolate, numerous, from 12 to 15, disposed in three rows: flowers naked, upright, of a pale blue colour, and sweet smell. This flowers at the same time as the *Wood Anemone* (No. 23.) and makes a fine variety when intermixed with it. Double flowers of both sorts have been obtained from seeds.—Native of the Apennines, near Rome; and of Wimbledon, near Harrow on the Hill, in a wood by Luton Hoe, Bedfordshire, and near Berkhamstead, in Hertfordshire.—It may be propagated by offsets from the root, and will flourish in almost any situation, but loves a light loamy soil.

25. *Anemone Ranunculoides*; *Yellow Wood Anemone*. Seeds acute, tailless; leaflets gashed; petals roundish; stem mostly one-flowered; flower naked.—This has a yellow corolla; and grows wild in almost all parts of the European continent. In Great Britain it has been found near King's Langley in Herts, and near Wrotham in Kent.

26. *Anemone Narcissiflora*; *Narcissus-flowered Anemone*. Flowers umbelled; seeds oval, depressed, naked, tailless. Flowers white within, reddish without, forming a salver-shaped corolla.—It grows wild on the mountains of Austria, Switzerland, and Siberia.

27. *Anemone Fasciculata*. Flowers umbelled, collected, naked; leaves multifid; seeds tailless.—Found in the mountains near the Baikal lake; first observed in the Levant.

28. *Anemone Thalictroides*; *Meadow Rue-leaved Anemone*. Flowers umbelled, naked; stem-leaves simple, verticillate; radical leaves biternate; seeds tailless.—The corolla is white; and it is a wild native of Virginia and Canada.

Anethum; a genus of the class Pentandria, order Digynia. —GENERIC CHARACTER. *Calix*: umbel universal and partial manifold; involucre neither universal nor partial; perianth proper obsolete. *Corolla*: universal uniform; floscules all fertile, proper; petals five, involute, entire, very short. *Stamina*: filamenta capillary; antheræ roundish. *Pistil*: germen inferior; styles approximating, obsolete; stigmas obtuse. *Pericarp*: none; fruit subovate, compressed, striated, bipartite. *Seeds*: two, subovate, margined, convex, and striated on one side, flat on the other. ESSENTIAL CHARACTER. *Fruit*: subovate, compressed, striated. *Petals*: involuted, entire.—The species are,

1. *Anethum Graveolens*; *Common Dill*. Fruit compressed. Dill differs from Fennel, which it otherwise greatly resembles, in having an annual root, and a smaller and lower stem; the umbel of flowers yellow, but smaller than those of Fennel. It has a peculiarly strong and aromatic smell. The bruised herb is anodyne and resolvent; and the seeds being aromatic, and containing an ethereal oil, are used in flatulencies, for which purpose they rub the bellies of children with the oil prepared by infusion; the essential oil is also good for the colic. The seeds given in doses of a drachm, disperse wind in the stomach, help digestion, and cure the colic: they likewise operate by urine, and are said to be an infallible cure for the chincough, but probably without foundation. Culpeper says, that the seeds being roasted or fried, and used in oils or plaisters, dissolve imposthumes and dry up all moist ulcers. The decoction, whether of herb or seed, which must be first bruised, he also prescribes as a "gallant expeller of wind, and provoker of the terms." A distilled water, drawn off to the quantity of a gallon from a pound of seeds, was ordered in the London Pharmacopœia; and occasionally made the basis of carminative draughts and juleps, having a more agreeable flavour than the seeds themselves. Together with this water arises a considerable quantity of essential oil, which is given from one

to three or four drops, or more, as a carminative, and in hiccoughs.—It grows wild among the corn in Spain and Portugal, and also upon the coast of Italy.—This plant is propagated by sowing the seeds soon after they are ripe, in autumn, in a light soil, where they are to remain, allowing them eight or ten inches room to grow. When they appear, hoe them in the same manner as onions, leaving them every way eight or ten inches asunder, and clearing them from weeds. When the seeds begin to form, cut up those intended to put into the pickle for Cucumbers, leaving those that are for seed till ripe; when you must cut, and spread them upon a cloth to dry; and then beat out for use. If the seeds be suffered to fall upon the ground, the plants will appear in the spring without any further care.

2. *Anethum Segetum*. Three stem leaves; fruits oval; corolla flosculous, yellow. Annual.—Native of Portugal.

3. *Anethum Fœniculum*; *Fennel*, or *Finkle*. Of this there are three varieties, viz. *Fœniculum Vulgare*, or Common Fennel; which has a strong fleshy root, penetrating deep into the ground, and continuing many years.—*Fœniculum Dulce*, or Sweet Fennel;—and *Fœniculum Azoricum*; Azorian Fennel, or *Finochio*.—Fruits of both the species and varieties ovate. The first, or *Common Fennel*, flowers in July, and ripens seed in autumn, and though not a native of England, but of Germany, Spain, Italy, Madeira, and China, has sown itself so plentifully in many places where it has been introduced, that it is now become common upon our chalky cliffs, near Gravesend, and other parts of Kent; in Sussex; near Marazion in Cornwall; and inland, near Nottingham castle, Spetchly in Worcestershire, and Burwell in Cambridgeshire. *Sweet Fennel*; the leaves of which are very long and slender; the stalks shorter than those of the common sort; and the seeds longer and of a lighter colour. The seeds are imported from Germany and Italy, and are by some preferred to the common sort, being much sweeter.—The tender buds of *Fennel* are eaten in salads, and the boiled leaves as a sauce to fish, and also raw with pickled fish. In Spain, they are cut up with olives and pickled pork. The seeds of Common Fennel are warmer than those of the *Sweet Fennel*, but less sweet, and not of so grateful a flavour. There is the same difference in the preparations from them: the spirituous tincture of *Sweet Fennel* is yellowish; of the common, greenish. The distilled leaves impregnate water with a grateful flavour, and yield a considerable portion of essential oil. An extract made from them by rectified spirit is by no means a despicable aromatic. The essential oil procured from the seeds expels wind, and increases the urinary evacuation, but is not of a heating nature. The roots taken up early in the spring have a pleasant sweetish taste, with a slight aromatic warmth, and are ranked among aperient roots. Hill recommends a decoction of it made with common water, when given in large quantities, as operating by urine, and relieving the gravel and jaundice. Meyrick says, a strong decoction of the root is a good medicine in the jaundice, dropsy, and all other disorders arising from obstructions of the viscera. The seeds reduced to powder, and taken every morning fasting, are said to preserve the sight from decaying, and to restore it when impaired. A decoction of them is good in the small pox and measles; it likewise relieves shortness of breath, and other complaints of the lungs, and promotes urine and the menses. The seeds applied externally in poultices, are found to be useful in dispersing hard swellings in any part of the body. Culpeper remarks, that *Fennel* is boiled with fish to correct the phlegmatic tendency of that kind of food, though few persons know why they use it, as it is a very ancient custom. He recommends the leaves or seeds to be boiled in

barley-water, and drank, as good to increase the quantity and improve the quality of nurses' milk; also, when boiled in water, for the hiccough, and heat of the stomach and loathing; and boiled in wine, as an antidote for those who have eaten poisonous herbs or mushrooms. A pound of *Sweet Fennel* seeds impregnates a gallon of water strongly with their flavour, in distillation. A great quantity of mild, sweetish, and yellowish essential oil, like that of Aniseeds, floats on the surface of the water, and, like it, also congeals by a slight cold into a white mass like butter. These seeds also contain a considerable quantity of expressed oil, which is extracted by digestion in rectified spirit, along with the aromatic matter of the *Fennel*, but rises to the surface upon inspissating the filtered tincture; the concentrated extract retains much of the greatest part of both taste and smell.—The best time to sow the seeds of *Fennel* is soon after they are ripe; the plants will come up in autumn or the following spring, and, as they will grow in any situation, only require to be thinned when too close, and kept free from weeds.—The third variety, or *Finochio*, though a favourite salad herb of Italy, is not much liked, and therefore little cultivated in England, where it seldom survives the cold of winter. It has very short stalks, swelling just above the surface of the ground, to four or five inches broad, and two inches thick, which being tender and fleshy, is eaten, when blanched, with oil, vinegar, and pepper; as a cold salad. The seeds are narrow, crooked, and of a bright yellow colour, with a strong smell like Aniseed, and a very sweet taste. They should be sown in light rich earth early in March, and will be fit for use in July. Sow the seeds about two inches apart, in shallow drills eighteen inches asunder. As soon as the plants appear, remove the weeds with a hoe, and thin them occasionally until they are at least seven or eight inches asunder. When the plants begin to swell in the stems above the surface of the ground, they must be earthed up like Celery to blanch, which will make them very crisp and tender. You may sow successive crops until July, after which it will be too late for them to come to perfection. In case of sharp frosts in autumn, they may be covered with pease-haulm, which will screen them from the cold, and preserve them for winter use. A small bed will suffice for a moderate family; but it will require a bed twenty feet long and four broad to supply a large one.

Angelica; a genus of the class Pentandria, order Digynia. GENERIC CHARACTER.—*Calix*: universal, umbel manifold, roundish; partial when flowering exactly globular; universal involucre three or five leaved, small; partial eight-leaved, small; proper, perianth, five-toothed, scarcely observable. *Corolla*: universal uniform; floscules all fertile; partial, petals five, equal, lanceolate, flattish, incurved, caducous. *Stamina*: filamenta simple, longer than the corolla; antheræ simple. *Pistil*: germen inferior; styles reflex; stigma obtuse. *Pericarp*: none; fruit roundish, angular, solid, bipartite. *Seeds*: two, ovate, flat on one side, and margined, convex on the other, scored with three lines. ESSENTIAL CHARACTER. *Fruit*: roundish, angular, solid, with reflex styles. *Corolla*: equal, with petals bent inwards.—Every species of this genus may be increased by seed; they are all hardy biennial or perennial plants.—The species are,

1. *Angelica Archangelica*; *Garden Angelica*. The odd leaflet of the leaves lobed. Root thick, branched, very long, brown on the outside, white within. The stalks of this plant were formerly blanched and eaten as celery. The Norwegians make bread of the roots; and the young shoots are greatly esteemed by the Laplanders. In gardens near London, through which small streams of water run, great quantities of this plant are propagated, the tender stalks of which are

cut in May for the confectioners, who have a great demand for it as a sweetmeat. The roots once formed one of the principal aromatics of European growth, though little regarded at present; the other parts of the plant have the same flavour, but their active principles are far more perishable. Though the seeds, which come nearest to the roots, can scarcely be kept till the spring after they are gathered, they are the only part of the plant ordered by the London College, and that only in compound spirit of Aniseed. Of this plant, Hill says, every part is fragrant, when bruised, and every part is used in medicine; but the roots and seeds possess the highest degree. They are cordial, sudorific, and stomachic, and of great efficacy in pestilential disorders, and contagions of every kind, in all cold flatulent complaints, and seldom fail of removing the ague, if taken three or four times repeatedly on the approach of the fit. A scruple of the dried root in powder, or ten grains of the seed, is a moderate dose. The roots and stalks are sometimes candied, and are then more palatable, and equally efficacious. The root is long and large; that of our own growth is used fresh, but the fine fragrant dried roots are brought from Spain. The whole plant possesses the same virtues, and is cordial and soporific; it has always been famous against pestilential and contagious diseases. The root, the stalks candied, the seeds bruised, or the water distilled from the leaves, may be used; but the seeds are the most powerful, and they are also an ingredient in many compositions. Culpeper prescribes also a water distilled in a glass from the root steeped in wine, as more effectual than the water of the leaves, and, in two or three spoonfuls at a time, to ease all pains produced by cold or wind, if the body be not costive; and taken with some of the root in powder, for the pleurisy and all other diseases of the lungs and breast, such as coughs, phthisic, and shortness of breath, for which he remarks, that a syrup of the stalks will be found equally good.—This plant flowers with us from June till August, and delights in a moist soil. To propagate it, sow the seeds soon after they are ripe; when they are six inches high, transplant them three feet asunder upon the sides of ditches or pools of water, where they will not fail to thrive. The second year they will flower; and if you wish to continue the root, the stems must be cut down in May, which will occasion their putting out heads from the sides of the roots, whereby they may be continued for three or four years; but if they come to seed, they will perish soon after. Where they are cultivated for the seeds, there should be fresh plantations every year.—It is a native of the northern parts of Europe.

2. *Angelica Sylvestris*; *Wild Angelica*. Leaflets equal, ovate-lanceolate, serrate. It has a smooth stem, six feet high; is perennial; and very common in moist woods and hedges; and by the sides of rivers, flowering in July and August.—This herb yields a good yellow dye; and may be safely used as a medicine instead of the Garden *Angelica*; but as it only possesses its virtues in an inferior degree, it has been long neglected.

3. *Angelica Verticillaris*. Leaves very much divaricate; leaflets ovate, serrate; stem verticelled with peduncles; six feet high; flowers green.—A native of Italy and Silesia.

4. *Angelica Atropurpurea*; *Purple Angelica*. The outermost pair of leaves coadjoined; the terminal leaf petioled. Stem six feet high. A native of North America.

5. *Angelica Lucida*; *Shining Angelica*. Leaflets equal, ovate, gash-serrate. Stem from one to two feet high; petals of a dirty white or very pale yellow colour; seeds brown, and of a hot aromatic flavour. It flowers in June, ripens its seeds in August.—Native of Canada.

6. *Angelica Razulii*. Leaves bipinnate; leaflets lanceolate, serrate, decurrent. Stem three feet high; corollas a bright purple before they are unfolded, afterwards white.—Native of the Apennines and Piedmontese mountains.

Angelica Tree. See *Aralia*.

Anguina. See *Calla* and *Tricosanthes*.

Anguria; a genus of the class Monœcia, order Diandria.—GENERIC CHARACTER. *Male Flowers*. *Calix*: monophyllous, quinquefid, swelling at the base; divisions lanceolate, short. *Corolla*: pentapetalous, spreading, growing to the border of the calix. *Stamina*: filamenta two, opposite, inserted into the calix; anthera creeping up and down. *Female Flowers*. *Calix* and *Corolla*, as in the male. *Stamina*: filamenta as in the male, but without antheræ. *Pistil*: germen inferior, oblong; style semibifid; stigmas bifid, acute. *Pericarp*: a pome, oblong, quadrangular, bilocular. *Seeds*: very many, oval, compressed, nestling. ESSENTIAL CHARACTER. *Male*. *Calix*: five-cleft. *Corolla*: five-petalled. *Female*: *Calix* and *Corolla*: as in the Male. *Pome*: inferior, two celled, many seeded.—The species are,

1. *Anguria Trilobata*. Leaves three-lobed.—This plant has a very shining appearance; and is a native of Carthage in South America, flowering there in June.

2. *Anguria Pedata*. Leaves pedate, serrate. This is a perennial plant, which climbs trees to the height of twenty feet, by means of tendrils. The flowers, which are destitute of smell, and have orange-coloured petals, appear in September, and the fruit ripens in December.—Native of St. Domingo.

3. *Anguria Trifoliata*. Leaves ternate, quite entire.—Native of St. Domingo.

Anise. See *Illicium*, *Pimpinella*, and *Bubon*.

Annona; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved, small; leaflets cordate, concave, acuminate. *Corolla*: petals six, cordate, sessile; the three alternate interior ones less. *Stamina*: filamenta scarcely any; antheræ very numerous, placed on the receptacle. *Pistil*: germen roundish, placed on a roundish receptacle; styles none; stigmas obtuse, numerous, covering the whole germen. *Pericarp*: a berry, very large, roundish, clothed with a scaly bark, one-celled. *Seeds*: very many, hard, ovate-oblong, placed in a ring, nestling. ESSENTIAL CHARACTER. *Calix*: three-leaved. *Petals*: six. *Berry*: many seeded, roundish, with a scaly bark.—These plants require a bark-stove and careful management, plenty of air in warm weather, and to remain constantly in the tan-bed. They have flowered, but never borne fruit in England, where they are only preserved for the beauty of their leaves. They have been known to reach the height of twenty feet, but seldom exceed twelve or fourteen. The earth in which they are planted should be light and rich, and the tan-bed frequently turned over and refreshed, keeping the stove in which these plants are placed at the Ananas' heat, as marked upon the botanical thermometers.—The species are,

1. *Annona Muricata*; *Rough-fruited Custard Apple*, or *Sour Sop*. Leaves oval-lanceolate, smooth, acute; fruits muricate; petals ovate, the interior ones obtuse, shorter. This tree is twelve, fourteen, or twenty feet high, with an upright trunk, and stiff, round, smooth branches; the flowers coriaceous, yellow. It is common in every savanna of Jamaica, flowering in spring. The large succulent fruit is agreeable to new comers, and over-heated habits; but is so commonly used by the negroes, that the richer sort of people refuse it. The smell and taste of the fruit, flowers, and whole plant, very much resemble those of black currants.

2. *Annona Tripetala*; *Broad-leaved Custard Apple*. Leaves

ovate, acute, pubescent, beneath; flowers three-petalled; petals lanceolate, coriaceous, tomentose.—A very large tree in South America, producing a fruit highly esteemed by the Peruvians for its delicacy: it is oblong, scaly on the outside, and of a dark purple colour when ripe; the flesh is soft and sweet, and has many brown, shining seeds intermixed with it.

3. *Annona Squamosa*; *Undulated Custard Apple*, or *Sweet Sop*. Leaves oblong, acute, smooth; fruits obtusely scaled; outer petals lanceolate, inner ones minute.—A small tree, of eight feet high; flowers green without and whitish within.—A native of both Indies; where the fruit, which is sweet, is eaten.

4. *Annona Reticulata*; *Netted Custard Apple*. Leaves oblong-lanceolate, acute, smooth; fruits ovate, reticulate-areolate; outer petals lanceolate, inner minute. This species attains to the height of twenty-five feet or more, with spreading branches.—Native of both Indies: some say the fruit is much esteemed, and others that it is seldom eaten.

5. *Annona Hexapetala*; *Long-leaved Custard Apple*. Leaves elliptic-oblong, acute, smooth; petals spatulate, equal, acute.—Native of China, and cultivated in the East Indies.

6. *Annona Palustris*; *Shining-leaved Custard Apple*. Leaves oblong, rather obtuse, smooth; fruits areolate. This tree seldom exceeds six feet high; grows wild in soft marshy places of Jamaica. Its wood is so very soft, even after it is dried, that it is frequently used instead of corks, and is hence universally called *Corkwood* by the natives; who also call the fruit the *Alligator Apple*, which, though sweet-scented and of no ill flavour, is not eaten, because it is said to be a strong narcotic.

7. *Annona Triloba*; *Trifid-fruited Custard Apple*. Leaves elliptic, acute, smooth; flowers pendulous, campanulate; calices ovate; petals many, oval. The fruit grows in clusters of three or four together; they are at first green, and when ripe yellow, with a pulp of a sweet luscious taste. Every part of this tree has a rank, if not a fetid smell; and the fruit is relished by few except negroes. It grows in a fat soil, and low shady swamps.—It is a native of the Bahama Islands, also of Carolina, Maryland, and Virginia; and the seeds are frequently brought to England by the title of *Papaw Tree*. It will thrive in warm situations in the air of this country.

8. *Annona Glabra*; *Smooth Custard Apple*. Leaves lanceolate-ovate; fruits conoid, smooth. This tree attains the height of sixteen feet, and bears an insipid, sweet, eatable fruit, which is the food of guanas and other creatures.—Native of North America.

9. *Annona Asiatica*; *Asiatic Custard Apple*. Leaves lanceolate, smooth, shining, marked with lines. Native of the East Indies and of China; where it is cultivated; but the fruit, which is an oblong conical berry, filled with a whitish, sweet, eatable pulp, is inferior in flavour to the third sort.

10. *Annona Africana*; *African Custard Apple*. Leaves lanceolate, pubescent.—Notwithstanding its name *Africana*, it is said to be a native of America.

Anotta. See *Bixa*.

Anserina. See *Potentilla*.

Anteuphorbium. See *Cacalia*.

Anthemis; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common hemispherical; scales linear, subequal. *Corolla*: compound radiate; corollules hermaphrodite, tubular, numerous, in a convex disk; females more than five in the ray. Proper of the hermaphrodite, funnel-shaped, five-toothed, erect:

of the female, ligulate, lanceolate, sometimes three-toothed. *Stamina*: in the hermaphrodites, filamenta five, capillary, very short; anthera cylindrical, tubular. *Pistil*: in the hermaphrodites, germen oblong; style filiform, the length of the stamina; stigmas two, reflex: in the females, germen oblong; style filiform, the length of the hermaphrodite; stigmas two, revolute. *Pericarp*: none; calix unchanged. *Seeds*: solitary, oblong; down margined, or none. *Receptacle*: chaffy, convex, or conical. ESSENTIAL CHARACTER. *Receptacle*: chaffy. *Down*: none. *Calix*: hemispherical, nearly equal. *Floscules of the ray*: more than five.—Some plants of this genus are annuals, others perennials, and all, except the fifteenth and nineteenth species, are hardy enough to bear the open air. They are propagated by seeds sown upon poor land in the spring; they flower in July; and only require to be weeded and kept well asunder, as they are generally bushy, and require room.—The species are,

* *With a discolour, or white Ray.*

1. *Anthemis Cota*. Chaffs of the flowers rigid, pungent. The largest flower of this genus.—An annual; native of ploughed fields in Italy and Spain.

2. *Anthemis Altissima*; *Tall Chamomile*. Erect, with leaves pinnate; the bases of the pinnae rough, with a reflex toothlet.—Annual; growing wild in the south of France, Spain, and Italy.

3. *Anthemis Maritima*; *Sea Chamomile*. Leaves pinnate, toothletted, fleshy, naked, dotted; stem prostrate; calices rather tomentose. The flowers have the smell of Feverfew; they flourish in July and August.—It grows wild about Montpellier, in Italy, and in England.

4. *Anthemis Tomentosa*; *Downy Chamomile*. Leaves pinatifid, obtuse, flat; peduncles shaggy, leafy; calices tomentose.—Native of the coasts of Greece, Italy, and France.

5. *Anthemis Mixta*; *Simple-leaved Chamomile*. Leaves simple, jagged, toothed.—An annual; growing wild in Italy and France.

6. *Anthemis Alpina*; *Alpine Chamomile*. Leaves tooth-pinnate, quite entire, linear; stem villose, one flowered; petals ovate; chaffs sphacelate.—Perennial; native of Italy.

7. *Anthemis Chia*; *Cut-leaved Chamomile*. Leaves pinatifid, jagged; peduncles naked, subvillose.—Seen by Tournefort in the isle of Chios.

8. *Anthemis Nobilis*; *Common or Sweet Chamomile*. Leaves pinnate-compound, linear, acute, subvillose.—It abounds in most of the dry commons of Surry, and in Cornwall, flowering in July and August. The leaves and flowers have a strong, but not ungrateful smell, with a very bitter nauseous taste, especially the flowers, which are more aromatic than the leaves. If they be carefully dried, the taste and smell will not diminish, but improve. The single flowers only should be kept, because the white florets of the ray, which are multiplied in the double flowers, are almost tasteless; and yet double flowers are the only sort ever found in the shops. An infusion of the flowers is often used as a stomachic and antispasmodic, but in large quantities it excites vomiting. Large doses of the powdered flowers have cured agues, even where the bark has failed. Both leaves and flowers are very useful in antiseptic fomentations and poultices. From their antispasmodic powers, they are frequently found to relieve pain, whether internally or externally applied. The decoction is used for clysters, as well as in fomentations; which, with poultices made of the flowers, often prove beneficial in putrid sore throats. Independently of its general virtues as a bitter, it is good in different kinds of colic, particularly such as arise from flatulencies or cold. It is also recommended in hysterical and hypochondriacal dis-

orders, in the gravel, and intermittent fevers. The dose of the dried flowers in substance is from ten or twelve grains to half a drachm, or more; in tea, two or three drachms. The expressed juice is an excellent remedy for the strangury, asthma, jaundice, and dropsy; and the flowers are much used, in conjunction with other ingredients of a similar nature, to promote perspiration. Culpeper says, that bathing with a decoction of Chamomile removes weariness and eases pain, to whatever part of the body it is applied; and that the flowers boiled in posset-drinks provokes sweating, and bringeth down women's courses. Syrup of the juice of Chamomile, with flowers of white wine, he also recommends for the jaundice and dropsy; and a decoction of the flowers in Ice, as good to wash the head in disorders of the brain.—This plant may be increased by planting slips a foot asunder in the spring; as it is hardy, it will soon cover the ground; and the gardener would do well to prefer the single-flowered kind, for the reasons above given.

9. *Anthemis Arvensis*; *Corn Chamomile*. Receptacles conic; chaffs bristle-shaped; seeds crown-margined; leaves thinly downed. Biennial.—It flowers in June and July, and is a common weed amongst corn in most parts of Europe.

10. *Anthemis Austriaca*; *Austrian Chamomile*. Receptacles conic; chaffs oblong, mucronate; seeds naked; leaves bipinnate, woolly-villose. Root annual. It has a bitter taste; flowers the whole summer.—Found by way-sides, in corn-fields, and sometimes covering fallow grounds in Austria.

11. *Anthemis Cotula*; *Stinking Chamomile*, or *Mayweed*. Receptacles conic; chaffs bristly; seeds naked; leaves smooth. Stems much branched, smooth; leaves light green; bipinnatifid; disk of the flower convex, yellow; florets white. An annual plant, the whole of which is fetid, and so acrid as to blister the skin of those who handle it. Loeselius avers, that it drives away fleas, is offensive to bees, and is given as a medicine to sheep troubled with the asthma. An infusion of the root is good in hysteric disorders, and promotes the menses. The herb boiled till it becomes soft, and then applied by way of poultice, is an excellent thing for the piles. Mr. Ray says, it has been beneficially administered in scrophulous cases.—It is a common weed, flowering from May to August, and abounding by way-sides, on dung-hills, and in corn-fields; and farmers are little aware of the vast fertility of this and some other weeds, which they first suffer to exhaust their dunghills, and afterwards to be distributed with them over their fields.

12. *Anthemis Pyrethrum*; *Spanish Chamomile*, or *Pellitory of Spain*. Stems simple, one-flowered, decumbent; leaves pinnate-multifid. Root perennial; as big as a man's finger, the colour of horse-radish, white within, of an acrid biting taste. Flower large, the florets of the ray purple on the outside. Lewis says, the roots having a hot pungent taste when chewed in the mouth, by stimulating the salivary glands, promote a flow of viscid humours from the head and the adjacent parts, and frequently by this means relieve the tooth-ach, head-ach, lethargy, and palsy of the tongue. It is also successfully given in small doses for paralytic and rheumatic complaints. In palsies, its stimulation alone will sometimes restore the voice. According to Culpeper, an ounce of the juice taken in a draught of Muscadell an hour before the fit of the ague comes on, will remove it at the second or third time of taking it; and the powder of the herb, snuffed up the nostrils, removes the head-ach by exciting sneezing.—It is a native of the Levant, and southern parts of Europe.

**With a concolour, or yellow Ray.*

15. *Anthemis Valentina*; *Purple-stalked Chamomile*. Stem

branching; leaves pubescent, tripinnate, bristle-shaped; calices villose, peduncled.—It grows naturally in Spain, Portugal, and Provence; and is supposed to be the same which Dioscorides recommends as good for the jaundice, and to restore the skin to a good colour. This plant may be easily increased by sowing the seeds upon a bed of common earth in spring, and transplanting them three feet asunder, when they are strong enough to remove. Some of the flowers are white, some sulphur-coloured, and some of a deep yellow; and in large open spots they form a pleasing variety from June till November, which is the time they continue to flower. The Levant seeds produce the tallest plants and largest flowers.

14. *Anthemis Repanda*; *Repand-leaved Chamomile*. Leaves simple, ovate-lanceolate, repand-crenate.—Native of Spain and Portugal.

15. *Anthemis Trinervia*; *Three-nerve-leaved Chamomile*. Leaves ovate, serrate, three-nerved, opposite, petiolate; receptacle conic.—Found in South America.

16. *Anthemis Americana*; *American Chamomile*. Leaves triternate; peduncles terminal, longer than the branch.—Native of America.

17. *Anthemis Tinctoria*; *Yellow Chamomile*, or *Ox-eye*. Leaves bipinnate, serrate, tomentose underneath; stem corymbed.—A native of dry open pastures in Germany and Sweden; and Mr. Ray found it near the river Jaco in Durham. Linneus says, it is much used in Gothland for dyeing yellow. A decoction of the fresh herb with ale, is given as a remedy for the jaundice; it operates by urine.

18. *Anthemis Arabica*; *Arabian Chamomile*. Stem decumbent; calices branch-bearing. Root annual.—A native of Arabia. Its flavour is bitter and aromatic, but far weaker than Common Chamomile. It is an ornamental plant, and merits a place among hardy annuals. Its flavour is bitter and aromatic, but far weaker than the official Chamomile. Unless the seeds be sown in autumn they will seldom be reproduced in perfection in England.

19. *Anthemis Odorata*; *Shrubby Chamomile*. Leaves pinatifid at the tip; peduncles elongate; calices membranaceous; ray barren.—Native of the Cape; flowering in April.

Anthericum; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong, obtuse, spreading very much. *Stamina*: filamenta subulate, erect; antheræ small, incumbent, four-furrowed. *Pistil*: germen obscurely three-cornered; style simple, the length of the stamina; stigma obtuse, three-cornered. *Pericarp*: capsule ovate, smooth, three-furrowed, three-celled, three-valved. *Seeds*: numerous, angular. ESSENTIAL CHARACTER. *Corolla*: six-petalled, expanding. *Capsule*: ovate.—All the plants of this genus, except the 17th species, are perennial, and may be increased by offsets or suckers, taken off during the summer or autumn; and those which do not throw out these freely, by seeds sown in the spring or autumn, on a bed of light sandy earth in a warm situation. They require covering with straw or pease haulm in severe weather, and will last several years if not destroyed by frost.—The species are,

1. *Anthericum Floribundum*; *Thick-spiked Anthericum*. Leaves flat, smooth, linear-lanceolate, acute, channelled; scape simple; raceme many-flowered, cylindric, compact; petals spreading, stamina smooth. Native of the Cape; flowering in March and April.

2. *Anthericum Scrotinum*. Leaves flattish; scape one-flowered; filamenta generally smooth.—A vernal plant, which appears in Switzerland and on Snowden in Wales, after the melting of the snows, and flowering in April and May,

3. *Anthericum Græcum*. Leaves flat, channelled; scape simple; flowers corymbed; filaments woolly.—Native of the Levant.

4. *Anthericum Planifolium*. Leaves flat, channelled; scape and filaments woolly.—Native of Portugal, where it flowers in April.

5. *Anthericum Revolutum*; *Curled-flowered Anthericum*. Leaves flat, channelled; scape branched; corollas revolute; filaments generally smooth.—Native of the Cape.

6. *Anthericum Ramosum*; *Branching Anthericum*. Leaves linear-subulate, flat, channelled; scape branched; peduncles solitary; corollas flat; pistilla straight; filaments generally smooth. The flowers, which are generally white, watch from seven in the morning to three or four in the afternoon.—Native of Sweden, France, Switzerland, and Austria.

7. *Anthericum Elatum*; *Tall Anthericum*. Leaves flat, channelled; scape branched; peduncles aggregate; corollas flat; filaments generally smooth. Flowers in a loose spike white, and handsome when fully blown; they appear in August and September.—It is a native of the Cape.

8. *Anthericum Triflorum*; *Three-flowered Anthericum*. Leaves channelled, sword-shaped; scape simple; bractes remote, three flowered; filaments generally smooth.—It flowers in November, and is a native of the Cape.

9. *Anthericum Canaliculatum*; *Channelled Anthericum*. Leaves rather fleshy, hairy, sword-shaped, triquetrous, channelled on the narrow side; scape simple; filaments generally smooth. It flowers in April.—Native of the Cape.

10. *Anthericum Albucoides*; *Striped-flowered Anthericum*. Leaves linear, channelled, smooth, with a cartilaginous edge; scape simple; filaments generally smooth. It flowers in August.—Native of the Cape.

11. *Anthericum Liliago*; *Grass-leaved Anthericum*. Leaves flat, channelled; scape perfectly simple; corollas flat; pistil bending down; filaments generally smooth.—Native of Italy, Switzerland, Germany, France, and Denmark.

12. *Anthericum Liliastrum*; *Savoy Anthericum*, or *Spiderwort*. Leaves flat, channelled; scape perfectly simple; corollas bell-shaped; stamina bending down; filaments generally smooth. There are two varieties of this plant.—It grows wild upon the mountains of Switzerland and Savoy.

13. *Anthericum Spirale*. Scape spiral; filaments generally smooth.—A leafless native of the Cape.

14. *Anthericum Frutescens*; *Shrubby Anthericum*. Leaves fleshy, columnar; stem shrubby; filaments bearded.—Native of the Cape.

15. *Anthericum Alooides*; *Aloe-leaved Anthericum*. Leaves fleshy, subulate, flattish; filaments bearded. It grows close to the ground. Native of the Cape.

16. *Anthericum Asphodeloides*; *Glaucous-leaved Anthericum*. Leaves fleshy, subulate, semicolumnar, upright and stiff; filaments bearded; flowers yellow, growing on long loose spikes.—Native of the Cape.

17. *Anthericum Annuum*; *Annual Anthericum*. Leaves fleshy, subulate, columnar; scape subracemed; filaments bearded; flowers yellow.—It is found at the Cape.

18. *Anthericum Hispidum*; *Hairy-leaved Anthericum*. Leaves fleshy, compressed, hispid; filaments bearded; flowers white; antheræ yellow.—A native of the Cape.

19. *Anthericum Ossifragum*; *Lancashire Anthericum*, or *Asphodel*. Leaves sword-shaped; filaments woolly.—It grows wild on the bogs of the northern countries of Europe; and in Lancashire, and other northern counties; in Cambridgeshire, in Norfolk, on Putney heath; flowering in July and August.

20. *Anthericum Caliculatum*. Leaves sword-shaped; perianths three-lobed; filaments smooth; flowers three-pis-

tilled.—Grows wild in Lapland, Sweden, Denmark, Siberia, Switzerland, and in several places in Scotland.

21. *Anthericum Japonicum*. Leaves sword-shaped, convolute, smooth; scape branching, angled; flowers racemed, nodding.—Native of Japan, China, and Java.

22. *Anthericum Filiforme*; *Thread-leaved Anthericum*. Leaves filiform, rather cylindric, rough; filaments smooth; petals lanceolate; perennial.—It flowers in April.

23. *Anthericum Flexifolium*. Leaves subulate, smooth, flexuose; stem branching.

24. *Anthericum Muricatum*. Leaves fleshy, compressed, muricated, streaked.

25. *Anthericum Latifolium*. Leaves fleshy, wide, sword-shaped, smooth; raceme very long; stem simple.

26. *Anthericum Cauda-felis*. Leaves channelled, sword-shaped, scape simple; raceme oblong.

27. *Anthericum Triquetrum*. Leaves filiform, triquetrous, shorter than the simple scape; raceme ovate.

28. *Anthericum Ciliatum*. Leaves sword-shaped, fleshy, subtriquetrous, ciliate; scape simple; raceme very long.

29. *Anthericum Falcatum*. Leaves fleshy, sword-shaped, sickled, smooth; stem branching, racemed.

30. *Anthericum Contortum*. Leaves flat, sword-shaped; stem branching; flowers very remote.

31. *Anthericum Scabrum*. Leaves triquetrous, serrulate; stem branching, rugged; fruit-bearing peduncles, recurved.

32. *Anthericum Squameum*. Scape imbricate, with membranous tumid scales.—The above species, from 22 to 31, are all natives of the Cape.

33. *Anthericum Cirratum*. Leaves lanceolate, flattish; scape panicled; leaves bearded, bicirrate.—Native of New Zealand.

34. *Anthericum Adenanthera*. Leaves linear, ensiform, connate at the base; a gland between the filament and anther.—Native of New Caledonia.

Antheria; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Calix*: glume four-valved, three or four flowered; valves equal, oblong, flat, blunt, leathery, erect-expanding; hermaphrodite floscule, sessile; males pedicelled, very like the hermaphrodite. *Corolla*: glume two-valved; valves lanceolate, acute, awnless, the outer larger. *Stamina*: filaments three, short, filiform; antheræ oblong, erect. *Pistil*: in the hermaphrodite; germen oblong, from the base a twisted awn; styles two; stigmas club-shaped, hairy. *Pericarp*: none, except the closed calix. *Seed*: oblong, smooth, marked with a furrow. ESSENTIAL CHARACTER. *Calix*: cleft at the base into four equal divisions.—There is only one species discovered, viz.

1. *Antheria Ciliata*. Root annual; culms many, a foot high, branched, jointed, smooth, nodding a little; raceme terminating, leafy, decomposed, nodding.

Anthoceros; a genus among the Algæ, in the class Cryptogamia.

Antholyza; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: spathes two-valved, alternate, imbricate, separating the flowers, permanent. *Corolla*: petal one, gradually dilated from the tube into a compressed ringent throat; upper lip straight, slender, very long furnished with two short divisions at the base; under lip shorter, trifid. *Stamina*: filaments long, slender, under the upper lip; antheræ acute. *Pistil*: germen inferior; style filiform, situation and length of the upper stamina; stigma trifid, capillary, reflex. *Pericarp*: capsule roundish, three-cornered, three-celled, three-valved. *Seeds*: many, triangular. ESSENTIAL CHARACTER. *Corolla*: tubular, irregular, recurved. *Capsule*: inferior.—Plants of this genus are propa-

gated by offsets, which the bulbous roots send forth in great plenty; or by seeds sown soon after they are ripe, in pots of light earth, plunged into an old tan-bed which has lost its heat, and is shaded during hot weather from the heat of the day. They must be screened by glasses from the cold, and may be kept two years in the pots, and may then be transplanted into small separate pots, placed during summer in the open air, but in winter must go back to the hot-bed frame. The flowers are ornamental; and as the plants do not require much culture, they deserve a place in every good garden. The seeds are very seldom perfected in Europe; and every one of the species is a native of the Cape.—They are,

1. *Antholyza Ringens*; *Narrow-leaved Antholyza*. Lips of the corolla divaricate; throat compressed. The flower-stem rises immediately from the root, two feet high, hairy, with several flowers on each side, they are red, and appear in June; the seeds ripen in September.

2. *Antholyza Plicata*; *Plaited-leaved Antholyza*. Leaves plaited, stem branching, hirsute; corolla ringent, shorter than the stamina. The stamina are shorter in this than those of the first species.

3. *Antholyza Cunonia*; *Scarlet-flowered Antholyza*. Corollas straight; the two outer lobes of the five-parted lip broader and ascending. This has a compressed bulbous root somewhat like that of the corn-flag; from which rises the flower-stalk above a foot high, generally curved two opposite ways, the upper part terminated by a spike of loose flowers, coming out of large spathes, of a beautiful scarlet colour, and flowering about the latter end of April or beginning of May, and makes a fine appearance.—Plant it in pots of light earth, which may remain in the open air till October, and must then be sheltered under a glass-case, or hot-bed frame, where the leaves will grow throughout the winter, and the stalks arise and flower in spring. Water them sparingly once a week in winter, in spring oftener; and when the flowers are past, remove them into the open air to perfect their seeds; these ripen at the latter end of June, the stalk then decays, and remains inactive until September. As soon as they decay, take them up, keep them in a dry room till the end of August, and then plant them again. It may also be easily increased by offsets, which require the same treatment: both seeds and offsets should be planted in the middle of August, where they can enjoy the morning sun.

4. *Antholyza Æthiopica*; *Broad-leaved Antholyza*. Corollas incurvate; the two alternate lobes of the five-parted lip spreading, large, and lanceolate. Flowers scarlet, appearing in May and June.

5. *Antholyza Meriana*; *Red-flowered Antholyza*. Corollas funnel-shaped; leaves linear, sword-shaped. The flowers have long tubes of a copper colour outside, and deep red within, appearing in April and May.

6. *Antholyza Merianella*; *Dwarf Antholyza*. Corollas funnel-shaped; leaves linear. The flowers are of a pale red and larger than those of the fifth species.

7. *Antholyza Lucidior*. Radical leaves, with filiform base, broad-awled, furrowed at top; stem simple, leafy, spiked. Flowers oblong, a little bent, purple above, cut into six lanceolate parts.

Anthospermum; a genus of the class Polygamia, order Diœcia, or Diœcia Tetrandia.—GENERIC CHARACTER. *Male Calix*: perianth one-leafed, conical, quadrifid beyond the middle; divisions ovate-oblong, revolute, obtuse, a little coloured. *Corolla*: none, unless the calix be so termed. *Stamina*: filamenta four, capillary, erect, the length of the calix, inserted into the receptacle; anthera twin, oblong, four-cornered, obtuse, erect. *Female Calix and Corolla*: as in the

male. *Pistil*: germen inferior, ovate, four-cornered; styles two, recurved; stigmas simple. **ESSENTIAL CHARACTER.** *Calix*: four-parted. *Corolla*: none. *Stamina*: four. *Pistil*: two. *Germen*: inferior. Male and Female in the same, or a distinct plant.—These plants are propagated by cuttings placed in a border of light earth, during any of the summer months; or if planted in pots, plunged into a very moderate hot-bed, they will sooner take root, and be of surer growth. Afterward they should be taken up with a ball of earth to their roots, and replanted in a pot of light sandy earth, and exposed to the open air until October, but must then be removed under shelter for the winter, during which they must be sometimes watered, and have fresh air admitted. The first and second sorts may be raised from layers. They are all natives of the Cape of Good Hope.

1. *Anthospermum Æthiopicum*; *Amber-tree*. Leaves polished. The beauty of this shrub consists in its small evergreen leaves, which grow as close as heath, and emit a very fragrant odour when bruised between the fingers.

2. *Anthospermum Ciliare*. Leaves ciliated along the keel and edge; root perennial and woody, much branched.

3. *Anthospermum Herbaceum*. Leaves six, polished; stem herbaceous; flowers axillary.

Anthoxanthum; a genus of the class Diandria, order Digynia.—GENERIC CHARACTER. *Calix*: glume one-flowered, two-valved; valves ovate, acuminate, concave; the inner one larger. *Corolla*: glume one-flowered, two-valved, the length of the greater valve in the calix; each valve emitting an awn from the lower part of the back, one of them jointed. Nectary two-leaved, very slender, cylindric; leaflets subovate, embracing. *Stamina*: filamenta two, capillary, very long; anthera oblong, forked at both ends. *Pistil*: germen oblong; styles two, filiform; stigmas simple. *Pericarp*: glume of the corolla grows to the seed. *Seed*: one, pointed at both ends, roundish. **ESSENTIAL CHARACTER.** *Calix*: glume two-valved, one-flowered. *Corolla*: glume two-valved acuminate. *Seed*: one.—For the propagation and culture of this genus, see *Grass*.

1. *Anthoxanthum Odoratum*; *Sweet Vernal Grass*. Spike oblong-ovate; flowers longer than the awn, on short peduncles. Root perennial, odorous; colour of the spike pale yellow.—This is the Grass which gives that delightful sweetness of scent to new-mown hay, from which it has derived its specific name *Odoratum*, *sweet-scented*; from the earliness of its flowering, it has obtained the other English name of *Vernal* or *Spring Grass*. It will grow on any soil, but prefers that which is moderately dry, having, according to some, a great tendency to curl its leaves in rich ground. It is common in pastures and also in woods, and in the middle of May is in full bloom; the seed, which is never very abundant, ripens in June, and separates easily when rubbed. Cattle of all sorts are fond of it, and in good meadows it grows to a considerable height, forming a thick tuft of tender succulent leaves at the bottom, though in point of crop it is not so productive as some other Grasses. As the best mutton comes from places where it abounds, it is probably a good Grass for sheep pastures; especially as it is found on all grounds, from the driest and sandiest to the most stiff and moist, and even in bogs. It is very easy to gather, and abounds plentifully in the best meadows about Hampstead and Hendon, near London. It retains its odour for a long time; and Boecone says, that a distilled water is prepared from it, as the vehicle of some perfumes.

2. *Anthoxanthum Indicum*. Spike linear; flowers sessile, shorter than the awn.—Native of the East Indies.

3. *Anthoxanthum Crinitum*. Culm high, smooth; panicle spike-form, cylindrical, awned, the awns long, spreading, loose.—Native of New Zealand.

ANTHOLYZA
Scarlet-flowered Antholyza.

CUNONIA.
Antholyza.

G. Davis sc.

Anthyllis; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, ovate-oblong, swelling, villose; the mouth five-toothed, unequal, permanent. *Corolla*: papilionaceous; banner longer than the wings; the sides reflex; claw the length of the calix; wings oblong, shorter than the banner; keel compressed, the length of the wings. *Stamina*: filamenta connate, rising; antheræ simple. *Pistil*: germen oblong; style simple, ascending; stigma obtuse. *Pericarp*: legume roundish, concealed within the calix, very small, bivalve. *Seeds*: one or two. ESSENTIAL CHARACTER. *Calix*: swelling. *Legume*: roundish, concealed.—The species are,

1. *Anthyllis Tetraphylla*; *Four-leaved Anthyllis*, or *Kidney-Vetch*. Leaves pinnate, with four lobes; flowers lateral. An annual plant with trailing branches; leaves by fours, at each joint; flowers in clusters on the sides of the stalks. The flowers yellow, appearing in July, and producing seeds in September.—Native of France, Spain, Portugal, Italy, and Sicily, where it is a weed in arable land.

2. *Anthyllis Vulneraria*; *Common Ladies' Finger*, or *Kidney-Vetch*. Leaves pinnate, unequal; head double. There are several varieties, with red, white, and yellow flowers.—Native of most parts of Europe, and flowers from May to July. This and the following species may be propagated by seed sown either in autumn or spring.

3. *Anthyllis Montana*; *Mountain Anthyllis*, or *Kidney-Vetch*. Leaves pinnate, equal; head terminal, one-ranked; flowers oblique.—Both this and the preceding species are found wild in several parts of Europe; in Pembrokeshire, and Anglesea in Wales, and in the Isle of Man. They abound greatly in the best meadows of the Pyrenees; and are recommended as an excellent pasture for sheep.

4. *Anthyllis Cornicina*. Leaves pinnate, unequal; heads solitary.—Native of Spain.

5. *Anthyllis Lotoides*. Leaves three-parted; calices prismatic, fasciated, the length of the legumes.—Native of Spain.

6. *Anthyllis Gerardi*. Leaves pinnate, unequal; peduncles lateral, longer than the leaf; heads leafless. Annual.—It grows wild upon the sea-shores of Provence.

7. *Anthyllis Quinquiflora*; *five-flowered Anthyllis*. Leaves ternate, linear; head five-flowered; corollas yellow.—A native of the Cape.

8. *Anthyllis Involucrata*. Sub-herbaceous: leaves ternate, petiolate, stipuled, sword-shaped; flowers in a head, yellow.—A native of the Cape.

9. *Anthyllis Linifolia*. Leaves ternate, sessile, sword-shaped; flowers in a head, yellow, shrubby, eight feet high.

10. *Anthyllis Barba Jovis*; *Silvery Anthyllis*, or *Jupiter's Beard*. Leaves pinnate, equal, tomentose; flowers in a head. This is sometimes called *Silver Bush*, from the whiteness of its leaves. It is a shrub, often growing ten or twelve feet high, with flowers of a bright yellow colour, appearing in June.—Native of the south of France, Spain, Portugal, Italy, and the East. It may be propagated either by seeds or cuttings, sown or planted in pots filled with light earth, and placed under a frame to protect them from the winter's frost. They may be planted during any of the summer months.

11. *Anthyllis Heterophylla*. Leaves pinnate, the floral leaves ternate. A small shrub, bearing minute flowers in pairs.—Grows naturally in Portugal and Spain.

12. *Anthyllis Visciflora*. Leaves digitate-pinnate; calices shaggy; corolla yellow.—Seen at the Cape.

13. *Anthyllis Cytisoides*; *Downy-leaved Anthyllis*. Leaves ternate, unequal; calices woolly, lateral; corolla yellow.—It is a low shrub, and a native of Spain, &c.

14. *Anthyllis Hermannia*; *Lavender-leaved Anthyllis*.

Leaves ternate, sub-peduncled; calices naked.—Six feet high; a native of Greece, Crete, and Palestine; and may be propagated by cutting in the same manner as the tenth species. It was formerly in several English gardens, but the severe frost of 1739-40 destroyed most of them.

15. *Anthyllis Erinacea*; *Prickly Anthyllis*. Spinose; leaves simple.—Grows nine feet high; native of Portugal and Spain. It is propagated by seeds only, and will survive mild winters in the open air, but hard frosts destroy it.

16. *Anthyllis Tragacanthoides*. Shrubby: leaves pinnate, equal, tomentose; petioles spinescent; flowers in racemes, purple.—Native of Mount Lebanon.

17. *Anthyllis Indica*. Shrubby: leaves pinnate, equal, smooth; racemes oblong, subterminating; corolla white.—Native of the Cochin-chinese mountains.

Antichorus; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved, very much expanded; leaflets lanceolate, acuminate, deciduous. *Corolla*: petals four, obovate, obtuse, the length of the calix. *Stamina*: filamenta setaceous, erect, shorter than the corolla; anthera roundish. *Pistil*: germen superior, ovate; style cylindric, the length of the stamina; stigma obtuse. *Pericarp*: capsule subulate, four-celled, four-valved. *Seeds*: very many, truncate, placed over each other in four rows. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Petals*: four. *Capsule*: superior, subulate, four-celled, four-valved. *Seeds*: very many.—There is but one species.

1. *Antichorus Depressus*. It resembles the *Corchorus*; and is a small procumbent annual plant, with alternate branches, bearing yellow-flowers.—Native of Arabia.

Antidesma; a genus of the class Diœcia, order Pentandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth five-leaved; leaflets oblongish, concave. *Corolla*: none. *Stamina*: filamenta five, capillary, longer than the calix, equal; antheræ roundish, semibifid. *Female*. *Calix*: as in the male, permanent. *Corolla*: none. *Pistil*: germen superior, ovate; style none; stigmas five, obtuse, *Pericarp*: drupe roundish, one-celled, crowned with the stigmas, and having a furrowed shell. ESSENTIAL CHARACTER. *Male*. *Calix*: five-leaved. *Corolla*: none. *Antheræ*: semibifid. *Female*. *Calix*: five-leaved. *Corolla*: none. *Stigmas*: five. *Berry*: cylindric, one-seeded.—The species are,

1. *Antidesma Alexiteria*. This is a middle-sized tree, the bark of which is used for making ropes. A decoction of the leaves is reputed to be an antidote against the bite of serpents.—It is a common evergreen in Malabar, where the fruit, which it continues to bear to the age of seventy years, is much esteemed for its pleasant cooling qualities.

2. *Antidesma Acida*. Leaves obovate; spikes solitary.—Native of the East Indies.

3. *Antidesma Scandens*. Leaves palmate, serrate; stem climbing, without tendrils.—Native of China, near Canton.

Antirrhinum; a genus of the class Didynamia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth five-parted, permanent; divisions oblong, the two lower more gaping. *Corolla*: monopetalous, ringent; tube oblong, gibbous; limb bilabiate; upper lip bifid, reflex on the sides; lower trifid, obtuse; palate convex, usually closed by a prominence between the lips produced from the under lip; the throat being concave beneath; nectary at the base of the corolla, produced downwards, prominent. *Stamina*: filamenta four, enclosed under the upper lip, nearly of the same length with the corolla, yet two are shorter; antheræ converging. *Pistil*: germen roundish; style simple, of the length and in the situation of the stamina; stigma obtuse. *Pericarp*: capsule roundish, obtuse, two-celled, of different form and

aperture in the different species. *Seeds*: very many. *Receptacles*: reniform, solitary, affixed to the partition. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: with the base produced downwards, and nectariferous. *Capsule*: two-celled.—The species are,

**Leaves angular.*

1. *Antirrhinum Cymbalaria*; *Ivy-leaved Toadflax*. Leaves heart-shaped, five-lobed, alternate; stalks procumbent. Root perennial.—A native of Italy, but is now become common upon walls in and near London. The whole plant is smooth, and has a disagreeable smell, varying a white flower: it flowers from June until October; and is well adapted to ornament rock-work, which if moist, it will soon cover with a thick tapestry. When once established it is hard to eradicate, and will thrive in any situation.

2. *Antirrhinum Pilosum*; *Hairy-leaved Toadflax*. Leaves kidney-shaped, hairy, alternate.—Native of the Alps.

3. *Antirrhinum Elatine*; *Sharp-pointed Toadflax*, or *Fluellin*. Leaves hastate, alternate; stalks procumbent. Root annual, whitish: the whole plant is hairy, and varies with blue and yellow flowers.—It grows wild in corn-fields in Italy, Germany, France, Switzerland, and England, and flowers with us from July till October. It is the bitterest plant of the whole genus; and the expressed juice, or distilled water, is said to check foul old ulcers, disposing them to heal. It is likewise a good medicine for internal bruises, the bloody flux, and other hæmorrhages, such as the overflowing of the menses. The leaves bruised, and applied with barley-meal to watery eyes that are hot and inflamed by defluxions of the head, is said to be very efficacious. Culpeper informs us, that this herb was originally named the *Female Speedwell*; and gravely adds, that it received its present name of *Fluellin* from the gratitude of a Welsh gentleman whose nose it had preserved from the dreadful ravages of the venereal disease. But notwithstanding he avers, if taken inwardly it may cure that disorder, its antivenereal virtues are entirely unknown at the present day; though he is probably correct, in calling it a herb of a fine cooling and drying quality.—The seeds ripen in autumn, and if sown or permitted to scatter at that time, will produce an abundant crop.

4. *Antirrhinum Spurium*; *Round-leaved Toadflax*, or *Fluellin*. Leaves ovate, alternate; stalks procumbent.—Grows wild in the fields of Germany, England, France, and Italy.

5. *Antirrhinum Cirrhosum*; *Tendrilled Toadflax*. Leaves hastate, alternate; stems spreading; petioles every where tendrilled.—Annual; and a native of Egypt.

6. *Antirrhinum Ægyptiacum*; *Egyptian Toadflax*. Leaves hastate, alternate; stem erect, very branching; peduncles stiffish. Corolla yellow, with a purplish dotted palate.—A native of Egypt.

***Leaves opposite.*

7. *Antirrhinum Triphyllum*; *Three-leaved Toadflax*. Leaves ternate, ovate. An annual plant, with yellow flowers.—Native of Spain and Portugal. It seldom ripens its seed in England, where it flowers in July. The seeds should be sown in spring, upon a warm dry border. Thin and weed them when they come up, which is all the culture they require.

8. *Antirrhinum Triornithophorum*. Leaves in fours, lanceolate; stem erect, branching, flowers peduncled. It has large purple flowers.—Native of Portugal and America.

9. *Antirrhinum Purpureum*; *Purple Toadflax*. Leaves quaternate, linear; flower-bearing stem erect, spiked. Root perennial; corolla all purple.—Native of Italy, about Naples, and at the foot of Mount Vesuvius, flowering from July till September. The seeds of this and the three following species, if permitted to scatter, will produce plenty of young plants with-

out any further care; they prefer a dry soil, and when placed upon an old wall, they will come up, and endure longer than upon the ground. They may also be increased by parting the roots.

10. *Antirrhinum Versicolor*; *Spike-flowered Toadflax*. Leaves linear-lanceolate; the lower ones ternate; stem erect, spiked.—A native of the southern countries of Europe; resembling Common Toadflax. See the ninth species.

11. *Antirrhinum Repens*; *Creeping Toadflax*. Leaves linear, crowded, below quaternate; calices equalling the capsule. It has a perennial root, and pale blue flowers, destitute of scent, which appear in July, and seed in autumn.—Native of France, Italy, and England, in Hertfordshire, and about Henley in Oxfordshire. See the ninth species.

12. *Antirrhinum Monspensulanum*; *Montpellier Toadflax*. Leaves linear, filiform, succulent, scattered, crowded; stem erect; spur shorter than the calix. Root perennial; flowers in loose spikes, of a pale blue colour, and sweet smell.—Found near Montpellier in the south of France, and in England near Penryn in Cornwall. See the ninth species.

13. *Antirrhinum Sparteum*; *Branching Toadflax*. Leaves awl-shaped, channelled, fleshy; the lower ones ternate; stem panieled, and corollas yellow, very smooth, flowering in May and June, and very common in a dry sandy soil about Madrid.—It may be sown in spring like other hardy annuals, but will flower earlier if raised in the autumn.

14. *Antirrhinum Bipunctatum*; *Dotted-flowered Toadflax*. Leaves linear, smooth; the lower ones quaternate; stem erect, panieled; flowers spike-headed.—It is an annual plant, growing wild in the corn-fields of France, Spain, and Italy; and producing a yellow flower in May and June.

15. *Antirrhinum Triste*; *Dark-flowered Toadflax*. Leaves linear, scattered, the inferior ones opposite; nectaries awl-shaped; flowers subsessile. Corolla very dark purple; capsule shaped like the human skull.—Native of Spain; flowering during most of the summer months. It is easily propagated by cuttings, which if watered and shaded will soon take root, and may be afterwards planted in pots filled with light fresh undunged earth, which may have plenty of free air in mild weather, but must be sheltered in winter.

16. *Antirrhinum Supinum*; *Procumbent Toadflax*. Leaves subquaternate, linear; stalk diffused; flowers racemed; spur straight.—Native of sandy grounds in France and Spain.

17. *Antirrhinum Arvense*; *Yellow Corn Toadflax*. Leaves sublinear, the lower ones quaternate; calices hairy viscid; flowers spiked; stem erect. It varies with flowers blue or yellow.—Grows in the sandy corn-fields of Italy, France, Germany, or England.

18. *Antirrhinum Peliserianum*; *Violet-coloured Toadflax*. Stem-leaves linear, alternate; root-leaves lanceolate, ternate; flowers corymbed, purple, with a white palate, marked with obscure purple veins.—Native of France and Italy. Annual.

19. *Antirrhinum Saxatile*; *Rock Toadflax*. Leaves lanceolate-linear, scattered, villose; the inferior quaternate; stem decumbent; flowers spiked. Root perennial; corolla yellow, with two orange spots on the palate.—Native of Spain.

20. *Antirrhinum Viseosum*; *Clammy Snapdragon*. Root-leaves quaternate, lanceolate; stem-leaves linear, alternate; calices villose, approximating the stem.—Native of Spain.

21. *Antirrhinum Multicaule*; *Many-stalked Toadflax*. Leaves quinate, linear, fleshy; flowers headed. There are two varieties, one with a deep yellow, the other with a sulphur-coloured flower.—Native of Sicily and the Levant.

22. *Antirrhinum Glaucum*. Leaves quaternate, awl-shaped; fleshy; stems erect; flowers spiked. An annual, with a yellow corolla.—Native of the south of Europe and the Levant.

P. 115

ARBUTUS. *Common Strawberry Tree.*

P. 122

ARISTOLOCHIA. *Common Birthwort.*

23. *Antirrhinum Alpinum*; *Alpine Toadflax*. Leaves quaternate, linear-lanceolate, sea-green; stem diffuse; flowers racemed, with a straight spur. Root perennial; flowers very elegant, of a fine violet purple colour, with a rich gold-colour in the centre, and which blows most part of the summer. The plant has a bitter disagreeable taste.—Native of moist rocky places in the Alps. This beautiful flower may be propagated by cuttings, as well as seeds, which it does not produce plentifully in England. It succeeds best in a pot or on rock-work, but requires some care.

24. *Antirrhinum Bicornis*; *Horned Toadflax*. Leaves opposite, ovate-oblong, serrate; stem erect; flowers racemed; capsules two-horned.—An annual; native of the Cape.

25. *Antirrhinum Villosum*. All the leaves opposite, ovate, villose; stems simple; flowers yellow, opposite, lateral.—Observed in Spain. Perennial.

26. *Antirrhinum Origanifolium*. Leaves mostly opposite, oblong; flowers alternate.—Annual; growing wild upon the Pyrenees, and near Marseilles.

27. *Antirrhinum Pinnatum*. Leaves opposite, pinnatifid; stem erect; flowers racemed.—Native of the Cape.

*** *Leaves alternate.*

28. *Antirrhinum Minus*; *Lesser Toadflax*. Leaves mostly alternate, lanceolate, obtuse; stem very much branched, diffuse. The corolla is small, the tube and upper lip violet, the beard and chin whitish, and the throat closed with a pile of orange hairs. Annual; flowering from June till September, and growing wild in corn-fields, dry pastures, and upon walls in most parts of Europe.

29. *Antirrhinum Dalmaticum*. Leaves alternate, heart-shaped; stem-clasping. The flowers, which are of a deep yellow colour, appear in July, but seldom produce ripe seed in England. Native of Crete and Armenia. It is propagated by seed, sown early in the spring, upon a border of light earth, removing them, when they come up, to pots of light sandy earth placed in the shade, till they take root, and under a hot-bed frame after October, to preserve them from the frost. It will endure more cold than the other species.

30. *Antirrhinum Hirtum*; *Hairy Toadflax*. Leaves lanceolate, sbaggy; flowers spiked, the upper leaf of the calix largest. Annual; having a pale yellow flower, with a few dark stripes, and the chaps of a gold colour.—Native of Spain.

31. *Antirrhinum Genistifolium*; *Brown-leaved Toadflax*. Leaves lanceolate, acuminate; panicle wand-like, flexuose; flowers bright yellow.—Native of Siberia, Lower Austria, Switzerland, Dauphiny, and Piedmont.

32. *Antirrhinum Junceum*; *Rush-stalked Toadflax*. Leaves linear, alternate; stem panicled, wand-like; flowers racemed.—Discovered in Spain.

33. *Antirrhinum Linaria*; *Common Yellow Toadflax*, or *Calves-snout*. Leaves lanceolate-linear, crowded; stem erect; spikes terminal, sessile; flowers imbricate. Root perennial, hard, woody, creeping; stems several, one to two feet high, full of leaves, round and smooth; leaves pointed, bluish, growing without order; flowers yellow, with orange palates, in a thick terminal spike.—It grows wild in most parts of Europe upon banks by road-sides, and in dry pastures, flowering from June till August. In Worcestershire it is called *Butter-and-Eggs*, from the colour of its flowers. It abounds in an acrid oil, that is almost empyreumatic; and when inwardly given, excites nausea, purges, and increase of urine. The fresh tops are used: an infusion of them works by urine, and has been recommended by some in the jaundice, and other diseases arising from obstructions in the viscera; but Hill says, We have so many English plants that excel in this particular, and the taste of the infusion is so far from

agreeable, that it is not worth while to have recourse to it. Withering prescribes an infusion of the leaves as both diuretic and purgative, and informs us that an ointment prepared from them gives relief in the piles. A decoction of the whole plant, in all, purges briskly, operates by urine, and is frequently found serviceable in the jaundice and incipient dropsies. The juice of the leaves cleanses old ulcerous sores.—The plant is very apt to spread so as to become troublesome, and therefore is seldom admitted into gardens. The flowers however make a pretty appearance, and are well worth retaining in pots.

34. *Antirrhinum Linifolium*. Leaves lanceolate, three-nerved; flowers racemed; peduncles distant, shorter than the bracte. Corolla yellow; spur the length of the flower.—It is perennial, and found upon the sea-coasts of Italy.

35. *Antirrhinum Chalepense*; *White-flowered Toadflax*. Leaves linear-lanceolate, alternate; flowers in racemes, white; calix longer than the corolla; stem erect. An annual, flowering in July, and ripening seed in autumn.—Native of Sicily, Italy, and France.

36. *Antirrhinum Reflexum*. Leaves ovate, smooth; peduncles axillary, fruit-bearing, elongate, recurved; stem procumbent. Root annual; corolla white, with a yellow mouth.—It flowers in May and June; and is common in vineyards and gardens about Messina; and has been found in Barbary.

37. *Antirrhinum Pedunculatum*. Leaves linear, remote; flowers panicled; peduncles longer than the leaf, stiff, and upright. Corollas yellow, streaked with blue.—Found in Spain.

38. *Antirrhinum Lagopodioides*. Leaves scattered, soft, recurved at the tip; spikes ovate, villose.—Native of Siberia.

39. *Antirrhinum Aphyllum*. A very singular plant, having no appearance of an herb, but resembling a Moss, no part of it producing any leaves.—Found near the Cape.

**** *Corollas gaping, or tailless.*

40. *Antirrhinum Majus*; *Great Toadflax*, or *Snap-dragon*. Corollas tailless; flowers in spikes; calices rounded. Stem a foot, eighteen inches, two, and even three feet high. There are several varieties of this species, and the differences in the colour of the flowers are endless; the most common are red, yellow, purple, white; red with white or yellow mouths; white and red; yellow and red; yellow and white; purple and white; purple, with yellow mouths, and scarlet dotted with gold colour.—Found in the southern countries of Europe, growing in hedges, and on rocks and ruins. In England it flowers during June and July, and grows on walls, Dover cliffs, between Northfleet and Gravesend, &c. In Russia they express an oil from the seeds of this plant, which is little inferior to oil of olives.—All the varieties of Snap-dragon are raised from seed sown in April or May upon a dry soil, and transplanting them to large borders in July, where they will flower in the following spring. Any of the sorts may be continued by parting the roots, or by planting cuttings in the summer months, which will easily take root. They resist the cold of winter well, require little attention, and are pretty ornaments, well worthy of admittance into every garden. Whenever these plants are intended for rocky barren soils, or to grow upon walls, sow the seed early in March, where they are designed to remain; and all the further trouble they require is merely to keep them free from weeds: they will begin to flower in July, and continue till the frost prevents them. They will continue two or three years, and are rarely hurt by frost.

41. *Antirrhinum Orontium*; *Small Toadflax*. Corollas tailless; flowers subspiked; calices longer than the corolla. Stem seldom more than a foot high; corollas a pale purple;

lips rose-coloured; palate yellow; spur very short, obtuse. It is a poisonous annual plant, native of England, growing on a light soil, in cornfields and vineyards, and flowering in July and August, and is seldom admitted into gardens.

42. *Antirrhinum Papilionaceum*. Corollas tailless; flowers axillary; calices papilionaceous, five-leaved; leaves fleshy, ovate, entire, alternate.—Native of Persia.

43. *Antirrhinum Asarina*; *Heart-leaved Toadflax*. Corollas tailless; leaves opposite, heart-shaped, crenate; stems procumbent.—Native of Italy, and the south of France; a low trailing annual plant.

44. *Antirrhinum Molle*; *Woolly-leaved Toadflax*, or *Snapper-dragon*. Corollas tailless; leaves opposite, ovate, tomentose; stems procumbent. Corollas villose, white, with a yellow palate; the upper lip streaked with red.—Native of Spain.

45. *Antirrhinum Unilabiatum*. Corollas tailless, with two calluses; leaves alternate, pinnate; stem paniced.—Found near the Cape of Good Hope.

***** *Corollas gaping*.

46. *Antirrhinum Bellidifolium*; *Daisy-leaved Toadflax*. Root-leaves tongue-shaped, toothed, marked with lines; stem-leaves parted, quite entire. A biennial, or at most triennial plant, with a blue corolla.—Native of Spain, Italy, and the south of France; also found near Geneva. Propagated by seeds sown where they are to remain, upon a border of light earth, and to be thinned and weeded when they appear in the following spring, which is all the culture they require.

47. *Antirrhinum Canadense*; *Canada Toadflax*. Leaves linear, alternate; lower lip of the corolla spreading and flat. Annual.—Native of Virginia and Canada.

48. *Antirrhinum Micranthum*; *Small-flowered Toadflax*. Stem herbaceous, upright; lower leaves in fours, upper ones alternate; flowers very small, white; spur short, interior. Root annual.—Native of Spain, near Madrid, where it flowers in March and April.

49. *Antirrhinum Reticulatum*; *Reticulate Toadflax*. Leaves linear, channelled, scattered, those on the radical shoots generally in fives; calix hairy; flower-stalks shorter than the bractes. Root perennial; flowers very beautiful, variable in colour, and without scent.—Discovered in Algiers.

50. *Antirrhinum Pygmaeum*; *Dwarf Toadflax*. Leaves sagittate; peduncles capsulaceous; corolla yellow.

51. *Antirrhinum Ærugincum*. Lower leaves in fours, linear; flowers in racemes; the upper leaflet of the calix twice as long as the rest. An annual, with a yellow corolla; and a native of Spain.

52. *Antirrhinum Hexandrum*. Leaves opposite, cordato-ovate, serrate; peduncles axillary, one-flowered.—Native of Otaheite in the South Seas.

Apactis; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: four-petalled; petals roundish, crenate, concave, unequal; two opposite broader. *Stamina*: filamenta from sixteen to twenty. *Pistil*: germen superior; style one. ESSENTIAL CHARACTER. *Corolla*: four-petalled. *Calix*: none.—The only species known is,

1. *Apactis Japonica*. A tree erect and very branching; flowers in racemes at the end of the branchlets.

Apargia; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common imbricate, oblong, scales several, linear, parallel, unequal, longitudinal, incumbent. *Corolla*: compound imbricate, uniform; corollets hermaphrodite, numerous, equal; proper, monopetalous, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: germen subovate; style filiform,

length of the stamina; stigmas two, recurved. *Pericarp*: none. *Calix*: oblong, straight. *Seeds*: solitary, oblong, striated; down sessile (in the central seeds somewhat stiped) pulmose; rays chaffy beneath; receptacle naked, subvillose.

ESSENTIAL CHARACTER. *Calix*: subimbricate, with linear, parallel, unequal scales. *Down*: pulmose, subsessile. *Receptacle*: naked, subvillose.—The species are,

1. *Apargia Hispida*. The whole calix upright; leaves lanceolate, toothed, hispid with forked bristles; scape one-flowered, naked.—It is common in meadows and pastures, where it flowers in May: the flowers open at four in the morning, and close at three in the afternoon.

2. *Apargia Hirta*. The whole calix upright, smoothish; leaves toothed, rough with hairs that are undivided; scape smooth, without any floral leaf; outer seeds without down.—The whole of this plant is much smaller than the first species.—It grows in Germany, Switzerland, France, and Spain, and is frequent on Hampstead Heath, Barnes Common, and other commons near London.

3. *Apargia Danubialis*. The whole calix upright, smooth; leaves toothed, smooth; scape one-flowered, almost naked.—It flowers in June, and is found in meadows on the islands in the Danube.

4. *Apargia Tuberosa*. Calix acute, hirsute; leaves runcinate, scabrous.—Native of meadows in Tuscany and the south of France.

5. *Apargia Autumnalis*. Stem branched, almost naked; peduncles scaly; leaves lanceolate, toothed, quite entire, smooth. Root perennial; florets yellow on both sides, the tubular part a little hairy. The flowers open at seven in the morning, and close at three in the afternoon; they appear from July until October.—This plant is common in pastures; horses, goats, and swine are said to eat it, but cows and sheep refuse it. Old English writers call it *Yellow Devil's Bit*; *Small Hare's Hawkweed*; or *Small Hawkweed with bitten roots*.

6. *Apargia Pyrenaica*. Peduncles scaly; leaves lanceolate; with very few teeth; calices villose, root end-bitten. Perennial; florets yellow.—Native of the south of Europe.

7. *Apargia Taraxaci*. Peduncles somewhat scaly at the top; leaves entire or pinnatifid, smooth; calix woolly; root end-bitten.—Found in Lapland, the south of Europe, and in Wales and Scotland in mountainous situations; flowering in July.

Aphanes; a genus of the class Tetrandria, order Digynia, or class Monandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, permanent; mouth flat, eight-parted. *Corolla*: none. *Stamina*: filamenta four, or one, erect, subulate, very small, placed on the mouth of the calix; antheræ roundish, or one, twin. *Pistil*: germen ovate; style filiform, the length of the stamina, inserted into the base of the germen; stigma headed. *Pericarp*: none. *Calix*: containing the seeds in the bottom, converging at the mouth. *Seeds*: ovate, acuminate, compressed. ESSENTIAL CHARACTER. *Calix*: eight-cleft. *Corolla*: none. *Seeds*: two, or one naked.—The only species is,

1. *Aphanes Arvensis*; *Parsley Piert*. Stems many, slender, leafy, four inches long, round; leaves roundish, three-parted, deeply lacinate; flowers herbaceous, axillary; calix cut into eight segments. An European small annual plant, growing in fallow fields and dry pastures, and flowering from May to August.—As a medicine, the whole plant is to be made use of, and it is best when fresh gathered, in which state it is easy to obtain it. A strong infusion of it is beneficial in the gravel, as it operates powerfully by urine, cleansing the kidneys and urinary passages from all sabulous concretions in a short time. It is likewise good in the jaundice, and other complaints arising from obstructions of the liver or any other viscera; and

many people fancy that it has the power of dissolving the stone in the bladder; hence its old name of *Parsley Breakstone*. Culpeper calls this plant a very good salad herb, and says it were well that the gentry would pickle it up as they pickle up samphire, for their use all the winter, because it is a very wholesome herb, and it may be kept either dried or in a syrup. He prescribes a drachm of the powder in white wine, to carry off gravel from the kidneys insensibly and without pain.

Aphyllanthes; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: glumes univalve, lanceolate, several, imbricate. *Corolla*: petals six, ovate, spreading in the border; claws slender, erect, converging into a tube. *Stamina*: filamenta setaceous, shorter than the corolla, inserted into the throat; antheræ oblong. *Pistil*: germen superior, three-cornered, turbinate; style filiform, the length of the stamens; stigmas three, oblong. *Pericarp*: capsule turbinate, triangular, trilocular. *Seeds*: ovate. **ESSENTIAL CHARACTER.** *Corolla*: six-petalled. *Filamenta*: inserted into the throat of the corolla. *Capsule*: superior. *Glume*: of the calix univalve, imbricate.—One species only is known,

1. *Aphyllanthes Mospeliensis*. Root creeping; culm naked; glume two-valved; two-flowered.—Grows wild in barren pastures and rocky places, about Montpellier and Nice.

Aphyteia; a genus of the class Monadelphia, order Triandria.—**GENERIC CHARACTER.** *Calix*: perianth monophyllous, semitrid, funnel-shaped, large, fleshy, erect, permanent. *Corolla*: rudiments of three petals, growing to the divisions of the calix. *Stamina*: filamenta connate at bottom, short; antheræ convex, cordate, striated. *Pistil*: germen inferior; style thickish, short; stigma three-cornered, channelled. *Pericarp*: berry one-celled. *Seeds*: numerous, nestling. **ESSENTIAL CHARACTER.** *Calix*: large, funnel-shaped, semitrid. *Petals*: three, inserted into the throat of the tube in the calix, and shorter than it.—The only known species belonging to this genus is,

1. *Aphyteia Hydнора*. A vegetable without leaves, stem or root, being parasitical, terrestrial, consisting of a fructification only. The smell of the flower and ripe fruit is not unpleasant. The latter is much liked by foxes and weasels; and eaten both raw and roasted by the Hottentots.—This plant is parasitical at the root of *Euphorbia*, and was first observed in the parched sandy plains of the Cape.

Apios. See *Glycine* and *Euphorbia*.

Apium; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel universal, of fewer rays than those of the partial; involucre universal small, of one or more leaflets; partial similar: proper perianth obsolete. *Corolla*: universal uniform; floscules almost all fertile; proper petals roundish, inflex, equal. *Stamina*: filamenta simple; anthera roundish. *Pistil*: germen inferior; styles reflex; stigmas obtuse. *Pericarp*: none; fruit ovate, striated, splitting in two. *Seeds*: two, ovate, striated on one side, plane on the other. **ESSENTIAL CHARACTER.** *Fruit*: ovate, striated. *Involucre*: one-leafed. *Petals*: equal.—The species are,

1. *Apium Petroselinum*; *Common Parsley*. Stem-leaflets linear; involucels minute; stems round, smooth, striated; flowers pale yellow; seeds short, turgid. There are three varieties: the common Garden Parsley, the Curled, and the Large-rooted Parsley. It is a biennial plant, cultivated for culinary use.—Parsley roots are sometimes used in decoctions, and supposed to be aperient and diuretic, but liable to produce flatulencies. In distilling large quantities, two or three drachms of essential oil separate from two hundred pounds: the leaves, which are warmer but not so sweet as the roots, yield about ten drachms from the same quantity. The seeds are warmer and more aromatic than any other part, and are

accounted to be carminative, resolvent, and diuretic, and are recommended for destroying cutaneous diseases in children. Parsley is said to be fatal to small birds; and is accused of causing epilepsies, or of increasing them where before existing, and also of injuring the eyes. A poultice of the leaves is reported to be resolvent and discutient, if applied to glandular tumors; and also to be an efficacious remedy for the bites or stings of poisonous insects. Independently of its uses at table, the seeds disperse flatulencies in the stomach, and relieve those who are troubled with the colic. A strong decoction of the roots is a powerful diuretic, and is excellent in obstructions of the viscera, and such disorders as arise therefrom; and when drank for some time, will bring away gravel and other sabulous concretions from the kidneys and bladder, and is very serviceable in the jaundice and dropsy. The distilled water of Parsley, says Culpeper, is a familiar medicine with nurses, to give their children when they are troubled with wind in the stomach or belly. The leaves, laid to inflamed eyes, also are very efficacious; and when fried in butter, and applied to women's breasts, which are hard through the curdling of their milk, will give speedy relief; and also remove black and blue marks produced by blows or falls.—The Common and the Curled Parsley must be sown early in spring, and, if for medicinal use, but thinly. They only require hoeing and weeding. It is sown by skilful persons in fields about the end of February, for the use of sheep, and is a sovereign remedy to preserve them from the rot, provided they are fed twice a week for two or three hours each time. One bushel of seed will sow an acre of land.

2. *Apium Graveolens*; *Smallage*, or *Wild Celery*. Stem-leaves wedge-shaped; corolla small and white. It is biennial, flowering in ditches and marshes, from July to September. The varieties, according to Miller, are as follows: the Upright Celery, the Turnip-rooted Celery, and Portugal Celery. The fresh roots, especially in their native watery places, are fetid, acrid, and supposed to be noxious: they lose the greatest part of their ill flavour, and become sweetish when dried, and in that state have been used for decoctions as aperients and diuretics. The seeds have been sometimes used as carminatives and aperients; they have a moderately strong grateful smell, and a warm bitterish taste. Culture corrects its noxious qualities, and renders it mild and esculent. The lower part of the stem and leaf-stalks blanched, by being covered up with earth, are eaten raw, stewed, and boiled in soups, and are excellent antiscorbutics. A strong decoction of the roots operates by urine, and is good in fits of the stone or gravel: the seeds operate more powerfully by urine than any other part of the plant. Culpeper recommends the juice, with honey of roses and barley-water, as good to gargle within ulcerated sore throats; and says, that the seed kills worms, and sweetens a stinking breath.—Smallage is a common weed by the sides of ditches and brooks of water. The seeds should be sown soon after they are ripe, on a moist spot of ground; and when the plants have attained six or eight inches in height, they may either be transplanted into a moister soil, or into trenches, in order to be earthed up on each side as they advance in growth, and have their stalks blanched or whitened, to render them crisp and tender.

Apluda; a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** *Calix*: involucre common, univalve; valve ovate, concave, terminated by a very short point or leaflet, two-flowered; the inferior flower sessile in the short, ovate, truncate, hollow base, which is continued into opposite, glumaceous, linear, flat, vertical footstalks, on one of which sits the superior flower, on the other a very short

rudiment of a flower. *Flower inferior*, hermaphrodite, almost entirely lying hid between the foot-stalks. *Calix*: involucre-proper univalve; valvelets lanceolate, compressed, rigid, double-toothed at the tip, smooth, embracing the flower with its margins beneath, opposite to the common involucre. Glume one-flowered, two-valved; valvelets membranaceous, transparent, shorter than the involucre; the exterior navicular, gibbous on the back, keeled, contracted towards the tip, acuminate; the interior ventricose, somewhat sharp, smaller. *Corolla*: glume bivalve, membranaceous, extremely thin, transparent; valve exterior navicular, compressed, smooth, hyaline, gibbous on the back, bifid, acute, awned below the tip, hid within the exterior valve of the calix, and shorter than it; the interior lanceolate, flat, acute, doubled together at each margin, the exterior rather longer; nectary very small, two-leaved, truncate-rounded, hyaline. *Stamina*: filamenta three, capillary; antheræ linear, bifid on each side. *Pistil*: germen oblong, small; styles two, capillary, upright, longer than the germen; stigmas oblong, villose, spreading, protruded on each side from the flower. *Pericarp*: none; corolla cherishes the seed, gapes, and drops it. *Seed*: ovate-oblong, compressed, smooth. *Flower superior*, smaller. *Calix*: glume two-flowered, two-valved; valves lanceolate, broadish, flat, sharp, nervose, nearly equal; one floscule female, the other male or neuter. *Corolla*: of the female, glume bivalve; valves membranaceous, hyaline; the exterior ventricose, cornered, sharp-pointed; the interior lanceolate, narrower, shorter, obtuse. Glume of the male, bivalve; valves lanceolate, membranaceous, hyaline; the exterior somewhat ventricose, sharp; the interior narrower, shorter. Nectary on both, as in the *inferior* flower. *Stamina*: of the male, as in the *inferior* flower. *Pistil* of the female, as in the *inferior* flower. *Pericarp* and *Seed* of the female as in the *inferior* flower. **ESSENTIAL CHARACTER.** *Calix*: glume common, bivalve; female floret sessile; males peduncled. *Male. Calix*: none. *Corolla*: bivalve. *Stamina*: three. *Female. Calix*: none. *Corolla*: bivalve. *Style*: one. *Seed*: one, covered.—The species are,

1. *Apluda Mutica*. Leaves lanceolate; all the flowers awnless; culm very long, weak, smooth.—Native of India.
2. *Apluda Aristata*. Leaves lanceolate; male flowers awnless, except one at the end, which is sessile and awned; culm a foot long, inflected.—Native of India.

3. *Apluda Zugites*; *Mountain Reed Grass*. Leaves ovate; male flowers awnless; one at the end sessile and awned.—This curious little plant is a native of Jamaica.

4. *Apluda Digitata*. Spikes digitate; flowers pointing one way.—A lofty East Indian grass.

Apocynum; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-parted, acute, short, permanent. *Corolla*: monopetalous, bell-shaped, semiquinquefid; divisions revolute. Nectary, of five glandular oval corpuscles surrounding the germen. *Stamina*: filamenta very short; antheræ oblong, erect, acute, bifid at the base, converging. *Pistil*: germen two, ovate; styles short; stigma roundish, bifid at the tip, muricate, glued to the antheræ. *Pericarp*: follicles two, long, acuminate, one-valved, one-celled. *Seeds*: numerous, very small, crowned with a long down. *Receptacle*: subulate, very long, rough, free. **ESSENTIAL CHARACTER.** *Corolla*: bell-shaped. *Nectaries*: five, alternate with the stamina.—The first three species are propagated by parting the roots in March. They flower in July, are hardy, and will thrive in a light dry soil. The fourth will bear the open air in a warm situation and dry soil. All the rest are tender, and may be propagated by cuttings, and must be constantly kept in a hot-house,

plunged into a tan-bed. They rarely seed in England, and are an ornament at all seasons, retaining beautiful green leaves throughout the year.—The species are,

1. *Apocynum Androsæmifolium*; *Tutsan-leaved Dog's-bane*. Stem straightish, herbaceous; leaves ovate, smooth on both sides; cymes terminating. Root perennial; corolla white. This plant is said to kill the flies that alight upon it. The Canadian French say, that it is poisonous to some persons, but harmless to others. Kalm relates, that he saw a soldier whose hands were blistered all over, merely from plucking it; whereas he frequently rubbed his own hands with the juice, without feeling any inconvenience.—Native of Virginia and Canada; flowering from July till September.

2. *Apocynum Cannabinum*; *Hemp Dog's-bane*. Stem straightish, herbaceous; leaves oblong, in pairs, abounding with a milky juice; cymes lateral, longer than the leaf.—Native place and flowering time, same as No. 1.

3. *Apocynum Hypericifolium*; *St. John's-Wort-leaved Dog's-bane*. Stem straightish, herbaceous; leaves oblong-cordate, smooth; cymes shorter than the leaf. Root perennial, creeping; flower small, scentless, and white. The whole plant is smooth, and abounds in milk. Flowers in June and July.—Native of North America.

4. *Apocynum Venetum*; *Spear-leaved Dog's-bane*. Stem straightish, herbaceous; leaves ovate-lanceolate. Root perennial; stems two feet high. It varies with purple and with white flowers, which appear in July and August.—Found in the Adriatic Islands.

5. *Apocynum Minutum*; *Petty Dog's-bane*. Stem prostrate; leaves hastate.—Found at the Cape of Good Hope.

6. *Apocynum Filiforme*; *Thread-leaved Dog's-bane*. Stem prostrate, herbaceous; leaves filiform; flowers umbelled.—Native of the Cape of Good Hope.

7. *Apocynum Frutescens*; *Shrubby Dog's-bane*. Stem erect, shrubby; leaves lanceolate-oval; corollas acute, villose at the throat; flowers small, in loose bunches, and of a purple colour.—Native of the East Indies, Ceylon, and the coast of Guinea.

8. *Apocynum Reticulatum*; *Net-leaved Dog's-bane*. Stem twining, perennial; leaves ovate, veined. The leaves of this species are of a dark and very shining green, with a beautiful net of milky veins.—Native of the East Indies, and Cochin-china.

9. *Apocynum Lineare*; *Linear-leaved Dog's-bane*. Stem twining, herbaceous; leaves linear, flat; umbells axillary, compound.—Native of the Cape.

10. *Apocynum Triflorum*; *Three-flowered Dog's-bane*. Stem twining, herbaceous; leaves lanceolate; umbels axillary, two or three flowered.—Native of the Cape.

11. *Apocynum Juventas*; *Renovating Dog's-bane*. Stem twining, shrubby; leaves ovate, hairy; racemes dichotomous. Flowers greenish-yellow colour.—A native of Cochin-china, where the country physicians imagine the root of this plant to refresh the animal spirits to such a degree, as by long-continued use to endow old age with all the strength and vigour of youth.

12. *Apocynum Alterniflorum*; *Alternate-flowered Dog's-bane*. Stem climbing, shrubby; leaves ovate, acuminate, smooth; axils alternate, umbelliferous. Flowers pale, and scentless.—Native of the islands near Canton in China.

13. *Apocynum Africanum*; *African Dog's-bane*. Stem suberect, shrubby; leaves ovate-oblong; peduncles two or three flowered. Stem eight feet high; flower pale.—Found in a sandy plain upon the coast of Zanguebar in Africa.

14. *Apocynum Scandens*; *Climbing Dog's-bane*. Leaves oblong-cordate, stiff; flowers lateral; stem shrubby, twining.

It abounds near Carthagena, in New Spain; and flowers in August and September.

15. *Apocynum Nervosum*; *Nerve-leaved Dog's-bane*. Leaves ovate, nerved, cymes lateral; flowers yellow, large; tube very long; stem shrubby, climbing. Flowers large, bright yellow.—Native of New Spain, near Carthagena.

16. *Apocynum Cordatum*; *Heart-leaved Dog's-bane*. Leaves oblong-cordate, pointed, sessile; flowers lateral; stem climbing.—This and the following species are natives of Vera Cruz, in New Spain: they both have climbing stalks, by which they mount the highest trees; even in English hot-houses they have risen upwards of twenty feet high. The pods of these plants afford a cottony down, which is greatly esteemed in France (where it is called *Delawad*) for stuffing easy chairs, and making warm light quilts for persons afflicted with the gout; hence, in the south of France, where it will thrive and produce seed in the open air, there are many plantations of it, for the sake of the down. As these plants are plentiful in the uncultivated parts of Jamaica, abundance of the down might be procured from thence; and if it were only to become *fashionable*, would soon become *vendible* in England. There they require no cultivation; the only trouble would be to collect the down, which on some of the large-podded sorts is produced in great quantities.

17. *Apocynum Villosum*; *Villose-flowered Dog's-bane*. Leaves cordate, smooth; flowers villose, lateral, on long peduncles; stem climbing. See the foregoing species.

Aponogeton; a genus of the class Dodecandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: none, except a spatheaceous scale surrounding the outer side of the flower, simple, sessile, ovate, obtuse, entire, upright, smooth, coloured. *Corolla*: none. *Stamina*: filamenta eleven to nineteen, in the upper flowers fewer, inserted between the spathe and the capsules, subulate, smooth, white, many times shorter than the spathe. *Pistil*: germina usually four, seldom three or five; styles none; stigmas subulate, bent in. *Pericarp*: capsules four, seldom three or five, ovate, subulate-acute, gibbous on the outside, flat on the inner side, smooth, one-celled. *Seeds*: in each capsule three, affixed to the base of it, sessile, obovate, very blunt, subcompressed, smooth. ESSENTIAL CHARACTER. *Calix*: an amentum. *Corolla*: none. *Capsule*: three-seeded.—These plants belong to the greenhouse or cape-stove, and may be increased by offsets from the bulbs.—The species are,

1. *Aponogeton Monostachyon*; *Single-spiked Aponogeton*. Spike simple; leaves cordate-oval.—Common in fields that are flooded for rice in the East Indies.

2. *Aponogeton Distachyon*; *Broad leaved Aponogeton*. Spike bifid; leaves linear, oblong, floating; bractes entire; flowers many-stamined.—Found at the Cape of Good Hope. It bears white flowers almost all the year round; they have a very fragrant smell.

3. *Aponogeton Angustifolium*; *Narrow-leaved Aponogeton*. Spike bifid; leaves linear-lanceolate, erect; bractes two-parted; flowers six-stamined. Flowers almost all the year.—Native of the Cape.

Apple, Custard. See *Annona*.

Apple, Love, and Mad. See *Solanum*.

Apple, Pine. See *Bromelia*.

Apple, Purple, and Sour. See *Annona*.

Apple, Thorn. See *Datura*.

Apple-Tree. See *Pyrus*.

Apple, Water. See *Annona*.

Apricot, or Apricock. See *Prunus*.

Aquartia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth monophyl-

lous, permanent; tube bell-shaped; limb subquadrid, expanding; two opposite divisions obsolete. *Corolla*: monopetalous, rotate; tube very short; limb quadrid; divisions linear, widely spreading. *Stamina*: filamenta short; anthera erect, very large, linear. *Pistil*: germen ovate, style filiform, declined, the length of the corolla; stigma simple. *Pericarp*: berry, globular, one-celled. *Seeds*: very many, compressed. ESSENTIAL CHARACTER. *Calix*: bell-shaped. *Corolla*: wheel-shaped, with linear divisions. *Berry*: many-seeded.—One species only is known, viz.

1. *Aquartia Aculeata*. A perennial spinous plant, with a white inodorous flower. In St. Domingo, of which Jacquin says it is a native, it flowers and bears a yellow shining fruit, the size of a pea, in October.—Native of South America.

Aquilaria; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, permanent; tube bell-shaped; border five-cleft; clefts ovate, acute, flat, spreading. *Corolla*: none; nectary one-leaved, pitcher-shaped, length of the tube of the calix, half five-cleft; cleft bifid, obtuse. *Stamina*: filamenta ten, alternate to, and shorter than, the clefts of the nectary; anthera oblong, versatile. *Pistil*: germen ovate, on a very short pedicle, superior; style none; stigma simple. *Pericarp*: capsule on a very short pedicle, obovate woody, two-celled, two-valved; with the partition contrary, and bipartite. *Seeds*: solitary, oblong. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Nectary*: pitcher-shaped, half five-cleft, with bifid clefts. *Capsule*: superior, woody, two-celled, two-valved. *Seeds*: solitary.—The only species discovered is,

1. *Aquilaria Ovata*. Leaves alternate, ovate, mucronate.—This is a large tree, the wood of which in its natural state is white and inodorous: it has the name of lign-aloes, or *wood aloes*, from its bitter taste. No part of this plant is poisonous; the *aroma* which it produces arises from a disease, caused by oleaginous particles stagnating and concreting in the inner parts of the trunk into a resin, which is extracted from the wood when split. The perfume made of the wood is highly esteemed by the Oriental nations. From its bark of the tree the common writing paper of the Chinese is made. The perfume is said to be good in vertigo and palsy; the powder restrains vomiting and alvine fluxes, by its astringent and corroborating power. Three kinds of this wood are used in the shops; they are called *Calumbac*, *Common Lign-aloes*, and *Calambour*. The first is the finest and most resinous; the last is almost a mere chip; and the second a middling kind. They all have the property of acting as cordials, and strengthening the stomach, but in different degrees, and are not much used.

Aquilegia; a genus of the class Polyandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals five, lanceolate-ovate, flat, spreading, equal. Nectaries five, equal, alternate with the petals, each horned, gradually broader upwards, with an oblique mouth, ascending outwardly, annexed inwardly to the receptacle, each produced below into a long attenuated tube, with an obtuse top. *Stamina*: filamenta thirty to forty, subulate, the outer ones shorter; anthera oblong, erect, the height of the nectaries. *Pistil*: germina five, ovate oblong, ending in subulate styles, longer than the stamina; stigmas erect, simple; chaffs ten, wrinkled, short, separate, and involving the germina. *Pericarp*: capsules five, distinct, cylindric, parallel, straight, acuminate, one-valved, gaping from the tops inward. *Seeds*: very many, ovate, keeled, annexed to the gaping suture. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: five. *Nectaries*: five, horned between the petals. *Capsule*: five, distinct.—These plants should always be raised from seeds, since the old roots

are apt to degenerate, and produce plain flowers. Sow them in a nursery-bed in August or September; they will appear in spring, and in May should be transplanted, eight or nine inches every way apart, upon beds of good fresh undunged earth; and in the following autumn will be strong enough to be taken up, and placed in the borders of the flower-garden, where they will flower in the summer following. To ensure good flowers, let them flower in the nursery, and then select the best for transplantation; but the best way is to sow fresh seeds every year. Take care that no seeds of the plain sorts are mixed with the variegated kinds, or they will cause the whole to degenerate.—The species are,

1. *Aquilegia Viscosa*; *Clammy Columbine*. Stem almost naked, with viscid hairs, and one or two flowers; leaves subtrilobate. Root perennial; stem a foot high.—Native of the south of France, and the mountains of Piedmont.

2. *Aquilegia Vulgaris*; *Common Columbine*. Nectaries blue, yellow at the tip, and incurved. Stem three feet high, erect, leafy, branching; the flowers are produced from the tops of the naked branches, and hang down. There are many varieties. In a wild state, the flowers are usually blue: red and white is common about Berne in Switzerland, and also in Norfolk. Double flowers have been found in the Pays de Vand.—Native of most parts of Europe, in woods, hedges, and bushes. It is perennial, and the flowers vary much by culture; with us they appear in June, and are blue, white, red, purple, flesh-coloured, ash-coloured, chesnut-coloured, and striped or variegated blue and purple, blue and white, and red and white. The root, herb, flowers, and seed, are recommended as medicines upon good authority; but this plant is of a suspicious tribe, and Linneus says, that children have lost their lives by an over-dose of it. The sensible qualities of the seeds, says Lewis, afford little foundation for their supposed virtues in the jaundice, measles, and small-pox, as they only differ from the cold seeds in being somewhat more mucilaginous, with a disagreeable relish. The virtues ascribed to a tincture of the flowers, as an antiphlogistic, and for strengthening the gums, and deterring scorbutic ulcers in the mouth, are better founded. The tincture is made with an addition of the vitriolic acid, and differs little from our tincture of roses. Notwithstanding this, Hill observes, that the seeds operate by sweat and urine, open obstructions of the viscera, and are good in the jaundice, in fevers, and in the small-pox and measles, to throw out the pustules. A decoction of the leaves is good for sore throats; and a tincture of the flowers in brandy is recommended by Tournefort as an excellent gargle for scorbutic affections of the gums.

3. *Aquilegia Alpina*; *Alpine Columbine*. Nectaries straight, shorter than the lanceolate petal. Root biennial; corolla blue. Flowers in May and June.—Said to be found in Westmoreland; but is a native of the Alps.

4. *Aquilegia Canadensis*; *Canadian Columbine*. Nectaries straight; stamina longer than the corolla. Root perennial; stems very slender, redish; corolla red without, and yellow within.—Native of North America; flowering in April, and ripening seeds in August. It flowers a month sooner than the other sorts.

5. *Aquilegia Viridiflora*; *Green-flowered Columbine*. Nectaries straight, thickened, and a little bent in at the tip; stamina nearly equal to the corolla. Root perennial; petals pale green.—It flowers in May, ripens seed in July; and was found by Professor Pallas in Siberia.

Arabis; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved, deciduous; leaflets from parallel converging, two opposite

larger, ovate-oblong, acute, a little prominent at the base, gibbose, concave; the two others linear, erect. *Corolla*: four-petalled, cruciform; petals spreading, ending in claws the length of the calix; nectaries four, each from a little scale, within the bottom of the calicine leaflet, affixed to the receptacle, reflex, permanent. *Stamina*: filamenta subulate, upright, two the length of the calix, four twice as long; antheræ cordate, erect. *Pistil*: germen columnar, the length of the stamina; style none; stigma obtuse, entire. *Pericarp*: silique compressed, very long, linear, unequal, with swellings at the seeds; valves almost the length of the partition. *Seeds*: very many, roundish, compressed. ESSENTIAL CHARACTER. Nectareous glands four; one within each leaflet of the calix, like a reflex scale.—They are all hardy plants, producing seed plentifully, thriving in any situation, and may easily be propagated by sowing the seed in autumn, or permitting them to scatter themselves.—The species are,

1. *Arabis Alpina*; *Alpine Walleress*. Leaves stem-clasping, toothed; root creeping, perennial. The flowers grow in bunches towards the top; petals white; calix yellowish. It increases with great facility, and is esteemed for its early flowering, and the pretty appearance it makes in cold abject situations, where few other things will thrive.—Native of the Alps, and other European mountains, upon rocks, and in woods and caverns.

2. *Arabis Lucida*; *Shining Walleress*. Leaves stem-clasping, shining: perennial.—A native of Hungary.

3. *Arabis Grandiflora*; *Great-flowered Walleress*. Stem naked; perennial, with a white corolla.—Native of Siberia.

4. *Arabis Thaliana*; *Common Walleress*. Leaves petiole, lanceolate, quite entire. This flowers in March and April; seeds in May; and is common upon walls, and among corn in sandy soils.

5. *Arabis Bellidifolia*; *Daisy-leaved Walleress*. Leaves subdentate, the radical ones obovate, those of the stem lanceolate. Root perennial; the flowers corymbed, inodorous, white, appearing in May and June.—Native of moist places, near the Alps, and in Austria.

6. *Arabis Lyrata*; *Lyrate-leaved Walleress*. Leaves smooth; the radical lyrate; the stem leaves linear. Root annual; flower white.—Native of North America.

7. *Arabis Hispida*; *Rough Walleress*. Leaves wedge-shaped, sublyrate, hispid; the stem-leaves half stem-clasping, lanceolate; siliques stiff, acinapital. Root annual; petals white.—Native of the south of France, Switzerland, and Austria: observed also upon Mont Saleve in Savoy, near Geneva, by Mr. Ray, and upon St. Vincent's rocks near Bristol: it flowers in May.

8. *Arabis Halleri*; *Haller's Walleress*. Stem-leaves sublyrate, those on the branches lanceolate, gashed; stem erect, six inches high; petals white, with green claws.—Native of Germany, Carniola, and Piedmont.

9. *Arabis Canadensis*; *Canadian Walleress*. Stem-leaves lanceolate, toothed, smooth; flowers pendulous, in lateral racemes.—Native of North America.

10. *Arabis Pendula*; *Pendulous Walleress*. Leaves stem-clasping; siliques acinapital, linear; calices subpilose. Stem nearly a foot high; corolla white.—Native of Siberia.

11. *Arabis Turrata*; *Tower Walleress*. Leaves stem-clasping; siliques bending down, flat, linear; calices subrugose. Root biennial; stem from nine inches to two feet high; flowers white or yellowish, on short peduncles.—Native of Austria, Switzerland, and Dauphiny. It flowers with us in June, and grows upon the walls of St. John's College at Cambridge, and of Magdalen College at Oxford.

12. *Arabis Saxatilis*. Stem erect; leaves stem-clasping,

lanceolate, toothed; siliques the length of the raceme. Root annual; umbel of flowers terminating, nodding; petals white; stem a palm or a palm and a half high.—Found upon rocks, in most parts of the south of Europe.

13. *Arabis Scabra*. Root-leaves roundish, scabrous, toothed; stem-leaves embracing, hirsute. Stem six inches high; petals milky white.—Native of the south of Europe.

14. *Arabis Serpyllifolia*. All the leaves elliptic, quite entire; stem flexuose; biennial.—A Native of Dauphiny.

15. *Arabis Recta*. Stem straight; leaves rectangularly toothed, and sessile; siliques from erect spreading. The flowers are white. It grows upon rocks and walls about Grenoble in France.

Arach. See *Atriplex*.

Arachis; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth two-parted, gaping; upper lip ovate, semitrifid; the intermediate division the largest, emarginate; under lip lanceolate, concave, acute, rather longer than the upper. *Corolla*: papilionaceous, resupine; banner roundish, flat-deflex, very large, emarginate, longer than the calix; wings free, subovate, shorter than the banner; keel subulate, incurved, the length of the calix, very slightly bifid at the base. *Stamina*: filamenta ten, all united at the bottom, subulate, the length of the keel; antheræ alternately roundish and oblong. *Pistil*: germen oblong; style subulate, the length of the germen, ascending; stigma simple. *Pericarp*: legume, ovate-oblong, columnar, valveless, gibbous, torulose, veined, coriaceous, one-celled. *Seeds*: two, oblong, obtuse, gibbous, truncate at one end. **ESSENTIAL CHARACTER.** *Calix*: bilabiate. *Corolla*: resupine. *Filamenta*: connected. *Legume*: gibbous, torulose, veined, coriaceous.—The seeds must be sown upon a hot-bed in the spring, and kept under glasses till the middle of June, when, if the weather prove warm, they may be gradually exposed to the air. The branches trail upon the ground, and, as soon as the flower begins to decay, the germ thrusts itself into the ground, and there the pod is formed and ripened.—The species are,

1. *Arachis Hypogæa*; *Common Earth*, or *Ground Nut*. Stem herbaceous, procumbent. Annual; three feet high; flowers gold-coloured, growing singly on long axillary peduncles.—Native of the East Indies, and much cultivated in China and Cochin-china. All the European settlements of America now abound with this plant: in South Carolina the inhabitants roast the *nuts*, as they are called, and use them as chocolate. In the eastern countries they are a substitute for almonds, and abound in a thin limpid oil, much used for lamps in Cochin-china, where, though inferior in flavour, it supplies the place of oil of olives for culinary use.

2. *Arachis Fruticosa*; *Shrubby Earth*, or *Ground Nut*. Stem shrubby, upright; flowers of a yellow colour.—Native of the East Indies, in Tranquebar, and the island of Ceylon.

Aralia; a genus of the class Pentandria, order Pentagynia.—**GENERIC CHARACTER.** *Calix*: involucre very small, of a globular umbellule; perianth five-toothed, very small, superior. *Corolla*: petals five, ovate, acute, sessile, reflex. *Stamina*: filamenta five, subulate, the length of the corolla; anthera roundish. *Pistil*: germen roundish, inferior; styles very short, permanent; stigmas simple. *Pericarp*: berry roundish, striated, crowned, five-celled. *Seeds*: solitary, hard, oblong. **ESSENTIAL CHARACTER.** *Flowers* in an umbellule, with an involucre. *Calix*: five-toothed, superior. *Corolla*: five-petalled. *Berry*: five-seeded.—The species are,

1. *Aralia Spinosa*; *Thorny Aralia*, or *Angelica Tree*. Arboreous: stem and leaves prickly. Rises eight or ten feet high; and is a native of Virginia.—It is propagated by seed, which is easily procured from North America. Sow them in

pots of light earth as soon as they arrive, and plunge them during autumn either in an old tan-bed or a warm border, and cover them with pease-haulm, if the winter be severe. When they appear, water and weed, but do not disturb them the first season. They are also easily increased by the roots.

2. *Aralia Pentaphylla*; *Five-leaved Aralia*. Arboreous, prickly: leaves quinate; flowers in umbels, peduncled.—Native of Japan; flowering in May and June.

3. *Aralia Chinensis*; *Chinese Aralia*. Shrubby: stem and petioles prickly; leaflets unarmed, villose.—Native of Malabar; found in China and Cochin-china.

4. *Aralia Japonica*; *Japanese Aralia*. Shrubby: leaves lobate; stem unarmed, six feet high; flowering in November and December; has no involucre.—Native of Japan.

5. *Aralia Racemosa*; *Berry-bearing Aralia*. Stem leafy, herbaceous, smooth: height three or four feet. The flowers are of a whitish colour. The French and Indians of Canada eat the berries, and use both the leaves and roots as salads and pot-herbs.—This and the next sort should have their seeds sown soon after they are ripe in autumn, and weeded when they appear during the summer; and in the next autumn they may be transplanted where they are to remain. The roots also may be parted in autumn, and planted well asunder; they are hardy plants, and will grow in any situation.

6. *Aralia Nudicaulis*; *Naked-stalked Aralia*. Stem naked; leaves in pairs, ternate. The roots of this plant are used by the Canadians for Sarsaparilla. Propagated like No. 5.

7. *Aralia Cordata*; *Heart-leaved Aralia*. Herbaceous: stem angular, unarmed; leaves simple, heart-shaped; flowers axillary, umbelled.—Native of Japan.

8. *Aralia Octophylla*; *Digitate-leaved Aralia*. Stem arboreous, unarmed; leaves digitate, with eight leaflets; panicle umbelled. A tree ten feet high, with a yellow flower sprinkled with red.—It is cultivated in Cochin-china, where it is a native, and used medicinally in dropsical cases.

9. *Aralia Palmata*; *Palmate-leaved Aralia*. Stem scandent, prickly; leaves five-lobed; umbels simple, lateral. Stem shrubby; flower white.—Native of China; where the bark is employed in cutaneous and dropsical disorders.

Arbor Vita. See *Thuja*.

Arbutus; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, obtuse, very small, permanent. *Corolla*: monopetalous, ovate, flattish at the base, diaphanous, with a quinquefid mouth; divisions obtuse, revolute, small. *Stamina*: filamenta ten, subulate, swelling, very slender at the base, affixed to the edge of the base of the corolla, and half the length of it; antheræ slightly bifid, nodding. *Pistil*: germen subglobular, on a receptacle marked with ten dots; style cylindrical, the length of the corolla; stigma thickish, obtuse. *Pericarp*: berry, roundish, five-celled. *Seed*: small, bony. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Corolla*: ovate, diaphanous at the base. *Capsule*: five-celled.—The species are,

1. *Arbutus Unedo*; *Common Strawberry Tree*. There are three varieties, viz. the common white-flowered Strawberry-tree: flowers simple; corollas whitish. The red-flowered Strawberry-tree: flowers simple; corollas reddish. And the double-flowered Strawberry-tree: flowers full; stem arboreous; leaves oblong-lanceolate; panicles smooth, nodding. The common *Arbutus* rises to the height of twenty or thirty feet, and forms a great ornament, both with its flowers and fruit, when other trees are past their beauty.—Native of the south of Europe, Greece, and Palestine; and grows in the west of Ireland, near the lake of Killarney, on barren limestone rocks.—The best way of propagating them is from

seed. Gather the fruit when perfectly ripe, which is from the middle of November till the end of December, and mix it with dry sand, to preserve it until the time of sowing. The surest way of raising the plant, is to sow the seed in pots in December, plunging them into an old bed of tanner's bark which has lost its heat, and covering the bed with glasses. If the seeds be good, the plants will come up in the beginning of April, and must be often, but sparingly watered, and kept free from weeds. During the first summer shade them from the heat of the day, and in the beginning of October transplant them singly into small pots filled with light earth. When they are two or three feet high, in April following, shake them out of the pots, and replant them, with balls of earth about their roots, into the open ground where they are to remain. This tree delights in a moist soil, seldom producing much fruit in a dry ground.

2. *Arbutus Laurifolia*; *Laurel-leaved Strawberry Tree*. Stem arborescent; leaves oblong, acuminate at both ends, sharply serrate, smooth; racemes axillary, one-ranked, sessile, solitary.—Native of North America.

3. *Arbutus Andrachne*; *Oriental Strawberry Tree*. Stem arboreous; leaves oval, quite entire, and serrate; panicles pubescent, erect. A middle-sized tree.—Common in Crete, and between Aleppo and Antioch.

4. *Arbutus Ferruginea*; *Long-flowered Strawberry Tree*. Stem arborescent; leaves oblong, obtuse, smooth, quite entire; racemes terminal.—Found in America.

5. *Arbutus Mucronata*; *Pointed-leaved Strawberry Tree*. Stem shrubby; leaves alternate, ovate, serrate, pointed; peduncles axillary, one-flowered.—This is a very stiff shrub; found in Terra del Fuego.

6. *Arbutus Pumila*; *Dwarf Strawberry Tree*. Stems diffused; leaves alternate, distich, oblong, quite entire; flowers lateral, solitary.—A low shrub with nodding flowers; a native of Terra del Fuego.

7. *Arbutus Acadiensis*; *Acadian Strawberry Tree*. Stems procumbent; leaves ovate, subserrate; flowers scattered; berries many-seeded.—It never produces fruit in England; but grows naturally upon swampy land in Acadia, and other northern parts of America.

8. *Arbutus Alpina*; *Black-berried Alpine Arbutus*. Stems procumbent; leaves rugose, serrate.—This is a very common plant in Sweden, Denmark, Switzerland, Dauphiny, Savoy, Siberia, and many of the Highlands of Scotland; flowering in May, in a dry barren soil.

9. *Arbutus Uva Ursi*; *Berry-bearing or Trailing Arbutus*. Stems procumbent; leaves quite entire. This shrub abounds in most parts of the continent, and in heathy, mountainous, and rocky places, throughout the Highlands; also, near Hexham, in Northumberland.—The leaves have been greatly celebrated as a remedy in stony and gravelly complaints. The dose is half a drachm of the powder of the leaves, every morning, or twice or thrice daily. De Haen relates, after great experience of this medicine in the hospital of Vienna, that suppurations, though obstinate and of long continuance, in the kidneys, ureter, bladder, urethra, scrotum, and perinæum, where there was no venereal taint, nor marks of calculi, were in general completely cured by it; that even of those who had a manifest calculus, several found permanent relief, so that long after the medicine had been left off, they continued free from pain or inconvenience in making water, though the catheter shewed that the calculus still remained: that others, who seemed to be cured, relapsed on leaving off the medicine, and were several times successively relieved by again repeating its use; while others obtained from it only temporary and precarious relief, the complaints being often as severe during the ope-

ration of the medicine as when it was not used. The trials made of it in this country have not answered the general expectation. Some have had their complaints entirely removed, others have thought them aggravated by it. But though it frequently fails of performing a cure in those dreadful maladies, stone, gravel, &c. it many times alleviates the symptoms, and procures intervals of ease when all other means are ineffectual; which is a matter of no small moment, and certainly entitles it to some notice. It is probably not superior upon the whole to other vegetable astringents, some of which have long been successfully used by the country people in gravelly complaints, although they are not noticed by medical practitioners. Whatever may be the ultimate decision as to its medical qualities, the whole plant is certainly very serviceable in dyeing an ash-colour, but particularly in tanning leather. In this view it well deserves attention in those countries, the Highlands and Western Islands of Scotland for instance, where whole mountains are covered with this trailing shrub. The berries, which are red, and of the size of those of the Holly, are food for grouse and other game.

10. *Arbutus Thymifolia*; *Thyme-leaved Arbutus*. Stems procumbent; leaves oval, acute, obscurely serrate, strigose underneath; flowers axillary, eight stamined.—Very abundant in the swamps of North America; where the berries are used for tarts and other kinds of pastry, for which purpose the London confectioners import and employ them; but they are inferior to cranberries of our own growth.

Arbutus, Trailing. See *Epigæa*.

Archangel. See *Lanium*.

Archangel, Baum-leaved. See *Melittis*.

Archangel, Yellow. See *Galeopsis*.

Arctium; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common globular, imbricate; scales lanceolate, ending in long subulate prickles, reflex and toothed at the end. *Corolla*: compound tubular, uniform; corollules hermaphrodite, equal; proper monopetalous, tubular; tube slender, very long; limb ovate, quinquefid; divisions linear, equal. *Stamina*: filamenta five, capillary, short; anthera cylindrical, tubular, the length of the corolla, five-toothed. *Pistil*: germen oblong, with a villose top; style filiform, longer than the stamina; stigma bifid, reflex. *Pericarp*: none. *Calix*: converging. *Seeds*: solitary, vertically pyramidal, with the two opposite angles obliterated, gibbous on the outside; down simple, shorter than the seed. *Receptacle*: chaffy, flat; chaffs setaceous. ESSENTIAL CHARACTER. *Calix*: globular; the scales furnished at the end with inflected hooks.—These plants are readily increased by seeds, but will not flower till the second year, and the roots decay when the seeds are perfected.—The species are,

1. *Arctium Lappa*; *Common Burdock, Burr, or Clotburr*. Leaves alternate, large, rough, undulated; root biennial; stem three feet high; corolla purple, with a white tube.—It is very common by road-sides, on rubbish, and ditch-banks, throughout Europe, flowering in July and August; it also abounds in Japan. In England, few animals except the ass will touch it; birds feed upon the seeds; and snails, slugs, and some sorts of caterpillars, on the leaves. The stems are eatable, if stripped of their rind before the flowers appear, either boiled or raw, with oil and vinegar. Some excellent physicians think a decoction of the root equal if not superior to that of Sarsaparilla. Two ounces of the dried root are boiled in three pints of water till one pint is wasted, and a pint or more of this liquid is taken warm every day. A strong infusion of the root operates powerfully by urine, and is good in the jaundice and dropsy. The decoction above mentioned is also serviceable in the gravel, stone in the kidneys, and blad-

ARCTOTIS GRANDIFLORA.

P. 85.

AMARYLLIS REGINAE — Mexican Lily.

der, and venereal disorders; also for consumptive and asthmatical habits. The roots are said to be sudorific, and useful in fevers; but its virtue in operating by urine is its greatest value. The herb being burnt green between the time of flowering and seeding, in a hole made in the ground, without suffering the flame to escape, three pounds of the ashes produced sixteen ounces of very white alkaline salt, as good as the best potash.—There are many varieties of this common plant, differing in colour, and size, and smoothness or wooliness of the heads; the most remarkable of which is the Woolly-headed Burdock, which differs only in having the leaves whiter beneath, the heads more compact, and the florets of a bright red colour, but principally in having the calix all over beautifully netted with a fine down.

2. *Arctium Personata*: *Cut-leaved Burdock*. Leaves decurrent, ciliate, spiny; root-leaves pinnate; stem-leaves oblong-ovate. Root biennial, black, woody.—Flowers in July and August; native of Switzerland, Austria, Silesia, and Siberia.

3. *Arctium Carduelis*. Leaves pinnatifid, prickly; stem upright, prickly, grooved; root perennial.—Found in the mountains of Upper Carniola and Silesia.

Arctopus; a genus of the class Polygamia, order Diœcia.—GENERIC CHARACTER. *Male*. *Calix*: umbel universal long, unequal; partial shorter, more abundant; involucre universal five-leaved, short; partial five-leaved, the length of the umbellule; perianth five-parted, very small. *Corolla*: universal uniform; proper petals five, entire, oblong. *Stamina*: filamenta five, setaceous, longer than the corolla; antheræ simple. *Pistil*: germen none; styles two, setaceous, longer than the stamina; stigmas simple. *Pericarp*: abortive. *Female*, (or *androgynous*), on a distinct plant. *Calix*: umbel partial with sessile floscules; involucre partial one-leaved, four-parted, spreading, spiny at the edge, many-flowered, very large. *Corolla*: proper of the disk male, several, as in the male; of the ray female, four, pentapetalous. *Stamina*: to the males of the disk, as in the male. *Pistil*: to the females, germen subulate, hispid, under the receptacle of the floscule; styles two, reflex, permanent; stigmas simple. *Pericarp*: none; involucre converging with spines. *Seeds*: to the females solitary, cordate, acuminate, bent outward, hispid above, bilocular, the size of the involucre. ESSENTIAL CHARACTER. *Male*: umbel compound; involucre five-leaved; corolla five-petalled; stamina five; pistil two, abortive. *Female*, or *androgynous*: umbel simple; involucre four-parted, spiny, very large, containing very many male floscules in the disk, and four female ones in the ray. *Male*: petals five; stamina five. *Female*: petals five; styles two; seed one, bilocular, inferior.—The only species known is,

1. *Arctopus Echinatus*; *Prickly-leaved Arctopus*. A handsome plant; with the leaves crowded, sinuate and ciliate, with spines on the upper surface; flowers terminating among the leaves.—Native of the Cape.

Arctotis; a genus of the class Syngenesia, order Polygamia Necessaria.—GENERIC CHARACTER. *Calix*: common roundish, imbricate; lower scales more lax, subulate; middle ovate; inmost oblong, scarioso, rounded, and concave at the end. *Corolla*: compound radiate; corollules hermaphrodite, very many, in the disk; females ligulate, near twenty, longer than the diameter of the disk; proper of the hermaphrodites funnel-shaped; border quinquefid; ends reflex, equal; of the females ligulate, lanceolate, very finely three-toothed; tube very short. *Stamina*: of the hermaphrodites; filamenta five, capillary, short; anthera cylindrical, tubular, five toothed, length of the corolla. *Pistil*: of the hermaphrodites; germen scarcely visible; style cylindrical,

a little longer than the corolla; stigma simple: of the females, germ ovate, four-cornered, villose, crowned with its proper calicle; style filiform; stigmas ovate, oblong, thickish, erect. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites, none; in the females solitary, roundish, villose, crowned with a calicle, usually of five leaves; leaflets ovate, spreading. *Receptacle*: villose or chaffy, flattish. ESSENTIAL CHARACTER. Receptacle villose or chaffy; down with a five-leaved crown; calix imbricate, with scales scarioso at the end.—All the plants of this genus are natives of the Cape of Good Hope; the annual sorts may be raised from seed sown in a warm border of light earth in the middle of April: the shrubby sorts may be propagated by cuttings or slips from the roots in any of the summer months; and in six weeks will be rooted sufficiently to be transplanted into pots filled with fresh earth. Some of them require to be sheltered in the green-house during winter.

* *Receptacles villose*.

1. *Arctotis Calendulacea*; *Marygold-flowered Arctotis*. Radiant florets barren; leaves runcinate, rather tomentose. Annual. There are several varieties of this species, all natives of the Cape of Good Hope.

2. *Arctotis Serrata*. Radiant florets barren; leaves lanceolate, undivided, tooth-serrate; corolla yellow.

3. *Arctotis Tenuifolia*. Radiant florets barren; leaves linear, undivided, naked. Perennial.

4. *Arctotis Grandiflora*; *Great-flowered Arctotis*. Radiant florets fertile; leaves pinnatifid, toothletted, cobwebbed, three-nerved; petals straw-coloured, with a tinge of red underneath. Biennial; flowering from March to May.

5. *Arctotis Plantaginea*; *Plantain-leaved Arctotis*. Radiant florets fertile; leaves lanceolate-ovate, nerved, toothletted, stem-clasping. Perennial.

6. *Arctotis Argentea*; *Silvery Arctotis*. Radiant florets fertile; leaves lanceolate-linear, quite entire, tomentose. A biennial plant, with yellow flowers.

7. *Arctotis Angustifolia*. Leaves oblong, toothed. There is a variety with the stem creeping, cobweb-like; leaves lyrate, with two teeth on each side: the whole plant white.

8. *Arctotis Aspera*. *Rough Arctotis*. Radiant florets fertile; leaves pinnate-sinuate; villose; divisions oblong, toothed, stem stiff, villose, with purple streaks: perennial.—There are several varieties of this species.

** *Receptacle chaffy*.

9. *Arctotis Paradoxa*; *Chamomile-leaved Arctotis*. Radiant florets barren; chaffs coloured, longer than the disk; leaves bipinnate, linear; chaffs elongate, coloured, almost the length of the ray, whence the flower appears double.

10. *Arctotis Scariosa*; *Southernwood-leaved Arctotis*. Radiant florets barren; chaffs equalling the florets of the disk; leaves decomposed; stem shrubby.

11. *Arctotis Paleacea*; *Chaffy Arctotis*. Radiant florets barren; chaffs equalling the florets of the disk; leaves pinnate linear; corolla yellow. Flowers from April to August.

12. *Arctotis Dentata*; *Fine-leaved Arctotis*. Radiant florets barren; leaves pinnate; pinnas pinnatifid, indented; flowers small; ray purple. An annual, flowering in July.

13. *Arctotis Anthemoides*. Chaffs shorter than the florets; leaves supra decomposed, linear. Very like Chamomile.

14. *Arctotis Tenuifolia*. Radiant florets barren; leaves linear, undivided, smooth; corolla yellow.

15. *Arctotis Acaulis*; *Dwarf Arctotis*. Peduncles radical; leaves lyrate. A low plant, with large yellow flowers.

Ardisia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft; clefts subulate, upright, coloured, permanent.

Corolla: one-petalled; tube short, length of the calix; border five-parted; parts lanceolate, acute, spreading, at length reflex. *Stamina*: filamenta five, subulate, upright; anthera acute, upright, bifid at the base, converging at top round the style. *Pistil*: germen superior, ovate, very small; style subulate, longer than the stamina, upright, at length ascending; stigma simple, acute, permanent. *Pericarp*: berry roundish, large. *Seed*: single, roundish, covered with a hard brittle bark, like a nut. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Corolla*: one-petalled, five-parted, reflex. *Stigma*: simple. *Berry*: roundish, one-seeded.—The species are,

1. *Ardisia Excelsa*; *Laurel-leaved Ardisia* or *Aderno*. Racemes axillary, simple; leaves obovate, cartilaginous, serrate at the edge.—Native of Madeira.

2. *Ardisia Zeylanica*. Flowers terminating, paniced; leaves ovate, subpetioled, quite entire; stem arboreous.—Native of Ceylon, where the berries, which are esteemed cooling and refreshing, are given in ardent fevers.

3. *Ardisia Tinifolia*. Flowers paniced; leaves elliptic, entire, nerved; stem arboreous; flowers purplish.—A tree thirty feet high, and a native of Jamaica.

4. *Ardisia Coriacea*. Flowers paniced; leaves oblong, entire, veinless, coriaceous.—Native of the West Indies.

5. *Ardisia Serrulata*. Flowers paniced; leaves ovate, lanceolate, acuminate, wrinkled; stem shrubby, pubescent.—Native of St. Domingo.

6. *Ardisia Lateriflora*. Racemes lateral or axillary, compound; flowers umbelled; leaves oblong, acuminate, quite entire; stem shrubby.—Grows in the West Indies.

7. *Ardisia Parasitica*. Racemes axillary, simple; leaves sessile, lanceolate-ovate, marked with lines; stem shrubby.—Native of Montserrat.

Arduina; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, erect, acute, small, permanent. *Corolla*: one-petalled, funnel-shaped; tube cylindrical, a little curved inwards at top; border five-parted, acute, spreading. *Stamina*: filamenta five, simple, shorter than the tube, and inserted into the lower part of it; anthera oblong, within the throat of the corolla. *Pistil*: germen superior, ovate; style filiform, the length of the tube; stigma bifid, thickish. *Pericarp*: herry globular-oval, two-celled. *Seeds*: solitary, oblong, hard. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled. *Stigma*: bifid. *Berry*: two-celled. *Seeds*: solitary.—Only one species is known, viz.

1. *Arduina Bispinosa*; *Two-spined Arduina*. A low shrubby plant, seldom rising more than five feet high. The flowers are small, white, and have an agreeable smell, but seldom come to seed in England.—Native of the Cape of Good Hope. It may be increased by cuttings planted in July, and shaded from the sun, and must be preserved in the green-house during autumn and winter.

Areca; a genus of the class Monœcia, order Enneandria; ranking in the natural order of Palms.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: spathe bivalve; spadix branched. Proper perianth three-leaved. *Corolla*: petals three, acuminate, rigid. *Stamina*: filamenta nine, the three outer longer than the rest. *Female Flowers*: in the same spadix. *Calix*: spathe common with the males. Proper perianth three-leaved. *Corolla*: petals three, acuminate, rigid. *Pericarp*: berry subovate, fibrose, surrounded at the base with the imbricate calix. *Seed*: ovate. **ESSENTIAL CHARACTER.** *Corolla*: three-petalled. *Male*: nine stamina. *Female*: a drupe, with an imbricate calix.—For the propagation and culture, see *Palms*.—The species are,

1. *Areca Catechu*. Fronds pinnate; leaflets folded back, opposite, end-bitten.—This Palm is forty or fifty feet high,

the trunk six or eight inches in diameter. The fruit does not fall off even when ripe. The Indians call it *Chotool*, and present it to all their guests green when it can be procured, and stripped of the outer rind, but otherwise dried. They are continually chewing it, and swallowing their saliva tinged with the juice; which is esteemed to be an excellent antiscorbutic for the gums, and a strengthener of the stomach and appetite. It is also used in constipations of the bowels, and in worm cases. A decoction of the nuts is employed in dyeing, and is supposed both to set and enliven the colours.—A native of the East Indies and of Cochin-china.

2. *Areca Oryzaformis*. Fronds pinnate; leaflets smooth, three-nerved. A straight slender Palm, ten feet high, and only an inch and half in diameter; fruit smaller than the preceding.—Native of Cochin-china, Amboyna, &c.

Areca Oleracea; *Cabbage Tree*. Leaflets quite entire.—This is the loftiest of the American Palms. The West Indians cut off the green top of the trunk, take out the white heart of two or three inches in diameter, consisting of the leaves closely folded together, and eat it raw with pepper and salt, or fried with butter; it has somewhat the taste of an artichoke. The best cabbage is obtained when the tree is young. The outward part of the tree is used for lathing, and boards for outhouses; the seeds serve to feed the wild hogs in the season; and the spathes are frequently made into mats by the negroes.—The Barbadoes Cabbage-tree, says Browne, is the most beautiful tree I have ever seen: it grows to a very considerable size, and may be esteemed the queen of the woods.

Arenaria; a genus of the class Decandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets oblong, acuminate, spreading, permanent. *Corolla*: petals five, ovate, entire. *Stamina*: filamenta ten, subulate, five alternately interior; anthera roundish. *Pistil*: germen ovate; styles from erect reflex; stigmas thickish. *Pericarp*: capsulic ovate, covered, one-celled, three or six valved. *Seeds*: very many, kidney-shaped. **ESSENTIAL CHARACTER.** *Calix*: five-leaved, expanding. *Petals*: five, entire. *Capsule*: one-celled, many-seeded.—The species are,

1. *Arenaria Peplodes*; *Sea Sandwort*, or *Chickweed*. Leaves ovate-acute, fleshy; root creeping, perennial.—Common on sandy coasts in the north of Europe; as, near Sheerness in Kent, Yarmouth in Norfolk; Southwold in Suffolk, and Leith in Scotland: it flowers in June and July.

2. *Arenaria Tetraquetra*; *Square Sandwort*. Leaves pointed, recurved; flowers aggregate, they are white, and grow five or six together.—Native of the Pyrenean and Aragon mountains; flowering in July or August.

3. *Arenaria Biflora*; *Two-flowered Sandwort*. Leaves obovate, obtuse; stems procumbent; peduncles two-flowered, lateral.—Native of the high Alps of Savoy and Switzerland.

4. *Arenaria Lateriflora*; *Side-flowering Sandwort*. Leaves ovate, obtuse; peduncles lateral, two-flowered.—Discovered in Siberia.

5. *Arenaria Trinervia*; *Plaintain-leaved Chickweed* or *Sandwort*. Leaves ovate, acute; petiole-nerved.—This species has an annual root; and is not very common, growing only in and about woods, and flowering in May and June.

6. *Arenaria Ciliata*; *Ciliate Sandwort*. Leaves ovate, nerved, ciliate, acute. Biennial; flowering from March till August.—Found upon Mount Cenis, and in the turf of the mountains of Dauphiny, and by Sir Joseph Banks in Iceland.

7. *Arenaria Balearica*; *Majorca Sandwort*. Leaves ovate, shining, rather fleshy; stem creeping; peduncles one-flowered: perennial.—Native of Majorca and Minorca.

8. *Arenaria Multicaulis*; *Many-stalked Sandwort*. Leaves

ovate, nerveless, sessile, acute; corollas larger than the calix.—Native of the Swiss and Pyrenean mountains.

9. *Arenaria Serpyllifolia*; *Least Chickweed*, or *Thyme-leaved Sandwort*. Leaves ovate, subsessile, rough; calix hirsute, five-nerved; flowers small, white.—An annual plant, common upon walls, among rubbish, and in dry barren places, not only in Europe, but Japan; flowers from May to August.

10. *Arenaria Triflora*; *Three-flowered Sandwort*. Leaves lance-subulate, ciliate; branches mostly three-flowered; petals marked with lines, obtuse: perennial.—Found upon rocks in the south of Europe.

11. *Arenaria Montana*; *Mountain Sandwort*. Leaves linear-lanceolate, rugged; stems barren, very long, procumbent.—Native of Spain, and the south of France.

12. *Arenaria Rubra*; *Purple Spurrey*, or *Sandwort*. Leaves filiform; stipules membranous, sheathing. There is a variety called *Sea Spurrey*, with linear leaves, the length of the internodes. Corolla purple, appearing in June and July, and frequently continuing till September. Annual.—Sheep and goats dislike this plant.

13. *Arenaria Media*; *Middle or Downy Sandwort*. Leaves linear, fleshy; stipules membranous; stems pubescent. The flower, which appears in June and July, is purple, and open at noon.—It is found plentifully on the shell-coast of the isle of Shepey, and is also a native of Germany and France.

14. *Arenaria Bavarica*; *Bavarian Sandwort*. Leaves semi-cylindric, fleshy, obtuse; petals lanceolate; peduncles terminal, mostly binate: perennial.—Native of Bavaria, Monte Baldo, and Little St. Bernard.

15. *Arenaria Gypsophiloides*. Leaves linear, short; radical ones bristly; panicle subpubescent; petals lanceolate: perennial.—Native of the Levant.

16. *Arenaria Saxatilis*; *Rock Sandwort*. Leaves subulate; stems paniced; leaflets of the calix ovate, obtuse; petals white: perennial.—Native of France, Germany, Switzerland, Carniola, and Siberia.

17. *Arenaria Verna*; *Vernal Mountain Sandwort* or *Chickweed*. Leaves subulate; stems paniced; calices pointed, striated. Petals oval, and white: it flowers from May till August.—Found upon mountains in Dauphiny, Savoy, Austria, and Great Britain, as, near the Land's End in Cornwall, about Kendal, Settle, and Matlock; at Arthur's seat near Edinburgh; near Holywell, St. Asaph, and Llanberys, in Wales.

18. *Arenaria Hispida*; *Hispid Sandwort*. Leaves subulate, hispid underneath.—Native of Montpellier.

19. *Arenaria Juniperina*; *Juniper Sandwort*. Leaves subulate, thorny; stems erect; calices striated; capsules oblong; root perennial.—Native place unknown.

20. *Arenaria Tenuifolia*; *Fine-leaved Chickweed* or *Sandwort*. Leaves subulate, acute; stem paniced; capsules erect. Flowers small, white; petals shorter than the calix, and lanceolate; root annual.—Native of almost every country in the north of Europe; it is found in England upon Gog-magog Hills, and the borders of Triplow heath in Cambridgeshire; near Bury; near Cley in Norfolk; Cornbury quarry, near Charlbury in Oxfordshire; Malvern hill in Worcestershire; and at Battersea and Deptford, flowering in June and July.

21. *Arenaria Laricifolia*; *Larch-leaved Sandwort*. Leaves bristly; stem nakedish above; calices rather shaggy. Root perennial.—It flowers in July and August; and is a native of France, Switzerland, Savoy, Piedmont, and Westmoreland.

22. *Arenaria Striata*; *Striated Sandwort*. Leaves linear, erect, pressed to the stem; calices oblong, striated.—It flowers from July to August; and is a native of Switzerland.

23. *Arenaria Fasciculata*; *Cluster-flowering Sandwort*. Leaves subulate; stem erect, stiff; flowers fascicled; petals

very short, white; root annual.—It flowers in August, and is a native of the south of France, the alps of Piedmont, &c.

24. *Arenaria Grandiflora*; *Great-flowered Sandwort*. Leaves subulate, flat, stiff; the radical ones crowded; stems one-flowered; root perennial.—Native of the south of France, near Geneva, Mont Cenis, the Vaudois, Carniola, &c.

25. *Arenaria Austriaca*; *Austrian Sandwort*. Stems under-shrubby, prostrate, then herbaceous, and erect; leaves subulate; flowers twin: petals emarginate: perennial.—Native of the mountains of Austria, Switzerland, and Piedmont.

26. *Arenaria Liniflora*; *Flax-flowered Sandwort*. Stems erect, branching below, and under-shrubby; leaves subulate; flowers twin: perennial.—Native of the south of Europe.

27. *Arenaria Recurva*. Radical leaves heaped, recurved subulate; stem simple, bearing about three flowers. Root biennial.—Native of Provence, and of rocky pastures in the high Alps of the Vaudois in Piedmont; also of the high mountains of Switzerland.

28. *Arenaria Obtusa*. Leaves linear, flat, obtuse; calices viscid: perennial.—Native of the high Swiss alps, &c.

29. *Arenaria Lanceolata*. Leaves lanceolate, three-nerved, acute; calices lanceolate, three-nerved; root perennial, dark-coloured, tough, with a very few fibres, creeping.

30. *Arenaria Dianthoides*. Leaves linear, scabrous at the edge; flowers capitated; bracts ventricose, longer than the peduncles. Perennial.—Found by Tournefort in Armenia.

31. *Arenaria Cucubaloides*. Leaves linear, scabrous at the edge; panicles dichotomous, pubescent; petals obovate. Root perennial.—Found by Tournefort in Armenia.

Archuthusa; a genus of the class Gynandria, order Diandria.

—GENERIC CHARACTER. *Calix*: spathe leafy; perianth none.

Corolla: ringent; petals five, oblong, subequal, two outer, all converging into a helmet; nectary one-leaved, tubular at the base, within the bottom of the corolla two-parted; lower lip reflex, broad, wrinkled, the length of the petals, hanging down forwards; upper lip linear, very tender, fastened to the style, lobed at the top. *Stamina*: filamenta two, very short, sitting on the top of the pistil; anthera ovate, compressed, covered with the folding of the inner lip of the nectary. *Pistil*: germen oblong, inferior; style oblong, incurved, clothed with the inner lip of the nectary; stigma funnel-shaped. *Pericarp*: capsule oblong-ovate, one-celled, three-valved, gaping at the angles. *Seeds*: numerous, chaffy. ESSENTIAL CHARACTER. Nectary tubular, within the bottom of the corolla; the lower lip fastened to the style.—The first three are hardy, and will endure the rigour of our climate; the next three must be kept in the Cape-stove, and the last in the bark-stove. They grow in bogs and watery places.

—The species are,

1. *Arethusa Bulbosa*; *Bulbous-rooted Arethusa*. Root globose; scape sheathed; spathe two-leaved.—This and the two next species are natives of bogs in North America.

2. *Arethusa Ophioglossoides*; *Adder's Tongue-leaved Arethusa*. Root fibrous; leaf of the scape oval, spathaceous; leaflet lanceolate.

3. *Arethusa Divaricata*; *Lily-leaved, Heleborine* or *Arethusa*. Root subpalmate; leaf of the scape and leaflet of the spathe lanceolate; the outer petals rising.

4. *Arethusa Capensis*; *Cape Arethusa*. Bulb round; stem two-leaved, simple, one-flowered; leaves two, alternate, sheathing, awl-shaped.—Found at the Cape.

5. *Arethusa Villosa*; *Villose Arethusa*. Bulb round; leaves ovate, ciliate, pubescent.—Found also at the Cape.

6. *Arethusa Ciliaris*; *Ciliated Arethusa*. Root fleshy; leaf kidney-shaped, orbiculate; lip ciliate. Also a native of the Cape.

7. *Arethusa Biplumata*; *Two-feathered Arethusa*. Scape sheathed; spathe cowlid; flower terminal, erect, purple; the two lower petals elongated, bearded on the upper side; roots fascicled, or in bundles.—Found at Buenos Ayres.

Aretia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-shaped, semiquinquefid, bluntish, permanent. *Corolla*: monopetalous, salver-shaped; tube ovate, the length of the calix, contracted at the neck; limb five-parted; divisions obovate. *Stamina*: filamenta five, conic, in the middle of the tube very short; antheræ erect, sharpish, within the throat of the corolla. *Pistil*: germen roundish; style filiform, the length of the tube; stigma flat-headed. *Pericarp*: capsule one-celled, five-valved. *Seeds*: five. **ESSENTIAL CHARACTER.** *Corolla*: salver-shaped, five-cleft; tube ovate; stigma flat-headed. *Capsule*: one-celled, globular, with about five seeds.—These little Alpine plants are rather difficult to preserve in gardens; they require a shady situation, where the seeds should be sown as soon as ever they can be procured. They may be also propagated from offsets or slips, and by parting the roots.—The species are,

1. *Aretia Helvetica*; *Imbricated Aretia*. Leaves imbricate; flowers subsessile. Root perennial, corolla white.—Native of the western Swiss Alps, and of Dauphiny.

2. *Aretia Alpina*; *Linear-leaved Aretia*. Leaves linear, spreading; flowers pedunculated.—Found in various parts of Switzerland, and in Austria. There are besides two varieties of this species: the first has white flowers with a purple eye; and the second forms beautiful tufts of red flowers, which grow upon Mount St. Bernard, at the height of almost ten miles above the level of the sea!

3. *Aretia Vitaliana*; *Grass-leaved Aretia*. Leaves linear, recurved; flowers subsessile. A small plant, always lying on the ground; flowers of a deep yellow.—Native of the Pyrenees, and high Alps between the Valais and Italy, and in Dauphiny.

Argemone; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth three-leaved, roundish; leaflets roundish with a point, concave caducous. *Corolla*: petals six, roundish, from erect spreading, larger than the calix. *Stamina*: filamenta numerous, filiform, the length of the calix; antheræ oblong, erect. *Pistil*: germen ovate, five-angled; style none; stigma thickish, obtuse, reflex, quinquefid, permanent. *Pericarp*: capsule ovate, five-angled, one-celled, half-valved. *Seeds*: numerous, very small. *Receptacles*: linear, fastened to the angles of the pericarp, not gaping. **ESSENTIAL CHARACTER.** *Corolla*: six-petalled. *Calix*: three-leaved. *Capsule*: half-valved.—The species are,

1. *Argemone Mexicana*; *Prickly Argemone*, or *Poppy*. Capsules six-valved; leaves spiny.—This is called the *Yellow Thistle* in the West Indies, where it is a troublesome weed in cultivated lands. The whole plant abounds with a milky glutinous juice, which turns to a fine bright yellow in the air, and when reduced to consistence, is not distinguishable from gamboge; and, in very small doses, it is probably equally efficacious for dropsies, jaundice, and cutaneous eruptions. It is reckoned very detersive, and generally used in diseases of the eyes; but the infusion is looked upon as a sudorific and resolutive, which may be most successfully applied. The seeds are said to be a much stronger narcotic than opium. The inhabitants of the sugar colonies think them an excellent remedy in diarrhœas and bloody fluxes; they have a pungent warm taste, but it is not immediately perceived by the palate. They work both by stool and vomit, and have been administered in the dry belly-ach; but we have much bet-

ter medicines for both these disorders, though this may be successfully given when the parts are relaxed or weakly, or the disorder proceeds from indigestion, which is frequently the case in hot climates.—The seeds must be sown upon a bed of light earth in the spring, where they are to remain. They must be thinned till each is four inches apart from the rest.

2. *Argemone Armeniaca*. Capsules three-valved.—Discovered in Armenia by Tournefort.

3. *Argemone Pyrenaica*. Capsules four-valved; stem naked.—Native of the Pyrenees.

Argophyllum; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth short, quinquefid; divisions sharp. *Corolla*: petals five, lanceolate, spreading, three times greater than the calix. Nectary five-angled, pyramidal, open at the top, consisting of many converging papillæ, connate at the base. *Stamina*: filamenta five, subulate, inserted into the receptacle; shorter than the nectary; antheræ ovate. *Pistil*: germen turbinate, fastened at the bottom to the calix, flat above; style filiform, the length of the nectary; stigma globular. *Pericarp*: capsule hemispherical, flat above, growing to the calix, three-celled, opening into three parts. *Seeds*: very many, globular, porous. **ESSENTIAL CHARACTER.** *Capsule*: three-celled. *Nectary*: pyramidal, five-angled, the length of the corolla.—One species only is known, viz.

1. *Argophyllum Nitidum*. A perennial; found in New Caledonia.

Argythamnia; a genus of the class Monœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male flowers.* *Calix*: perianth four-leaved; leaflets lanceolate, erect. *Corolla*: petals four, lanceolate-ovate, ciliate on the margin, shorter than the calix; nectary four glands between the petals, roundish, depressed. *Stamina*: filamenta four, longer than the petals approximated at the base, dilated; antheræ simple. *Pistil*: rudiment of a style. *Female flowers*, in the same raceme under the male ones. *Calix*: perianth five-leaved leaflets lanceolate. *Corolla*: none. *Pistil*: germen ovate, somewhat three-cornered; styles three, spreading, half two-cleft; each of the clefts bifid; stigmas lacerate. *Pericarp*: capsule tricocous, three-celled, six-valved. *Seeds*: solitary, roundish. **ESSENTIAL CHARACTER.** *Male.* *Calix*: four-leaved. *Corolla*: four-petalled. *Female.* *Calix*: five-leaved, *Corolla*: none. *Styles*: dichotomous. *Capsule*: tricocous, with solitary seeds.—The only species known is,

1. *Argythamnia Candicans*.—A shrub seldom rising above five feet high, with long branches, and common upon the lower hills and gravelly soils of Jamaica. The leaves when bruised are very odoriferous.

Aristea; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: spathes bivalve. *Corolla*: petals six, oblong, spreading, nearly equal. *Stamina*: filamenta three, filiform, shorter than the petals; antheræ oblong, erect, incumbent. *Pistil*: germen inferior, three-cornered; style filiform, longer than the filamenta, declinate; stigma funnel-form, gaping, fimbriated on the margin, somewhat three-cornered. *Pericarp*: capsule oblong, three-cornered, three-celled, three-valved. *Seeds*: very many. **ESSENTIAL CHARACTER.** *Petals*: six. *Style*: declinate. *Stigma*: funnel-form, gaping. *Capsule*: inferior, with many seeds.—The only species yet discovered is,

1. *Aristea Cyanca*; *Grass-leaved Aristea*.—A small fibrous plant, six or eight inches high; native of the Cape.

Aristella. See *Stipa*.

Aristida; a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: glume one-flowered, bivalve; valves linear-subulate, membranaceous, unequal.

Corolla: glume bivalve, thicker than the calix; outer valve linear, converging longitudinally, hirsute at the base, terminated by three awns, subequal, patulous; inner valve lanceolate, sharp, very short, wrapped within the outer valve; nectary two-leaved; leaflets lanceolate, obtuse. *Stamina*: filamenta capillary; antheræ oblong. *Pistil*: germen turbinate; styles capillary; stigmas villose. *Pericarp*: none; glume converging, involving, gaping. *Seed*: one, filiform, the length of the corolla, naked. **ESSENTIAL CHARACTER.** *Calix*: two-valved. *Corolla*: one-valved, with three terminal awns.—The species are,

1. *Aristida Adscensionis*. Panicle branching; spikes scattered; corollas one-valved; culms in tufts.—Native of Jamaica, in dry sands; there called Bearded Grass.

2. *Aristida Americana*. Panicle simple; corollas two-valved, one with dorsal, the other with terminating awns; culm half a foot high.—Native of Jamaica.

3. *Aristida Plumosa*. Panicled: the middle awn longest and woolly; culms villose.—Found in America.

4. *Aristida Arundinacea*. Panicled: corollas two-valved, middle awn longer, smooth; culms four feet high; leaves narrow, even, striated.—It was found in the East Indies.

5. *Aristida Gigantea*. Panicle elongated, loose, one-ranked; calices one-flowered; awns of the corolla subequal, straight.—A very lofty, branching, and smooth Grass; found upon the island of Teneriffe.

6. *Aristida Hystrix*. Panicle divaricated, very spreading; flowers quite simple, smooth; awns straight, divaricated.—A creeping, stoloniferous, smooth Grass; observed in Malabar.

Aristolochia; a genus of the class Gynandria, order Hexandria.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: monopetalous, tubular, irregular; base swelling, subglobular, torulose; tube oblong, hexagon-cylindric; limb dilated, extended below into a long tongue. *Stamina*: filamenta none; antheræ six, fastened at bottom to the stigmas, four-celled. *Pistil*: germen oblong, inferior, angular; style scarcely any; stigma subglobular, six parted, concave. *Pericarp*: capsule large, six-angled, six-celled. *Seeds*: several, depressed, incumbent. **ESSENTIAL CHARACTER.** Stigmas six. *Calix*: none. *Corolla*: monopetalous, tongue-shaped, entire. *Capsule*: six-celled, inferior.—All the plants of this genus, that are natives of hot climates, are propagated by seed procured from their native countries; sown in small pots of light earth, as soon as they arrive, and, if it be autumn or winter, they must be plunged into the tan of the bark-stove between some large plants, to screen them from the sun, as they delight in shade. In March they must be removed into a hot-bed frame, where the plants will appear in May.—The species are,

1. *Aristolochia Bilobata*; *Two-lobed Birthwort*. Leaves two-lobed, cordate; stem twining, filiform, subdivided.—It flowers from November until January, and covers the trees and shrubs in Dominica and Hispaniola.

2. *Aristolochia Trilobata*: *Three-lobed Birthwort*. Leaves three-lobed; stem twining; flowers very large, bagged at the base; tongue linear, very long.—A climbing plant, with an aromatic stem.—The roots of this and the tenth species are accounted warm attenuants, and active diuretics and stomachics; they are administered in infusions, and greatly used among the slaves of Jamaica, where they naturally grow. This species abounds most on the north side of the island, and is therefore called *Contrayerva of the North-side*. It is also a native of the South American continent.

3. *Aristolochia Pentandra*; *Five-stamined Birthwort*. Leaves cordate, hastate, subtrilobate; stem twining; bracte cordate, embracing.—Native of America.

4. *Aristolochia Peltata*; *Peltated Birthwort*. Leaves kidney-shaped, subpeltate; stem twining, filiform, striated; root woody, corky, perennial.—It flowers in February and March, and is a native of St. Domingo, in very dry coppices and also of the continent of South America.

5. *Aristolochia Maxima*; *Greatest Birthwort*. Leaves oblong, acuminate; stem twining; peduncles many-flowered; flowers curved, in loose clusters; stem corky next the root.—Found near Carthage in New Spain.

6. *Aristolochia Bilabiata*; *Two-lipped Birthwort*. Leaves cordate, tongue-shaped, obtuse; stem twining; corollas two-lipped, brown-purple, striated.—Flowers in spring, and is found upon a calcareous soil, in the hedges of Hispaniola; it is also a native of South America.

7. *Aristolochia Erecta*; *Upright Birthwort*. Leaves lanceolate, sessile, subhirsute; stem erect; peduncles solitary, one-flowered; flowers very long, dark purple; rises three feet high.—It was discovered at La Vera Cruz, in New Spain.

8. *Aristolochia Arborescens*; *Tree Birthwort*. Leaves cordate, lanceolate; stem erect, shrubby; flowers solitary, axillary.—Called *Snakeroot* in North America, where it naturally grows to the height of two feet.

9. *Aristolochia Caudata*; *Tailed Birthwort*. Leaves cordate, obtuse, emarginate at the tip; lobes incumbent, lip-tailed.—Native of America.

10. *Aristolochia Odoratissima*; *Sweet-scented Birthwort*. Leaves cordate; stem twining, shrubby; peduncles solitary: lip of the corolla very large, yellowish.—It has a long round geniculated root, as thick as a finger; the whole plant has a strong and very grateful smell. In Jamaica, where it naturally grows, it is called *Contrayerva of the South-side*, to distinguish it from the second species; which see.

11. *Aristolochia Sipho*; *Broad-leaved Birthwort*. Leaves cordate, petioled; flowers solitary; border, trifid, equal; corolla purplish-brown; bracte ovate.—A tall twining shrub, flowering in June and July: a native of North America.

12. *Aristolochia Anguicida*; *Snake-killing Birthwort*. Leaves cordate, acuminate; stem twining, shrubby; peduncles solitary; stipules cordate; root long, thick, pale coloured; corolla purple.—If the juice of the root, mixed with the saliva, be put into the mouth of a serpent, he may be safely handled, but will recover himself after two hours; several of the other species are said to produce the same effect.—Native of Mexico and the West Indies.

13. *Aristolochia Maurorum*; *Moorish Birthwort*. Leaves hastate, quite entire; stem weak, simple; flowers solitary, recurved, brown.—This plant has an unpleasant smell; seen in olive-grounds near Aleppo.

14. *Aristolochia Indica*; *Indian Birthwort*. Leaves cordate, rather acute; stem twining, shrubby; peduncles many-flowered; corolla dusky purple.—A native of the East Indies, and Cochin-china. It is bitter, but has not much smell, and is thought to be an attenuant, and remover of obstructions.

15. *Aristolochia Bœtica*; *Spanish Birthwort*. Leaves cordate, rather acute; stem twining; peduncles about three, longer than the petioles; root very long, pale-coloured, acrimoniously astringent.—It is an evergreen, flowering in January and February, and a native of Spain.

16. *Aristolochia Sempervirens*; *Evergreen Birthwort*. Leaves cordate-oblong, acuminate, waved; stem weak; flowers solitary; roots many, slender, odorous.—It flowers in May and June, and is a native of the isle of Candia.

17. *Aristolochia Serpentaria*; *Virginia Birthwort*, or *Snake-root*. Leaves cordate-oblong, flat; stems weak,

flexuose, round; flowers solitary, blue or purplish; root a congeries of small fibres, of a yellow colour, and aromatic smell and taste.—It is a warm diaphoretic and diuretic; it is reckoned one of the principal alexipharmics, and is in general use in low malignant fevers, and epidemic diseases. It is given in substance from a few grains to a scruple or half a drachm; in decoction or infusion, to a drachm or upwards. A tincture of it is prepared by digesting three ounces in a quart of spirit of wine eight days; and a spiri-alexiterial water, mixed with one-sixth its quantity of distilled water. It is also an ingredient in the compound tincture of bark.—Native of Virginia and Carolina.

18. *Aristolochia Pistolochia*. Leaves cordate-crenulate, netted underneath, petioled; stems angular, branching, weak; flowers solitary; roots round, numerous.—Native of the south of France, Switzerland, and Spain.

19. *Aristolochia Rotunda*; *Round-rooted Birthwort*. Leaves cordate, subsessile, obtuse; stem weak; flowers solitary, of a purplish black colour.—This has long tap-roots, shaped like those of Carrots. It is a native of the south of Europe, and of Japan, and flowers at the same time in both, from June through the autumn. The root, which is the only part used, is a rough and disagreeable medicine; it often offends the stomach, but is an excellent drug for promoting the necessary evacuations after delivery. There are two kinds of Birthwort roots kept in the shops; the one called the Long Birthwort, the other the Climbing Birthwort. They possess the same virtues with the Round, but in a less degree, and are therefore less regarded: see species 20 and 22.

20. *Aristolochia Longa*; *Long-rooted Birthwort*. Leaves cordate, petioled, obtuse; stem weak; flowers pale purple, solitary; fruit ovate.—Native of the south of Europe, and Japan. Meyrick informs us, that it will sometimes resist the severity of an English winter in the open air, and that it flowers with us at the latter end of summer. He adds, the roots are kept in the shops, and many authors represent them as being of an extremely hot and pungent nature; but such as are commonly met with among druggists, exhibit no very striking qualities of that kind. On first chewing them when dry, scarcely any taste is perceptible; but they soon fill the mouth with a nauseous bitterness, which remains for a long time. As a medicine, they heat, stimulate, cut and attenuate a tough phlegm, and promote the fluid secretions in general; but their principal efficacy consists in removing feminine obstructions, and promoting the necessary evacuations after delivery; from which it is probable the plant received its name. The dose is from a scruple in weight to upwards of a drachm. A decoction of them is recommended to be used externally as a fomentation, for cleansing and healing wounds and ulcers, and in cutaneous disorders. They have likewise been recommended as powerful alterants in gouty complaints; but whoever has been attentive to their effects must have observed, that in some cases they are improper: see the 22d species. Simon Pauli informs us, that the *Long Birthwort* roots, applied as an epithem or fomentation, were found remarkably serviceable in stubborn ulcers of the legs.

21. *Aristolochia Hirsuta*; *Rough Birthwort*. Leaves cordate, rather obtuse, shaggy; flowers solitary, pendulous, recurved, subtruncate. The whole plant is bitter, the flower scentless: it has been recommended for the gout.—Native of the island of Schio or Chios.

22. *Aristolochia Clematitis*; *Common Birthwort*. Leaves cordate; stem erect; flowers axillary, crowded, pale yellow.—It has an erect stem, from two to three feet high, simple striated, round, and smooth; and is found all over the continent of Europe. In England, in a wood two miles from

Thorndon in Essex; near Maidstone and other places in Kent; near Stuston in Suffolk; and in the hedges at Whittlesford in Cambridgeshire.—The roots have an aromatic smell, and a warm bitterish taste; they are celebrated as warm attenuants and deobstruents, particularly in suppressions of the uterine purgations. The dose is from a scruple to a drachm and upwards. Boerhaave observes, that the pituitous gout, as he calls it, is often relieved by an infusion of these roots in spirit of Juniper berries, sweetened with sugar, and taken to the quantity of a spoonful at a time; but that in other kinds of gout, and in subjects of a tender constitution, this medicine produces loss of appetite, a weakness of the stomach, and a languidness more distressing than the gout itself: a powder composed of this and other similar materials, (prescribed by the ancients as an antiarthritic, and again come into esteem,) has produced complaints of the same kind.

23. *Aristolochia Scandens*. Leaves cordate, on very long petioles; stem climbing; flowers terminal, on very long peduncles.—This species grows naturally near Tolu in New Spain.

24. *Aristolochia Conferta*. Leaves cordate, petioled; stem climbing; flowers axillary, crowded, dark purple.—Discovered at Campeachy in New Spain.

25. *Aristolochia Bractea*. Leaves cordate, obtuse; stem weak; flowers solitary; bractes cordate, petioled.—Native of the East Indies, where it is used as a medicine.

26. *Aristolochia Obtusata*. Leaves cordate, rounded at the tip, three-nerved, netted and tomentose beneath; stem twining; peduncle solitary.—Native of the Caribbee Islands.

27. *Aristolochia Grandiflora*. Leaves broad, cordate; stem twining, subherbaceous; peduncles solitary; tip of the corolla very large, with a very long tail.—It bears very large flowers, seldom under five or six inches round the margin: very common in St. Ann's, Jamaica.

Aristolochia; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five parted; divisions lanceolate, concave, acute, upright. *Corolla*: petals five, wedge-shaped, concave, erect, lying over each other at the sides, scarcely longer than the calix. *Stamina*: filamenta fifteen, very short; anthera linear, shorter than the germen. *Pistil*: germen superior, roundish, rather three-cornered; style filiform, longer than the corolla; stigmas three, recurved. *Pericarp*: berry subglobular, obtusely three-cornered, three-celled. *Seeds*: two, or solitary in each cell, angular. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-petaled. *Berry*: three-celled. *Seeds*: two in each cell.—One species only is known,

1. *Aristolochia Macqui*; *Shining-leaved Aristolochia*.—A small shrub, native of Chili, where the inhabitants make a wine from the berries, which are slightly acid, and eatable, and given in malignant fevers. Dombey, while in Chili, used it successfully against the plague.—It flowers in April and May, and is hardy enough to bear the open air in general; though severe winters will probably kill it, unless protected by a green-house.

Arnica; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common, imbricate, shorter than the ray of the corolla; leaflets lanceolate, the length of the calix, erect. *Corolla*: compound, radiate. *Corollules*: hermaphrodite in the disk, very numerous. Females in the ray, about twenty. *Proper* of the hermaphrodite, tubular, erect, five-cleft, equal. Female lanceolate, very long, three-toothed, spreading. *Stamina*: to the hermaphrodites, filamenta very short: anthera cylindric: to the females, filamenta subulate, erect; anthera none. *Pistil*: germen oblong; style simple, the length of the stamina; stigma bifid. *Pericarp*: none. *Calix*: unchanged. *Seeds*:

solitary, oblong. *Down*: simple, in the hermaphrodites pubescent, long. *Receptacle*: naked. **ESSENTIAL CHARACTER.** *Receptacle*: naked. *Down*: simple; corollules of the ray have five filamenta without anthera.—The European sorts, which are hardy, require a moist shady situation; and may be propagated by parting the roots in autumn, when the stalks begin to decay, or by seeds sown soon after they are ripe in autumn, for those sown in spring often fail; but if the seeds are permitted to scatter, they will appear of themselves, and only require to be kept free from weeds. The other species must be kept in pots under a frame or in a dry-stove; they may be increased by seeds, cuttings, or parting the roots.—The species are,

1. *Arnica Montana*; *Mountain Arnica*. Leaves ovate, entire; stem-leaves twin, opposite; flowers a deep yellow; root perennial, and aromatic. The whole plant is acrid, and has a strong scent.—The flowers follow the sun; goats are fond of it, but cows refuse to touch it. In Smaland they snuff the powder of the leaves up the nostrils, and smoke them as tobacco. In Germany it is esteemed a specific for resolving coagulated blood, occasioned by falls and bruises, and is recommended in obstinate chronic disorders; but it appears to be too violent in its operation for general use. Dr. Collins, of Vienna, recommends beginning with an infusion of one drachm of the herb in flower, morning and evening, gradually increasing the dose to half an ounce, and keeping the body open. Infused in small beer, and taken as common drink, it is reported to have removed the chronic rheumatism of the loins; and in one or two doses, taken two hours before the fit, to have put a stop to intermittents of long standing. Bergius tried this infusion, and also the powder of the root, in quartan agues, without success. Allioni relates, that the palsy was cured by the flowers, but that his patients could not endure the quantity of the infusion of them which Dr. Collins above recommends; and that he never gave more than three drachms, and divided them into several doses. Villars celebrates the *Arnica* as one of the best remedies of the vegetable kingdom; as eminently diuretic and tonic; as a febrifuge, antiparalytic, and antiarthritic. He says, that all parts of it may be used in infusion or decoction; in a dose of *half a grain*, or, if given in substance, less, especially at the beginning, because it is apt to discourage patients by giving them the heartburn. "How many sick," he exclaims, "have I benefited, and even cured of the dropsy, by this simple remedy!"—It flowers in July in Great Britain, and is a native of most parts of Europe, and of Siberia.

2. *Arnica Piloselloides*; *Mouse-ear Arnica*. Leaves quite entire, elliptic, villose; scape one-flowered, woolly; calix equalling the ray.—Native of the Cape of Good Hope.

3. *Arnica Scorpioides*: *Alternate-leaved Arnica*. Leaves alternate, toothed. The roots are contorted, and the whole plant has a strong disagreeable smell, especially in the shade.—Native of Switzerland, Savoy, Dauphiny, and Austria.

4. *Arnica Dronicum*. Leaves alternate, subserrate, oblong, rough.—Natives of the high Alps of the Grisons, of Dauphiny, Piedmont, and Austria.

5. *Arnica Maritima*; *Sea Arnica*. Leaves lanceolate, the lower ones serrate; stem leafy, many-flowered.—Native of Kamtschatka and North America.

6. *Arnica Crocea*; *Saffron-flowered Arnica*. Leaves ovate, repand, toothletted, tomentose underneath; scape one-flowered.—Native of the Cape of Good Hope.

7. *Arnica Ciliata*; *Ciliate-leaved Arnica*. Leaves stem-clasping, ovate, toothed, ciliate, smooth; stem simple, one-flowered; flower terminating, red, the size of a small pear.—This, and the two following, are natives of Japan.

8. *Arnica Japonica*; *Japanese Arnica*. Leaves gash-palmated, toothletted; flowers red, terminal, sub-binate.

9. *Arnica Palmata*; *Palmate-leaved Arnica*. Leaves gash-palmated, toothed; flowers paniced, small, yellow.

10. *Arnica Gerbera*. Leaves pinnatifid; lobes rounded.—Native of the Cape of Good Hope.

11. *Arnica Coronopifolia*. Leaves pinnate; divisions linear.—Native of the Cape of Good Hope.

12. *Arnica Oporina*. Shrubby; leaves lanceolate, callous, crenate, tomentose beneath; peduncles one-flowered, solitary, terminating, scaly.—Native of New Zealand.

Arnotto. See *Bixa*.

Arrow-Head. See *Sagittaria*.

Arrow-headed Grass. See *Triglochin*.

Arrow-Root, Indian. See *Maranta*.

Arsemarkt. See *Polygonum*.

Artedia; a genus of the class Pentandria, order Digynia.

GENERIC CHARACTER. Umbel universal, spreading, flat, manifold; partial small, similar; involucre universal, about ten-leaved; leaflets ovate, oblong; three-bristled at the end, nearly the length of the umbel; partial two or three-leaved, verging outwards; leaflets linear, pinnate, longer than the umbellule. *Corolla*: universal, difform, radiate; floscules of the disk, abortive; proper of the disk, male; petals five, cordate-inflex, erect; of the ray, hermaphrodite, with similar petals, but the outmost larger. *Stamina*: filamenta five, capillary in all the florets; anthera simple, roundish. *Pistil*: of the ray; germen small inferior; styles reflex; stigmas simple. *Pericarp*: none; fruit roundish, compressed, leafy, scaled on the edge, bipartite. *Seeds*: two, oblong, set about the edge with roundish spreading scales. **ESSENTIAL CHARACTER.** Involucre pinnatifid; floscules of the disk male; fruit rough, with scales.—The only species known is,

1. *Artedia Squamata*. An annual plant, and a native of the East, producing a large umbel of white flowers in July. If the seed be sown where they are to remain upon a warm border in autumn, and the plants kept six or eight inches apart, and clear from weeds, they will thrive; but to secure their seeding in England, they should be raised in a hot-bed, and kept in a green-house.

Artemisia; a genus of the class Syngenesia, order Polygamia *Æqualis*.—**GENERIC CHARACTER.** *Calix*: common, roundish, imbricate; scales rounded, converging. *Corolla*: compound; corollula hermaphrodite, tubular, several in the disk; females almost naked in the circumference; proper of the hermaphrodite funnel-shaped; border five-cleft. *Stamina*: in the hermaphrodites; filamenta capillary, very short; anthera cylindric, tubular, five-toothed. *Pistil*: in the hermaphrodites; germen small, style filiform, the length of the stamina; stigma bifid, revolute; females, germen very small; style longer than in the hermaphrodites; stigma similar. *Pericarp*: none. *Calix*: scarcely changed. *Seeds*: solitary, naked. *Receptacle*: flat or villose. **ESSENTIAL CHARACTER.** *Receptacle*: subvillose, or almost naked. *Down*: none. *Calix*: imbricate, with rounded converging scales. *Corolla*: of the ray none.—Most of the numerous plants of this genus are hardy perennials, and may be increased without much difficulty, by seeds, by parting the roots, and by slips or cuttings.

* *Shrubby, erect.*

1. *Artemisia Vermiculata*. Leaves acrose, crowded, very small; panicle racemed; flowers sessile.—Native of the Cape of Good Hope: it requires a light soil in a green-house, and may be there increased by slips or cuttings.

2. *Artemisia Capillaris*. Leaves simple, capillaceous;

flowers white, inodorous, small, appearing in October.—Native of Japan, and cultivated in China and Cochinchina.

3. *Artemisia Judaica*. Leaves obovate, obtuse, lobed, small; flowers panicled, pedicelled.—Native of Judea, Arabia, Caramania, the Mogul country, and China. The taste is bitter, and the eastern nations use both the leaves and seeds in medicine as tonics, stomachics, and anthelmintics.

4. *Artemisia Æthiopia*. Leaves palmate, linear, very minute, panicled, racemed; flowers sessile.—Native of Spain and the Cape of Good Hope. This, and the fifth, sixth, and seventh species must be sheltered from frost under a frame during winter. They are easily propagated from cuttings.

5. *Artemisia Contorta*. Leaves palmate, linear, minute; panicle racemed; flowers sessile.—Found in Persia, see No. 4.

6. *Artemisia Abrotanum*; *Southernwood*. Leaves setaceous, very branching.—It seldom rises above three or four feet high. *Common Southernwood*, which is merely a variety of this species, is bitter and aromatic, with a very strong smell. It is not much in use, but promises considerable effects, outwardly, in discussing contusions and tumours; inwardly, for destroying worms, and in disorders peculiar to the female sex. It may have great efficacy in catarrhal malignant fevers, by its quality of promoting perspiration, which it possesses in a very high degree. A table-spoonful of the expressed juice may be given, half an ounce of the decoction, or a whole ounce of the infusion of the herb. In the present practice it is seldom used, except as an ingredient in discutient and antiseptic fomentations. A strong decoction of the leaves destroys worms; but it is a very nauseous medicine. The leaves are also esteemed as a good ingredient in fomentations, for easing pain, dispersing swellings, and stopping the progress of gangrenes. The top of the young branches, beaten into a conserve with three times their weight of sugar, are rendered less unpleasant to take, and in this form are good for all nervous disorders, and in all hysteric complaints. Culpeper says, that the distilled water was formerly given for the stone. It is held by all writers, ancient and modern, to be more offensive to the stomach than *Wormwood*. The branches of it dye wool a deep yellow.

7. *Artemisia Arborescens*; *Common Narrow-leaved Tree Wormwood*. Leaves tripinnatifid, silky, cinerous; leaflets linear; flower-bearing branchlets simple. The stalk is woody, six or seven feet high. The flowers globular, in spikes, terminating the branches.—Native of Piedmont: see No. 4.

8. *Artemisia Argentea*; *Broad-leaved Tree Wormwood*. Leaves bipinnatifid, silky, white; leaflets lanceolate-linear; flowers globose; flower-bearing branchlets wandlike.—Native of Madeira.

9. *Artemisia Arragoniæ*. Leaves linear, bipinnate, hoary; flowers racemed. Scarcely a foot high.

10. *Artemisia Messerschmidii*. Leaves linear, multifid; racemes erect, slender, loose, tomentose.—Found in Tartary.

11. *Artemisia Tatarica*. Lower leaves bipinnate; pinnae equal; upper leaves pinnate, linear; racemes erect, loose, many-flowered, tomentose.—Native of Tartary.

12. *Artemisia Nitrosa*. Lower leaves finely multifid; upper entire, obtuse; corymbs erect, hoary, oblong, spiked, sessile.—Native of Siberia.

13. *Artemisia Lerchiana*. Lower leaves pinnate, short, finely divided; pinnae palmate: upper leaves linear, undivided; corymbs sessile, very copious, spiked, oblong. A shrubby hoary plant.—Observed in Astracan, and on the Volga.

14. *Artemisia Tenella*. Leaves short, very finely multifid; panicles slender, loose, leafy; peduncles one or two flowered; stem woolly.—Native of Spain.

15. *Artemisia Pauciflora*. Branches virgate, filiform: corymbs one-ranked; spikes subsessile.—Native of the banks of the Volga.

16. *Artemisia Italica*. Leaves tomentose, loosely pinnate; pinnae long, linear; root-leaves dotted; spikes dense; flowers erect.—Native of Italy.

17. *Artemisia Hispanica*. Leaves loosely pinnate; pinnae long, linear; spikes very dense; calices oblong.—Native of Spain.

18. *Artemisia Gmelini*. Leaves doubly pinnate, obtuse, linear; corymbs green, roundish, nodding.

19. *Artemisia Lobellii*. Leaves petiolate palmate; multifid, linear: the upper ones single, angular.—The flowers are of a fine yellow; and the whole plant, which is a native of Piedmont, the Genoese Alps, and Dauphiny, is remarkable for a strong, balsamic, camphorated smell.

** *Procumbent before flowering.*

20. *Artemisia Santonica*; *Tartarian Southernwood*, or *Wormseed*. Stem-leaves pinnate, multifid; branches undivided; spikes one-ranked, reflex; flowers with five florets.—Native of Tartary: whence the seeds are brought to England, and used in worm cases: they are reckoned a good balsamic, tonic, and stomachic medicine. It will grow with us in a dry soil and sheltered situation. The seed supplied by our druggists is frequently mixed with the unripe flowers; they are an excellent medicine against worms, and are best given in treacle after reducing them to powder. They may be used in all cases where bitters are likely to be serviceable. For persons of delicate palates, they may be powdered and made into boluses.

21. *Artemisia Canpestris*; *Field Southernwood*. Leaves multifid, linear; stems procumbent, wand-like; root fusiform.—It grows at Elvedon or Elden, in Suffolk, between Newmarket and Lynn; also near Barton Mills and Thetford; and in most parts of Europe. It flowers in August, and has the same qualities, in a less degree, as *Garden Southernwood*. Linneus recommends an infusion of it in the pleurisy.

22. *Artemisia Palustris*; *Marsh Southernwood*. Leaves linear, pinnate, quite entire; flowers glomerate, subsessile, yellow.—Native of Siberia.

23. *Artemisia Crithmifolia*; *Sapphire-leaved Southernwood*. Leaves compound, divaricate, linear, fleshy, smooth; stem rising, panicled.—Native of the sandy shores of Portugal: flowering from May till August.

24. *Artemisia Vallesiaca*; *Downy Southernwood*. Leaves pinnate, many-parted, filiform, tomentose; flowers sessile, erect, subcolumnar, having few florets.—Native of Spain, Piedmont, and the Valais. It flowers in July and August; and sheep feed upon it.

25. *Artemisia Maritima*; *Sea Wormwood*. Leaves many-parted, tomentose; racemes drooping; receptacle naked; female florets three; root woody, perennial.—It has a strong smell of camphor when wild, but it diminishes upon cultivation. It is used as an ingredient in distilled waters. A conserve of the tops is made by beating them with thrice their weight of fine sugar; they are also used in decoctions for fomentations. It is less unpleasant, but not so strong, as *Common Wormwood*; and though not so valuable as an antiseptic or anthelmintic, is more eligible as a stomachic. The tops fresh gathered, and the whole plant dry, are used. In the shops and markets, it is called the *Roman Wormwood*, see No. 30. all the virtues of which it possesses; but it is more disagreeable than it, and less so than the *Common Wormwood*, see No. 34. It is friendly to the stomach, strengthening it, and expelling wind. It is a common ingredient in the bitter infusions and tinctures of the shops; but it answers very well

alone; boiling water poured upon it, and suffered to stand till it is cold, and then strained off, is an excellent medicine to procure an appetite. Put into white wine, it also gives a pleasant bitter flavour, with the same virtues.—It is common about ditches, in salt-marshes, and wherever salt-water comes.

26. *Artemisia Glacialis*; *Silky Wormwood*. Leaves palmate, multifid, silky; stems ascending; flowers glomerate, level-topped. Flowers in July and August.—Native of Switzerland, the Valais, Austria, Dauphiny, and Piedmont. It may be propagated by the side-shoots, planted in a shady border, during any of the summer months, where it will strike root if watered, and in the autumn may be transplanted where it is intended to remain: see No. 28.

27. *Artemisia Rupestris*; *Creeping Wormwood*. Leaves pinnate; stems ascending; flowers globose, nodding; receptacle papose; receptacle hairy.—Native of mountainous situations in most parts of Europe; very hardy, and easily increased by cuttings. See No. 28.

28. *Artemisia Spicata*; *Spiked Wormwood*. Root-leaves biternate; stem ascending, spiked; flowers erect; leaflets of the calix ovate, dark-coloured, and hence called *Genipi noir*.—Native of the Alps of Switzerland, Austria, Piedmont, and Dauphiny. This and the two preceding species are in great request among the inhabitants of the Alps, for restoring a suppressed perspiration, pains of the sides, and intermittent fevers. They are an useful medicine, where diaphoretics are employed, as in rheumatism, intermittent and catarrhal fevers; but are dangerous in the pleurisy, though they are used indiscriminately by the peasants in all inflammatory disorders.

*** *Erect, herbaceous, with compound Leaves.*

29. *Artemisia Anethifolia*; *Dill-leaved Wormwood*. Leaves multifid, very slenderly divided; corymbs roundish, nodding, one-ranked, loosely spiked.—Native of Siberia.

30. *Artemisia Pontica*; *Roman Wormwood*. Leaves many-parted, tomentose beneath; flowers roundish, nodding; receptacle naked; root creeping.—The bitterness of this plant is so mixed with a kind of aromatic flavour, as scarcely to be disagreeable; and it appears to be more eligible than either Common or Sea Wormwood, as a stomachic and corroborant; for which purpose, a conserve of the tops has been greatly recommended, and is, undoubtedly, an elegant and useful preparation. It will grow in any moderately moist soil, and may be propagated, by parting its creeping roots, in the middle of October, and planting them two or three feet asunder.—Native of Germany.

31. *Artemisia Austriaca*; *Austrian Wormwood*. Leaves many-parted, tomentose, hoary; flowers oblong, nodding; receptacles naked; stems upright: annual.—Native of Austria.

32. *Artemisia Annu*; *Annual Wormwood*. Leaves three-fold, pinnate, smooth on both sides; flowers subglobose, nodding; receptacles smooth, conical; stem erect, smooth, streaked. An annual.—Native of Siberia and China: it has a most agreeable scent, which it retains a long time after it has been dried. Loureiro, who introduced it into Portugal, where plants ten feet high have been produced from the seeds, recommends a decoction of the leaves and flowers in hectic fevers, the dysentery, and putrid ulcers.

33. *Artemisia Tanacetifolia*; *Tansy-leaved Wormwood*. Leaves bipinnate, underneath tomentose, shining; pinnae transverse: racemes simple; root perennial.—This has no perceptible odour; and is a native of very lofty situations in Dauphiny, Piedmont, and Siberia.

34. *Artemisia Absinthium*; *Common Wormwood*. Leaves compound, multifid, of a silky white; flowers subglobose, pendulous, yellow; receptacle villose.—It flowers from July

until October, and is found wild in the rocky places, roadsides, rubbish, and farm-yards, of almost every part of Europe. The leaves and flowers are very bitter; the roots are warm and aromatic. It produces a considerable quantity of essential oil in distillation, sometimes *two ounces* from ten pounds, which is used both externally and internally to destroy worms. The leaves put into sour beer soon destroy the acescency; they also resist putrefaction, and are therefore a principal ingredient in antiseptic fomentations. A weak infusion of them forms a good stomachic; and with the addition of fixed alkaline salt, produced from the burnt plant, is a powerful diuretic in some dropsical cases. The ashes yield a purer alkaline salt than most other vegetables, excepting Bean-stalks, Broom, and the larger trees. Linneus mentions two cases, wherein an essence prepared from this plant, and taken for a considerable time, forbidding the use of wine and acids, prevented the formation of stones in the kidneys or bladder; and though like other bitters, it will weaken the action of the nervous system, in these instances it did not produce that effect. The plant steeped in boiling water, and repeatedly applied to a bruise, will speedily remove the pain, and prevent the swelling and discoloration of the part. An infusion of it given to a nurse makes her milk bitter; and it gives a bitterness to the flesh of sheep that eat it. Wormwood leaves give out nearly the whole of their smell and taste both to aqueous and spirituous menstria; the cold water infusions are the least offensive. A bitter of little or no particular flavour may be extracted from it, either in a solid form, or in that of a watery or spirituous solution. The spirituous extract seems preferable as a vermifuge. Meyrick informs us, that a light infusion of the tops of this plant, is excellent for most disorders to which the stomach is subject, creating an appetite, promoting digestion, and preventing sickness after meals; but will produce the contrary effect if made too strong. The flowers, dried and powdered, destroy worms more effectually than worm-seed, and are excellent in agues. The expressed juice of the leaves operates by urine; and though insufferably nauseous, it is good in the jaundice and dropsy. There are two other kinds of Wormwood recommended; the *Roman*, see No. 30. and the *Sea Wormwood*, see No. 25. which possess the same virtues in a less degree, and therefore all three may be indiscriminately used.—Common Wormwood is easily propagated by parting the roots, by slips, or by seeds, sown in the autumn, soon after they are ripe; or if the seeds be permitted to scatter, the plants will spring up without further care.

35. *Artemisia Vulgaris*; *Mugwort*. Leaves pinnatifid, flat, gashed, tomentose underneath; racemes simple, recurved; ray five-flowered.—Found wild all over Europe, China, and Japan, on the borders of fields and ditch-banks, by way-sides, in waste places, and about farm-yards. It flowers with us in August and September. The *Moxa* of Japan, see No. 41. is, according to Thunberg, prepared from this species. The leaves are collected in June, dried in the shade, and beat in a mortar till they become like tow; this substance is then rubbed between the hands, till the harder fibres and membranes are separated, and there remains nothing but a very fine cotton, which the Japanese use for tinder; and twice in a year, young and old, rich and poor, are indiscriminately singed with it, either to prevent disorders, or cure the rheumatism. Mugwort has been chiefly recommended for promoting the uterine evacuations, and abating hysteric spasms; for which purposes infusions of it have been drunk as tea, and used as a bath. It appears to be one of the mildest substances used in such cases, and may perhaps be of service where medicines of more activity would be improper. The flowery tops are considerably stronger than the leaves. It is

used in some countries as a culinary aromatic, and a decoction of it taken for the ague. A woman who had been afflicted with hysteric fits for many years, and had taken assafœtida and æther without obtaining any relief, was cured in a few days by taking a drachm of the powdered leaves four times daily. The Chinese bruise the leaves, and apply them to fresh wounds, which they soon heal. It is, says Hill, an excellent medicine in hysteric complaints, and in all obstructions of the viscera, for which a strong infusion is most serviceable. Meyrick informs us, that a decoction of it, sweetened with honey, eases the most violent coughs, and is good in sciatic pains. An ointment, made of the juice of the leaves and hog's lard, disperses wens, and hard knots and kernels about the neck and throat. Culpeper observes, that the herb itself taken fresh, or the juice of it, is an especial remedy for removing the bad effects of taking too much opium. A decoction made with Chamomile and Agrimony, he assures us will remove all the pains of the sinews and the cramp, by bathing the affected part with it. No quadruped seems to feed on this plant.—It may be raised by slips, cuttings, or parting the roots. There are several varieties.

36. *Artemisia Pectinata*; *Leaves pinnate, pectinate, smooth, sessile; flowers axillary, solitary, sessile, having four florets.*—This is an elegant and exceedingly fragrant plant, with an annual root, and an upright herbaceous stem about eight inches high.—Found in the dry lands of Dauria.

**** *Leaves simple.*

37. *Artemisia Integrifolia*; *Entire-leaved Mugwort.* Leaves lanceolate, tomentose underneath, entire, or with one or two teeth; female florets five. It is as hardy as the Common Mugwort, and multiplies as fast.—Native of Siberia.

38. *Artemisia Japonica*; *Japanese Mugwort.* Leaves on the branches smooth, lanceolate, entire; on the stem, oblong and trifid; flowers racemed, nodding.—Native of Japan.

39. *Artemisia Cærulescens*; *Lavender-leaved Wormwood.* Stem-leaves lanceolate, entire; roots multifid; flowers ovate-cylindrical, small, woolly; female florets three.—Found in the southern parts of Europe upon the sea coast, and in Lincolnshire, near Boston. It flowers from August to October.

40. *Artemisia Dracunculul*; *Tarragon.* Leaves simple, lanceolate, smooth, quite entire; root perennial.—Native of Siberia and Tartary; it flowers in August. It is generally used in Persia, to excite an appetite at their meals; and the French employ it frequently in sallads to correct the coldness of other herbs. The leaves, which have a fragrant smell and an aromatic taste, make an excellent pickle.—This plant is very hardy, and propagates greatly by its creeping roots; or may be multiplied very fast by planting the young shoots in the same manner as Mint, and if well watered in dry weather, they will soon spread and meet.

41. *Artemisia Chinensis*; *Chinese Mugwort.* Leaves simple, tomentose, obtuse, lanceolate; the lower ones wedge-shaped, three-lobed.—Native of China and Siberia. This is the species from which the Moxa is prepared in China, where the natives term it the Physician's herb, and employ it in hemorrhages, dysenteries, pleurisies, and disorders of the stomach; girdles of the down are recommended in the sciatica; and those who are afflicted with the rheumatism in the legs, quilt their stockings with it. The Common Mugwort is more efficacious for making Moxa than this sort.—*Moxa* is celebrated in the East for preventing and curing many disorders, by being burnt on the skin; it produces a dark-coloured spot, the ex-ulceration of which is promoted by applying a little garlic, and the ulcer is either healed up when the eschar separates, or kept running, as circumstances require. A fungous substance found in the fissures of old Birch-trees, is

used by the Laplanders for the same purpose, and cotton impregnated with a solution of nitre, and then dried, will answer the end as well as the Moxa. All these applications are only means of producing an exulceration of the skin, and its consequence, a drain of humours.

42. *Artemisia Maderaspatana*; *Madras Wormwood.* Leaves simple, lyrate-sinuate; stems procumbent; flowers pedunculate, solitary, globose, opposite to the leaves, large, yellow.—Native of the East Indies, flowering in July and August.

43. *Artemisia Minima*; *Least Wormwood.* Leaves simple, wedge-shaped, repand; stem procumbent; flowers axillary, sessile.—Native of China: a minute, annual plant.

44. *Artemisia Littoralis.* Procumbent, strigose; leaves spatulate, serrate-toothed, simple; calices naked, pedicelled.—Found in the East Indies.

Artichoke. See *Cynara*.

Artichoke of Jerusalem. See *Helianthus*.

Artocarpus; a genus of the class Monœcia, order Monandria.—**GENERIC CHARACTER.** *Male flowers.* Calix: none; ament cylindrical, all covered with florets. *Corolla*: two petals each, oblong, concave, blunt, villose. *Stamina*: filamenta single, within each corolla, filiform, the length of the corolla; anthera oblong. *Female flowers*, on the same tree. *Calix* and *Corolla*: none. *Pistil*: germina very many, connected into a globe, hexangular; style to each filiform; stigmas single, or two, capillary, revolute. *Pericarp*: fruit ovate-globular, compound, muricate. *Seed*: for each germin solitary, oblong, covered with pulpy arils, placed on an ovate receptacle. **ESSENTIAL CHARACTER.** *Male*, ament. *Calix*: none. *Corolla*: two petalled. *Female.* *Calix* and *Corolla*: none; style one; berries one seeded, connected, and forming a roundish muricated fruit.—These are milky trees. Those varieties which bear seeds may be propagated by them, sown in a pot of rich earth, and plunged in the bark-bed. Those which have no seed in the fruit may be increased by suckers, in which they abound very much, or by layers.—The species are,

1. *Artocarpus Incisa*; *Bread-fruit Tree.* Leaves gashed. Capt. Cook observes, that this tree is about the height of a middling Oak; its leaves are frequently a foot and a half long, deeply sinuated like those of the Fig-tree, which they resemble in consistence and colour, and in exuding a milky juice when broken. The fruit is of the size and shape of a child's head, and the surface is netted not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small knife; the eatable part lies between the skin and the core; it is white as snow, and somewhat of the consistence of new bread. It must be roasted before it is eaten, being first divided into three or four parts; its taste is insipid, with a slight sweetness resembling that of the crumb of Wheaten bread mixed with Jerusalem Artichoke. As it is not in season at all times of the year, by reducing it to a sour paste, called *mahie*, they supply that defect. The tree is not only useful for food, (three trees yielding sufficient nourishment for one person,) but also for clothing; for the bark is stripped off the suckers, and formed into a kind of cloth. This plant is distributed very extensively over the East Indian continent and Islands, as well as in the innumerable islands of the South Sea. It was imported into the West India islands about the year 1793, where it has been most successfully established. The principal varieties are, that producing fruit with seeds, and that without; the former may be considered to be the tree in its wild state, as the want of seed is probably occasioned by cultivation.

2. *Artocarpus Integrifolia*; *Indian Jacca Tree.* Leaves entire.—This is about the same size or rather larger than the

Bread-fruit tree; it is a native of Malabar, and other parts of the East Indies. The fruit, which ripens in December, is eaten, but esteemed difficult of digestion: the unripe fruit is also pickled, or cut in slices and boiled, or fried in palm-oil. The nuts are eaten roasted, and the skin next them is used instead of the Areca-nut in chewing Betel. The wood of the tree is employed in building. Thirty varieties of this fruit are enumerated in Malabar.

Arum; a genus of the class Gynandria, order Polyandria. —GENERIC CHARACTER. *Male flowers*, on the same spadix as the females, closely placed between a double row of threads. *Calix*: spathe one-leaved, very large, oblong, convolute at the base, converging at the top; the belly compressed, coloured within; spadix club-shaped, quite simple, a little shorter than the spathe, coloured, fenced at bottom with germina, and shrivelling above them; perianth proper none. *Corolla*: none. Nectaries thick at the base, ending in threads or tendrils, in two rows, issuing from the middle of the spadix. *Stamina*: filamenta none; each anthera sessile, four-cornered. *Female flowers*, on the lower part of the spadix, close to each other. *Calix*: spathe and spadix common to them with the males; perianth proper none. *Corolla*: none. *Pistil*: germen each obovate; style none; stigma bearded with villose hairs. *Pericarp*: berry globular, one-celled. *Seeds*: several, roundish. ESSENTIAL CHARACTER. Spathe one-leaved, cowl'd; spadix naked above, female below, staminate in the middle.—The Arums are all perennial herbaceous plants, mostly natives of hot climates: their roots are fleshy, hot, and acrid, but many species eatable.—The species are,

* *Without Stems; Leaves compound.*

1. *Arum Crinitum; Hairy-sheathed Arum.* Leaves pedate, with the lateral segments involute; spathe hairy within; spadix ramentaceous above.—The flower of this plant smells very strong of carrion, by which flies are enticed to enter, but when they attempt to retreat, the reversed hairs prevent them, and they are there starved to death. In England it flowers in March, and is a native of Minorca.

2. *Arum Dracunculus; Long-sheathed Arum, or Common Dragon.* Leaves pedate, compound; leaflets lanceolate, quite entire; lamina ovate, longer than the spadix.—The flower is shaped like the Common Arum, having a very long spathe of a dark purple colour, standing erect, with a large spadix of the same colour; so that when it is in flower, it makes no unpleasing appearance, but has so strong a scent of carrion that it cannot be endured.—It grows naturally in most of the southern parts of Europe, and is preserved in gardens to supply the markets. It appears to be similar in medicinal virtues, as in botanical characters to Common Arum, but rather more pungent, and therefore might be used in the same cases in which the latter only is generally employed. It is very hardy, growing in any soil or situation. The offsets from the roots propagate very fast; the time to transplant it is in autumn, when the leaves decay.

3. *Arum Dracontium; Short-sheathed Arum, or Green Dragon.* Leaves pedate, compound; leaflets lanceolate, quite entire, longer than the spathe, which is shorter than the spadix.—It grows about eight or nine inches high; flowers with us in June; and grows in most places in Virginia and New England. The root of this, as well as that of the Common Dragon, is acrimonious and purgative. The whole plant, when fresh, is of an almost insupportably acrid taste, but loses the greatest part of that quality in drying. It was formerly much esteemed for its supposed efficacy in malignant fevers, the small-pox, and other disorders; and was also supposed to be a noble sudorific and resister of poison, but

is at present very little regarded. It is difficult to preserve this plant in gardens; they must have a moist shady situation, or they will not thrive.

4. *Arum Venosum; Purple-flowered Arum.* Leaves pedate, compound; leaflets suboval, quite entire; lamina lanceolate, longer than the spadix.—Native country unknown; it flowers in March.

5. *Arum Pentaphyllum; Five-leaved Arum.* Leaves quinac, compound.—Native of the East Indies and China. The root is accounted warm, attenuant, and deobstruent, and is given in the epilepsy, convulsions, obstructions of the uterus, bites of venomous animals, and other disorders, in the East.

6. *Arum Tryphyllum; Three-leaved Green-stalked Arum.* Leaves ternate; lamina lanceolate, acuminate, the length of the spadix, without stems; leaves compound.—Grows ten inches high, in Cochin China. This and the two following species are propagated by offsets. They will live in a sheltered situation in the open air, or if the surface of the ground be covered with tan, to keep out the frost in winter; and they will thrive better in the full ground than in pots.

7. *Arum Atrorubens; Three-leaved Purple-stalked Arum.* Leaves ternate, compound; lamina ovate, shorter by half than the spadix.—Native of Virginia; flowering with us in June and July: see the sixth species.

8. *Arum Ternatum.* Leaves compound, ternate; receptacle longer than the spathe.—Found in Japan, flowering in May and June: see the sixth species.

** *Without Stems; leaves simple.*

9. *Arum Colocasia; Egyptian Arum.* Leaves simple, peltate, ovate, repand, semibifid at the base.—Native of the Levant, Egypt, Sicily, and Italy, near Salerno, where it is esteemed a wholesome food; and though not very delicate, is frequently eaten in the East. The roots when young are sometimes eaten raw, the roots and petioles are boiled.—This, and the tenth, eleventh, twelfth, thirteenth, fourteenth, and sixteenth species, are easily propagated by the offsets which they put out plentifully from their roots; these must be planted in pots filled with light earth, and plunged into a hot-bed, to promote their taking root: and if they be afterward continued in the bark-stove, they will make greater progress, and produce larger leaves.

10. *Arum Bicolorum; Two-coloured Arum.* Leaves peltate, sagittate, coloured on the disk; simple spathe contracted in the middle, subglobular at the base; lamina roundish, acuminate, upright, somewhat convolute.—Cultivated in Madeira, and flowers in June and July: see the ninth species.

11. *Arum Esculentum; Esculent Arum, or Indian Kale.* Leaves peltate, ovate, quite entire, emarginate at the base; root large, tuberous.—It is very frequent in China and Cochin China, in shallow waters by the sides of rivers and marshes, and is a common food there, the root and tender petioles being eaten boiled. The bruised leaves are applied to tumors, and imagined to be an antidote for poisonous bites. It is also a native of, and frequently cultivated in, Japan, where the sliced roots and stalks are put into soups and broths. It is found in the islands of the Southern Ocean; and is cultivated every where within the tropics, and even in the northern extremity of New Zealand. The natives of the South Sea islands bestow great pains on the culture of this root; for in the first months of its growth it succeeds best when the ground is inundated; but afterwards it should be laid dry, which they do by means of ditches dug round the fields. The root, which is the common food in many of the islands, is extremely acrid, and when eaten raw will excoriate the mouth, but baked in hot ashes, loses its acrimonious quality, and becomes mild and well tasted; it is, however, heavy upon a weak

stomach, and tends to produce costiveness. The leaves are extremely soft, glaucous, and covered with a very fine silky nap, and are used by the natives instead of dishes: see the ninth species.

12. *Arum Macrorrhizon*; *Long-rooted Arum*. Leaves pettate, cordate, repand, two-parted at the base. This species is distinguished by its great size. It is a native of China and Cochin-china, the East Indies, Ceylon, and the islands of the Southern Ocean; and, as well as the foregoing species, is eaten by the natives, after the roots are deprived of their acrimony by dressing: see the ninth species.

13. *Arum Peregrinum*. Leaves cordate, obtuse, mucronate; angles rounded.—Native of America: see the 9th species.

14. *Arum Divaricatum*. Leaves cordate, hastate, divaricate.—Native of Malabar and Ceylon: see the 9th species.

15. *Arum Trilobatum*; *Three-lobed Arum*. Leaves sagittate-trilobate; flower sessile, fetid like carrion.—Native of Ceylon, Amboyna, Japan, and Cochin-china. It flowers here in May and June, and is propagated by offsets, which come out in abundance when the plants are in health. They are very impatient of cold, and must be placed in the tan-bed of the bark-stove.

16. *Arum Sagittæfolium*; *Arrow-leaved Arum*. Leaves sagittate, triangular; the angles divaricate, acute.—Native of the Spanish West Indies, China, and Cochin-china; where it is esteemed a wholesome green when boiled; and where the Common European vegetables are with difficulty procured, this proves a good succedaneum. See the ninth species. In Jamaica it is called Smaller Indian Kale.

17. *Arum Maculatum*; *Common Arum*. Leaves hastate, quite entire; spadix club-shaped; root whitish, tuberous, about the size of a large nutmeg; berries scarlet, in a naked cluster.—Native of all except the most northern parts of Europe, growing in shady places, on the banks of ditches, and flowering in May. The berries ripen at the close of summer. The fresh roots and leaves are extremely acrid; on first tasting them, they seem to be merely mucilaginous and insipid, but they soon affect the tongue for several hours with a pungency, as if it had been pricked with needles, which sensation may be allayed by milk, butter, or oil. When dried, they become farinaceous and insipid, in which case they might be used for food in case of necessity; and by boiling or baking would probably afford a mild and wholesome nourishment as well as those sorts which are natives of hot climates. The berries are devoured by birds; and it has been supposed that they, particularly pheasants, eat the roots. These, when dried and powdered, are used by the French as a wash for the skin, and sell under the name of cypress powder, at a high price, being an excellent and innocent cosmetic. Starch may also be made from them, but the hands are liable to be blistered in using it. They have occasionally been substituted for soap. When newly dried and powdered, the root has been given as a stimulant, in doses of a scruple and upwards; but in being reduced to powder, it loses much of its acrimony; and there is reason to suppose, that the compound powder, which takes its name from this plant, owes its virtues chiefly to the other ingredients. The *pulvis ari compositus*, or powder composed of Arum, is therefore discarded from the London dispensatory, and instead of it a conserve is inserted, made by beating half a pound of fresh root with a pound and half of fine sugar. In the medicine recommended by Sydenham against rheumatisms, the acrid antiscorbutic herbs are largely joined with it. Dr. Lewis orders the fresh root to be beaten with a little testaceous powder, and mixed with an equal quantity of gum-arabic, and three or four times as much conserve, and thus to be made up into an electuary; or else

to be rubbed with a thick mucilage of gum-arabic and spermaceti, adding any watery liquor, and a little syrup, to form an emulsion; two parts of the root, two of gum, and one of spermaceti. In these forms he has given the fresh root from ten grains to upwards of a scruple, three or four times a day: it generally occasioned a sensation of slight warmth, first about the stomach, and afterwards in the remoter parts; manifestly promoted perspiration, and frequently produced a plentiful sweat: several obstinate rheumatic pains were removed by this medicine, which he therefore recommends to further trial. Chewed in the mouth, it has been known to restore the speech in paralytic cases; and made into a conserve, it is efficacious in the scurvy and rheumatism; it likewise increases the urinary secretion, and is good in the gravel. But in whatever form it is used, the roots should be fresh, for it loses the greatest part of its efficacy in drying, and becomes insipid.—Both this and the large Italian variety propagate very fast by offsets from the root, and will thrive in any soil or situation. The best time to transplant these, is soon after the seeds are ripe, for by the end of October they will be putting out new fibres. There are also two other varieties.

18. *Arum Virginicum*; *Virginian Arum*. Leaves hastate, cordate, acute; angles obtuse.—Grows wild in wet places in Virginia, Carolina, Pennsylvania, &c. The savages boil the spadix with the berries, and devour it as a great dainty. The berries, when raw, have a harsh pungent taste, which they lose in a great measure by boiling.

19. *Arum Probocideum*; *Apennine Arum*. Leaves hastate; spathe declinate, filiform-subulate.—Native of the Apennines. This and the two following species flower in April, and multiply fast by offsets in a shady situation, but seldom produce seeds in England.

20. *Arum Arisarum*; *Broad-leaved Hooded Arum*, or *Friar's-cowl*. Leaves cordate, oblong; aperture of the spathe ovate.—Native of woods in the south of France, Italy, Spain, Portugal, and Cochin-china: see the nineteenth species.

21. *Arum Pictum*; *Painted Arum*. Leaves cordate, painted with coloured veins.—See the nineteenth species.

22. *Arum Ovatum*. Leaves ovate-oblong; spathe scabrous.—Native of the East Indies.

23. *Arum Tenuifolium*; *Grass-leaved Arum*, or *Narrow-leaved Friar's-cowl*. Leaves lanceolate; spadix bristle-shaped, declinate.—It grows naturally about Rome, Montpellier, and in Dalmatia and the Levant.

24. *Arum Cannæfolium*. Leaves simple, lanceolate, veinless; parasitical upon trees.—Native of Surinam.

*** *Caulescent*.

25. *Arum Arborescens*; *Tree Arum*. Straight: leaves sagittate.—Native of South America. This, and the four following species of this genus, are propagated by cutting off the stalks into lengths of three or four joints, which must be laid to dry for six weeks or two months; for if the wounded part be not perfectly healed over before the cuttings are planted, they will rot and decay. Plant them in small pots of light sandy earth, plunged into a moderate hot-bed of tan, taking care that they have little wet, until well rooted, and then some of them may be placed in a dry-stove, and others plunged into the tan-bed in the bark-stove, where they will grow fastest and flower most.

26. *Arum Seguinum*; *Dumb-cane Arum*. Nearly upright; leaves lanceolate, ovate.—This species grows naturally in the sugar islands and other warm parts of America, chiefly in the low grounds. The whole plant abounds in an acrid juice, so that if a leaf or a part of the stalk be broken, and applied to the tip of the tongue, it occasions a very painful sensation, and such an irritation of the salivary ducts,

Dumb Cane Arum;

Common Arum.

ARUM.

Common Asarabacca.

ASARUM.

that they presently swell so that the person cannot speak : from this quality, and its being jointed, they call it *Dumb-cane* in Jamaica, where it is said they sometimes cruelly rub the mouths of their negroes with it by way of punishment. The stalks are used for a better purpose, to bring sugar to a good grain, when the juice is too viscid, and cannot be brought to granulate rightly with the lime alone.—A decoction of this plant is recommended by way of fomentation in dropsies ; it certainly must be a strong resolutive, which cannot fail to strengthen and stimulate the relaxed fibres in such cases. See the twenty-fifth species.

27. *Arum Hederaceum* ; *Ivy-leaved Arum*. Radicant : leaves cordate, oblong, acuminate ; petioles round.—Native of the West Indies. See the twenty-fifth species.

28. *Arum Lingulatum* ; *Tongue-leaved Arum*. Creeping ; leaves cordate, lanceolate ; petioles edged with membranes.—Native of the West Indies, where it climbs the trees with great ease, and grows more succulent and luxuriant towards the top. See the twenty-fifth species.

29. *Arum Auritum* ; *Ear-leaved Arum*. Radicant : leaves ternate, those on the side three-lobed. A climbing plant.—Native of the West Indies. See the twenty-fifth species.

30. *Arum Indicum* ; *Indian Arum*. Nearly upright ; leaves ovate, bifid at the base, rounded ; spadices axillary ; stem thick, five feet high.—Native of the East Indies, and cultivated in Cochin-china, where the stalk is boiled and eaten.

31. *Arum Cucullatum* ; *Cowled Arum*. Upright : leaves peltate, cordate, with the ears cowled ; spadix short, nearly covered with florets.—Native of the suburbs of Canton.

32. *Arum Spirale* ; *Spiral Arum*. Stemless : leaves lanceolate ; spathe spiral, sessile.—Native of Tranquebar in the East Indies.

Aruncus. See *Spiræa*.

Arundo ; a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** *Calix* : glume one or many-flowered, two-valved, erect : valves oblong, acuminate, awnless, one shorter. *Corolla* : two-valved ; valves the length of the calix, oblong, acuminate ; from their base arises a lanugo almost the length of the flower ; nectary two-leaved, very small. *Stamina* : filamenta three, capillary ; antheræ forked at both ends. *Pistil* : germen oblong ; styles two, capillary, reflex, villose ; stigmas simple. *Pericarp* : none. *Corolla* : adheres to the seed without gaping. *Seed* : single, oblong, acuminate at both ends, furnished with a long down (pappus) at the base. **ESSENTIAL CHARACTER.** *Calix* : two-valved ; florets heaped, surrounded with wool.—The species are,

1. *Arundo Bambos* ; *Bambu* or *Bamboo Cane*. Calices many-flowered ; spikes in threes, sessile. The highest and the largest of all the Bamboos, covered very thick with spines.—The *Bamboo Cane* grows naturally almost every where within the tropical regions, and there is perhaps scarcely any plant which serves such a variety of domestic purposes. The houses of the meaner people in the East Indies are almost entirely composed of it, and it is said to be strong and perfect after lasting a hundred years ; bridges also, masts for boats, boxes, cups, baskets, mats, and a great variety of other utensils and furniture, both domestic and rural. Paper is also made from it by bruising it, and steeping it in water, and thus forming it into a paste. It is the common fence for gardens and fields, and is frequently used as pipes for conveying water. The leaves are generally put round the chests of tea which are sent to Europe from China, as package, fastened together so as to form a kind of mat. The tops of the tender shoots are frequently pickled in the West Indies. In the cavities or tubular parts of the *Bamboo*, is found, at certain seasons, a

VOL. I.—11.

concrete white substance, called *tabasher*, or *tabashir*, an article which the Arabian physicians hold in great estimation : it is commonly found in what are called the female or large Bamboos, which, on shaking, are found to contain a fluid, which after some time gradually lessens, and then they are opened, in order to extract the tobacco. The nature of this substance is very different from what might have been expected in the product of a vegetable. Its indestructibility by fire, its total resistance to acids, its uniting by fusion with alkalies, in certain proportions, into a white opaque mass, or a transparent permanent glass ; and its being again separable from these compounds, entirely unchanged by acids, &c. seem to afford the strongest reasons for considering it as very nearly identical with common silicious earth. As to the medicinal virtues of this part of the plant, though in great esteem as a drug among the Orientalists, it is not regarded in modern Europe. *Loureiro* informs us, that the bark, buds, and root, are used. The leaves, he says, are cooling, emollient, and resolvent ; their decoction is good in fevers ; coughs, pains of the throat, &c. the thin bark is cooling and agglutinant, and a gentle astringent : it is good in feverish heats, hæmorrhages, nausea, and vomitings : the roots and buds are attenuating, and promote uriae, and purify the blood, and are used for disorders of the kidneys, bladder, and urethra, wandering pains, obstructions, and in venereal cases : from the fresh roots, mixed with *Tobacco* leaves and *Betel*, in equal portions, and infused and macerated for some days in oil, is prepared an ointment of great efficacy in discussing hard and schirrous swellings. In England, it must be preserved in a warm stove ; and, as the roots spread very wide, it should be planted in a large tub, filled with rich earth : this must be plunged into a hot-bed in the bark-stove, and be well supplied with water. It may be propagated by slips from the roots, which should be taken off in the spring, that they may be well established before winter. There are many varieties of this species, with one of which the Turks make their writing pens.

2. *Arundo Donax* ; *Cultivated* or *Evergreen Reed*. Calices five-flowered ; panicle diffusé ; culm shrubby.—Native of the south of Europe, Siberia, Egypt, and Cochin-china. It will bear the cold of our winters in the open ground, provided it be planted in a soil not too wet, and laying in severe winters a little mulch to the roots. It is propagated by parting the roots early in the spring, before they begin to shoot, and will in a year or two, if the ground be good, make very large stools, from each of which eight or ten canes are produced. It never flowers in England.

3. *Arundo Phragmites* ; *Common Reed*. Calices five-flowered ; panicle loose.—It flowers from July till September, and ripens its seeds in October and November. It is very common by the sides of rivers, in ditches, and large standing waters. In autumn, when the leaves begin to fall, and the stems are changed brown, it is cut for making screens in kitchen-gardens, and for many other uses, as thatching, for which it is more durable than straw ; for ceilings, and to lay across the frame of wood-work, as the foundation for plaster-floors. The panicles are used by the country people in Sweden, to dye wool green, and the root has been recommended as answering the same purposes as *Dog's Grass*, or *Triticum Caninum*.—According to *Hill*, the juice of the fresh root excites the menstrual discharge powerfully, but not violently : it likewise increases the urinary evacuation, and is serviceable in stranguries and the gravel.

4. *Arundo Epigejos* ; *Wood Reedgrass*. Calices one-flowered ; panicle erect ; leaves smooth underneath.—Native of many parts of Europe, in shaded ditches, flowering in July.

5. *Arundo Calamagrostis* ; *Small Reedgrass*. Calices

one-flowered, smooth; corollas woolly; culm erect, 3 or 4 feet high; root perennial, creeping.—Native of most parts of Europe, in moist woods and hedges; flowering in June and July.

6. *Arundo Arenaria*; *Sea Reedgrass*. Calices one-flowered; leaves rolled inward, dagger-pointed, and pungent.—A native of sandy coasts in Europe and America; flowering in June and July. By means of its creeping roots it helps very much to consolidate driving sands, which gather about it in hills or banks, and are thus prevented from dispersing over and impoverishing the adjoining fields. The Dutch have profited by their knowledge of this fact; and Mr. Woodward informs us, that it is planted about Wells in Norfolk, to aid in repelling the sea. The country people know it by the name of *Sea Matweed*, *Maram*, and *Helne*. They cut and bleach it for making mats; and where it is plentiful, houses are thatched with it.

7. *Arundo Colorata*; *Canary Reedgrass*. Calices one-flowered, keeled; corollas smooth with two lanuginose pencils at the base; leaves flat.—This is a native of Europe, on the banks of rivers and ditches; flowering in July and August. It is used to thatch ricks and cottages, for which purpose it is more durable than straw. In the province of Scania, they mow it twice a year, and their cattle eat it. The texture is so hard that it must be cut young, if cattle be expected to touch it. There is a cultivated variety of this Grass in our gardens, with beautifully striped leaves. The stripes are generally green and white; but sometimes they have a purplish cast. This is called *Ladies' Laces*, *Painted Grass*, or *Riband Grass*.

8. *Arundo Conspicua*. Calices one-flowered; panicle loose, form erect spreading; awn of the outer petal reflex, and very long.—Native of New Zealand.

9. *Arundo Agrestis*. Flowers six-stamined; panicle spiked; spikelets heaped; lower branches of the culm very spiky; calices one-flowered, thirty feet high.—Native of mountains and dry desert places in Cochin-china.

10. *Arundo Mitis*. Flowers six-stamined; panicle erect, contracted; spikes long, imbricate; culm very even, unarmed; calices one-flowered. Higher and thicker than the *Agrestis*.—It is cultivated in the fields and hedges of Cochin-china; and being divided into long thin pieces, is used for weaving into hats, coffers, baskets, and a variety of very elegant utensils.

11. *Arundo Multiplex*. Flowers six-stamined; spikes interrupted; spikelets in whorls; culm divided; calices one-flowered. Twelve feet high.—Used in the cultivated parts of the northern provinces of Cochin-china, where it is used as fence-work or hedges to separate gardens.

12. *Arundo Bengalensis*. Calices two-flowered; panicle erect, with three-flowered pedicles.—Native of Bengal.

13. *Arundo Piscatoria*. Calices one-flowered; spike terminating; culm branched; leaves minute.—Native of Cochin-china: being very tough, and tapering towards the end, it is very fit for fishing-rods.

14. *Arundo Dioica*. Calices one-flowered; spikes in bundles, compound; spikelets linear.—Native of woods in Cochin-china.

Asarabacca. See *Asarum*.

Asarina, a genus of the class Diœcia, order Monandria.—GENERIC CHARACTER. *Male flowers*. *Calix*: ament filiform; floscules scattered, sessile; perianth a very short scale. *Corolla*: none. *Stamina*: filamenta single, very short; anthera oblong, from spreading recurve, four-furrowed, large. *Female flowers*, in a different plant. *Calix*: as in the male. *Corolla*: none. *Pistil*: germen globose; style none; stigma flat, three-lobed, growing to the germen. *Pericarp*: drupe. *Seeds*: single. ESSENTIAL CHARACTER.

Calix: ament, filiform. *Corolla*: none. *Male*, anthera worm-shaped. *Female*, style none; stigma three-lobed.—One species only has been hitherto discovered, viz.

1. *Asarina Polystachya*.—A native of the Society Isles, in the South Sea.

Asarum; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, bell-shaped, three or four cleft, coriaceous, coloured, permanent; clefts erect, bent in at the top. *Corolla*: none. *Stamina*: filamenta twelve, subulate, half the length of the calix; antheræ oblong, fastened to the middle partition of the filamenta. *Pistil*: germen inferior, or concealed within the substance of the calix; style cylindric, the length of the stamina; stigma stellate, six-parted; parts reflex. *Pericarp*: capsule coriaceous, within the substance of the calix, mostly six-celled. *Seeds*: several, ovate. ESSENTIAL CHARACTER. *Calix*: three or four cleft, placed on the germen. *Corolla*: none. *Capsule*: coriaceous; crowned. *Stigma*: six-cleft.—These plants delight in a moist shady situation, and may be increased by parting the roots in autumn.—The species are,

1. *Asarum Europæum*; *Common Asarabacca*. Leaves kidney-shaped, blunt, in pairs; root perennial, creeping; stems short, simple, round, pubescent, one-flowered; flowers terminal, pitcher-shaped, of a dark purple colour, villose.—A native of many parts of Europe, in woods and shady places; flowering in April and May. With us it has been found only in Lancashire. The root powdered, and taken to the amount of thirty or forty grains, excites vomiting; and when coarsely powdered, it generally purges. The powder of the leaves is the basis of most cephalic snuffs. An infusion of one or two drachms of the leaves vomits. Allioni gives a particular account of the qualities of *Asarabacca*, and seems to have a high opinion of it, especially in obstinate intermittents, and above all in the quartan ague. Others entirely reject it, as too acrid when fresh, and too insipid when dry. The *Pulvis Asari Compositus*, or Powder of *Asarabacca*, is composed of equal quantities of the dried leaves of *Asarum Marjorum*, and *Marum*, and of the dried flowers of *Lavender*. The powdered root, taken to the amount of thirty or forty grains, is a rough emetic; and the leaves powdered, and snuffed up the nose, occasion a considerable discharge of mucus from the head without exciting much sneezing. The salutary discharge occasioned by snuffing a grain or two of this powder up the nose, will sometimes confine for two or three days together; by which head-ache, tooth-ache, ophthalmia, and some paralytic and soporific complaints, have been effectually relieved; a single dose has been known to remove a palsy of the mouth and tongue. It is an excellent medicine in soporific distempers, and those disorders of the head which proceed from a redundancy of viscid matter; but the patient should carefully avoid cold during the operation, as it might subject him to inflammations of the face, and other alarming consequences. The dried roots or leaves, according to Meyrick, taken in large doses, vomit and purge violently, but in smaller doses they operate safely and effectually by urine, and are of great efficacy in obstructions of the menses, the jaundice, and the dropsy.

2. *Asarum Canadense*; *Canadian Asarabacca*. Leaves kidney-shaped, mucronate.—Native of Canada; flowering from April to July. Too much wet in winter will cause this species to rot.

3. *Asarum Virginicum*; *Sweet-scented Asarabacca*. Leaves heart-shaped, blunt, smooth, petioled.—This seldom thrives well if it be too much exposed to the sun in summer, and should be planted so as to have only the morning sun.—Native of North America.

Asclepias; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets roundish, concave, coriaceous, coloured on the margin. *Corolla*: petals five, ovate, acute, larger than the calix, inserted into the receptacle. *Stamina*: filamenta very many, short, three-sided, inserted into the receptacle; antheræ oblong. *Pistil*: germen ovate; style very short; stigma headed. *Pericarp*: berry? one-celled. *Seeds*: very many. **ESSENTIAL CHARACTER.** *Calix*: five-leaved, coriaceous. *Corolla*: five-petalled. *Berry*? one-celled, with very many seeds.—Only one species is yet known.

1. *Ascium Norantea*.—This tree is a native of Guiana.

Asclepias; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth five-cleft, sharp, very small, permanent. *Corolla*: monopetalous, flat or reflex, five-parted; divisions ovate, acuminate, slightly bending with the sun; nectaries five, growing to the tube of the filamenta below the anthera, fleshy or cowled, a sharp horn protruding from the bottom, bending inwards. *Stamina*: filamenta five, collected into a tube, swelling at the base; antheræ oblong, upright, two-celled, terminated by an inflex membrane lying on the stigma, having a reversed wing on each side, growing broader downwards, with its edge contiguous to the next. The pollen is collected into ten corpuscles, inversely lanceolate, flat, hanging down into the cells of the anthera by short threads, frequently flexuose; which are annexed by pairs to five cartilaginous twin tubercles, each placed on the tip of the wings of the anthera, adhering to the angles of the stigma between them. *Pistil*: germina two, oblong, acuminate; styles two, subulate; stigma common to both, large, thick, five-cornered, covered at the top by the apices of the antheræ, umbilicate in the middle. *Pericarp*: follicles two, large, oblong, acuminate; swelling, one-celled, one-valved. *Seeds*: numerous, imbricate, crowned with down; receptacle membranaceous, free. **ESSENTIAL CHARACTER.** Contorted; nectaries five, ovate, concave, putting out a little horn.—The North American and European species of this genus are hardy enough to bear the open air; and therefore are proper for large borders in pleasure-grounds, and to mix with shrubs. The other species require the protection of the green-house or stove; all of them are tall perennials, flowering from June to August or September, mostly dying down to the root in autumn. They should have little water, especially in winter, for as they abound with a milky juice, much wet will rot them. They may be propagated by seeds, where these can be obtained, or by cuttings: the hardy sorts may be increased by parting the roots.—The species are,

* *Leaves opposite, flat.*

1. *Asclepias Undulata*; *Waved-leaved Swallowwort*. Leaves sessile, oblong, lanceolate, waved, smooth; petals ciliate.—Native of the Cape; and flowers here in July.

2. *Asclepias Crispa*; *Curled-leaved Swallowwort*. Leaves cordate, lanceolate, waved, scabrous, opposite; umbel terminal.—Native of the Cape of Good Hope.

3. *Asclepias Pubescens*; *Pubescent Swallowwort*. Leaves ovate, veined, naked; stem shrubby; peduncles villose; flowers purple.—Native of the Cape of Good Hope.

4. *Asclepias Volubilis*; *Twining Swallowwort*. Leaves ovate, quite entire, acuminate; stem arboreous, twining; umbels erect; flowers greenish.—Native of Malabar and Ceylon.

5. *Asclepias Asthmatica*; *Asthmatic Swallowwort*. Leaves petiolate, cordate-ovate, above smooth, quite entire; stem shrubby, twining, hirsute; umbels few-flowered.—Found in Ceylon; where the root is esteemed a good medicine in asthmatic disorders.

6. *Asclepias Gigantea*; *Curled-flowered Gigantic Swallowwort*. Leaves obovate-oblong; petioles very short; segments of the corolla reflex, involute; flowers white.—Native of the East and West Indies.

7. *Asclepias Syriaca*; *Syrian Swallowwort*. Leaves oval, tomentose underneath; stem quite simple; umbels nodding, flowers of a dingy purple.—It flowers in July, and is a native of North America.

8. *Asclepias Amoena*; *Oval-leaved Swallowwort*. Leaves ovate, rather hairy underneath; stem simple; umbels and nectaries erect. The flowers, which appear in July, are of a bright purple colour, but are not succeeded by pods in England.—It is a native of North America.

9. *Asclepias Purpurascens*; *Purple Virginian Swallowwort*. Leaves ovate, villose underneath; stems simple; umbels erect; nectaries resupinate.—Native of North America.

10. *Asclepias Variegata*; *Variegated Swallowwort*, or *Wisank*. Leaves ovate, wrinkled, naked; stem simple; umbels subsessile; pedicles tomentose.—Flowers in July; native of North America.

11. *Asclepias Curassavica*; *Curassoa Swallowwort*, *Bastard Ipecacuanha*. Leaves lanceolate, smooth, shining; stem simple; umbels erect, solitary, lateral.—Mr. Miller says, that the roots of this plant have been sent to England for ipecacuanha. The juice, made into syrup with sugar, has been observed to kill and bring away worms wonderfully, even when most other vermifuges have failed; it is given to children in the West Indies, from a tea-spoonful to a table-spoonful. The juice and pounded plant are applied to stop the blood in fresh wounds, and is said to be a powerful astringent in such cases. The root, dried and reduced to powder, is frequently used by the negroes as a vomit; and hence its name of *Wild or Bastard Ipecacuanha*.

12. *Asclepias Nivea*; *White or Almond-leaved Swallowwort*. Leaves ovate-lanceolate, smoothish; stem simple; umbels erect, lateral, solitary.—Native of North America.

13. *Asclepias Incarnata*; *Flesh-coloured Swallowwort*. Leaves lanceolate; stem divided at top; umbels erect, twin; flowers purple. Native of North America.

14. *Asclepias Decumbens*; *Decumbent Swallowwort*. Leaves villose; stem decumbent.—Native of North America.

15. *Asclepias Lactifera*; *Milky Swallowwort*. Leaves ovate; stem erect; umbels proliferous, very short.—Native of Ceylon.

16. *Asclepias Vincetoxicum*; *Official Swallowwort*, or *Tame-poison*. Leaves ovate, bearded at the base; stem erect; umbels proliferous; corolla white.—Native of most parts of the continent of Europe. It was formerly imagined to be an alexipharmic, and hence its name of *Vincetoxicum*, *Tame-poison*, absurdly composed of a Latin and a Greek word. It has been also recommended in dropsical cases, and disorders peculiar to women, but is disused in the present practice, and is too suspicious a plant to be internally taken, except with great caution. The external application for foul ulcers, abscesses of the breast, and scrofulous tumors, is more plausible. The root is the part to be used; an infusion of it, fresh gathered, removes obstructions, increases the urinary discharge, and is good in the jaundice; dried, and given in powder, it promotes perspiration, and is good against fevers, the small-pox, measles, and other eruptive complaints. No animal, except the goat, is said to eat it; though Linnæus affirms that the horse will crop it after it is frost-bitten. The down or cotton may be used for stuffing cushions, pillows, &c. There are several varieties of this species.

17. *Asclepias Nigra*; *Black Swallowwort*. Leaves ovate, bearded at the base; stem twining a little at top; flowers

black.—It is rather rare, being only found in the south of France, the mountains about Nice, and in Spain.

** *Leaves revolute at the sides.*

18. *Asclepias Arborescens*; *Arborescent Swallowwort*. Leaves ovate; stem shrubby, subvillose; corolla white.—Native of the Cape of Good Hope.

19. *Asclepias Fruticosa*; *Shrubby, or Willow-leaved Swallowwort*. Leaves linear-lanceolate; stem shrubby. It flowers from June to September.—Native of the Cape.

20. *Asclepias Repanda*; *Repand Swallowwort*. Leaves revolute, repand, hairy.—Native country unknown.

21. *Asclepias Sibirica*; *Siberian Swallowwort*. Leaves linear-lanceolate, opposite, or in threes; stem decumbent.—Native of Siberia, where it flowers in July and August.

22. *Asclepias Verticillata*; *Verticillate Swallowwort*. Leaves linear, verticillate; stem erect; flowers in umbels, small, white.—Native of North America.

*** *Leaves alternate.*

23. *Asclepias Rubra*; *Red Swallowwort*. Leaves ovate; umbels many, from the same common peduncle.—Native of Virginia.

24. *Asclepias Tuberosa*; *Tuberous Swallowwort*. Leaves lanceolate; stem divaricate, hairy.—The flowers are of a bright orange colour. It flowers from the end of July until September, sometimes ripening seeds in England; and is a native of North America.

25. *Asclepias Filiformis*; *Narrow-leaved Swallowwort*. Leaves filiform; stem erect; umbels lateral, elongate-peduncled.—Found at the Cape of Good Hope.

26. *Asclepias Grandiflora*; *Great-flowering Swallowwort*. Leaves petiolate, oblong, hairy; stem simple, rough, erect; flowers axillary, peduncled.—Found at the Cape.

27. *Asclepias Carnosa*, *Fleshy-leaved Swallowwort*. Leaves ovate, fleshy, very smooth.—It is a native of China.

28. *Asclepias Scandens*; *Climbing Swallowwort*. Leaves oblong-lanceolate, subhirsute; stem shrubby, climbing; umbels lateral, compact; flowers sulphur-coloured.—Native of Carthagena in South America.

29. *Asclepias Procera*; *Bell-flowered Gigantic Swallowwort*. Leaves obovate-oblong; petioles very short; corollas subcampanulate.—Native of Persia.

30. *Asclepias Parviflora*; *Small-flowered Swallowwort*. Leaves lanceolate, acuminate, smooth, opposite, drawn to a point at the base; stem suffruticose, upright; umbels lateral, solitary.—Native of Carolina and East Florida.

31. *Asclepias Linaria*; *Toadflax-leaved Swallowwort*. Leaves scattered, subulate, channelled; umbels lateral, many-flowered; corolla white.—Native country unknown; flowers from August to October.

32. *Asclepias Mexicana*; *Mexican Swallowwort*. Leaves six together in whorls, lanceolate; flowers umbelled.—Native of Mexico: also flowering from August until October.

33. *Asclepias Fusca*. Stems creeping; leaves cordate, lanceolate; umbels axillary, in pairs.—Native of Cochinchina, growing in waste places and upon old walls.

34. *Asclepias Viminalis*. Stem suffruticose, twining, filiform; leaves opposite, lanceolate, smooth; umbels lateral, many-flowered. The whole plant is of a dark green colour, full of milk.—Common in the larger inland woods of Jamaica.

Ascyrum; a genus of the class Polyadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth four-leaved; the outer leaflets opposite, very minute, linear; the inner heart-shaped, large, flat erect, all permanent. *Corolla*: petals four, ovate; the outer opposite, very large; the inner less. *Stamina*: filamenta numerous, bristle-shaped, slightly united at the base in four parts; antheræ roundish. *Pistil*:

germen oblong; style scarcely any; stigma simple. *Pericarp*: capsule oblong, acuminate, one-celled, two-valved, enclosed by the larger leaves of the calix. *Seeds*: numerous, small, roundish; fixed to the edge of the valves. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Petals*: four; filamenta many, in four divisions.—The species are,

1. *Ascyrum Crux Andree*; *Common Ascyrum*, or *Saint Andrew's Cross*. Leaves ovate; stem round; panicle dichotomous.—Native of N. America; flowering in July and August.

2. *Ascyrum Hypericoides*. Leaves oblong; branches apical; flowers terminating, yellow. An elegant little shrub, seldom above three feet in height.—Native of South Carolina, Maryland, and the cooler mountains of Jamaica.

3. *Ascyrum Villosum*. Leaves hirsute; stem stiff, and straight. Reaches three feet in height; and grows naturally in Virginia.—They are all perennial plants.

Ash, Common, Flowering, and Manna. See *Fraxinus*.

Ash, Mountain. See *Sorbus*.

Ashweed. See *Ægopodium*.

Asp or Aspen Tree. See *Populus*.

Aspalathus; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft; divisions acuminate, equal, except that the upper is larger. *Corolla*: papilionaceous; banner compressed, ascending, obovate, generally hirsute on the outside, obtuse, with a point; wings lunate, obtuse, spreading, shorter than the banner; keel bifid, conformable with the wings. *Stamina*: filamenta ten, uniting into a sheath, gaping longitudinally at top, ascending; anthera oblong. *Pistil*: germen ovate; style simple, ascending; stigma sharp. *Pericarp*: legume ovate, awnless. *Seeds*: generally two, kidney-shaped. ESSENTIAL CHARACTER. *Calix*: five-cleft, the upper divisions largest; legume ovate, awnless, with about two seeds.—With few exceptions, the plants of this genus are natives of the Cape of Good Hope; few of them have been cultivated in Europe, but they may be propagated by seeds obtained from the country where they spontaneously grow, and sown in light earth as soon as they arrive. When they come up, transplant them into separate pots of light earth, and plunge them into a moderate hot-bed, till they have again taken root; after which they may be gradually inured to the open air in summer, but in autumn and winter they must be carried into the green-house.—The species are,

1. *Aspalathus Spinosa*; *Thorny Aspalathus*. Leaves fasciated, linear, naked, surrounding a gemmaceous spine.

2. *Aspalathus Verrucosa*; *Warted Aspalathus*. Leaves fasciated, filiform; huds warted; tomentose, naked.

3. *Aspalathus Capitata*; *Headed Aspalathus*: Leaves fasciated, linear, sharp; flowers headed; bractes naked.

4. *Aspalathus Glomerata*; *Glomerate Aspalathus*. Leaves fasciated, linear, sharp, villose, bent inward; flowers headed; divisions of the calix ovate; corollas smooth.

5. *Aspalathus Astroites*; *Starry Aspalathus*. Leaves fasciated, subulate, mucronate, smooth; stem villose; flowers scattered.—This has the appearance of Juniper.

6. *Aspalathus Chenopodia*. Leaves fasciated, subulate, mucronate, rough with hairs; flowers headed, very hirsute.

7. *Aspalathus Albens*; *White Aspalathus*. Leaves fasciated, subulate, silky, spreading at top; bunches of flowers scattered, of a silky white.

8. *Aspalathus Thymifolia*; *Tyme-leaved Aspalathus*. Leaves fasciated, subulate, unarmed, smooth, very short; flowers alternate.—The leaves resemble those of Thyme.

9. *Aspalathus Ericifolia*; *Heath-leaved Aspalathus*. Leaves fasciated, linear, unarmed, hirsute; flowers alternate; banner villose; calices linear.

ASTER - *Virginian Starwort.*

P. 143.

ASTRAGALUS - *Taller Fox-tail Milk-Vetch.*

L. Chorley sculp.

10. *Aspalathus Nigra*; *Black Aspalathus*. Leaves fascicled, linear, rather obtuse; flowers headed, spiked, pubescent; bractes in pairs, narrow.

11. *Aspalathus Carnosa*; *Fleshy Aspalathus*. Leaves fascicled, almost columnar, obtuse; calices subpubescent, sharp; corollas smooth; flowers yellow, terminal, umbelled.

12. *Aspalathus Ciliaris*; *Ciliate-leaved Aspalathus*. Leaves fascicled, filiform, scabrous; flowers terminal, sessile; banners pubescent; corolla yellow, with an ash-coloured banner.

13. *Aspalathus Genistoides*; *Broom-like Aspalathus*. Leaves fascicled, filiform, polished; calices subracemed, pendulous; they and the corollas smooth, and yellow.

14. *Aspalathus Hystrix*; *Porcupine Aspalathus*. Leaves fascicled, filiform, rigid, spiny, silky; flowers lateral, sessile, solitary; corollas villose.

15. *Aspalathus Galioides*. Leaves fascicled, linear, polished; peduncles two-flowered, elongate, leafy at the end.

16. *Aspalathus Retroflexa*. Leaves fascicled, subulate, smooth, very small; branches filiform, very spreading; flowers solitary, terminal; keel of the corolla tomentose.

17. *Aspalathus Uniflora*; *One-flowered Aspalathus*. Leaves fascicled, linear, unarmed, smooth; stipules sharp, permanent; flowers solitary; divisions of the calices boat-shaped.

18. *Aspalathus Araneosa*. Leaves fascicled, bristle-shaped, unarmed, hispid; flowers headed; banner hairy on the outside.

19. *Aspalathus Asparagoides*. Leaves fascicled, setaceous, rather hairy; calices leaf-shaped, the length of the corolla, solitary; banner scarcely pubescent.

20. *Aspalathus Sericea*; *Silky Aspalathus*. Leaves fascicled, lanceolate, silky; peduncles terminal; two-flowered; banner almost naked; flowers large, smooth.

21. *Aspalathus Canescens*; *Hoary Aspalathus*. Leaves fascicled, subulate, tomentose, silky; flowers lateral; banners pubescent; corolla yellow, with a hoary pubescent banner.

22. *Aspalathus Heterophylla*; *Various-leaved Aspalathus*. Leaves of the branches fascicled, of the branchlets ternate, linear, hairy; spikes terminal; calix and corollas villose; flowers yellow.—All natives of the Cape.

23. *Aspalathus Indica*; *Small-flowered Aspalathus*. Leaves quinate, sessile; peduncles one-flowered; flowers pale red.—Native of the East Indies.

24. *Aspalathus Cretica*; *Evergreen Aspalathus*. Leaves trinate, wedge-shaped, smooth, the lateral ones shorter; stipules obsolete; flowers headed, very small, yellow.

25. *Aspalathus Quinquefolia*; *Five-leaved Aspalathus*. Leaves in fives, sessile; leaflets lanceolate; peduncles spiked; corollas tomentose.

26. *Aspalathus Tridentata*; *Three-toothed Aspalathus*. Leaves trine, lanceolate, smooth; stipules three-toothed, mucronate; flowers headed.

27. *Aspalathus Pilosa*; *Hairy Aspalathus*. Leaves tern, linear, villose; heads terminal, very hairy; corollas pubescent.

28. *Aspalathus Anthylloides*. Leaves trine, lanceolate, equal, subpubescent; stipules none; heads terminal.

29. *Aspalathus Laxata*; *Loose-leaved Aspalathus*. Leaves tern, linear, villose; flowers in bunches of five; calices woolly; stems prostrate, round; corolla smooth and yellow.

30. *Aspalathus Argentea*; *Silvery Aspalathus*. Leaves trine, linear, silky; stipules simple, mucronate; flowers scattered, tomentose, purple.

31. *Aspalathus Callosa*; *Callous Aspalathus*. Leaves trine, subulate, equal; stipules roundish; callous; flowers spiked, smooth, yellow.—The eight last species are natives of the Cape of Good Hope.

32. *Aspalathus Orientalis*; *Levant Aspalathus*. Leaves

ternate, lanceolate, pubescent; flowers in bunches of five; corollas yellow; calices pubescent; stems erect, angular.—Found in the Levant.

33. *Aspalathus Mucronata*. Leaves tern, polished; branches acuminate; flowers in racemes; stem smooth.

34. *Aspalathus Pinnata*; *Pinnate-leaved Aspalathus*. Leaves pinnate-quinata, obovate; peduncles headed.

35. *Aspalathus Pedunculata*; *Small-leaved Aspalathus*. Leaves fascicled, subulate, smooth; peduncles filiform, twice the length of the leaf.—It flowers in August.

36. *Aspalathus Candicans*; *Fair Aspalathus*. Leaves trine and fascicled, filiform, silky; flowers sublateral; banners naked.

37. *Aspalathus Arborea*; *Tree Aspalathus*. Leaves pinnate-quinata; racemes terminating. It is a middling-sized tree.—The five last, natives of the Cape.

Asparagus; a genus of the class Hexandria, order Monogynia. — **GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals six, cohering by the claws, oblong, erected into a tube; three alternately interior, reflex at the end, permanent. *Stamina*: filamenta six, filiform, inserted into the petals, erect, shorter than the corolla; anthera roundish. *Pistil*: germen turbinate, three cornered; style very short; stigma a prominent point. *Pericarp*: berry globular, umbilicated with a point, three celled. *Seeds*: two, round, angular on the inside, smooth. **ESSENTIAL CHARACTER.** *Corolla*: six parted, erect, equal. *Calix*: none; style very short; stigmas three; berry superior, three celled, two seeded.—The species are,

1. *Asparagus Officinalis*; *Common Asparagus*, or *Sperage*. Stem herbaceous, round, erect; leaves setaceous; stipules uniform, subsolitary.—It is propagated by seeds; sown broadcast, but not too thick, on a level bed of good rich earth, in the beginning of March: the bed must be afterwards trodden all over, to bury the seed. Keep it clear of weeds during the following summer, and towards the latter end of October, when the haulm is quite withered, you may spread a little rotten dung, about two inches deep, over the surface of the ground, which will preserve the young buds from being injured by the frost. In the following spring the young plants will be fit to remove. Prepare the ground by trenching, and burying therein a good quantity of rotten dung at the bottom of each trench, that it may lie at least six inches above the ground, and level the whole, after taking out all the large stones. In the beginning of April, with a narrow-pronged dung-fork, carefully fork up the roots, shaking them out of the earth, and separating them from each other, observing to lay their heads even, then range a very tight line across the plot of ground, throwing out by it a trench six inches deep, into which trench you may lay your roots, spreading them with your fingers, and placing them upright against the back of the trench, that the buds may stand forward, and be about two inches below the surface of the ground, and at twelve inches distance from each other; then with a rake draw the earth into the trench again, laying it very level, which will preserve the roots in their right position. Then remove your line a foot farther back, and proceed as before. A small crop of Onions may be sown at the same time, treading in the seeds, and raking the ground level. Six weeks after planting, you must cut up the weeds with a small hoe, and thin the Onions wherever they rise in bunches, cutting up those Onions which grow near to the *Asparagus* shoots. This must be three times repeated, until the Onions are fit to be pulled up, which is commonly in August, and is known by the falling down and withering of their greens. Some persons cut their *Asparagus* for use, in the second spring after planting, but it is better to defer it till the third year.

In the summer of the second year keep them free from weeds, digging the alleys between them in October, and forking the beds towards the end of the following March; observing every other year to lay some rotten dung from a Melon or Cucumber bed, all over the beds, burying some in the alleys; also at the time for digging them up. When they appear about four inches above ground, you may then cut them sparingly, only taking the larger buds, and suffering the small to run up to strengthen the roots; for the more you cut, the greater will be the increase of buds, but they will be smaller, and the roots sooner decay. A very prevalent error is, that which has long prevailed with those people who will not dung their Asparagus beds, because they think that the dung communicates a strong rank taste to the Asparagus. This is a great mistake, for the sweetest Asparagus grows upon the richest ground, and it is the poor land that occasions that rank taste so often complained of; the sweetness of Asparagus being also proved by experiment to arise from the quickness of its growth, which is always proportionable to the goodness of the ground, and the warmth of the seasons. Eight rods of ground will be sufficient to supply a small family, and double that quantity for a large one.—*Forcing Asparagus.* Some persons, who delight in having early Asparagus, force it in the following manner. They provide a quantity of good roots, either of their own raising, or purchased from such gardeners as plant for sale, such as has been two or even three years out from the seed-bed; and having fixed upon the time at which they would wish to have their Asparagus fit to cut, they prepare a quantity of new horse-dung about six weeks before, which is thrown into a heap for ten days or more in order to ferment, and having some sea-coal ashes mixed with it, they turn it over into a heap, where it must lie another week, when it will be fit for use. They then dig out a trench in the ground where they intend to make the bed, a foot and a half deep, of the width of the frames which are designed to cover it, and the length proportioned to the quantity which they design to raise: if it be only to supply a small family, three or four lights at a time will be sufficient, but for a larger family, six or eight lights will not be too much: they then lay down the dung into the trench, working it very regularly, and beating it down very tightly with a fork, laying it at least three feet in thickness, or more, when the beds are made in December; upon this they put the earth, taking great care to break the clods and lay it level, beginning at one end to lay the roots against a little ridge of earth, raised about four inches high, and as close as possible to each other, in rows, with their buds standing upright, with a small quantity of fine mould between every row, observing to keep the crown of the roots exactly level. When you have finished laying your beds with roots, you must lay some stiff earth up to the roots, on the outsides of the bed, which are bare, to keep them from drying; and thrust two or three sharp-pointed sticks about two feet long, down between the roots in the middle of the bed at a distance from each other. The use of these sticks is to inform you what temper of heat the bed is in, which you may find by drawing up the sticks, and feeling the lower part: and if after the bed has been made a week, you find it does not heat, you may lay a little straw or litter round the sides, and also upon the top, which will greatly help it; or if you find it very hot, so as to endanger scorching the roots, it will be advisable to let it remain wholly uncovered, and to thrust a large stick into the dung on each side of the bed in two or three places, to make holes for the great steam of the bed to pass off, which in a short time will reduce the bed to a moderate heat. After the bed has been made a fortnight, you must cover the crowns of the roots with fine earth about two inches thick,

and when the buds begin to appear above ground through that earth, you must again lay on a fresh quantity, about three inches thick; so that in the whole it may be five inches above the crowns of the root, which will be sufficient. Then you must make a band of straw, or long litter, about four inches thick, which must be fastened round the sides of the bed, that the upper part may be level with the surface of the ground; this must be fastened with straight sticks about two feet long, sharpened at the points to run into the bed; and upon this band you must set your frames, and put your glasses thereon; but if, after your bed has been made three weeks, you find the heat decline, you must lay a good lining of fresh hot dung round the sides of the bed, which will add a fresh heat thereto; and in bad weather, as also every night, keep the glasses covered with mats and straw; but in the day-time let it be all taken off, especially whenever the sun appears, which, shining through the glasses, will give a good colour to the Asparagus. A bed thus made, if it work kindly, will begin to produce buds for cutting in about five or six weeks, and will hold about three weeks in cutting; if rightly planted with good roots, it will produce in that time about three hundred buds in each light; so that where it is proposed to be continued until the season of natural Asparagus, a fresh bed should be made every three weeks, until the beginning of March, from the time of the first bed being made; but if the last bed be made about a week in March, it will last till the season of natural Asparagus; for the last beds will come a fortnight sooner to cut after making, than those made about Christmas; and the buds will be larger, and better coloured, as they will then enjoy a greater share of the sun. The best ground for planting Asparagus, to have large roots for hot-beds, is a moist rich soil; but for those intended for a natural produce, a middling soil, neither too wet nor too dry; yet a fresh sandy loam, when well dunged, is preferable to any other.

2. *Asparagus Declinatus; Long-leaved Asparagus.* Stem unarmed, round; branches declined; leaves setaceous. This species is higher than the common sort; the leaves also are twice as long, and more abundant; the stem is annual.—Native of the Cape of Good Hope.

3. *Asparagus Falcatus; Sickle-leaved Asparagus.* Prickles solitary, reversed; branches round; leaves ensiform, falcated; stem round and branching.—A native of Ceylon.

4. *Asparagus Retrofractus; Larch-leaved Asparagus.* Prickles solitary; branches round, reflected, and retrofracted; leaves setaceous, fasciated. It has very crooked irregular stalks, shrubby, and rising eight or ten feet high, putting out several weak side-branches, having long narrow leaves, in clusters like those of the Larch-tree; under each of these clusters is placed a single sharp thorn. The stalks continue several years, and the leaves retain their greenness through the winter.—It flowers in August and September; and is a native of the Cape of Good Hope.

5. *Asparagus Æthiopicus.* Prickles solitary, reversed; branches angulate; leaves lanceolate, linear. This resembles the third species; but the leaves are smaller, and about seven in a bunch.—Native of the Cape of Good Hope.

6. *Asparagus Asiaticus; Slender-stalked Asparagus.* Prickles solitary; stem erect; branches filiform; leaves fasciated, setaceous.—It is a native of Asia.

7. *Asparagus Albus; White Asparagus.* Prickles solitary; branches angular, flexuose; leaves fasciated, triquetrous, awnless, deciduous. The spines are straight, spreading, or reflex.—It is a native of the south of Europe, especially of Spain and Portugal.

8. *Asparagus Acutifolius; Acute-leaved Asparagus.* Stem

unarmed, angular, shrubby; leaves needle-shaped, rather rigid, perennial, mucronate, equal. This has white crooked shrubby stalks, which rise four or five feet high, but have no spines on them, the leaves come out in clusters like those of the Larch-tree, but are very short, and end in sharp prickles so that they are troublesome to handle.—It is a native of Spain, Portugal, and the Levant.

9. *Asparagus Horridus*; *Thorny Asparagus*. Leafless, shrubby, five-cornered; prickles four-cornered, compressed, striated. The spines are about the length of a finger.—It is a native of Spain.

10. *Asparagus Aphyllus*; *Prickly Asparagus*. Stem unarmed, angular, shrubby; leaves subulate, striated, unequal, diverging. The flowers are small, and of an herbaceous colour; the berries are larger than those of the common sort, and are black when ripe.—Native of the southern parts of Europe.

11. *Asparagus Capensis*; *Cape Asparagus*. Spines in fours; branches aggregate, round; leaves setaceous; root tuberous; stems shrubby, filiform, flexuose; spines spreading, a little recurved, very acute.—Native of the Cape of Good Hope.

12. *Asparagus Sarmentosus*; *Linear-leaved Asparagus*. Leaves solitary, linear-lanceolate; stem flexuose; prickles recurved. It sends out many weak climbing branches, which rise about five or six feet high from the root; the shoots are armed with short crooked spines, which are so closely set on that it is difficult to touch the branches.—The roots, which are long, fusiform, whitish, and fleshy, of a sweetish pleasant flavour, are eaten in Ceylon, (where it grows naturally,) with broth or milk, and the inhabitants appear to be very fond of them.

13. *Asparagus Verticillaris*; *Whorl-leaved Asparagus*. Leaves verticillate.—It was found by the French botanist Tournefort in the Levant, about Derbent, and in other parts of the East.

Asperugo; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, erect, with unequal toothlets, permanent. *Corolla*: one-petalled, funnel-shaped; tube cylindrical, very short: border semiquinquefid, obtuse, small; throat closed, with five convex, prominent, converging little scales. *Stamina*: filamenta five, in the throat, very short; antheræ oblongish, covered. *Pistil*: germen four, compressed; style filiform, short; stigma obtuse. *Pericarp*: none. *Calix*: very large, erect, compressed; lamellas flat-parallel, sinuate. *Seeds*: four, oblong, compressed, distant, by pairs. ESSENTIAL CHARACTER. *Calix*: of the fruit compressed; lamellas flat-parallel, sinuated.—The species are,

1. *Asperugo Procumbens*; *Procumbent Asperugo*. Calices of the fruit compressed; root annual; corolla scarcely exceeding the calix, deep blue, often white.—It is found in roads and among rubbish at Newmarket, Boxley in Sussex, Holy Island, and near Purfleet, flowering in April and May. Horses, goats, sheep, and swine, eat it, but cows are not partial to it. Small Wild Bugloss, or Borrage, Great Goosegrass, are also names under which it has been known.—It may be easily propagated by seeds sown in autumn; or, if they be permitted to scatter, the plants will come up of themselves.

2. *Asperugo Ægyptiaca*; *Egyptian Asperugo*. Calices of the fruit swelling; root annual, columnar, the thickness of a quill, red; stem half a foot high or more; flowers void of scent; petals pale yellow, and the scales of the throat yellow.—It flowers from June to August, and is a native of Egypt. It may be raised by seeds, but they must be sown in a mode-

rate hot-bed. The plants will flower in the open air in summer, but they must be housed in winter.

Asperula; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth small, four-toothed, superior. *Corolla*: one-petalled, funnel-shaped; tube cylindrical, long; border four-parted; divisions oblong, obtuse, reflex. *Stamina*: filamenta four, at the top of the tube; antheræ simple. *Pistil*: germen twin, roundish, inferior; style filiform, bifid at top; stigmas headed. *Pericarp*: two dry globular united berries. *Seed*: solitary, roundish, large. ESSENTIAL CHARACTER. *Corolla*: one-petalled, funnel-shaped; seeds two, globular.—All these plants, except the second species, being perennial, may be increased by the roots as well as by seeds. The first sort will prosper under the shade of shrubs in wilderness quarters. The fifth must have the protection of a green-house, and does not continue many years; but it may be increased both by seeds and cuttings. The eighth growing naturally in chalk, and most of the others being natives of rocky places, require a dry open situation.—The species are,

1. *Asperula Odorata*; *Sweet-scented Woodroof*. Leaves eight in a whorl, lanceolate; flowers in bunches, peduncled; root perennial, slender, jointed, yellowish, creeping a little below the surface, and sending out many small fibres.—Native of many parts of Europe, in woods, and shady places, flowering in May, and sometimes in April. The scent is pleasant; and when dried, this plant diffuses an odour like that of *Vernal Grass*, or *Anthox Anthrum Odoratum*. It is said to give a grateful flavour to wine; and when kept among clothes, not only to impart an agreeable perfume to them, but to preserve them from insects: cows, horses, sheep, and goats, are reported to eat it. Since it is known to contain an acrid principle, with much fixed alkaline salt, it is thought by some that it may be useful in obstructions of the liver and biliary ducts, although modern practitioners generally reject it. A strong decoction of the green herb opens obstructions of the viscera, and is good in the jaundice; it likewise strengthens the stomach, and is often taken as a cordial.

2. *Asperula Arvensis*; *Blue or Field Woodroof*. Leaves six in a whorl; flowers sessile, terminal, aggregate; root annual, slender, with a yellow bark; corollas blue, with streaks of darker blue; germs smooth.—The roots dye a fine red colour. It flowers in July, and is a native of France, Germany, and various parts of Italy.

3. *Asperula Taurina*; *Broad-leaved Woodroof*. Leaves four in a whorl, ovate, lanceolate, revolute, bluntish, pubescent; flowers in terminal bunches; roots perennial, red, branching, intertwined.—Flowering from April till June, and a native of Switzerland and Italy.

4. *Asperula Crassifolia*; *Thick-leaved Woodroof*. Leaves four in a whorl, oblong-lateral, revolute, bluntish, pubescent; the flowers are few, in terminal branches, pubescent on the outside.—Native of Crete, and the Levant; flowering in June.

5. *Asperula Calabrica*; *Calabrian Woodroof*. Leaves four in a whorl, oblong, lateral, revolute, bluntish, pubescent.—This is an undershrub, about a cubit high, prostrate, and extremely fetid in all its parts; which, with its shrubby stalks and leaves in pairs, sufficiently distinguishes this species. It flowers during most of the summer, and some part of the autumn; and is a native of Syria, between Aleppo and Antioch, and also of Calabria and Sicily.

6. *Asperula Tinctoria*; *Narrow-leaved Woodroof*. Leaves linear, the lowersix, the middle four, in a whorl; stem flaccid; flowers generally trifid, white: the whole plant is green and smooth.—In Gothland the roots are used instead of Madder

for dyeing wool of a red colour.—It is a native of Sweden, Germany, Switzerland, France, Carniola, and Siberia.

7. *Asperula Pyrenaica*; *Pyrenean Woodroof*. Leaves four in a whorl, lanceolate-linear; stem erect; flowers generally trifid, red; roots perennial.—Native of the Pyrenees, and about Basil.

8. *Asperula Cynanchica*; *Squinancywort*, or *Small Woodroof*. Leaves four in a whorl, linear, the upper ones opposite; stem erect; flowers quadrifid; roots perennial; stems from four inches to a foot and half in length, prostrate, hard, numerous, branching dichotomously. The corollas are bluish-coloured, elegantly marked with red lines; sometimes they are white. The flowers have a sweet smell.—It is found in France, Germany, Switzerland, Carniola, Italy, and the Levant: it abounds in many parts of England, on chalk-downs, as, about Dartford in Kent; in Epsom downs, Hertfordshire, Gog-magog hills, Newmarket heath, Swaffham in Norfolk, Armingale wood near Norwich, and on the Sussex downs. It flowers from June till August. This plant had formerly a great reputation for curing the quinsy, for which it was both internally and externally applied: it is now entirely obsolete.

9. *Asperula Aristida*; *Awn-flowered Woodroof*. Leaves linear, rather fleshy; the lower ones four in a whorl; stem upright; flowers subtern-awned, pale yellowish, placed parallel with the divisions, bluntly awned.—Native of the south of Europe.

10. *Asperula Lævigata*; *Shining Woodroof*. Leaves four in a whorl, elliptic, nerveless, smoothish; peduncles divaricate, trichotomous; seeds scabrous; stems simple, smooth, spreading; leaves subpetioled, obtuse, spreading, scarcely ciliate; flowering branches horizontal, bifid; two small lanceolate bracts; flowers usually in threes, peduncled, white.—It flowers in June and July; and is a native of the south of Europe.

11. *Asperula Hexaphyllia*; *Six-leaved Woodroof*. Leaves six in whorl, linear; flowers umbelled, terminal, sessile; root perennial; stems sometimes branching at the base, but generally simple; corollas purple, white within, the segments a little revolute; seeds oblong, compressed; the whole plant is smooth. It grows in the fissures of the rocks near Tende.

Asphodelus; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: one-petalled, six-parted; divisions lanceolate, flat, spreading; nectary six very small valves, converging into a globe, inserted into the base of the corolla. *Stamina*: filamenta six, subulate, inserted into the valves of the nectary, bowed, alternately shorter; antheræ oblong, incumbent, rising. *Pistil*: germen roundish, within the nectary; style subulate, in the same situation with the stamina; stigma truncate. *Pericarp*: capsule globular, fleshy, three-lobed, three-celled. *Seeds*: several, triangular, gibbous on one side. *Observe*: the filamenta decline in some, and are bowed outwardly in others. ESSENTIAL CHARACTER. *Corolla*: six-parted. *Nectary*: six valves covering the germen.—The *Asphodels* are pretty ornaments in a garden; and requiring but little trouble to cultivate, are the more acceptable.—The species are,

1. *Asphodelus Luteus*; *Yellow Asphodel*, or *King's Spear*. Stem leafy; leaves three-sided, striated.—The roots are composed of many thick, yellow fleshy tubers, joined into a head at the top, whence arise strong round single stalks, nearly three feet high, covering their whole length with long, three-cornered boat-shaped leaves, of a sea-green colour; the upper part of the stalk is adorned half way with yellow star-shaped flowers, which begin to open at bottom, so that on the same spike there is often a succession of flowers during a full month from the time of its beginning to flower, which is in June or

towards the end of May.—It is a native of Sicily, multiplying very fast by roots, which will soon overspread a large border if permitted to remain, or if the side shoots are not taken off.

2. *Asphodelus Ramosus*; *Branched Asphodel*, or *King's Spear*. Stem naked; leaves ensiform, keeled, smooth. The flowers are star-shaped, white, with a purple line running longitudinally along the outside of each segment; they grow in long spikes, flowering successively, from the bottom upwards, appearing in the first part of June, and producing seed in autumn.—It is a native of the south of Europe: immense tracts of land in Apulia are covered with it, and it affords excellent food for sheep. It does not increase very fast by roots, nor should it be often transplanted, for that will weaken it, so that the flower-stems will not rise so tall, or produce so many flowers, as when left undisturbed for some years; the best way therefore is to propagate it by seeds, which should be sown soon after they are ripe, on a warm border of light fresh earth: in the spring the plants will appear, when you should carefully clear them from weeds, and in dry weather they must be frequently watered: if this be done, at the following Michaelmas, the plants will be strong enough to bear transplanting, at which time you must prepare a bed of fresh earth in the flower nursery, into which you should plant the roots, at about six inches' distance every way; observing to plant them so low as that the top of the roots may be three or four inches under the surface of the bed; and some old tan or dung should be spread over the ground, to keep out the frost: in this bed they may remain one year, during which time they should be kept clear from weeds; by which time, the roots having acquired strength enough to produce flowers the following year, in autumn, when their leaves are decayed, they should be carefully taken up, and transplanted into the flower-garden, observing to place them in the middle of the borders, amongst other hardy kinds of flowers, where, being properly intermixed, they will create an agreeable variety, and continue a long time in flower.—Mothery recommends the bruised root to be applied to serophulous swellings, which, he says, it will speedily dissolve and disperse. This plant is of an acrid, heating, diuretic quality; and, taken internally, is said to be particularly useful in removing obstructions of the menstrual discharge: it has likewise gained the credit of being an excellent antispasmodic.

3. *Asphodelus Fistulosus*; *Onion-leaved Asphodel*. Stem naked; leaves stiff, subulate, striated, subfistulose. The roots are composed of many fleshy yellow fibres. The leaves spread out from the crown of the root close to the ground, in a large cluster; they are convex on their under side, but flat above, and hollow. The flower-stalks rise immediately from the root, and grow about two feet high, dividing upwards into three or four branches, which are adorned with white starry flowers, having purple lines on the outside, which appear in July and August, and ripen seed in October, soon after which the plants decay.—It grows naturally in the south of France, and the island of Crete. It is an annual plant and can be propagated by seeds only, which should be sown in the autumn, when they will be more certain to grow than if sown in the spring: when the plants are up, they will require no other trouble but to keep them clean from weeds, until they have put out four or five leaves, when they should be carefully removed to the place where they are designed to remain. If the seeds are permitted to scatter, the plants will come up without care, and those which are not removed will be the strongest plants, and produce a great number of flowers.

Asplenium; a genus of the class Cryptogamia, order Filices.—GENERIC CHARACTER. Fructifications disposed in right lines along the under disk of the frond.—Whoever desires to

cultivate any of these Ferns, must have walls, rocks, or heaps of stones, to set the hardy species in; or pots may be filled with loamy undunged earth, or sand, gravel, and lime rubbish for that purpose, placing them in the shade. Hart's-tongue has been raised from seed; but every species of the genus may be increased by parting the roots. Some of the foreign sorts must be placed under a common frame in winter; and it is evident, that such as are natives of the West Indies, and other hot climates, require the protection of a stove.—The species are,

**Fronde simple.*

1. *Asplenium Rhizophyllum*; *Root-leaved Spleenwort*. Fronds cordate, ensiform, undivided, top filiform, rooting; root fibrose; fructifications irregularly dispersed over the whole disk of the leaf in oblong spots. The ends of the fronds bend down to the ground, and there throw out roots, by which means this species of Fern propagates itself.—Native of North America.

2. *Asplenium Hemionitis*; *Mule's tongue* or *Mule's-Fern Spleenwort*. Fronds cordate-hastate, five-lobed, quite entire; stipes smooth and even. It is a low Fern, nearly allied to Hart's-tongue, not above six inches in height, with a fibrous root.—Native of Madeira and the south of Europe.

3. *Asplenium Scolopendrium*; *Hart's-tongue Spleenwort*. Fronds cordate-ligulate, quite entire; stipes hirsute; root black, hard, covered with scales, and emitting numerous strong black fibres.—The fronds are greatly subject to variation, and hence several varieties have been noticed by authors, as the Curled, Curved, Clustered, and Branching Hart's-tongue.—It is a native of most parts of Europe, in shady lanes, on walls and rocks, in wells, and damp caverns. Common in the north of England, and is in full seed from September till November.—The leaves, which were recommended as aperients and corroborants, in obstructions of the viscera, have been principally used in apozems and infusions. Ray recommends the plant, from his own experience, as a good medicine against convulsive disorders; but it is discarded from the present practice, although the common people indeed still use an ointment made with the leaves of this plant, as also with those of *Ophioglossum*, or *Alder's-tongue*, in burns and scalds. According to Hill, the expressed juice of the plant taken in small quantities, for a considerable length of time, is an excellent medicine in obstructions of the viscera, and has been known to cure many of the most obstinate chronic disorders, when all other means have proved ineffectual.

4. *Asplenium Nidus*; *Bird's-nest Spleenwort*. Fronds lanceolate, quite entire, smooth. The leaves are two feet long, broad, firm, thick, smooth, and streaked. It roots into the tops of trees. The leaves come out in a circle, are erect, and form a kind of umbel, in the middle of which birds make their nests.—Native of Java and the Society Isles.

5. *Asplenium Serratium*; *Serrate-leaved Spleenwort*. Fronds lanceolate, serrate, subsessile. The root consists of brown fibres, sending up eight or nine fronds about three inches long.—Native of woods in the inland parts of Jamaica.

6. *Asplenium Plantagineum*; *Plantain-leaved Spleenwort*. Fronds ovate-lanceolate, subternate: stipe four-cornered. The margin of the fronds is even, and the stipe smooth.—Native of Jamaica.

7. *Asplenium Lanceum*; *Lance-leaved Spleenwort*. Frond elliptic, entire, smooth: stipe round, scaly. It differs from the third species, in having a lanceolate frond, not cordate.—Native of Japan.

8. *Asplenium Bifolium*; *Double-leaved Spleenwort*. Fronds pinnate; leaflets lanceolate, subsinuate, connate.—Native of South America.

***Fronde Pinnatifida.*

9. *Asplenium Ceterach*; *Common Spleenwort*, or *Mil-waste*. Lobes alternate, confluent, obtuse.—Native of most parts of Europe, on old walls, and on the clefts of moist rocks; as, about Bristol; Bury, in Suffolk; Heydon, in Norfolk; Asheridge, in Hertfordshire; near Malham, Tarn, and many other places, in the northern counties. It is in seed from May till October. It has been recommended as a pectoral, and as an aperient in obstructions of the viscera and an infusion of the leaves has been prescribed for the gravel. It was recommended by the ancients for the various disorders of the spleen: and, although rejected from modern practice, is prescribed by Meyrick to be administered in a strong decoction of the whole plant for all obstructions of the liver and spleen, which it will remove, if persevered in; and is also excellent in those disorders which arise from the same cause.

10. *Asplenium Obtusifolium*; *Blunt-leaved Spleenwort*. Fronds subpinnate; pinnae obtuse, sinuate, decurrent, alternate.—Native of South America.

****Fronde pinnate.*

11. *Asplenium Nodosum*; *Knotted-stalked Spleenwort*. Pinnae opposite, lanceolate, quite entire.—Native of the West Indies, and Cochin-china.

12. *Asplenium Salicifolium*; *Willow-leaved Spleenwort*. Pinnae sickle-lanceolate, crenate from the base upwards, angular; height a foot and half.—Native of Jamaica and the Antilles.

13. *Asplenium Trichomanes*; *Common Maidenhair*. Pinnae roundish, crenate; roots small, consisting of brown capillary fibres.—Native of Europe, in the crevices of rocks and walls, and in shady places among stones. It is in seed from May to October. The country people sometimes give a tea or syrup of it, for coughs and other complaints of the thorax. A little of the syrup, mixed with water, makes a very pleasant draught. That which is brought from abroad has orange-flower water in it: but several different Ferns are used for Syrup of Capillaire.

14. *Asplenium Viride*; *Green Spleenwort*. Pinnae roundish, crenate, truncate at the base.—Native of moist rocks on the mountains of Yorkshire, Westmoreland, and North Wales.

15. *Asplenium Ebeneum*; *Ivory-stiped Spleenwort*. Pinnae lanceolate, subfalcate, serrate, eared at the base; stipe very glossy, simple.—Native of North America.

16. *Asplenium Dentatum*; *Tooth-leaved Spleenwort*. Pinnae wedge-shaped, obtuse, crenate, emarginate.—Native of South America and the West Indies.

17. *Asplenium Marinum*; *Sea Maidenhair*, or *Spleenwort*, or *Dwarf Sea-fern*. Pinnae obovate, serrate, gibbous, above obtuse, wedged at the base; fronds from three inches to a foot in length, but commonly about six inches.—Native of Sussex, Devonshire, Cornwall, Cumberland, Lancashire, Scotland, and Wales, on the rocks of the sea coast.

18. *Asplenium Cultrifolium*; *Sickle-leaved Spleenwort*. Pinnae sickle-lanceolate, gash-serrate, from the base downwards angular.—Native of the island of Martinico.

19. *Asplenium Rhizophorum*. Fronds rooting at top; pinnae ovate, repand, somewhat eared; very small ones, remote, quite entire. This seldom grows above ten or twelve inches in length, and is always found with the top bending towards the ground.—Native of Jamaica.

20. *Asplenium Monanthemum*; *One-flowered Spleenwort*. Pinnae trapezium shaped, obtuse, serrate, entire behind; one line of fructifications; fronds numerous, ascending, a foot high, frequently twisted, linear-lanceolate, acute, very smooth.—Native of the Cape of Good Hope.

21. *Asplenium Ruta Muraria*; *Wall-rue*, *Tentwort*, or *White*

Spleenwort. Fronds alternately decompose; leaflets wedge-shaped, crenulate.—It seeds from June till October, and is a native of Europe, in the fissures of walls and rocks. It was formerly employed as a medicine in coughs and obstructions but is now wholly out of repute.

22. *Asplenium Alternifolium*; *Alternate-leaved Spleenwort*. Fronds simply pinnate; leaflets alternate, wedge-shaped, gashed above. It differs from Wall-rue in having the stems more simple.—Native of Switzerland and Austria.

23. *Asplenium Adiantum Nigrum*; *Black Maidenhair*. Fronds subtripinnate; leaflets alternate; pinnae lanceolate, gash-serrate. In the leafing of this Fern there are varieties.—It seeds from April till October, and is a native of Europe; found in the fissures of rocks, and old walls, or among stones in shady places.

24. *Asplenium Lanceolatum*; *Lanceolate Spleenwort*. Fronds doubly pinnate, lanceolate; pinnae obovate, crenate; root crowned with tufts of long narrow dark scales.—Found on rocks near Tunbridge, and in Fayal.

25. *Asplenium Marginatum*; *Margined Spleenwort*. Pinnae opposite, cordate, lanceolate, submarginate, quite entire.—Native of South America.

26. *Asplenium Squamosum*; *Scaly-stiped Spleenwort*. Pinnae acuminate, gashed; stipe scaly.

27. *Asplenium Striatum*; *Striated Spleenwort*. Pinnae pinnatifid, obtuse, crenate; the terminal one acuminate.—This and the preceding are natives of South America.

28. *Asplenium Erosum*; *Lacerated Spleenwort*. Pinnae trapeze-oblong, striated, erose, eared at the base. Height from fourteen to eighteen inches. Stipe black and simple.—Native of Jamaica.

29. *Asplenium Japonicum*; *Japanese Spleenwort*. Pinnae acute, gash-pinnatifid, serrulate; stipe scaly at bottom, two feet high.—Native of Japan.

30. *Asplenium Resectum*; *Half-leaved Spleenwort*. Pinnae trapezium-shaped, acuminate, gash-crenate, entire behind; frond a foot high, lanceolate, acute, smooth.—Found in the Isle of Bourbon.

31. *Asplenium Bulbosum*; *Bulbous-rooted Spleenwort*. Pinnae lanceolate, slightly crenate; root bulbous; fructifications in oblique parallel lines.—Native of the mountains of Cochin-china, where the root is eaten.

32. *Asplenium Proliferum*. Fronds subsessile, broad-lanceolate, the first leaves obovate rooting at the end.—Native of Jamaica.

33. *Asplenium Pumilum*. Frond ternate; leaflets three-parted, gashed.—Native of Jamaica and Martinico.

34. *Asplenium Dimidiatum*. Pinnae trapeze-oblong, acuminate, angular upwards, entire, and flat downwards.—Native of Jamaica.

35. *Asplenium Fragrans*. Fronds subtripinnate; leaflets alternate; pinnae lanceolate, broadish, serrate at the tip.—Native of Jamaica.

36. *Asplenium Grandiflorum*. Pinnae alternate, lanceolate, subserrate, at the base rectangular, lower ones rounded.—Native of Jamaica.

37. *Asplenium Dissectum*. Pinnae lanceolate, gash-serrate, tailed at the tip.—Native of Jamaica.

38. *Asplenium Præmorsum*. Fronds tripinnatifid; pinnae somewhat wedge-shaped; pinnules erose, toothed at the tip.—Native of Jamaica.

39. *Asplenium Cicutarium*. Frond tripinnate, very smooth, the upper ones pinnatifid; leaflets lanceolate, entire.—It has a solid black root, covered with a hairy moss towards its top, whence rise nine or ten leaves, about three inches high.—Native of Jamaica.

40. *Asplenium Flaccidum*. Fronds pinnate; leaflets alternate, remote, pinnatifid, linear, stiff.—This, and the seven following, are natives of New Zealand.

41. *Asplenium Lucidum*. Fronds pinnate; leaflets opposite, oblong-ovate, acuminate, serrulate.

42. *Asplenium Polyodon*. Fronds pinnate; leaflets trapezoid, acuminate, acute, doubly serrate.

43. *Asplenium Obliquum*. Fronds pinnate; stipes scaly; leaflets oblong, opposite, acuminate, serrate, the outer margin shorter.

44. *Asplenium Obtusatum*. Fronds pinnate; leaflets opposite, oblong, obtuse, serrate.

45. *Asplenium Tenerum*. Fronds pinnate; leaflets rhomb-oblong, obtuse, gash-serrate.

46. *Asplenium Caudatum*. Fronds pinnate; leaflets pinnatifid, linear; bristle-shaped at the tip; segments blunt, gash-serrate at the tip; stipe rough with hairs.

47. *Asplenium Bulbiferum*. Fronds subbipinnate; leaflets decurrent, oblong, obtuse, pinnatifid; fructifications proliferous.

Assafœtida. See *Ferula*.

Assonia; a genus of the class Monadelphia, order Dodecandria—**GENERIC CHARACTER.** *Calix*: perianth double. *Outer*, three-leaved, unilateral, deciduous. *Inner*, one-leaved, five-parted; parts lanceolate, acute, reflex. *Corolla*: petals five, roundish, narrowed at the base, spreading, withering, affixed to the pitcher of the stamina. *Stamina*: filamenta fifteen, filiform, upright, shorter than the corolla, conjoined at the base into the form of a pitcher; antheræ oblong, subsagittate, erect; five, linear-lanceolate, somewhat erect, coloured, petal-formed straps between the stamina, proceeding from the pitcher. *Pistil*: germen roundish, five-furrowed; style simple, longer than the stamina, permanent; stigmas five, recurved. *Pericarp*: capsule subglobose or turbinate, five-celled; cells separable, bivalve. *Seeds*: solitary, or in pairs, subovate. **ESSENTIAL CHARACTER.** *Calix*: double, outer one-leaved or three-leaved, inner one-leaved. *Corolla*: five-petalled, without any tube affixed to the pitcher of stamina. *Filamenta*: connected in the form of a pitcher, with petal-shaped straps between them. *Style*: one or five. *Capsule*: five-celled. *Seeds*: not winged.—For the propagation and culture of plants of this genus, see *Hibiscus* and *Pentapetes*.—The species are,

1. *Assonia Populnea*. Leaves cordate, ovate acuminate; flowers corymbed. This is a middle-sized tree, the wood of which is sweet-scented, and blue in the centre, and becomes very hard when it has arrived at a certain age.—It is a native of hilly woods in the Isle of Bourbon, where it flowers in May.

2. *Assonia Palmata*. Leaves cordate, palmate, smoothish lobes seven, acute, serrate-crenate; flowers corymbed; stem arboreous, branched.—Flowers in May and June; native of the Isle of Bourbon.

3. *Assonia Acutangula*. Leaves cordate, roundish, three-cusped, crenate, at first tomentose; flowers racemed; stem arboreous; fruit shaped like a pear.—Native of the Isle of Bourbon.

4. *Assonia Angulata*. Leaves cordate, roundish, angular at top, serrate-toothed, tomentose; umbels numerous; common peduncles shorter than the petiole; fruit globular. Native of the Isle of Bourbon.

5. *Assonia Tiliæfolia*. Leaves cordate, roundish, acute, crenate; flowers raceme-corymbed; corolla an inch in diameter.—Native of the Isle of Bourbon.

6. *Assonia Tomentosa*. Leaves cordate, roundish, crenate, tomentose, with almost circular veins; flowers umbellid.—Native of Madagascar.

7. *Assonia Punctata*. Leaves ovate-lanceolate, long, quite entire, tomentose underneath, rugged with dots on the upper surface.—Native of the Isle of Bourbon.

8. *Assonia Decanthera*. Leaves ovate-acuminate, repand-crenate, smooth; stamina five, two-anthered; flowers small, umbelled, scarcely three lines in diameter; stem arborescent with a brown furrowed bark; germen five-cornered, one seed in each cell of the fruit.—Native of Madagascar.

9. *Assonia Umbellata*. Leaves cordate, ovate-oblong, acuminate, repand, smooth; flowers umbelled, globular.—Native of the Isle of Bourbon, where ropes are made of the bark.

10. *Assonia Ovata*. Leaves ovate, toothed, five-nerved, tomentose; style very small.—Native of the Isle of Bourbon.

11. *Assonia Ferruginea*. Leaves ovate-oblong, seven-nerved, ferruginous beneath; petioles, peduncles, and calices, tomentose; stem arborescent, from eight to ten feet high; the branches, especially the younger ones, clothed with a rufous nap; fruit tomentose, roundish, five-cornered.—Native of the Isle of Mauritius.

Aster; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common imbricate, the inner scales prominent a little at the end, the lower ones spreading. *Corolla*: compound, radiate; corollules hermaphrodite, numerous in the disk; females ligulate, more than ten in the ray. Proper of the hermaphrodite, funnel-shaped, with a five-cleft spreading border; of the female ligulate, lanceolate, three-toothed, at length rolling back. *Stamina*: hermaphrodite; filamenta five, capillary, very short; antheræ cylindric, tubulous. *Pistil*: hermaphrodite; germen oblong; style filiform, the length of the stamina; stigma bifid, spreading:—females germen and style the same; stigmas two, oblong, revolute. *Pericarp*: none. *Calix*: scarcely changed. *Seeds*: solitary, oblong, ovate; down capillary. *Receptacle*: naked, flattish. ESSENTIAL CHARACTER. *Receptacle*: naked. *Down*: simple. *Corolla*: rays more than ten. *Calix*: imbricate, lower scales spreading.—In the numerous species of this genus, the far greater part are hardy, herbaceous, fibrous-rooted, autumnal, flowering, showy, perennials, with annual stems, from one to five feet in stature. America has furnished a considerable number of them; and they are particularly adapted to adorn large borders and plantations of shrubs, in the latter season. Only two are annuals; five natives of Europe; and the first four species from the Cape, are shrubby plants of the green-house.—The species are,

**Shrubby.*

1. *Aster Taxifolius*; *Yew-leaved Starwort*. Under shrubby: leaves decurrent, subulate, channelled, ciliate; flowers terminal. Native of the Cape of Good Hope.—It produces no seeds in England, but may be propagated by cuttings any time during the summer. These should be planted in small pots filled with light earth, and plunged into an old hot-bed; where if they be shaded from the sun, and gently watered, they will put out roots in six weeks, when they may be placed in the open air, and in about a month after they should be separated, each into a small pot filled with light sandy earth. In October they must be removed into the green-house, and placed where they may enjoy as much free air as possible: but be secured from frost or damps, either of which will destroy them; so that they are much easier preserved in a glass-case, where they will enjoy more light and air than in a green-house; but they must not be placed in a stove, for artificial heat will soon destroy them.

2. *Aster Reflexus*; *Reflected-leaved Starwort*. Shrubby: leaves ovate, subimbricate, recurved, serrate-ciliate; flowers terminal; ray blood-red.—For the propagation and culture

of this plant, see the preceding species. Native of the Cape of Good Hope.

3. *Aster Crinitus*. Somewhat shrubby: leaves ovate-oblong, acute, tomentose underneath; calices terminated with a hair; peduncles terminal, leafy, one-flowered; ray of the flower blue. For the propagation and culture of this plant, see the first species.—Native of the Cape.

4. *Aster Fruticosus*; *Shrubby Starwort*. Shrubby: leaves linear, dotted; peduncles one-flowered, naked; flowers solitary, upon long slender peduncles, of a pale blue colour.—For the propagation and culture of this plant, see the first species.—Native of the Cape.

***Herbaceous, entire-leaved Peduncles naked.*

5. *Aster Tenellus*; *Bristly-leaved Starwort*. Leaves filiform, prickle-ciliate; calices hemispheric, with equal leaflets; disk of the corolla yellow; ray blue, often, and especially in the night, rolled back.—Native of the Cape of Good Hope. For the propagation and culture of this plant, see the first species of this genus.

6. *Aster Alpinus*; *Alpine or Great Blue Mountain Starwort*. Leaves subpatulate, rough with hairs, quite entire; stems simple, one-flowered; calix equal; stem-leaves two, seldom three; sometimes the ray of the flower is white. It seldom rises above nine inches high on the Alps, and, when transplanted into a garden, not above sixteen, with a large blue flower at the top of each stalk. It flowers in June, and grows wild on the Alps and Pyrenees.—There are two varieties of this species; one also a native of the Alps, the other of Austria.

7. *Aster Sibiricus*; *Siberian Starwort*. Leaves lanceolate, almost stem-clasping, serrate, hairy, scabrous; calices lax; leaflets lanceolate, acuminate, leafy, hispid; peduncles one-flowered; ray of the corolla blue.—It flowers in August, and is a native of Siberia.

8. *Aster Tripolium*; *Sea Starwort*. Leaves linear-lanceolate, quite entire, fleshy, smooth, three-nerved; calicine leaflets submembranaceous, obtuse; root perennial.—It is found in the Isle of Wight; flowers sometimes occur without any ray, and sometimes the ray is white. It is a native of salt marshes on the sea-coast of Europe, and by inland salt lakes in Germany and Siberia. It is frequent about Bristol, and not only on the coast, but in the interior parts of the kingdom, where Dr. Hokes, with good reason, supposes that its presence indicates the existence of salt-springs. It flowers in July and August. Morison observes, that in the morning the flowers being expanded, appear blue; the blue florets quickly vanishing, and the disk remaining, they then appear yellow; in the evening, these go off, and the white down of the seeds shows itself: it thus undergoes a triple change in the course of the day, and hence derives its name of Tripolium.

9. *Aster Amellus*; *Italian Starwort*. Leaves oblong-lanceolate, entire, scabrous; branches corymbed; calices imbricate subsquarrose; leaflets obtuse, the inner membranaceous, coloured at the end. The stems grow in large clusters from the root, and each of them branch at the top into eight or ten peduncles, each terminated by a single large flower, having blue rays with a yellow disk. It flowers in August or September, and in mild seasons will often continue till the middle of November.—It grows naturally in the valleys of Italy, Sicily and Narbonne; also in Austria, Carniola, Germany, and Switzerland, and is very common about Bienne. The leaves and stalks being rough and bitter, the cattle seldom browse upon them, so that they remain in the pastures after the grass is eaten bare, and make a fine appearance when full of flowers.—This species is propagated by parting the roots, soon after the plant is out of flower; for those which are

removed in the spring, will not flower so strong in the succeeding autumn. The roots should not be removed oftener than every third year, if expected to produce many flowers.

10. *Aster Divaricatus*; *Divaricate Starwort*. Branches divaricate; leaves ovate, serrate; floral leaves quite entire, rather obtuse, stem clasping; stems rough, about two feet high, dividing towards the top into many forked branches, diverging from each other. The flowers grow almost in an umbel, and appear in the beginning of September.—Native of Virginia.

***Herbaceous, entire-leaved; Peduncles scaly.

11. *Aster Hyssopifolius*; *Hyssop-leaved Starwort*. Leaves linear-lanceolate, drawn to a point at the base; quite entire, stiff; branchlets corymbed, fastigiate; leaflets frequently linear, imbricate; calices imbricate; stem a foot high; eight purple florets in the ray; pistil yellow.—Native of N. America.

12. *Aster Dumosus*; *Bushy Starwort*. Leaves linear, quite entire, smooth, those on the branchlets very short; branches paniced; calices cylindric, closely imbricate; stems upright, two feet high; flowers small, very white; disk yellow.—Native of North America.

13. *Aster Ericoides*; *Heath-leaved Starwort*. Leaves linear, quite entire, very smooth, those of the branchlets subulate, approximating, those of the stem elongated; calices subsquarrose; leaflets acute; stem smooth, three feet high.—Native of North America.

14. *Aster Tenuifolius*; *Fine-leaved Starwort*. Leave sub-linear, quite entire; peduncles leafy; stem five feet high, slender, angular, smooth, not branching much; flowers terminal, small, white.—Native of North America.

15. *Aster Linarifolius*; *Saboty-leaved Starwort*. Leaves linear, entire, mucronate, scabrous, stiff, upper ones lax, remote; calices imbricate; branches fastigiate; stem purplish; flowers terminal, solitary, few.—Native of North America.

16. *Aster Linifolius*; *Flax-leaved Starwort*. Leaves linear, entire, roughish; branches corymbed; fastigiate, with small leaflets; calices imbricate; rays about equal to the disk; stem two to three feet high, with many branches, terminated by a blue flower.—Native of North America.

17. *Aster Acris*. Leaves lanceolate, linear, stiff, quite entire, flat; flowers corymbed, fastigiate, of a pale bluish colour; peduncles leafy.—It grows naturally in the south of France, and in Italy, Spain, and Hungary.

18. *Aster Concolor*. Leaves ovate, sessile, quite entire; stem simple; raceme terminal; flowers of a pale blue colour. The whole plant tomentose.—Native of Virginia.

19. *Aster Rigidus*; *Stiff-leaved Starwort*. Leaves linear, alternate; flowers terminal, solitary; leaves small, stiff, many; stem woody, weak, not branching, terminated by one specious flower.—Native of Virginia.

20. *Aster Novæ Angliæ*; *New England Starwort*. Leaves lanceolate, quite entire, cordate, stem-clasping, hairy; calices longer than the disk, loose; leaflets linear lanceolate, nearly equal; stem hispid; stems many, five feet high, brown, terminated by large purple violet flowers, growing in a loose panicle, and expanding in August. The peduncles are so short, as scarcely to appear among the flowers.—Native of New England and Virginia.

21. *Aster Undulatus*; *Waved Starwort*. Leaves serrate, hairy, waved, lower cordate; petioles winged, dilated at the base; branchlets virgate; calices imbricate; stem hispid; flowers pale blue, inclining to white.—Native of N. America.

22. *Aster Grandiflorus*; *Catesby's Starwort*. Leaves stem-clasping, linear, quite entire, hispid, ciliate, those of the branches and calix reflex; each branch is terminated by a large blue flower.—Native of Virginia.

***Herbaceous; Leaves serrate, Peduncles smooth.

23. *Aster Cordifolius*; *Hart-leaved Starwort*. Leaves heart-shaped, acute, finely serrate, underneath hairy; petioles almost simple; branches paniced; stem rough with hairs.—Native of America, and of the northern parts of Asia.

24. *Aster Puniceus*; *Red-stalked Starwort*. Leaves stem-clasping, lanceolate-serrate, substabrous; branches paniced; calices surpassing the disk; leaflets linear-lanceolate, nearly equal; stem hispid; flowers on single peduncles, forming a corymb at top, and of a pale blue colour; they appear in September.—Native of North America.

25. *Aster Annuus*; *Annual Starwort*. Leaves somewhat hairy, the lower ones subovate, serrate, the upper lanceolate; calices hemispheric; leaflets subequal, strigose.—The seeds of this plant will scatter, and come up without care: annual.—A native of North America.

26. *Aster Vernus*; *Vernal Starwort*. Root-leaves lanceolate, quite entire, obtuse; stem almost naked, filiform, a little branching; peduncles naked.—Native of Virginia.

*****Herbaceous; Leaves serrate, Peduncles scaly.

27. *Aster Indicus*; *Indian Starwort*. Leaves ovate-oblong, serrate; floral leaves oval-lanceolate, quite entire; branchlets one-flowered; flowers terminal, solitary.—Native of Japan and China, flowering from August till October.

28. *Aster Lævis*; *Smooth Aster*. Leaves stem-clasping, oblong, quite entire, shining; root-leaves subserrate; branches simple, bearing about one flower; calices imbricate; peduncles leafy, subdivided; leaflets somewhat wedge-shaped, acute, thickened at the end; stem smooth; ray of the corolla blue.—Observed by Kalm in North America.

29. *Aster Mutabilis*; *Variable Starwort*. Leaves almost stem-clasping, lanceolate, serrate, glossy, drawn to a point below; branchlets virgate; calices somewhat leafy, lax; stem smooth; disk yellow to purple.—Flowers at the end of October.

30. *Aster Tradescanti*; *Tradescant's Starwort*. Leaves lanceolate, serrate, sessile, smooth; the middle branches virgate; calices closely imbricate; stem round, smooth. The ray of the corolla is first white, and afterwards becomes purplish.—Native of Virginia.

31. *Aster Novi Belgii*; *New Holland Starwort*. Leaves almost stem-clasping, lanceolate, smooth, but scabrous about the edge, the lower serrate; branches subdivided; calices loosely imbricate, leaflets linear-lanceolate; stem round, smooth; disk yellow; ray purple. The flowers appear at the latter end of August.—Native of Virginia and Pennsylvania.

32. *Aster Tardiflorus*; *Late-flowering Starwort*. Leaves sessile, lanceolate, drawn to a point at the base, serrate, smooth; calices lax; leaflets lanceolate-linear, subequal, smooth. Flowers in England, from July to September.—Native of North America.

33. *Aster Miser*; *Small White-flowered Starwort*. Leaves sessile, lanceolate, subserrate, smooth; calices imbricate; leaflets acute; disk equal to the rays.—Native of N. America.

34. *Aster Macrophyllus*; *Broad-leaved Blue Starwort*. Leaves serrate, oblong; the upper ovate, sessile, those on the stem cordate, petioled; upper petioles winged.—Native of North America.

35. *Aster Chinensis*; *Chinese Starwort, China Aster*. Leaves ovate, angular, toothed, petiolate; calices expanding, leafy, terminal.—The flowers of this species are the largest and handsomest of any belonging to the genus: the disk yellow, at first flat, then convex; the floscules of the ray broad and long, and scarcely notched at the end. It came originally from China to Europe, and is an annual plant, pro-

pagated by seeds, which must be sown in the spring on a warm border, or rather upon a gentle hot-bed, just to bring up the plants: for they should be inured to the open air as soon as possible, which will prevent them from being drawn up very weak; when they are three inches high they should be taken up, and planted in a bed of rich earth, at six inches distance every way, observing to shade them from the sun till they have taken root; and if the season proves dry, they must be often refreshed with water. In this bed they may remain a month or five weeks, by which time they will be strong enough to transplant into the borders of the flower-garden, where they are designed to remain; or into pots to adorn court-yards, &c. The plants should be taken up carefully, with large balls of earth to their roots, and the ground dug up and well broken with the spade, where the holes are made to receive the plants; and after they are planted with the earth closed about their roots, there should be some water given them to settle the earth. In August they will flower, by which time, if the ground be rich, they will be about two feet high, and furnished with many side branches, each terminated by a large radiated flower, forming one of the finest autumnal ornaments of the flower-garden. The seeds ripen in the beginning of October, and should be gathered when they are perfectly dry. In order to preserve the varieties with double flowers, those which grow upon the side branches, being commonly fuller of leaves than the flowers on the main stem, should always be preserved for seeds.—Besides the common varieties, white, blue, purple, and red, both single and double, there is now another in the gardens with variegated blue and white flowers.

36. *Aster Tataricus*; *Tartarian Starwort*. Root-leaves lanceolate-ovate, serrate, scabrous; stem few-flowered; ray of the corolla blue.—Native of Siberia.

37. *Aster Hispidus*; *Shaggy Starwort*. Lowest leaves oblong, crenate, scabrous; stem-leaves lanceolate, entire, ciliate; stem scabrous, erect, a foot high; flowers perennial, solitary; ray white.—Native of Japan.

38. *Aster Scaber*; *Rugged Starwort*. Leaves oblong, serrate, scabrous; peduncles panicled; stem herbaceous, a foot high.—Native of Japan.

Species from Miller, and from Aiton's Hort. Kew.

39. *Aster Glaber*; *Peach-leaved Starwort*. Leaves oblong-lanceolate, acute, serrate; stem branching; flowers terminal, pale blue; calices linear, erect.—Native of North America; flowering in October.

40. *Aster Serotinus*; *Late-flowering Blue Starwort*, or *Michaelmas Daisy*. Leaves oblong, acute, broader at the base, half stem-clasping; stem branching; flowers terminal, for the most part solitary; stems numerous, three feet and a half high, shooting out many lateral branches, terminated by pretty large flowers, very pale blue, tending to white.—Imported from Virginia.

41. *Aster Præcox*; *Early Starwort*. Leaves oblong, acute, scabrous, sharply-toothed, half stem-clasping; stem erect, hairy; flowers corymbed; calices hairy, erect; stems a foot and a half high; flowers large and blue, appearing in July.—Native of the Alps and Pyrenees.

42. *Aster Altissimus*; *Lofty Starwort*. See No. 24, *Aster Panicus*; *Red stalked Starwort*.

43. *Aster Ramosissimus*; *Branching Starwort*. Leaves linear-lanceolate, stiff; stem very branching, spreading; flowers placed regularly one above another; peduncles leafy; flowers small, pale, and purple, appearing in November.—Native of North America.

44. *Aster Umbellatus*; *Umbelled Starwort*. Leaves lanceolate, drawn to a point at the base, quite entire, about the

edge scabrous; branches corymbed, fastigate; ray of the flowers, which appear in July and August, white.—Native of Nova Scotia.

45. *Aster Nervosus*; *Three-nerved Starwort*. Leaves linear-lanceolate, acute, nerved; stem simple; flowers terminal, in a kind of umbel.—Native of Pennsylvania.

46. *Aster Paniculatus*; *Panicled Starwort*. Lower leaves ovate, half stem-clasping at the base; upper leaves lanceolate, small; stem panicled; branches one-flowered; peduncles leafy, height four feet; branches erect, forming a loose spike of large blue flowers.—Native of North America.

47. *Aster Latifolius*. Leaves linear-lanceolate, smooth, three-nerved; flowers corymbed, terminal. The stems a foot and a half high, terminated by peduncles on every side, each sustaining a pale blue flower.—Native of Canada.

48. *Aster Procumbens*; *Procumbent Starwort*. Leaves ovate, toothed; stem procumbent; peduncles naked, axillary, one-flowered; the calix is scaly.—From Vera Cruz. This species cannot endure the open air of England. The seeds must be sown in a hot-bed; and the plants will require a stove to protect them during the winter.

49. *Aster Holosericeus*. Herbaceous; leaves oblong-lanceolate, serrate, underneath silver-silky; scapes one-flowered, leafy.—Native of New Zealand.

50. *Aster Coriaceus*. Herbaceous; leaves ovate, quite entire, furrowed above, woolly underneath; scapes one-flowered, leafy, woolly.—Native of Zealand.

51. *Aster Cymbalariae*; *Cymbalaria-leaved Starwort*. Shrubby; leaves ovate, sinuate, rough with hairs; calices imbricate, rough with hairs.—It flowers most of the summer, and is a native of the Cape of Good Hope.

52. *Aster Nemoralis*; *Wood Starwort*. Leaves linear-lanceolate, drawn to a point at the base, somewhat scabrous; branches filiform, one-flowered; calices lax, imbricate; leaflets acute; stem a foot high; ray of the flower blue, disk white. It flowers in August.—Native of Nova Scotia.

53. *Aster Paludosus*; *Marsh Starwort*. Leaves linear, stem-clasping, quite entire, very smooth, scabrous at the edge; peduncles almost naked; calices squarrose; ray blue, large; disk yellow. Flowers appearing in September and October.—Native of the swamps of Carolina.

54. *Aster Patens*; *Spreading Hairy-stalked Starwort*. Leaves oblong, entire, acute, cordate, almost stem-clasping, scabrous; branches spreading, elongated, few-flowered; calices imbricate, sub-squarrose; stem rough with hairs; ray of the flower pale blue; disk tawny.—Native of Virginia, flowering in September and October.

55. *Aster Foliolosus*; *Leafy Starwort*. Leaves lanceolate-linear, quite entire, smooth, those on the branchlets spreading very much; calices imbricate; leaflets acute; stem pubescent.—It flowers in October, and is a native of North America.

56. *Aster Multiflorus* *Small-leaved Starwort*. Leaves linear, quite entire, smoothish; branches one-ranked; calices imbricate, squarrose; scales somewhat leafy, acute; stem pubescent; ray white, small.—It flowers in September and October, and is a native of North America.

57. *Aster Salicifolius* *Willow-leaved Starwort*. Leaves linear, lanceolate, quite entire, smooth; calices imbricate, lax; stem glossy, the height of a man; ray of the flower bluish flesh colour.—Native of North America.

58. *Aster Æstivus*; *Labrador Starwort*. Leaves lanceolate, almost stem-clasping, quite entire, smooth, scabrous about the edge; calices lax, with equal leaflets; ray blue. Native of North America; flowers in July and August.

59. *Aster Junceus*; *Slender-stalked Starwort*. Leaves

lanceolate-linear, sessile, smooth, the lowest subserrate, those of the branchlets lanceolate; branches virgate; calices imbricate; stem smoothish, four feet high; ray slightly flesh-coloured; disk elevated, pale yellow.—It flowers in October, and is a native of North America.

60. Aster Pendulous; *Pendulous Starwort*. Leaves elliptic-lanceolate, serrate, smooth, those of the branchlets rather remote; branches very much divaricated, pendulous; stem pubescent; ray of the flower white; disk yellow, changing to ferruginous. It flowers in October.—Native of North America.

61. Aster Diffusus; *Diffuse Starwort*. Leaves elliptic-lanceolate, serrate, smooth, proportioned; branches spreading; calices imbricate; stem pubescent; ray white.—Native of North America; flowering in September.

62. Aster Divergens; *Spreading Downy-stalked Starwort*. Leaves elliptic-lanceolate, serrate, smooth, those on the stem linear, lanceolate, elongated; branches spreading; calices imbricate; stem pubescent; ray white, shorter than the calix; disk reddish.—Native of North America.

63. Aster Corymbosus; *Corymbed Starwort*. Leaves cordate, smooth, acuminate, all finely serrate; petioles simple; branches fastigiate; stem smooth.—It flowers in September, and is a native of North America.

64. Aster Spectabilis; *Showy Starwort*. Leaves lanceolate, somewhat scabrous, the lower serrate; branches corymboid; calicine leaflets lax, nearly wedge-shaped, sharpish, squarrose; stem two feet high; ray blue.—It flowers in August and September, and is a native of North America.

65. Aster Radula; *Rough Starwort*. Leaves lanceolate, serrate, acuminate, wrinkled, very scabrous; calices imbricate; leaflets lanceolate, obtuse.—It flowers in September, and is a native of Nova Scotia.

Astragalus; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth-one-leafed, tubular, five-toothed, acute; lower toothlets gradually less. *Corolla*: papilionaceous, banner longer than the other petals, reflex on the sides, emarginate, obtuse straight; wings oblong, shorter than the banner; keel length of the wings, emarginate. *Stamina*: filamenta diadelphous, simple, and nine-cleft, almost straight; antheræ roundish. *Pistil*: germen nearly columnar; style subulate, ascending; stigma obtuse. *Pericarp*: legume two-celled, the cells bent to one side, with a longitudinal bifid septum parallel to the valves. *Seeds*: kidney-shaped.—ESSENTIAL CHARACTER. *Legume*: two celled, gibbous.—Every species of this genus may be raised from seeds: these should be sown in April on an open border of light earth; the annual sorts where they are to remain; the perennials to be transplanted to the places for which they are destined. They are in general hardy, and require no other care but to draw the plants out where they come up too thick, leaving them a foot and half or two feet asunder, and to keep them clean from weeds.—The species are,

* *Stems leafy, erect; not prostrate.*

1. *Astragalus Alopeuroides*; *Fox-tail Milk Vetch*. Caulescent; spikes cylindrical, subsessile; calices and legumes woolly.—The flowers, which are yellow, are produced in June or July, and ripen the seeds in September.—Native of the Alps, and Siberia.

2. *Astragalus Christianus*. Caulescent, erect; flowers glomerate, subsessile, from all the leafy axillas. The flowers are large, and of a bright yellow colour; they appear in July, and in very favourable seasons are succeeded by seeds in England, and will only succeed when planted in a warm border.—It is a native of the Levant.

3. *Astragalus Capitatus*. Caulescent: heads globular;

peduncles very long; leaflets emarginate. From the axils come out long peduncles supporting a head of purple flowers, which appear in July, but are rarely succeeded by pods in England.—Discovered in the Levant by Tournefort. This species must be raised on a moderate hot-bed in the spring, and when the plants are fit to remove, they should be each put into a small pot filled with light earth, and plunged again into the hot-bed, shading them from the sun till they have taken root; after which they should have free air admitted to them daily, in proportion to the warmth of the season, and should be frequently and gently watered. In May they should be removed to a sheltered situation, where they may remain till October, when they should be placed under a common frame. In the spring they may be turned out of the pots, and planted in a warm border, where they will flower, and sometimes produce seeds. If the winter prove very severe, a little old tan should be laid over the roots.

4. *Astragalus Pilosus*; *Pale-flowered Milk Vetch*. Caulescent, erect, hairy: flowers in spikes; legumes subulate, hairy; root woody, perennial. It flowers from June till August; the corolla is of a light yellow colour.—Native of the Valais, Siberia, Thuringia, and Austria.

5. *Astragalus Sulcatus*; *Furrowed Milk Vetch*. Caulescent, erect, smooth, striated, stiff: leaflets linear-lanceolate, acute; legumes three-sided; root perennial, woody; corollas pale violet; seeds many, brown, shining, round, kidney-shaped. It flowers in the open air in June and July, and ripens seed in August. A native of Siberia.

6. *Astragalus Galegiformis*; *Goat's Rue-leaved Milk Vetch*. Caulescent, stiff, smooth; flowers in racemes, pendulous, small, yellow; legumes three-sided, mucronate at both ends; root perennial.—It flowers in June or July, ripens seeds in autumn, and is a native of Siberia. To cultivate this plant, you must place it in an open situation and dry soil.

7. *Astragalus Chinensis*. Caulescent, stiff, smooth; flowers in racemes, pendulous; legumes ovate, inflated, mucronate at both ends. The colour of the calix is greenish yellow; of the banner pale yellow, streaked with green at the base; of the wings and keel, white with yellow tips; the flower itself finally becomes white.—It is a native of China, as its name imports. For the propagation and culture of this species, see the third species of this genus.

8. *Astragalus Onobrychis*; *Purple-spiked Milk Vetch*. Caulescent, procumbent, diffused: spikes peduncled; banner twice as long as the wings; leaflets linear; corollas red: it flowers in June and July.—Native of Austria.

9. *Astragalus Uliginosus*; *Violet-coloured Milk Vetch*. Caulescent, almost upright: flowers in spikes; legumes almost upright, naked, tumid, round-flatted; point reflex.—It flowers from June till August.—Native of Siberia.

10. *Astragalus Carolinianus*; *Carolina Milk Vetch*. Caulescent, upright, even: peduncles in spikes; flowers greenish yellow; legumes ovate-cylindric, acuminate by the style; root perennial. It flowers in July and August; but unless the season be warm, seldom ripens seed in England.—Native of Carolina. For the culture and propagation of this plant, see the third species of this genus.

11. *Astragalus Asper*; *Rough Milk Vetch*. Caulescent, stiff, even, roughish; flowers pale, in spikes, on elongated peduncles; legumes oblong.—Native of Astracan.

** *Stems leafy, diffuse.*

12. *Astragalus Canadensis*; *Woolly Milk Vetch*. Caulescent, diffuse; legumes subcylindric, mucronate; leaflets almost naked; corollas all yellow; antheræ saffron-colour.—Native of Virginia and Canada. For the propagation and culture of this species, see the third species of this genus.

13. *Astragalus Cicer*; *Bladdered Milk Vetch*. Caulescent, prostrate: legumes subglobular, inflated, mucronate, hairy; root thick, sweet; corollas pale yellow. It flowers in July, and the seeds ripen in autumn. This species is recommended to be cultivated as the food for cattle.—It is a native of Italy, Austria, Switzerland, and Germany.

14. *Astragalus Microphyllus*; *Small Round Podded Milk Vetch*. Caulescent, erect, expanding: leaflets oval; calices rather tumid; legumes roundish; corollas yellow, twice as long as the calix.—Native of Siberia and Germany, flowering in June and July.

15. *Astragalus Glycyphyllus*; *Wild Liquorice*, or *Liquorice Vetch*. Caulescent, prostrate: legumes subtriquetrous, bowed; leaves oval, longer than the peduncle; corolla greenish yellow. It spreads much at the root in gardens. The leaves are sweet with a mixture of bitterness, and do not seem to be agreeable to cattle, at least the plant in its wild state is left untouched; otherwise this being the largest of the European species, it might have been desirable to cultivate it.—Native of most parts of Europe, in woods, hedges, and pastures, especially in a calcareous soil. Its flowers appear in June, its seeds in September.

16. *Astragalus Hamosus*; *Dwarf Yellow-flowered Milk Vetch*. Caulescent, procumbent: legumes subulate, recurved, smooth; leaflets obcordate, villose underneath; root annual; flowers of a pale yellow colour.—Native of Messina and Montpellier.

17. *Astragalus Contortiplicatus*; *Wave-podded-Milk Vetch*. Caulescent, procumbent: legumes writhed, channelled, villose. This is an annual plant, and varies wonderfully in size and height in different soils.—Native of Siberia.

18. *Astragalus Boëticus*; *Triangular-podded Milk Vetch*. Caulescent, procumbent: spikes peduncled; flowers yellow; legumes prismatic, straight, three-sided, hooked at top. Annual, flowering in July, and ripening seeds in autumn.—Native of Spain, Portugal, and Sicily.

19. *Astragalus Laxmanni*. Caulescent, procumbent: spikes elongated: legumes oblong, three-cornered, marked with a furrow, mucronate, villose; root perennial, branching; corolla pale blue; antheræ yellow.—It flowers in June and July, and is a native of Siberia.

20. *Astragalus Stella*. Caulescent, diffuse: heads peduncled, lateral; legumes straight, subulate, mucronate; corollas bluish purple.—Native of Montpellier.

21. *Astragalus Sesameus*; *Starry Milk Vetch*. Caulescent, diffuse: heads sessile, lateral; legumes subulate, reflected at the point. It is an annual plant; flowering in June and July, and a native of France and Italy.

22. *Astragalus Austriacus*; *Austrian Milk Vetch*. Caulescent, prostrate, smooth, striated, weak: leaflets sublinear, emarginate; legumes round; root perennial, woody; flowers bluish, small, and without smell: they appear in May and June.

23. *Astragalus Leontinus*. Caulescent, prostrate: legumes ovate, villose; flowers spiked, erect, whitish or pale blue. This plant has no smell.—Native country unknown.

24. *Astragalus Pentaglottis*. Caulescent, procumbent: legumes headed, folded back, compressed, converging, crested, with a reflected point. It flowers in the beginning of August, and bears seed at the end of the same month.—Native of Spain.

25. *Astragalus Epiglottis*; *Heart-podded Milk Vetch*. Caulescent, procumbent: legumes headed, sessile, nodding, cordate, mucronate, folded back, naked. The plant is an annual, with largish flowers of a deep purple colour. It flowers in July, and ripens seed in autumn.—Native of Provence, Spain, Portugal, and of mountainous woods in the Levant.

26. *Astragalus Hypoglottis*; *Purple Mountain Milk Vetch*. Caulescent, prostrate: legumes headed, ovate, folded back, compressed, hairy, with a reflex point; root perennial; corolla bluish, purple, large, and handsome.—Native of sandy and chalky pastures, flowering from May till July. It varies with naked leaves and white flowers. It requires a shady situation and a strong soil.

27. *Astragalus Syriacus*; *Syrian Milk Vetch*. Caulescent, procumbent: heads peduncled; flowers reflected; legumes tomentose, ovate-oblong.—Native of Siberia.

28. *Astragalus Arenarius*. Subcaulescent, procumbent: flowers subracemed, erect; leaves tomentose; root perennial, filiform; corolla blue, without blue streaks.—Native of Scania, in loose sand.

29. *Astragalus Glaux*; *Small Milk Vetch*. Caulescent, diffuse; heads peduncled, imbricate, ovate; flowers erect; legumes ovate, callous, inflated.—Native of Spain.

30. *Astragalus Sinicus*; *Chinese Astragalus*. Caulescent, prostrate; umbels peduncled; legumes prismatic, three-sided, erect, subulate at top; root annual.—The flowers appear in July and August, and the seeds ripen in autumn. It grows naturally in China. For the propagation and culture of this species, see the third species of this genus.

31. *Astragalus Alpinus*; *Alpine Milk Vetch*. Caulescent, procumbent; flowers pendulous, racemed; legumes acute at both ends, hairy; stems rather more than a foot high; flowers specious, white; banner the length of the keel, blue with deeper-coloured lines, white at the base; wings stiff, short, narrow, hooked, white; keel white, with a broad obtuse beak.—Native of the mountains of Switzerland and Lapland.

32. *Astragalus Ammodytes*. Caulescent, undershrubby: flowers twin; legumes ovate, twin, woolly. Annual.—Native of the sandy hills of southern Siberia.

33. *Astragalus Trimestris*; *Egyptian Milk Vetch*. Subcaulescent: scapes mostly two-flowered; legumes hooked, subulate, two-keeled; root annual.—Native of Egypt, flowering in June and July, and ripening its seeds in August. This requires to be planted in a warm border.

*** *Scape naked, with a leafy Stem.*

34. *Astragalus Verticillaris*. Leaflets aggregate, semiverticilled.—Native of eastern Siberia, beyond the lake Baikal.

35. *Astragalus Montanus*. Nearly stemless: scapes longer than the leaf; flowers loosely spiked; erect; legumes ovate, with an inflected point.—Native of the mountains of Spain. This plant requires a shady situation and a strong soil.

36. *Astragalus Vesicarius*. Scapes longer than the leaves; flowers loosely spiked; calices and legumes inflated, hirsute; root perennial; banner of the corolla purple; wings yellow, keel white.—Native of Dauphiny and Siberia.

37. *Astragalus Physodes*. Scapes equal to the leaves; legumes inflated, subglobular, naked; root perennial, creeping; flowers in a spike, yellow, appearing in June.—Native of Siberia. It requires a shady situation and a strong soil.

38. *Astragalus Caprinus*. Scape erect; leaflets ciliate; legumes ovate, tumid, villose; root perennial, creeping; flowers pale yellow, very fragrant.—Native of Barbary and Russia.

39. *Astragalus Uralensis*; *Silly Milk Vetch*. Stemless: scape erect, longer than the leaves; legumes subulate, inflated, villose, erect; root long, woody; flowers pale violet colour.—Native of Dauphiny, Carinthia, the Pyrenees, and Siberia; also of mountainous pastures in Scotland. It requires an open situation and dry soil.

40. *Astragalus Monspensulanus*; *Montpellier Milk Vetch*. Scapes declining, the length of the leaves; legumes subulate,

round, rather bowed; smooth; root very large, woody, sweet. The raceme contains nearly thirty purple flowers.—Native of the south of France, the lower Valais, and the Grisons.

41. *Astragalus Incanus*. Scapes declining; leaflets tomentose; legumes subulate, rather bowed, hoary, incurved at top; root perennial.—Native of the south of France.

42. *Astragalus Campestris*; *Field Milk Vetch*. Calices and legume villose; leaflets lanceolate, acute; scape decumbent, bearing ten or twelve flowers in a loose raceme; corollas pale yellow.—Native of Switzerland and Germany.

43. *Astragalus Depressus*; *Dwarf White-flowered Milk Vetch*. Scapes shorter than the leaf; legumes nodding; leaflets submarginate, naked; corollas small, white; keel purple at the tip.—Native place unknown.

44. *Astragalus Uncatus*. Scapeless; legumes subulate, hooked, longer than the leaf; leaflets obovate.—It flowers in July and August, and the seeds ripen in autumn, and is found growing naturally in the neighbourhood of Aleppo.

45. *Astragalus Exscapus*; *Hairy podded Milk Vetch*. Scapeless; legumes woolly; leaves villose; flowers numerous, radical, subsessile, first pale and afterwards full yellow.—Native of Hungary. This plant has been much celebrated as a remedy in syphilitic complaints; the root is employed in decoction, half an ounce to a pint of water, to be taken warm night and morning.

**** Stem woody.

46. *Astragalus Tragoides*. Nearly stemless; flowers radical, numerous, subsessile; corollas yellow.—Native of Switzerland, Siberia, and Armenia.

47. *Astragalus Tragacantha*; *Goat's Thorn*. Trunk arborescent; petioles becoming spinescent; root large, woody, and branching; corollas long, stiff, of a pale violet colour.—Native of Switzerland, Mount Ætna, Mount Olympus, and of the sea-shore near Marseilles. Mr. Miller describes four varieties of this species.—From this plant is gathered the gum called gum-tragacanth, so much used in various preparations of the materia medica. It differs from all other known gums, in giving a thick consistence to a much larger quantity of water, and in being difficultly soluble, or dissolving only imperfectly. When put into water, it imbibes slowly a great quantity of the fluid, swells into a large volume, and forms a soft but not fluid mucilage. The demulcent qualities of this gum are to be considered as similar to those of gum-arabic. It is seldom given alone, but frequently in combination with more powerful medicines, especially in the form of troches, for which it is peculiarly well adapted.—It may be propagated by seeds, if they can be procured from abroad, in the same manner with the others. They should be carefully taken up when large enough to transplant, and some of them reset in small pots filled with fresh earth, placed in the shade till they have taken root; after which they may be removed into an open situation, where they may remain till the end of October, when they should be placed under a common frame, to shelter them from severe frosts, and allow them free air in mild weather. The remainder of the plants may be set on a warm dry border. The plants in pots may be preserved a year or two under frames in winter, and then being taken out of the pots, may be planted in a lean dry soil and warm situation. These plants may also be increased by slips; and as they rarely produce seeds in this country, the latter method is generally used here. The best time for this work is in April, just as the plants begin to shoot, at which time the tender branches should be slipped off, and their lower parts divested of the decayed leaves; then they should be placed on a very moderate hot-bed, which must be covered with mats, to screen them from

the heat of the sun by day, and the cold by night. These slips should be frequently but gently watered, until they have taken root; after which they may be exposed to the open air, and in very dry weather they must be refreshed with water. On this bed they may remain until the following spring, being covered with mats in very severe weather. In April they may be transplanted, either into pots filled with light sandy earth, or into warm borders; where, if the soil be dry, gravelly, and poor, they will endure almost the severest cold of our climate; but if planted in a very rich soil, will often decay in winter.

48. *Astragalus Fœtidus*. Stemless; leaves prostrate, viscid, sharply linear; scapes erect, with few yellow flowers.—Native of Dauphiny and of Mount Cenis.

49. *Astragalus Halleri*. Scapes leafless; leaves ovate-lanceolate, smooth; legumes inflated, hirsute, erect.—Native of the mountains of the Valais, and of Piedmont.

50. *Astragalus Vulneraroides*. Stemless, hirsute; scapes longer than the leaves; legumes inflated, ovate, in heads.—Native of Mount Cenis.

51. *Astragalus Tenuifolius*; *Upright Milk Vetch*. Cauliscent, erect; spikes peduncled; banner twice as long as the wings; leaflets linear.—Flowers in July and August; a native of Siberia.

52. *Astragalus Virescens*; *Green-flowered Milk Vetch*. Cauliscent, erect; legumes bent back; peduncles many-flowered, longer than the leaf; leaflets lanceolate, acute.—It flowers in June, and is a native of Siberia.

53. *Astragalus Garbancillo*. Stem shrubby, upright; pinnules ovate-oblong, somewhat tomentose; peduncle naked, elongated; spikes of flowers pale violet-coloured. It is reported to be very hurtful to cattle.—Native of Peru.

54. *Astragalus Hispidus*. Cauliscent, procumbent; leaflets and legumes ovate-oblong, hispid; flowers in spikes, yellow; corollas shorter than the calix; seeds very few, kidney-shaped.—Native of Mount Libanus.

55. *Astragalus Emarginatus*. Almost stemless; scapes very long; heads globose; legumes woolly; flowers in a globose head, purplish; seeds very few, nearly kidney-shaped.—Native of Mount Libanus.

56. *Astragalus Lanatus*. Stemless, with a naked scape, the length of the leaves; legumes in close spikes, woolly, half cordate, three-sided, subulate; leaves villose; flowers in a close spike, yellow; seeds few, kidney-shaped.—Native of Mount Libanus.

57. *Astragalus Leucophæus*. Cauliscent, procumbent; legumes subcylindric, straight, smooth; leaflets obovate, villose underneath.—Native country unknown.

58. *Astragalus Deflexus*. Subcauliscent, prostrate; scapes twice as long as the leaf; legumes gaping; leaves pectinate, right-angled.—Native of the loftiest mountains of Siberia.

59. *Astragalus Unifolius*. Suffruticose, procumbent; stipules solitary, stem-clasping, opposite to the leaves, bifid.—Native of Peru.

60. *Astragalus Varius*. Cauliscent, fruticulose, upright; flowers in loose spikes; legumes linear; stipules fuliginose downwards. This is a hoary little shrub, about a cubit high, with flowers subsessile, purple, with linear, acute, villose bracts; stem upright, round, branched from the base.—Native of Siberia.

61. *Astragalus Aristatus*. Suffruticose, prostrate; leaves hairy; petioles spinescent; calices awned; flowers purple.—Native of Switzerland and Provence.

62. *Astragalus Pugniformis*. Shrubby, procumbent; heads stem-clasping, tomentose; petioles and leaves pun-

gent and smooth.—This species is remarkable for the largeness of the heads or balls of flowers, which are almost as large as those of the first species.—Native of the Levant.

63. *Astragalus Echinoides*. The leaves are minute; the flowers small, white, with a purple line on the banner; peduncles axillary, short, two-flowered.—Native of Crete or Candia.

Astrantia; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel universal with very few rays (often three); partial with very numerous ones. Involucre universal, with leaflets double to the ray; partial with leaflets (about twenty) lanceolate, spreading, equal, coloured, longer than the umbellule. Perianth proper, five-toothed, acute, erect, permanent. *Corolla*: universal uniform; floscules of the ray abortive; proper with petals five, erect, inflex, bifid. *Stamina*: filamenta five, simple, the length of the corollule; anthera simple. *Pistil*: germen oblong, inferior; styles two, erect, filiform; stigmas simple, spreading. *Pericarp*: fruit ovate, obtuse, crowned, striated, bipartite. *Seeds*: two, ovate-oblong, covered with the crust of the pericarp, wrinkled. **ESSENTIAL CHARACTER.** *Partial Involucres*, lanceolate, spreading, equal, longer, coloured. *Flowers*, very many, abortive. All the plants of this genus, except the fourth species, are very hardy, and may be propagated either by sowing their seeds, or by parting their roots. If from seeds, they should be sown in autumn soon after they are ripe, on a shady border; and when the plants are come up, they should be carefully weeded, drawing out some wherever they are found to be too close, in order that the others may have room to grow, until Michaelmas, when they should be transplanted where they are to remain, which should always be in a moist soil and a shady situation. They should be planted three feet asunder, as their roots will spread to a considerable width, if they be permitted to remain long in the same place. They require no other culture but to keep them clear from weeds, and every third or fourth year to be taken up at Michaelmas, and their roots parted, and planted again. They are seldom preserved except in botanic gardens, as there is no great beauty in the flowers.—The species are,

1. *Astrantia Major*; *Great Masterwort*. Leaves five-lobed, lobes trifid; stem eighteen inches high, branched a little.—It is a native of the mountains of Switzerland, where it was found abundantly, flowering in August. Its singularity has long obtained for it a place in our gardens, where it flowers in June and the succeeding months of summer. The whole plant has a warm aromatic taste, but little is known respecting its virtues, except that it is a violent purgative.

2. *Astrantia Carniolica*. Leaves five or seven lobed, simple or bifid; root nearly the thickness of the little finger, about an inch long, præmorse, dark brown, having an aromatic balsamic smell, with a taste at first slightly aromatic but nauseous, and afterwards acrid. The whole plant is smooth.—Native of Carniola; flowering there in July and August.

3. *Astrantia Minor*; *Little, or Alpine Masterwort*. Leaves digitate-serrate. This seldom rises a foot high.—Native of the Alps, and Alpine valleys of Switzerland, but not of the lower mountains, flowering there in August.

4. *Astrantia Ciliaris*. Leaves lanceolate, serrate-ciliate; stem simple, a foot high; rushes erect.—Native of the Cape of Good Hope. This species always requires to be protected by a dry-stove in winter.

5. *Astrantia Epipactis*. Leaves five-parted, obtuse-serrate; flowers in a head, yellow.—Native of Idria, Gorizia, and also of Hungary, flowering in March.

Astronium; a genus of the class Diœcia, order Pentandria.—**GENERIC CHARACTER.** *Male.* *Calix*: perianth five-leaved, coloured, small; leaflets ovate, concave, obtuse, spreading. *Corolla*: petals five, ovate, very obtuse, flat, spreading very much. Nectary, five roundish, very small glands in the disk of the flower. *Stamina*: filamenta five, subulate, spreading, the length of the corolla; anthera oblong, incumbent. *Female.* *Calix*: perianth five-leaved, coloured; leaflets oblong, concave, obtuse, converging. *Corolla*: petals five, subovate, obtuse, concave, erect, less than the calix, permanent. *Pistil*: germen ovate, obtuse; styles three, short, reflex; stigmas subcapitate. *Pericarp*: none. *Calix* increased, coloured; its leaflets at first expanded into a pendulous star, at length dropping the seed. *Seed*: one, oval, the length of the calix, lactescent. **ESSENTIAL CHARACTER.** *Male.* *Calix*: five-leaved. *Corolla*: five-petalled. *Female.* *Calix*: five-leaved. *Corolla*: five-petalled. *Styles*: three. *Seed*: one.—The following is the only species:

1. *Astronium Graveolens*. An upright tree, from twelve to thirty feet in height, abounding every where in a slightly glutinous terebinthine juice, which has a disagreeable smell. After the fruits of the female, and the flower in the male plants, have fallen off, new branches are put forth, having unequally pinnate leaves on them, with three pairs of leaflets, which are oblong, ovate, acuminate, quite entire or serrulate, smooth, veined, three inches in length. Panicles lax, half a foot long in the males, but a foot and a half long in the females, scattered on the outmost twigs; flowers small, red. The calices are expanded into stars, nine lines in diameter.—Native of the woods about Carthage in New Spain; flowering in May and June, and fruiting in July.

Athamanta; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel, universal, manifold; spreading; partial, has few rays. Involucre universal, many-leaved, linear, a little shorter than the rays; partial linear, equal with the rays. Perianth proper, obscure. *Corolla*: universal, uniform; floscules all fertile; proper, with five petals, inflex-emarginate, a little unequal. *Stamina*: filamenta five, capillary, the length of the corolla; anthera roundish. *Pistil*: germen inferior; styles two, distant; stigmas obtuse. *Pericarp*: none; fruit ovate-oblong, striated, bipartite. *Seeds*: two, ovate, convex on one side, striated; on the other flat. **ESSENTIAL CHARACTER.** *Fruit*: ovate-oblong, striated. *Petals*: inflex, emarginate.—These plants are propagated by seeds, which should be sown in autumn, on an open bed of dry light ground; and, when the plants come up in the spring, they should be kept clear from weeds, and thinned where they are too close, so that they may have room to grow till the following autumn, when they should be carefully taken up, and planted at about a foot distance, in a bed of light sandy earth, where the roots will continue several years; except the eighth species, which is annual; and the ninth, which probably requires some shelter, but has not been cultivated with us.—The species are,

1. *Athamanta Libanotis*; *Mountain Spignel, or Stone Parsley*. Leaves bipinnate, flat; umbel hemispherical; seeds hirsute; root perennial; stem from one to two feet high, erect, not much branched, leafy.—Native of Denmark, Sweden, Germany, Switzerland, Austria, Carniola, the south of France, and on Gog-magog hills near Cambridge.

2. *Athamanta Cervaria*; *Broad-leaved Spignel, or Black-Hart Root*. Leaves pinnate, decussated, gash-angled; seeds naked; root perennial, thick, very long, annulated, full of resinous juice, sweet-smelling, with a bristle-shaped crown.—This plant is recommended in the gout, and in Stiria they use it in intermittent fevers.—Native of the mountains of France,

Switzerland, Germany, Austria, and Carniola. It flowers in July and August.

3. *Athamanta Sibirica*; *Siberian Spignel*. Leaves pinnate, gash-angled; stem four feet high, much grooved, angular; corollas red underneath.

4. *Athamanta Condensata*; *Close-headed Spignel*. Leaves subbipinnate; leaflets imbricate downwards: umbel lens-form; root perennial; stem simple, a foot high; anthers and receptacles of the florets, purple.—Native of Siberia.

5. *Athamanta Oreoselinum*; *Divaricated Spignel*; or *Mountain Parsley*. Leaflets divaricate; root perennial, thick, aromatic, resinous, crowned with bristles. Petals white, with a blush of rose-colour. It is gratefully aromatic, and deserves to be better known.—Native of the continent of Europe, but not of Great Britain.

6. *Athamanta Sicula*; *Flixweed-leaved Spignel*. Lower leaves shining, primordial; umbels subsessile; seeds hairy. This is a perennial plant, sending up from the root several upright stems, nearly three feet high. The flowers are white, and are succeeded by oblong woolly fruit.—Native of Sicily.

7. *Athamanta Cretensis*; *Cretan Spignel*, or *Candy Carrot*. Leaflets linear, flat, hirsute; petals two-parted: seeds oblong, hirsute. The whole plant is villose in a wild state; when cultivated in a garden, the leaves become succulent, brittle, and very shining. Petals white. It flowers in June. Was found by the celebrated English botanist, Mr. Ray, upon the highest parts of Mount Jura.—It is a native of the southern parts of Europe. The seeds have been occasionally employed as carminatives, and were supposed likewise to be diuretic and emmenagogue: lately they been little used, except as ingredients in theriaca and mithridate. Haller, however, judges it to be much superior to the common *Daucus*, or Wild Carrot, in medicinal efficacy. It was celebrated anciently as a specific in the stone; and it will scarcely be credited, that Van Helmont seriously affirms, that it has even cured the water in a well of this disorder.

8. *Athamanta Annua*; *Annual Spignel*. Leaves many-parted; divisions linear, roundish, acuminate.—Annual; a native of Candia or Crete.

9. *Athamanta Chinensis*. Seeds membranaceous, striated; leaves super-decompound, polished, multifid; stem angular, erect; umbel not much expanded, white.—Native of China.

10. *Athamanta Rupestris*. Leaflets bristle-shaped; recurved, smooth; all the flowers fertile; stem eighteen inches high, branching, subvillose, finely streaked; petals white, equal.—Native of Carniola and Dauphiny.

Athanasia; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common imbricate, ovate; scales lanceolate, pressed close. *Corolla*: compound uniform, longer than the calix; corollules hermaphrodite, equal, numerous; proper, funnel-form; border five-cleft, acute, erectish. *Stamina*: filamenta five, capillary, short; antheræ cylindric, tubular. *Pistil*: germen oblongish; style filiform, a little longer than the stamen; stigma bifid, obtuse. *Pericarp*: none. *Calix*: unchanged. *Seeds*: solitary, oblong; down chaffy, of very short bristles. *Receptacle*: chaffy; chaffs lanceolate, longer than the seed. ESSENTIAL CHARACTER. *Calix*: imbricate; down chaffy, very short. *Receptacle*: chaffy.—The perennial Cape sorts of *Athanasia* are easily propagated by cuttings during the summer months. If these are planted either in pots or upon an old hot-bed, and closely covered with glasses, shading them in the heat of the day, and refreshing them with water when they require it, they will put out roots in five or six weeks; and in two months they may be taken up and planted in pots filled with light earth, and placed in a shady situation,

until they have taken new root; after which they should be removed to a sheltered situation, mixing them with other exotic plants, where they may remain till the middle or end of October, according as the season proves favourable; then they should be removed into a dry-stove or glass-case, where they may enjoy as much free air as possible, but secured from frost, with which management they will thrive, and produce plenty of flowers; but where they are drawn weak in winter, they will not appear sightly. The annual Cape sort is propagated by seeds when they can be obtained good: they should be sown on a moderate hot-bed the latter end of March; when the plants are come up, they should have air, in proportion to the warmth of the season, admitted to them, to prevent their drawing up weak; and so soon as they are big enough to remove, they should be transplanted on another gentle hot-bed, at three inches distance, observing to shade them until they have got fresh root; after which they must have air and water, and, by the end of May, the plants will have acquired strength enough to be transplanted into the open air; when some may be planted in pots, to place among other exotic plants in summer, and the others into warm borders, where they will flower all the autumn; but unless the season is very warm, they will not ripen seeds. The European species may be propagated by planting slips or cuttings during the summer months, in the same way as the African sorts: some of the plants should be put into pots to be placed under a hot-bed frame in winter; the others may be planted in a warm border, where, if the winter proves favourable, they will live; but they rarely survive cold winters.—The species are;

1. *Athanasia Squarrosa*; *Cross-leaved Athanasia*. Peduncles one-flowered, lateral; leaves ovate recurved.—Native country unknown; supposed to be the Cape of Good Hope.

2. *Athanasia Sessiliflora*; *Sessile-flowered Athanasia*. Peduncles one-flowered, shorter than the leaf; leaves linear, hairy.

3. *Athanasia Pumila*; *Dwarf Athanasia*. Peduncles one-flowered, longer than the leaf; leaves linear, hairy.—A very small plant; found by Thunberg at the Cape.

4. *Athanasia Crenata*; *Notch-leaved Athanasia*. Flowers solitary, terminal; leaves linear, alternate; stem shrubby; one terminal flower.—Native country unknown.

5. *Athanasia Uniflora*; *One-flowered Athanasia*. Flowers solitary, terminal, sessile; leaves obovate, imbricate, smooth.

6. *Athanasia Capitata*; *Hairy Athanasia*. Flowers terminal; subsessile; leaves lanceolate, hirsute; flowers discoid and flosculose.

7. *Athanasia Maritima*; *Sea Athanasia Cudweed*, or *Cottonweed*. Peduncles two-flowered; leaves lanceolate, crenate, obtuse, tomentose; root perennial; woody, putting out many fibres, which spread near the surface. The flowers are produced towards the end of the branches, upon short peduncles, and are of a bright yellow colour. The whiteness of the leaves and branches, makes a pretty appearance.—Native of the south of Europe, on the sea-coast; found also in the isle of Anglesea, Cornwall, isle of Shepey, near Pool in Dorsetshire, and Landguard fort in Essex.

8. *Athanasia Genistifolia*; *Broom-leaved Athanasia*. Corymbs simple; leaves lanceolate, undivided, naked, crowded; corymbs small, with three or four subsessile flowers.

9. *Athanasia Pubescens*; *Villose-leaved Athanasia*. Corymbs simple; leaves lanceolate, undivided, villose. It rises six or seven feet high, with a shrubby stem; the flowers are yellow. The seeds do not ripen in England.

10. *Athanasia Annua*; *Annual Athanasia*. Corymbs simple, contracted; leaves pinnatifid, toothed; root annual; stem

nine inches high, branched at top; flowers large, bright yellow, appearing in July and August, but rarely producing seed in this country. There is a variety of this species, which is a tender plant, with a single-grooved stem.

11. *Athanasia Trifurcata*; *Trifid-leaved Athanasia*. Corymbs simple; leaves three-lobed, cuneiform, flat, glaucous; stem shrubby, five or six feet high. The flowers are of a bright yellow colour, and appear in August, but are seldom succeeded by ripe seeds in England.

12. *Athanasia Crithmifolia*; *Samphire-leaved Athanasia*. Corymbs simple, leaves semitrifid, linear, divided into three or five narrow segments; stem shrubby; flowers yellow.

13. *Athanasia Linifolia*; *Flax-leaved Athanasia*. Corymbs simple; leaves linear, alternate; stem simple; round, smooth, like that of Flax.

14. *Athanasia Dentata*; *Tooth-leaved Athanasia*. Corymbs compound; leaves recurved, the lower linear, toothed, the upper ovate-serrate; stem low, shrubby, branching, seldom rising three feet high. Flowers pale yellow; they appear early in summer, and, if the season prove favourable, will be succeeded by ripe seeds in autumn.

15. *Athanasia Parviflora*; *Small-flowered Athanasia*. Corymbs compound; leaves pinnate, linear. It has roundish bunches of bright yellow flowers; some of the peduncles sustain but one, others two, three, or four flowers upon each; they appear in the beginning of July, and continue in succession till late in autumn; those which come early in the season will ripen their seeds in winter.

16. *Athanasia Pinnata*. Corymbs dense, compound; leaves pinnate, linear, tomentose; stem proliferous, shrubby, tomentose; calices villose.

17. *Athanasia Pectinata*. Corymb compound; leaves pinnate, smooth.—Found at the Cape by Thunberg.

18. *Athanasia Dentata*. Corymb compound; leaves lanceolate, toothed, serrate. This differs from the fourteenth species, though it has the same name.

19. *Athanasia Filiformis*; *Fine-leaved Athanasia*. Corymb compound; leaves linear, smooth, spreading.—Found at the Cape of Good Hope by Thunberg.

20. *Athanasia Cinerea*; *Lavender-leaved Athanasia*. Corymb compound; leaves linear, tomentose, entire.—All the above are natives of the Cape of Good Hope, except the 7th; and they are all perennial, except the 10th species.

Athenæa; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, coloured, five-parted; parts oblong, acute, erect, spreading at top. *Corolla*: none. *Stamina*: filamenta eight, filiform; erect, of which five are of the length of the calix, the three alternate ones a little shorter; antheræ sagittate; eight plumose bristles, shorter than the filamenta, growing together with them to a gland surrounding the germ. *Pistil*: germen superior, ovate, surrounded at the base by an annular gland; style setaceous, longer than the stamina; stigma depressed, five-parted. *Pericarp*: capsule globose, one-celled, three-valved; valves somewhat fleshy. *Seed*: three to five, rounded, covered with a pulpy-coloured membrane, affixed to the receptacle in the bottom of the capsule. ESSENTIAL CHARACTER. *Calix*: coloured, five-parted; corolla none. *Bristles*, eight, feathered, between the filamenta; stigma five-parted; capsule globose, one-celled, three-valved. Seeds three to five.—The only species known is,

1. *Athenæa Guianensis*. A branching shrub; stem four or five inches in diameter, covered with a wrinkled gray bark. The flowers come out in bundles from the axils, and upon the tubercles of the stem and branches, each on a small pe-

duncle; their calix is white, and there is no corolla: capsule green, with a tinge of violet. The seeds are covered with a pulpy viscid membrane of a scarlet colour. The bark, leaves, and fruit, are sharp, and aromatic. The last are called *caffè-diabolo*, or devil's coffee, by the creoles.—It is a native of Cayenne, and the neighbouring continent of Guiana, in a sandy soil; a quarter of a league from the seashore, flowering and bearing fruit in September.

Atractylis; a genus of the class Syngehesta, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: outer many-leaved, linear, larger, roughened, permanent, imprisoning the common one; common, ovate, imbricate; the scales oblong, very many, lanceolate, converging, unarmed. *Corolla*: compound, radiate; corollules hermaphrodite, numerous, tubular in the disk: hermaphrodite ligulate in the ray; propper of the disk funnel-form, five-cleft; of the ray ligulate, flat; five-toothed. *Stamina*: filamenta five, capillary, very short; anthera cylindric, tubular. *Pistil* of the disk: germes very short; style filiform, the length of the stamina; stigma bifid; of the ray, very like that of the disk, but obscure and withered. *Pericarp* none; calix converging. *Seeds*: turbinate, compressed. Down plumose. *Receptacle*: villose, flat. ESSENCE. *CHAR.* *Corolla*: radiated: corollules of the ray five-toothed.—All the species of this genus, except the first, second, and third, are strangers to the European gardens; and whenever they are introduced, will require the protection of a greenhouse or stove.—The species are,

1. *Atractylis Gummifera*; *Gummy-rooted Atractylis*. Flower stemless: root perennial, sending out many narrow leaves; which are deeply sinuated, and armed with pines on their edges. These lie close to the ground, and between them the flower is situated. The florets on the border are white, but those which compose the disk are of a yellowish colour.—It is a native of Italy, and the islands of the Archipelago; it flowers in July; but never perfects seeds in England. The roots, if wounded when fresh, yield a viscous milky juice, which concretes into tenacious masses, whitish, and resembling wax. It was formerly chewed for the same purpose as Mastich.—It is propagated by seeds, which must be obtained from the countries where they grow naturally: these should be sown upon a border of light earth, in a warm situation, early in April; and when the plants come up, and are fit to transplant, they should be thinned, and those which are drawn out may be transplanted, leaving the others two feet asunder; after which, the only culture they require is, to keep them clean from weeds in summer, and in winter to cover the roots with some old tanner's bark, to prevent the frost from penetrating the ground.

2. *Atractylis Humilis*; *Dwarf Atractylis*. Leaves tooth-situated; flower radiated, fenced with an expanding involucre; stem herbaceous, near a foot high; flowers purple. The roots will live two or three years; it flowers in June; but, unless the summer be warm and dry, it will not perfect seeds in England.—It is a native of France and Spain; propagated in the same manner as the first species.

3. *Atractylis Cancellata*; *Netted Atractylis*. Involucres latticed, bellying, linear, toothed; calices ovate; flowers fuscous. It is an annual, seldom rising more than eight or nine inches high, with a slender stem, at the top of which are two or three slender branches, each terminated by a head of flowers, with an involucre of several narrow leaves, curiously netted over, and, by a surprising artifice of nature, keeping off the flies.—Native of Spain, Sicily; and other warm parts of Europe; flowers with us in July; and, if the season be dry and warm, will ripen its seeds in September.

4. *Atractylis Lancea*; *Lance-leaved Atractylis*. Involucres pinnate; leaves lanceolate, ciliate, smooth; stem a foot high, leafy; flowers terminal, solitary, subsessile.—Native of Japan.

5. *Atractylis Ovata*; *Ovate-leaved Atractylis*. Involucres pinnate; leaves ovate, ciliate, smooth, pale underneath; flower terminating, solitary.—Native of Japan.

6. *Atractylis Oppositifolia*; *Opposite-leaved Atractylis*. Leaves opposite; the leaves, and even the calix, tomentose underneath.—Native of the Cape of Good Hope.

7. *Atractylis Purpurata*; *Purple-flowered Atractylis*. Leaves hastate, rucinate; flowers large, purple; receptacle naked.—Found by Mutis in New Granada.

8. *Atractylis Mexicana*; *Mexican Atractylis*. Leaves oblong, quite entire; stem shrubby; stipules none; corolla purple.—Found in Mexico.

Atragene; a genus of the class Polyandria, order Polygynia.—GEN. CHAR. *Calix*: perianth four-leaved; leaflets oval, spreading, obtuse, deciduous. *Corolla*: petals twelve, linear, very narrow at the base, obtuse, spreading. *Stamina*: filamenta very many, very short; antheræ oblong, acuminate, shorter than the calix. *Pistil*: germina very many, oblong. Styles villose, permanent. Stigma simple, the length of the antheræ. *Pericarp*: none. *Seeds*: very many, ending in a hairy tail. ESSEN. CHAR. *Calix*: four leaved. *Petals*: twelve. *Seeds*; tailed.—The species are,

1. *Atragene Japonica*; *Japanese Atragene*. Erect: leaves opposite, triternate; leaflets ovate, gashed; stem angular and streaked, two feet high. It has all the appearance of *Anemone*; but it is referred to this genus on account of the number of petals.—Native of Japan.

2. *Atragene Alpina*; *Alpine Atragene*. Leaves doubly-ternate, serrate; other petals fourfold; stems many, branching, diffused, long, angular, smooth, brown, prostrate on the rocks, or scandent; petals dirty white, usually twelve.—This may be increased by cuttings or layers. In a strong soil, and trained against a wall, it will rise to the height of five or six feet. The flowers appear early, and, if the season prove favourable, make a handsome figure; but as this plant is apt to put out leaves very early in the spring, it is frequently nipped by the frosts.—Native of the high Alps in Switzerland.

3. *Atragene Capensis*; *Cape Atragene*. Leaves ternate; leaflets gashed, toothed, outer petals fivefold; scape simple, six or seven inches long.—Native of the Cape of Good Hope.

4. *Atragene Tenuifolia*; *Fine-leaved Atragene*. Leaves doubly pinnate; pinnules linear, entire.—Found at the Cape of Good Hope by Thunberg.

5. *Atragene Zeylanica*; *Ceylonese Atragene*. Tendrils two-leaved; this is caulescent, and scandent; panicle terminal, composed of a twice trifid peduncle, bearing commonly nine peduncled distinct purplish flowers.—Native of the island of Ceylon.

Atraphaxis; a genus of the class Hexandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved; leaflets opposite, lanceolate, coloured, permanent. *Corolla*: petals two, roundish, sinuate, larger than the calix, permanent. *Stamina*: filamenta six, capillary, the length of the calix. Antheræ roundish. *Pistil*: germen compressed. Style none. Stigmas two, capitate. *Pericarp*: none. Calix closed, including the seed. *Seed*: one, roundish, compressed. ESSENTIAL CHARACTER. *Calix*: two-leaved. *Petals*: two, sinuate. *Stigmas*: capitate. *Seed*: one.—The seeds of these plants not ripening seeds in England, they are propagated by cuttings, during any of the summer months. In winter they must be screened from hard frost, which

commonly destroys such as are planted in the air.—The species are,

1. *Atraphaxis Spinosa*; *Prickly-branched Atraphaxis*. Branches spiny.—This shrub rises four or five feet high, sending out many weak lateral branches, armed with spines, and garnished with small spear-shaped smooth leaves, of an ash colour. The flowers come out at the ends of the shoots in clusters, each consisting of two white petals, tinged with purple, included in a two-leaved calix, of a white herbaceous colour. They appear in August.—Native of Armenia, Siberia, and Persia.

2. *Atraphaxis Undulata*; *Wave-leaved Atraphaxis*. Without spines. This species sends out many slender branches, trailing on the ground; leaves small, oval, about the size of those of Knot-grass, waved and curled on their edges, embracing their stalk half round at their base, and placed alternate; flowers in oblong spikes, at the ends of the stem and branches.—Native of the Cape of Good Hope.

Atriplex; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite flower*. *Calix*: perianth five-leaved, concave, permanent; divisions ovate, concave, membranaceous at the edge. *Corolla*: none. *Stamina*: filamenta five, subulate, opposite to the leaves of the calix, and longer than them. Antheræ roundish, twin. *Pistil*: germen obiculate. Styles two-parted, short. Stigmas reflex. *Pericarp*: none. *Calix*: closed, pentagonal, with the angles compressed; deciduous. *Seed*: one, orbicular, depressed. *Female flower on the same plant*. *Calix*: perianth two-leaved; leaflets flat, erect, ovate, acute, large, compressed. *Corolla*: none. *Pistil*: germen compressed. Style two-parted. Stigmas reflex, acute. *Pericarp*: none. Valves of the calix very large, cordate, including the seed between them. *Seed*: one, orbiculate, compressed. ESSENTIAL CHARACTER. *Hermaphrodite*. *Calix*: five-leaved. *Corolla*: none. *Stamina*: five. *Style*: two-parted. *Seed*: one, depressed. *Female*. *Calix*: two-leaved. *Corolla* none. *Stamina* none. *Style*, two-parted. *Seed* one, compressed.—The species are,

1. *Atriplex Halimus*; *Tall Shrubby Orache*, or *Spanish Sea Purslane*. Stem shrubby; leaves deltoid, entire; root perennial, woody, dividing into many branches. The whole shrub is white; flowers small, purplish, at the ends of the branches; seeds small, brown.—It grows in hedges near the sea, about Nice; also in Spain, Portugal, and Sicily. Ray says, that he found it in great plenty about Messina. Although this shrub is not proper for hedges, for which it was introduced, it may have a place in wilderness-quarters, where it will serve to thicken; and the silver-coloured leaves will add to the variety, among other shrubs of the same growth. It will grow eight or ten feet high, and, if suffered to grow wild without pruning, will spread several feet in compass, and sometimes produce flowers.—This, the second, and third species, may be increased by cuttings, planted in any of the summer months on a shady border; where, if they be duly watered, they will soon take root, and be fit to transplant the Michaelmas following, when they should be planted where they are to remain; for they do not succeed well in transplanting, especially when they are grown large and woody.

2. *Atriplex Portulacoides*; *Dwarf Shrubby Orache*, or *Common Sea Purslane*. Stem shrubby; leaves obovate. This is a low undershrub, seldom rising above two feet and a half, or at most three feet high, but becoming very bushy. The leaves are narrow, and of a whitish colour; they are glaucous, opposite, petioled, generally elliptic, some obtuse, others lanceolate. The branches generally recline, are angular, and of a whitish green. The flowers are yellow, and

ATROPA BELLADONNA — Deadly Nightshade.

terminate the branches in clustered spikes.—It is found wild on the shores of the European ocean, and in salt marshes, flowering in July and August. It may be introduced into plantations among other low shrubs, and if planted on a poor gravelly soil, will abide several years, and make a pretty diversity. For the culture and propagation of it, see the first species.

3. *Atriplex Glauca*. Stem undershrubby, procumbent; leaves ovate, sessile, quite entire; the lower ones subdentate. Stem the thickness of a finger, covered with an ash-coloured bark, and divided into declining branches, three or four feet long, subdividing into other shorter ones. The leaves are thickish, from silver inclining to glaucous. At each axil of the upper branchlets come out three or four hermaphrodite flowers, with a few females among them, of a yellowish colour.—A native of France and Spain.

4. *Atriplex Rosea*. Stem herbaceous; leaves hoary, serrated; fruit quadrangular, toothed. The stem is erect, a foot and half or two feet high, somewhat angular, white, smooth, very branching; the branches alternate, subdividing, all diffused. Flowers in close sessile balls at the axils.—It is an annual plant, native of the southern countries of Europe. For the culture and propagation of it, see the first species.

5. *Atriplex Sibirica*; *Siberian Orache*. Stem herbaceous; leaves deltoid, angular; the calices of the fruit mucronate on the outside. The leaves are silvery beneath, and the flowers white.—An annual plant, and a native of Siberia.

6. *Atriplex Tatarica*; *Tartarian Orache*. Stem herbaceous; leaves deltoid, sinuate-toothed, waved alternate; stem about six feet high.

7. *Atriplex Hortensis*; *Garden Orache*. Stem erect, herbaceous, three feet high and more, thick, shining; leaves triangular; root annual.—It is a native of Tartary. There are three or four varieties of this, differing only in the colour of the plants; one is of a deep green, another of a dark purple, and a third with green leaves and purple borders.—It is used of many, says Parkinson, boiled and buttered, to make the stomach and belly soluble, and is put among other herbs into the pot, to make pottage. There are many dishes of meat made with it while it is young; for being almost without savour, it is the more convertible into what relish any one will make it, with sugar, spice, &c. It was formerly cultivated in the kitchen-gardens, as a culinary herb, being used as Spinage, and is now by some persons preferred to it, though in general it is not esteemed among the English; but the French cultivate this plant for use. The Red Orache is formed to dye wool of a good olive colour.—This must be sown for use early in the spring, or at Michaelmas, soon after the seeds are ripe, at which time it generally succeeds better than when it is sown in the spring, and will be fit for use at least a month earlier. These plants require no other culture, but to hoe them when they are about an inch high, to cut them down when they are too thick, leaving them about four inches asunder, and also to cut down all the weeds. This must be done in dry weather, otherwise the weeds will take root again, and render the work of little or no use. When the plants are grown about four inches high, it will be proper to hoe them a second time, in order to clear them from weeds; and if you observe the plants are left too close in any part, they should then be cut out. If this be well performed, and in dry weather, the ground will remain clean until the plant is fit for use. Where it is sown on a rich soil, and the plants are allowed a proper distance the leaves will be very large, and in that the excellence of the herb consists. It must be eaten when young, for when the stalks become tough, it is good for nothing. The seed

will ripen in August, when the plants may be cut or pulled up, and laid on a cloth to dry; after which the seeds may be beaten out, and laid up in bags for use.

8. *Atriplex Laciniata*; *Jagged Sea Orache*. Stem herbaceous; leaves deltoid, toothed, silvered underneath. The whole plant is covered with a skin that peels off, and is of a gray hoary colour.—It is an annual, flowering in July and August, and is a native of the sea-shores of Europe.

9. *Atriplex Hastata*; *Broad-leaved Wild Orache*, vulgarly called *Fut-her*. Stem herbaceous; valves of the calix in the female flowers large, deltoid, sinuated; root annual; stem generally upright, one to three feet high, four-cornered, of a purplish colour; flowers on the tops of the stalks in narrow reddish spikes. It varies much, according to age and situation; on dunghills it is very strong and luxuriant; by roadsides, it is weaker, and its branches are long and procumbent; in wet places, it becomes more upright, and the leaves are very mealy on the under side, particularly when it grows on the sea-shore; at other times they are altogether smooth. In its young state, this plant is frequently eaten instead of Spinach. Birds are very fond of the seeds, but cattle do not seem much to like the plant.—In gardens, and other cultivated grounds, it is a very troublesome weed, flowering from June till August: it should not be suffered to grow and seed on dunghills.

10. *Atriplex Patula*; *Narrow-leaved Wild or Spreading Orache*. Stem herbaceous, expanding; leaves subdeltoid, lanceolate; calices of the seeds toothed in the disk; root fibrous, annual.—Native of Europe, in waste places, on ditch-banks, and in cultivated grounds, flowering in August.

11. *Atriplex Littoralis*; *Grass-leaved Sea Orache*. Stem herbaceous, erect; all the leaves linear, quite entire; root annual.—Native of the sea-coasts of Europe, flowering in August: found at Ramsgate in Kent; Yarmouth, Blakeney, and Wells, in Norfolk.

12. *Atriplex Pedunculata*; *Peduncled Sea Orache*. Stem herbaceous, much branched; branches divaricated; leaves lanceolate, obtuse, entire; calices of the female flowers peduncled.—Native of the sea-shores of Denmark and England; as, near Boston, in the isle of Thanet; near Yarmouth, Lynn, &c. Annual; flowering from July till September.

13. *Atriplex Marina*; *Serrated Sea Orache*. Stem herbaceous, erect; leaves linear, serrate.—It is an annual plant, native of Sweden and England; on sea-shores and in waste places, flowering in August.

14. *Atriplex Albicans*; *White Orache*. Stem shrubby, erect; leaves hastate, quite entire, acute, spikes terminating.—Native of the Cape; flowering in June and July.

Atropa; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted, gibbous; divisions acute, permanent. *Corolla*: one-petalled, bell-shaped; tube very short; border ventricose, ovate, longer than the calix; mouth small, five-cleft, spreading; divisions subequal. *Stamina*: filamenta five, subulate from the base of the corolla, and of the same length with it, converging at the base, above diverging outwards, bowed. *Antheræ* thickish, rising. *Pistil*: germen semi-ovate. *Style* filiform, the length of the stamina, included. *Stigma* headed, rising transversely, oblong. *Pericarp*: berry globular, sitting on a large calix, two-celled. *Receptacle*: fleshy, convex on both sides, reniform. *Seeds*: very many, reniform. ESSENTIAL CHARACTER. *Corolla* bell-shaped. *Stamina* distant. *Berry* globular, two-celled.

1. *Atropa Mandragora*; *Mandrake*. Stemless; scapes one-flowered. It has a taper root, like a Parsnep, which runs three or four feet deep in the ground; it is sometimes

single, and at others divided into two or three branches, almost of the colour of the Parsnep, but a little darker; immediately from the crown of the root arises a circle of leaves, which at first stand erect, but when grown to their full size, spread open, and lie upon the ground; they are more than a foot in length, and are four or five inches broad in the middle, growing narrow towards both ends, of a dark green colour, and a fetid scent; among these come out the flowers, each on a scape about three inches long; they are five-cornered, of an herbaceous white colour, spreading open at top like a Primrose, having five hairy stamina, and a globular germen, supporting an awl-shaped style, which becomes a globular soft berry, when full grown as large as a nutmeg, of a yellowish green colour when ripe, full of pulp. Haller adds, that the leaves are ovate-lanceolate, and waved about the edges; that the flowers have a tinge of violet, and that a circular gland surrounds the germen, produced into two horns. The roots have been supposed to bear a resemblance to the human form, and in the old Herbals are figured as a male, with a long beard, and female with a prolix head of hair. Mountebanks carry about fictitious images, shaped from roots of Briony, and other plants cut into form, or forced to grow through moulds of earthenware, as Mandrake roots. It was fabled to grow under the gallows, where the matter falling from the dead body, gave it the shape of a man; to utter a great shriek, or terrible groans at the digging up; and it was asserted, that he who would take up a plant of Mandrake, should in common prudence tie a dog to it for that purpose, for if a man should do it himself, he would surely die soon after. The bare mention of such fables, is a sufficient confutation of them, nor would they have been mentioned here, had it not been for the allusions to them which occur in ancient authors.—The whole plant is fetid, and reputed to be poisonous, though in small doses it was used medicinally, and particularly as an opiate.—Native of Spain, Portugal, Italy, and the Levant. It flowers with us in March, and the seeds ripen in July. Mandrake is propagated by seeds, which should be sown upon a bed of light earth, soon after they are ripe, for if they are kept until the spring, they seldom succeed well; but those which are sown in autumn, will come up in the spring, when they should be carefully cleared from weeds; and in very dry weather, they must be refreshed with water, which will greatly promote their growth. In this bed they should remain till the end of August, when they must be taken up very carefully, and transplanted into the places where they are to remain: the soil should be light and deep, for their roots run far down; but if the soil be wet, they are often rotted in winter, and if it be too near gravel or chalk, they will make little progress; but where the soil is good, and they are not disturbed, the plants will grow to a large size in a few years, and will produce great quantities of flowers and fruit. These plants should have a warm situation, otherwise in severe winters they will be destroyed.

2. *Atropa Belladonna*; *Deadly Nightshade*, or *Dwale*. Stem herbaceous; leaves ovate, entire; peduncles one-flowered. *Deadly Nightshade* has a perennial, thick, long, branching root, sending out strong, herbaceous, upright, round, trichotomous, branching stems, from three to five feet, and sometimes six feet in height, frequently tinged with purple: the branches are dichotomous. The root-leaves are often a foot long, and five inches broad; the stem-leaves are petioled, acute, soft, dusky green above, and paler green beneath, a little hairy on both sides, and fattish to the touch, changing to a purple colour in the autumn: there are generally two leaves at each branch, one smaller than the other, running down along the short petiole. Peduncles axillary,

one-flowered: flowers large, nodding, void of scent; calix dirty green; corolla lurid; within dusky, purple, and streaked, with a yellow variegated base, without greenish red, or dusky brown; berry large, at first green, but when ripe of a beautiful shining black colour, full of purple juice, with roundish dotted channelled seeds immersed in the pulp; and a glandular ring surrounding it. Scopoli observes, that there are two tubercles between the cells of the antheræ; that the stigma is two-lobed; that the berry sits on the stellate calix, is very succulent, obtuse, marked with small dots, and has two heart-shaped receptacles, to which the seeds adhere. When this plant was found to differ from *Solanums* or *Nightshades*, it received the Italian name of *Belladonna*, which was given it, according to some, because it was used as a wash among the ladies, to take off pimples and other excrescences from the skin; or, according to others, from its quality of representing phantasms of beautiful women to the disturbed imagination. The qualities of this plant are malignant, and it is extremely deleterious in all its parts. Numerous instances have occurred of the berries proving fatal, after causing convulsions, delirium, &c. Buchanan relates the destruction of the army of Sweno the Dane, when he invaded Scotland, by the berries of this plant, which were mixed with the drink which the Scots, according to truce, were to supply the Danes with. The Danes were so inebriated therewith, that the Scottish army fell on them in their sleep, and slew such numbers, that there were scarcely men enough left to carry off their king. A remarkable case is related by Mr. Ray, of the dilatation of the pupil of the eye, caused by a part of a leaf of this plant applied outwardly, and which took place successively on the repetition of the experiment. With respect to the berries, they have frequently been fatal to children; and, if a considerable number are eaten, to grown persons likewise. The symptoms are said to occur in less than half an hour after taking them, and consist of vertigo, great thirst, delirium, swelling and redness of the face, &c. The general sensibility of the system is said to be weakened to a great degree, so that the stomach will bear a far larger dose of emetic medicines than it would otherwise have done. Vinegar, liberally drank, has been found efficacious in obviating the effects of the poison. Dr. Hill relates a very remarkable case, which occurred under his own observation. A labourer found some of the plant in the park of a nobleman, where he was repairing the pales; he eat heartily of the berries, and gave some to two of his children. After two hours he grew giddy, and unable to stand; was extremely thirsty, complained of dreadful pain in his breast, and difficulty of breathing. He afterwards fell into violent ravings, which continued, with slight intervals, during great part of the night. All this time he was also afflicted with a very painful strangury. He recovered, however, some time afterwards, without the assistance of medicine; but both the children died in the course of the night. The leaves are said to have been sometimes successfully applied in cancerous tumors. The ingenious Dr. Milne, in his *Indigenous Botany*, has very properly remarked, that nature has been more parsimonious in her warnings with respect to this plant, than to others of the same natural family. Neither the smell nor the taste is offensive; and if the colour of the flowers proves in some degree a repellant, that of the fruit, on the other hand, is in an equal degree, at least, attractive and inviting. Accordingly, *Belladonna*, notwithstanding its deleterious nature, is not totally excluded from the precincts of physic: nay, some diseases, and those of the most malignant kind, have been known to yield to the anodyne and antispasmodic virtues of this plant, when administered with caution, after

resisting the force of medicines, more innocent indeed, but of less powerful efficacy. Bergius relates, that he has often given relief in epilepsy and convulsion by the internal use of the powder of the leaves, taken in doses of from one to four grains, twice a day; and Gesner, in his *Medical Epistles*, recommends the expressed juice of the berries, boiled with sugar into a syrup, and given a tea-spoonful at a time, as excellent in every case requiring an opiate, and as peculiarly efficacious in the cure of the dysentery. It was some time ago supposed to be a specific in cancerous complaints, and in the *Philosophical Transactions*, there is a well-attested case, of a woman that was cured of a cancer in her breast, by taking a tea-cupful of an infusion of the dried leaves every morning. The malady at first grew worse, but after persevering some time in the use of the medicine, the symptoms abated, and in about half a year she was perfectly well. The infusion was made by pouring ten tea-cupful of boiling water on twenty grains of the dried leaves, and letting it stand to infuse all night in a warm place. In consequence of this it was tried in many of our hospitals, and frequently mitigated the symptoms, but without effecting the cure. The leaves externally applied are cooling and softening; they are good against the ringworm and tetter, and against hard swellings.—This plant is a native of Europe, particularly of Austria and England, in churchyards and on dunghills, skulking in gloomy lanes and uncultivated places: in other countries it is said to be common in woods and hedges. With us, it is not so common in a wild state, but that the places where it has been found may be set down. About Fulborn, in Cambridgeshire; near Wisbeach, in the isle of Ely; Holland, in Lincolnshire; between Temsford-mills and Welwyn, in Herts; Charley forest and Grace Dieu, in Leicestershire; north Luffenham, in Rutland; Sutton Colefield, in Warwickshire; Clifton Hill, near Nottingham and Mansfield, in the same county; and in Westmoreland. Mr. Miller observed it in Woodstock-park in Oxfordshire, and in Up-park in Hampshire. In the counties round London it is not very common; it has, however, been remarked about Rochester, between that and Maidstone, and near Feversham, in Kent; about Harefield and More-park near Rickmansworth; at Dorking, in Surry; and, by old Gerarde, near Highgate.—This may be propagated both by its roots and by seeds. It loves a shady situation, but, on account of its deadly poison, is rarely admitted into gardens. It should by no means be suffered to grow where children or common people resort, because they are likely to be attracted by the splendid black colour of the berries.

3. *Atropa Physaloides*; *Peruvian Deadly Nightshade*, or *Blue-flowered Atropa*. Leaves sinuate-angular; calices closed, acute-angular; root fibrous, annual; stem herbaceous, two feet high, spreading, erect; branches angular. The stem, though herbaceous, is very strong, in our gardens four or five feet high, and of a purplish colour, dividing into several branches, spreading out wide on every side; leaves oblong, deeply sinuate, deep green; peduncles short; calix large, bell-shaped; corolla large, of the open bell-shape, of a light blue-colour; berries about the size of common cherries, enclosed in a large swelling bladder, having five sharp angles.—Native of Peru. It flowers in July, and the seeds ripen in autumn; and if permitted to scatter, the plants will come up in the following spring; or if the seeds be sown on a bed of rich earth in the spring, the plants will rise easily, and may be afterwards readily transplanted to the borders of the pleasure garden, where they must be allowed room, for if the ground be good, the plants will grow very large.

4. *Atropa Solanacea*. Stem shrubby; peduncles solitary;

corollas bell-shaped; leaves subovate; stem six feet high; shrubby, somewhat branching, and angular; calix bell-shaped, five-cleft; corolla three times larger than the calix.—Native of the Cape of Good Hope. It may be propagated by seeds, which should be sown in the spring, on a hot-bed; when they are fit to remove, they should be each put into a separate small pot, filled with loamy earth, and shaded until they take root; and then placed in a sheltered situation.

5. *Atropa Arborescens*; *Tree Atropa*. Stem shrubby; peduncles crowded; corollas revolute; leaves oblong, in tufts towards the ends of the branches; flowers peduncled, white, and fragrant.—A small tree, or shrub; native of South America, and Jamaica, on the temperate mountains. It must be kept in the bark-stove, or it will not thrive well in England.

6. *Atropa Frutescens*; *Shrubby Atropa*. Stem shrubby; peduncles crowded; leaves cordate-ovate, obtuse. This rises with a shrubby stem to the height of six or eight feet, and divides into many branches: the leaves are alternate, roundish, in shape like those of the Storax tree. The flowers come out between the leaves upon short peduncles, and are shaped like those of Deadly Nightshade, but much smaller, of a dirty yellowish colour, with a few brown stripes; they are never succeeded by berries in England.—It is a native of Spain; and may be planted with other hardy exotic plants, in a sheltered situation, from whence it must be removed in October into the green-house. See the fourth species.

7. *Atropa Herbacea*; *Herbaceous Atropa*. Stem herbaceous, channelled, about two feet high; leaves ovate, nerved, with wavy edges; root perennial. The flowers come out from between the leaves, on short peduncles; they are white, and bell-shaped. It flowers in July and August, but seldom ripens its fruit in England. It must be kept in a bark-stove, or it will not thrive in this country.

8. *Atropa Procumbens*; *Wheel-flowered Atropa*. Stem procumbent, herbaceous; leaves twin, unequal, ovate, smooth; flowers in umbels; root annual; corolla herbaceous, yellow, wheel-shaped, spreading very much, the border five-cornered, rolled back a little with sharp angles.—Native of Mexico: cultivated in the royal garden at Madrid, where it flowers and fruits in October. It must be kept in the bark-stove, or it will not thrive well in this country.

Aubletia; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five leaved, rigid, spreading, coloured within, pubescent without, deciduous, five-parted; parts linear-lanceolate, acute, with thick margins, which before flowering are contiguous. *Corolla*: petals five, roundish-oblong, smaller than the calix, with very short claws. *Stamina*: filaments very many, very short. *Antheræ* ovate-oblong, outwardly gibbous, gaping on the inner side, foliaceous at the tip, acute; the exterior ones sterile, lanceolate, ending in a foliaceous point, shorter than the corolla. *Pistil*: germen roundish, depressed. Style long, striated, gradually thickening, slightly incurved. Stigma spreading, perforated, ten-toothed. *Pericarp*: capsule large, orbiculate, depressed, coriaceous, echinate; ten-celled, gaping at the base. *Seeds*: very many, small, roundish, somewhat compressed. *Receptacle of the seeds*, fleshy. ESSENTIAL CHARACTER. *Calix*, five-leaved. *Corolla*, five-petalled. *Capsule*, many-celled, echinate, with many seeds in each cell.—The species are,

1. *Aubletia Tibourbou*. Leaves acutely-serrate, hirsute. This is a middling-sized tree, with a trunk seven or eight feet high, about a foot in diameter, with an irregular chopped soft bark, fibrous, and fit for making ropes. *Apeiba* is the Brazilian name, though it is called Tibourbou by the Caribbees. Aublet found it in flower and fruit from August till

October.—It is a native of Brazil, Guiana, the islands of Cayenne and Tobago.

2. *Aubletia Petoumo*. Leaves elliptic-acute, serrulate, hoary beneath. This is a large tree, being often forty feet high, and a foot and a half or more in diameter, with a brown thick filamentose bark, fit for making cordage. The wood is light, and of a white colour; the corolla yellow.—It bears flowers and fruit in October; and is a native of Guiana, in the vast forests of Sinemari.

3. *Aubletia Aspera*. Leaves quite entire, pubescent beneath; fruit compressed. Also a large tree, from thirty to forty feet high, and a foot and half or more in diameter, with a grayish, irregular, thick, filamentose bark, proper for making cordage: the wood is light and white; corolla yellow, four or five petalled.—Native of Guiana, and the isle of Cayenne; flowering and bearing fruit in the month of May.

4. *Aubletia Lævis*. Leaves quite entire, smooth on both sides; fruit rough, depressed. This is a middling-sized tree, its trunk being from ten to twelve feet in height, and eight or ten inches in diameter; with a smooth, thin, greenish bark; the wood is white, tender, and so light that the trunk may be easily carried in one hand; corolla greenish.—Native of Guiana; flowering and bearing fruit in the month of May.

Aucuba; a genus of the class Monœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male flowers.* Calix: perianth one-leaved, truncate, obscurely four-toothed, villose, very short, permanent. *Corolla:* four-petalled. Petals ovate, acute, spreading; underneath concave, hairy; above convex, deciduous. *Stamina:* filamenta four, inserted into the receptacle among the petals, thick, erect, very short. *Antheræ* ovate, twin, with four furrows. Receptacle plano-convex, smooth, with a square hole impressed upon the middle. *Female flowers on the same Tree.* Calix and Corolla as in the male. *Pistil:* germen inferior. Style thick, short. Stigma simple, capitate. *Pericarp:* nut ovate, one-celled. **ESSENTIAL CHARACTER.** *Male.* Calix: four-toothed. *Corolla:* four-petalled. *Berry:* one-seeded. *Female.* Nut: one-celled.—The following species alone is known:

1. *Aucuba Japonica*. A large tree; branches and subdivisions dichotomous, smooth, rather fleshy, divaricate, erect, angular, scarred from the falling of the leaves; leaves aggregate, at the tops of the branches, petiolate, opposite, oblong, sharp, remotely serrate, smooth, pale underneath, a handbreadth long, nerved; flowers terminal, paniced; panicle trichotomous, superdecumbent; peduncles and pedicles villose; bractes lanceolate.—Native of Japan.

Avena; a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** Calix: glume generally many-flowered, two-valved, loosely collecting the flowers; valves lanceolate, acute, ventricose, loose, large, awnless. *Corolla:* two-valved; lower valve harder than the calix, the size of the calix, roundish, ventricose, acuminate at both ends, emitting from the back an awn spirally twisted, reflex. *Nectary* two-leaved; leaflets lanceolate, gibbous at the base. *Stamina:* filamenta three, capillary. *Antheræ* oblong, forked. *Pistil:* germen obtuse. Styles two, reflex, hairy. Stigmas simple. *Pericarp:* none. *Corolla:* most firmly closed, grows to the seed, and does not gape. *Seed:* one, slender, oblong, acuminate at both ends, marked with a longitudinal furrow. **ESSENTIAL CHARACTER.** Calix two-valved, many-flowered; awn from the back of the corolla, jointed, twisted.—For the propagation and culture of the grasses belonging to this genus, see *Grass*.—The species are,

1. *Avena Siberica*; *Siberian Oat-grass*. Paniced; calices one-flowered; seeds hirsute; awns thrice the length of the

calix; culms from two to three feet in height, very slender. It flowers in July and August.—Native of Siberia.

2. *Avena Elatior*; *Tall Oat-grass*. Paniced: calices two-flowered; hermaphrodite, floscule almost awnless, male awned; root perennial; germen villose.—It is common on banks, in hedges, on the borders of fields, and sometimes in meadows, especially wet ones; flowering in June and July. It is an early grass, very productive, and yields a plentiful aftermath. The stem and leaves are by no means coarse, but soft, tender, and of a pleasant taste; and it may be propagated with facility. It is cultivated in some places abroad, and may perhaps be no bad substitute for Meadow Fox-tail Grass.

3. *Avena Stipiformis*. Paniced: calices two-flowered; awns twice the length of the seed; culm branching, a foot high, often reclining, smooth, with brown joints.—Native of the Cape of Good Hope.

4. *Avena Pennsylvanica*; *Pennsylvanian Oat-grass*. Panicle attenuated; calices two-flowered; seeds villose; awns twice the length of the calix.—Observed in Pennsylvania by Kalm.

5. *Avena Læffingiana*; *Spanish Oat-grass*. Panicle contracted; floscules in pairs, hirsute; one-peduncled, with two awns at the top, the middle awn largest; root annual, capillary.—Found in a dry soil near Madrid, and at the Cape of Good Hope.

6. *Avena Sativa*; *Cultivated Oat*. Paniced; calices two-seeded; seeds very smooth, one-awned; root annual, fibrous.—No botanist has been able to ascertain satisfactorily the native place of growth of this, or any other sort of grain now commonly cultivated in Europe. There are three sorts of Oats cultivated in England, viz. the White, the Black, and the Brown or Red Oat; to which we may add the Blue, the Poland, the Friesland or Dutch, and the Siberian or Tartarian Oat. The White sort is the most common about London, makes the whitish meal, and is chiefly cultivated where the inhabitants live much upon oat-cakes. The Black is more cultivated in the northern parts of England, and is esteemed a hearty food for horses. The Red Oat is much cultivated in Derbyshire, Staffordshire, and Cheshire, but is rarely seen in any of the counties near London; though, as it is a very hardy sort, and gives a good increase, it would be well worth propagating, especially in strong land; the straw is of a brownish red colour, as is also the grain, which is very full and heavy, and esteemed better food for horses than either of the former sorts. The Blue Oat is said, in Merrett's *Pinax*, and Ray's *Synopsis*, to have been sown about Keighley, in Yorkshire. It is probably the same with what is cultivated in Lincolnshire, under the name of Scotch Grays. The Poland Oat has a short plump grain, but the thickness of the skin seems to have brought it into disrepute among farmers: the grains are mostly single, it has no awn, and the straw is short. Friesland or Dutch Oats affords more straw, and is thinner skinned: the grains are mostly double, the larger one sometimes awned, with the awn placed high. Siberian or Tartarian Oat, is, according to Mr. Marshall, a distinct species, unnoticed by Linneus. Each flower frequently contains three perfect florets, never less than two, with a pedicelled rudiment of a third.—The Oat is a very profitable grain, and esteemed the most wholesome food for horses, being sweet, and of an opening nature; other sorts of grain are apt to bind, which is injurious to labouring horses; but if they be fed with this grain soon after it is housed, before it has had a sweat in the mow, or has been otherwise dried, it is as bad on the other hand, for it is then too laxative. This grain is a great improvement to many estates in the north of England, Scotland, and Wales; for it will thrive on cold barren

soils, which will produce no other sort of grain; it will also thrive on the hottest land; in short, there is no soil too rich or too poor, too hot or too cold for it; and in wet harvests, when other grain is spoiled, this will receive little or no damage; the straw and husks being of so dry a nature, that if they be housed wet, they will not heat in the mow, or become mouldy, as other grain usually do; it is therefore of great advantage in the northern parts of England, and in Scotland, where the harvest is generally late, and their autumns wet. The meal of this grain makes tolerably good bread, and is the common food of the country people in the north. In the south it is esteemed for pottage and other messes, and in some places they make beer with it. *Culture.* The best time for sowing Oats is in February or March, according as the season is early or late; and sometimes I have known them sown in April, upon cold land; and they have been early ripe. The Black and Red Oats may be sown a month earlier than the White, because they are harder. In the papers of the Bath Agricultural Society, there is an experiment made, in order to ascertain the effect of early sowing. Black Oats were sown on the 27th and 28th of February, which is a month sooner than the common practice. The quantity sown was four Winchester bushels to the acre. The land was a mellow, deep, sandy loam, on which potatoes had grown. The produce was ninety-eight bushels and a quarter to the acre. The success, however, is not wholly imputed to early sowing, but partly to good deep tillage. White Oats, sown the last week in May, have produced seven quarters to the acre. In Hertfordshire, they do not put them in till they have done sowing Barley: in Suffolk, on the contrary, they are sown before Barley. The former practice is seemingly the best, this Oat being more tender. Mr. Marshall gives the blowing of the Sallow as a direction for the time of sowing this grain. Oats are often sown on land which has in the preceding year produced Wheat, Rye, or Barley. The common method is to plough in the stubble about the beginning of February, and sow the Oats, and harrow them in; but they must be harrowed the same way as the furrows lie; for, if it be done crosswise, the stubble will be raised on the surface: but this is not a good method of husbandry, for when there is time to plough the stubble in autumn, it will rot in winter, and then, giving the land another ploughing, and a good harrowing just before the Oats are sown, it will make the ground finer, and better to receive the grain. Oats are also sown upon land when it is first broken up, before the ground is brought to a tilth for other grain, and are frequently put in upon the sward with one ploughing; but it is much better to give the sward time to rot before the seed is sown, for the roots of the grass will prevent those of the corn from striking downwards. Most people allow four bushels of Oats to an acre, but I am convinced that three bushels are more than enough; the usual produce is about twenty-five bushels to an acre, though I have sometimes known more than thirty bushels. This indeed is no very great crop, forty bushels and upwards being no very unusual produce; but not from sowing thin. With respect to the proper quantity of seed to be sown, practical men differ widely in opinion. Mr. Young is decidedly of opinion, that the quantity of the seed should be proportioned to the poverty of the ground; yet there are not wanting others, who say, that poor soils ought not to be loaded with too much seed, and that six or seven bushels an acre would utterly destroy cold clay lands. On a rich soil, Oats are very apt to run to straw, if sown thin; and one capital advantage which arises from sowing thick, is, that the weeds are thereby effectually smothered.

7. *Avena Nuda*; *Naked Oat*, *Pilcorn*, or *Pillis*. Paniced; calices three-flowered; receptacle exceeding the calix; petals awned at the back; the third flossele awnless.—This is nearly allied to the cultivated Oat, differing in little else except that the grains quit the husks, and fall naked when they are ripe. Mr. Ray informs us, that in his time it was cultivated abundantly in the farther part of Cornwall, where it fetched no less a price than Wheat. It is still sown there in the poorest croft-land, that has been tilled two or three seasons before with Potatoes, and, for the uses of the poor, answers all the purposes of oatmeal. It is a small yellow grain, and accounted superior to any other nourishment for fattening calves. Mr. Miller says, that the Naked Oat is less common than the others, especially in the southern parts of England; but in the north of England, Scotland, and Wales, it is cultivated in plenty. This sort, according to Worlidge, is esteemed, because the grain thrashes clean out of the husk, and need not be carried to the mill to be made into oatmeal or grist. An acre of ground does not yield so many bushels of these, as of the common Oats, because the grain is small and naked, and goes near in measure; but what is wanting in the measure, is supplied in value. Naked Oat is called *pillis*, or *piles*, according to the orthography in Borlase; or *pill-corn*, from its quality of depositing the husk or chaff: *pill*, which we now write *peel*, being formerly put for the outer coat of any sort of fruit.

8. *Avena Fatua*; *Bearded Wild Oat*, or *Haver*. Paniced; calices three-flowered; all the floscules awned, and hairy at the base; root annual.—It is taller than the cultivated Oat, the culm of straw being commonly three, and frequently four feet in height; it is erect, firm, leafy, smooth, with four joints or knots; sheaths streaked, smooth; the seed has a hairy covering. This is one of the most destructive annual weeds, and is too frequently so prevalent among Barley, as almost to choke it. The seed ripens, and falls before harvest, thus filling the ground, in which it will lie several years without vegetating. It cannot easily be extirpated without repeated fallowing, or by laying down the land to grass. The awns of this species are sometimes used for hygrometers; and the seeds, instead of artificial flies, in fishing for trout.

9. *Avena Sesquiteria*. Paniced: calices subtriflorous; all the floscules awned; receptacles bearded; panicle oblong.—Native of Germany, Switzerland, Austria, and Piedmont.

10. *Avena Pubescens*; *Soft Oat Grass*. Subspiked: calices subtriflorous, upper florets hairy at the base; leaves flat, pubescent; root perennial. This grass is hardy, early, and productive.—Native of Portugal, France, Germany, Siberia, and England, where it grows in dry and chalky soils.

11. *Avena Sterilis*; *Great Wild Oat*, or *Bearded Oat-grass*. Paniced: calices five-flowered; the outer floscules and awns hairy at the base, the inner ones awnless; root annual; culms three or four feet high, round, upright, smooth; flowers pendulous; antheræ oblong, pale yellow, scarcely emerging from the corolla; germens oblong, round, hirsute.—Native of Barbary and Spain.

12. *Avena Flavescens*; *Yellow Oat-grass*. Panicle loose; calices three-flowered, short; all the florets awned; it has a perennial creeping root.—This grass is found in most pastures, especially high ones, in some meadows, and frequently on banks by road-sides. In many of our counties it forms the principal part of the finest pasturage on the downs; and in some meadows contributes to the goodness as well as greatness of the crop.

13. *Avena Hispida*. Paniced: calices three-flowered,

hairy; culms a foot high, upright, smooth.—A native of the Cape of Good Hope.

14. *Avena Capensis*. Panicle contracted; calices three-flowered, subulate; corolla pubescent; middle awn twisted, curved; root creeping.—Native of the Cape of Good Hope.

15. *Avena Purpurea*. Panicle contracted; calices two-flowered, ovate; corollas villose; outer glume bifid; awn terminal, bent in.—Native of Martinico.

16. *Avena Lutea*. Panicle spreading; calices two-flowered, subulate; corollas naked, three-awned, middle awn flexuose.—Native of Martinico.

17. *Avena Lupulina*. Panicle contracted, ovate; calices three-flowered, lanceolate, corollas villose; outer glume bisubulate; middle awn reflex.—Native of the Cape.

18. *Avena Fragilis*; *Brittle Oat-grass*. Spiked; calices four-flowered, longer than the floret; culms many, smooth, with threejoints; root annual.—Native of Spain and Portugal.

19. *Avena Pratensis*; *Meadow Oat-grass*. Subspiked; calices mostly five-flowered; florets smooth; leaves channelled, serrulate, naked; root perennial.—Native of Europe and Siberia, on dry pastures and heaths, flowering in July.

20. *Avena Spicata*. Spiked; calices six-flowered, longer than the outer petal, which is awned and forked at top; flowers six, sessile, upright.—Native of Pennsylvania.

21. *Avena Bromoides*. Subspiked; spikelets binate, one-peduncled; awns divaricate; calices eight-flowered; height two feet; culm round, scarcely the thickness of a needle.—Native of Switzerland, and the neighbourhood of Montpellier.

22. *Avena Strigosa*. Panicle: calices two-flowered; corolla smooth at the base; outer valve ending in two awns, shorter than the valve, and with a bent awn from the back; root annual; culm and leaves bare; seeds hairy.—Native of Europe.

23. *Avena Aurata*; *Golden Oat-grass*. Calices two-flowered; panicle sparse, erect; corollas golden, villose at the base. This is a handsome grass; culms nine inches high. Whilst the plant is young, the calix is greenish; the corolla shining, pale yellow, but when arrived at maturity, the whole culm, calix, and corolla, are of a resplendent gold-colour.—Native of the Alps of Switzerland and Piedmont.

24. *Avena Scheuchzeri*. Spikelets five-flowered, pubescent at the base; peduncles branching; culms from six to twelve inches in height; leaves smooth, keeled.—Native of the Alps of Switzerland, Savoy, and Piedmont.

25. *Avena Filiformis*. Panicle erect, very slender; calices one-flowered; awns twice the length of the calix.—Native of New Zealand, and Eastern Island.

Avenues; in Gardening, are walks of trees leading to a house, and are generally terminated by some distant object. These were formerly much more in request than at present, there being few old seats in the country but had one or more of these avenues; and some had as many of them as there were views from the house; but of late, these are with good reason disused; for nothing can be more absurd, than to have the sight contracted by two or more lines of trees, which shut out the adjacent grounds, whereby the verdure and natural beauties of the country are lost; and, where the avenues are of a considerable length, even though their breadth be proportionable, they appear at each end to be only narrow cuts through a wood, which never can please any person of real taste; and when the road to the house is through the avenue, nothing can be more disagreeable; for in approaching the house, it is like going through a narrow lane, where the objects on each side are shut out from the view; and when viewed from the house, it at best has only the appearance of a road, which being extended to a great length in a straight line, is not near so beautiful as a common road, which is lost by the

turnings, so as seldom to be seen to a great extent; but as these avenues must be made exactly straight, when the trees grow to any size, they entirely break the view, whatever way the sight is directed through them; and if this is in a park, the lawn of grass through which the avenue is planted, is thereby entirely deprived of the beauty which it naturally would afford, if left open and well kept: therefore, whenever the situation of a house will admit of a large open lawn in front, the road to the house should be carried round at a proper distance; and, if it be carried sometimes through trees, and serpented in an easy natural way, it will be much more beautiful than any stiff formal avenue, how large soever made. But, as there may be some persons so much wedded to the old way of laying out and planting grounds, as to prefer avenues to the most beautiful disposition of lawns, woods, &c. I shall mention the usual methods of designing and planting them, that have been esteemed the best.—The usual width allowed to these avenues was generally as much as the whole breadth of the house and wings; but if they are planted twelve or fourteen feet wider, they will be the better; because, when the trees are grown to any considerable size, they will spread and overhang so as to contract the view; and as for such avenues to woods or prospects, they ought not to be less than sixty feet in breadth; and because such walks are a long time before they are shady, it will be convenient to plant another row on each side, rather than to lose the stateliness that the main walk will afford in time by being broad, where any thing of a prospect is to be gained. As to the distance, the trees should not be planted nearer one another than thirty-five or forty feet, especially if they are of a spreading kind; and the same distance if they are for a regular grove. The trees proper for planting avenues, are English Elm, the Lime-tree, the Horse-chesnut, the Common Chesnut, the Beech, and the Abele. First, the English Elm is approved for all places where it will succeed, (and that it will do in most places, except in very wet and cold shallow lands;) because it will bear cutting, heading, lopping in any manner whatsoever, and probably with better success than any other tree. Secondly, The Lime-tree: this is approved by others, because it will do well in any tolerable soil, if the bottom be not hot and gravelly; and because of the regular shape it has in growing, the agreeableness of its shade, and the beautiful colour of its leaves. Thirdly, The Horse-chesnut is also to be used in such places as are very well defended from strong winds; because wherever it grows freely, if it be not skilfully managed now and then by cutting, the branches are subject to split down. This tree is valuable on account of its quick growth, the earliness of its coming out, the nobleness of its leaves, and the beauty of its flowers; being a fine plant both for shade and ornament. This delights in a strong hearty soil, but will do well in any tolerable ground, if good care be taken in the planting of it; but wherever these trees are planted in avenues, they should be placed thirty feet asunder, that their heads may have room to spread, otherwise they will not appear so beautiful. Fourthly, The Common Chesnut will do well in a proper soil, and will rise to a considerable height, if planted close together; but if it be planted singly, where the tree can take its own natural shape, it is rather inclined to spread and grow globous than tall. Fifthly, The Beech is recommended by some; but this seldom succeeds well after transplanting, without extraordinary care; though it arrives to a very large tree in many places of England, where it grows naturally, but is the most tedious and troublesome to raise to any tolerable size in a nursery way. Sixthly, The Abele; this indeed grows more dispersed, and looser in its head, than any of the former, and consequently is worse for

defence; but yet is not to be left out of the number of trees for avenues, because it is the quickest in growth of all the forest trees, and will thrive tolerably well in almost any soil, and particularly in wet ground, where few of the before-mentioned trees will thrive, and this seldom fails in transplanting. As for the Alder, Ash, Platanus, and Sycamore, they are but rarely used for planting avenues. All the trees that are employed for avenues should be permitted to take their natural growth, without being much cut or pruned.

Averrhoa; a genus of the class Decandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, erect, small; leaflets lanceolate, permanent. *Corolla*: petals five, lanceolate, the lower part erect, the upper spreading. *Stamina*: filamenta ten, setaceous, alternately the length of the corolla, and shorter. *Antheræ* roundish. *Pistil*: germen oblong, obscurely five-cornered. *Styles* five, setaceous, erect. *Stigmas* simple. *Pericarp*: pome turbinate, five-cornered, five-celled. *Seeds*: angular, separated by membranes. ESSENTIAL CHARACTER. *Calix*: five-leaved; petals five, expanding above; pome five-cornered, five-celled.—The species are,

1. *Averrhoa Bilimbi*. Trunk naked, fruit-bearing; pomes oblong, obtuse-angled.—This tree is only about eight feet in height, with a few reclining branches. It is a native of Goa, and many parts of India, of both sides the Ganges. Burman describes it as a beautiful tree, with green fleshy fruit, filled with a grateful acid juice; the substance and seeds not unlike those of Cucumber: it grows from top to bottom at all the knots and branches. They make a syrup of the juice, and a conserve of the flowers, which are esteemed excellent in fevers and bilious disorders. This and the following species are singular for the fruit growing upon the trunk itself, below the leaves. The flowers resemble that of Geranium, but the fruit is widely different. The flowers are red purple, on oblong small racemes, adhering to the trunk. The fruit is an oblong pome, the thickness of a finger, smooth on the outside.

2. *Averrhoa Carambola*. Axillas of the leaves fruit-bearing; pomes oblong, acute-angled. This is a tree above the middle size, with spreading branches, and a very close head; pome the size of a hen's egg, acutely five-cornered, five-celled, many-seeded; the rind is yellow, thin, and smooth; the pulp clear, watery, in many sweet, in others acid, with scarcely any smell: seeds small, oblong, angular, flattened, and brown. Rheede relates, that the Carambola is twelve or fourteen feet in height, scarcely a foot in girth, with a rough brown bark; that it bears three times a year from the age of three to fifty; that the root-leaves and fruit are used medicinally, either alone or with areca or betel leaves; that the latter, when ripe, are esteemed delicious; unripe, are pickled; and that they are also used in dyeing, and for other economical purposes. Burman informs us, that the acid juice of this plant is not so pleasant as that of the first species; that the fruit is rather larger, and is used for the same purposes; and that it is a very beautiful tree. The Bramins and Portuguese call this tree *carambola*; the Malabars, *tamara-longa*; and in Bengal it is called *camruc*, or *camrunga*.

Avicennia; a genus of the class Didynamia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth five-parted, permanent; leaflets subovate, obtuse, concave, erect, increased by three scales. *Corolla*: monopetalous; tube bell-shaped, short; border bilabiate; upper lip square, emarginate, flat; lower trifid; divisions ovate, equal, flat. *Stamina*: filamenta four, subulate, erect, the two front ones rather shorter, bent back to the upper lip. *Antheræ* roundish, twin. *Pistil*: germen ovate; style subulate, erect, the length of the stamina; stigma bifid, acute; the lower division

bent down. *Pericarp*: capsule coriaceous, rhomboidal, compressed, one-celled, two-valved. *Seed*: one, large, the form of the capsule, constructed of four fleshy folds, germinating. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: two-lipped, upper lip square. *Capsule*: coriaceous, rhomboidal, one-seeded.—The species are,

1. *Avicennia Tomentosa*. Leaves cordate-ovate, tomentose underneath. This tree agrees mostly with the Mangrove, rising not above sixteen feet high; its trunk is covered with a smooth whitish green bark; and the twigs from the stem, propagate the tree like those of the Mangrove.—Native of the East and West Indies. Dr. Patrick Browne says, that it is frequent near the sea, both on the north and south side of Jamaica, growing in low moist ground.

2. *Avicennia Nitida*. Leaves lanceolate, shining on both sides; height forty feet.—Native of Martinico.

3. *Avicennia Resinifera*. Leaves ovate-lanceolate, tomentose underneath. The green-coloured gum, so much esteemed by the natives of New Zealand, and which is so very hot in the mouth, is supposed to be the produce of this tree.—Native of New Zealand.

Awlwort. See *Subularia*.

Axyris; a genus of the class Monœcia, order Triandria.—GENERIC CHARACTER. *Male flowers in an ament.* *Calix*: perianth three parted, spreading, obtuse. *Corolla*: none. *Stamina*: filamenta three, capillary, spreading; antheræ roundish. *Female flowers scattered.* *Calix*: perianth five-leaved, concave, obtuse, converging, permanent, the two outer leaflets shorter. *Corolla*: none. *Pistil*: germen roundish; styles two, capillary; stigmas acuminate. *Pericarp*: none. *Calix*: closely involving the seed with its three leaflets. *Seed*: one, ovate, compressed, obtuse. ESSENTIAL CHARACTER. *Male.* *Calix*: three-parted. *Corolla*: none. *Female.* *Calix*: two-leaved. *Corolla*: none. *Styles*: two. *Seed*: one.—The species are,

1. *Axyris Amaranthoides*; *Simple-spiked Axyris*. Leaves ovate; stem erect; spikes simple. The leaves are rugged, with stellate hairs.—Annual; a native of Siberia.

2. *Axyris Hybrida*. Leaves ovate; stem erect; spikes conglomerate.—An annual plant; and a native of Siberia.

3. *Axyris Prostrata*. Leaves obovate; stem subdivided, much branched, six or seven inches high; flowers capitated.—An annual plant; a native of Siberia.

Agenia; a genus of the class Gynandria, order Pentandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted; parts ovate-oblong, acute, coloured in the middle, reflex, withering. *Corolla*: pentapetalous; petals five, united at the top to the nectary into a flat star; claws capillary, very long, bowed outward; borders obcordate, resupinate, with a clubbed point at the top, turned upward. Nectary bell-shaped, sitting on a cylindrical erect column, shorter than the calix; border five-lobed, lobes elevated, above flatish, with a longitudinal furrow, excavated underneath, and sharp. *Stamina*: filamenta five, very short, inserted into the margin of the nectary, on the top of the ribs, between the divisions of the border, each bent downwards archwise, through a notch at the end of each petal. *Antheræ* roundish, under the borders of the petals. *Pistil*: germen roundish, five-cornered, at the bottom of the nectary; style cylindrical; stigma obtuse, five-lobed. *Seeds*: solitary, rather oblong, gibbous on one side, angular on the other. ESSENTIAL CHARACTER. Monogynous. *Calix*: five-leaved. *Petals*: united into a star, with long claws. *Antheræ*: five under the star. *Capsule*: five-celled.—These plants are propagated by seeds, sown upon a moderate hot-bed early in the spring; when they come up, and have four leaves, they should be

transplanted on a fresh hot-bed, to bring them forward; part of them may be planted in small pots, and the others on the bed; those in the pots should be plunged into a hot-bed of tanner's bark; they must be shaded until they have taken new root, and then they must have free air admitted to them every day, in proportion to the warmth of the season: they require to be frequently watered in warm weather, but they should not have it in too great plenty. The plants should continue all the summer in the hot-bed, where they must have a good share of air; for those which are fully exposed to the open air will not thrive, and if they be too much drawn, they do not flower well. The plants will live through the winter in a moderate stove; but as they perfect their seeds well the first year, few persons care to continue the old plants.—The species are,

1. *Ayenia Pusilla*; *Smooth Ayenia*. Leaves cordate, smooth; stem weak, woody, about a foot high; corolla purple. Many of the flowers being abortive, Linneus suggests, that they may possibly be of different sexes. The flowers continue in succession from July till winter.—Native of Peru.

2. *Ayenia Tomentosa*. Leaves ovate-roundish, tomentose; leaflets of the calix lanceolate, acute, permanent; anthers three.—Native of South America.

3. *Ayenia Magna*. Leaves cordate, pubescent; germ of the flowers sessile. An upright shrub, five feet high.—Native of Carthage, and other places of South America.

4. *Ayenia Lævigata*. Leaves ovate, entire, smooth; germen pedicelled; nectary ten-cleft, radiated.—Native of Jamaica.

Azalea; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, acute, erect, small, coloured, permanent. *Corolla*: monopetalous, bell-shaped, (in some species funnel-shaped,) semi-quinquefid, the sides of the divisions bent in. *Stamina*: filamenta five, filiform, inserted into the receptacle, free. *Antheræ* simple. *Pistil*: germen roundish. Style filiform, the length of the corolla, permanent. *Stigma* obtuse. *Pericarp*: capsule roundish, five-celled, five-valved. *Seeds*: many, roundish. **ESSENTIAL CHARACTER.** *Corolla*: bell-shaped. *Stamina*: inserted into the receptacle. *Capsule*: five-celled.—The species are,

1. *Azalea Pontica*; *Pontic Azalea*. Leaves shining, lanceolate, smooth on both sides; racemes terminal; flowers yellow.—Native of Pontus.

2. *Azalea Indica*; *Indian Azalea*. Flowers subsolitary, covering the whole upper part of the shrub, and are of a beautiful bright red colour; calices hairy.—Native of the East Indies.

3. *Azalea Nudiflora*; *Naked-flowered Azalea*. Leaves ovate; corolla hairy; stamina very long.—Grows naturally in shade, and upon moist ground, in most parts of North America; where it is called *Mayflowers*, *Wild Honeysuckles*, and *Upright Honeysuckles*. Many of the plants have been sent, of late years, to England, and several of them have produced their beautiful flowers in the gardens of the curious.—They must have a moist soil and a shady situation, otherwise they will not thrive. They can only be propagated by shoots from their roots, and laying down their branches, for they do not produce seeds here; and if good seeds could be obtained, they would be difficult to raise, and a long time before they would flower; but when they are in a proper situation, their roots extend, and put out shoots which may be taken off and transplanted. When any of them are laid down, it should be only the young shoots of the same year, for the old branches will not put out roots. The best time for this, is at Michaelmas; and if they are covered with some old tan to keep out the frost, it will be of great use to them. The autumn is also the best time to remove the plants, but the ground about their roots should be covered in winter to keep out the frost; and if this be every year practised to the old plants, it will preserve them in vigour, and cause them to flower well.

4. *Azalea Viscosa*; *Viscid Azalea*. Leaves scabrous at the edge; corollas with glutinous hairs. This is a low shrub, rising with several slender stems, nearly four feet high. The flowers have much the appearance of Honeysuckle, and are as agreeably scented. They appear in the middle of July, but are not succeeded by seeds in England.—It is a native of woods and moist places in North America. For its propagation and culture, see the third species.

5. *Azalea Lapponica*; *Lapland Azalea*. Leaves with excavated dots sprinkled over them. This is a divaricated shrub, six or seven inches high. It is, like the sixth species, a low plant of little beauty; and growing naturally on boggy ground upon the mountains, is difficult to keep in gardens.

6. *Azalea Procumbens*; *Procumbent Azalea*. Branches diffusely procumbent; calix purple, a little shorter than the corolla, five-cleft almost to the base; corolla bright rose-colour, or pale scarlet.—Native of the mountains of Europe, and also found in the Highlands of Scotland.

7. *Azalea Punctata*; *Dotted Azalea*. Leaves rugged about the edge; flowers dotted, heaped. This shrub is five feet high, upright, and branched; corolla white; calix whitish, dotted with red, as are also the corolla, anthers, and germen.—Native of the woods of Cochin-china.

B A C

BACCHARIS; a genus of the class Syngenesia, order Polygamia Superflua.—**GENERIC CHARACTER.** *Calix*: common, cylindrical, imbricate; scales linear, acute. *Corolla*: compound, equal; corollules hermaphrodite and female mixed; proper, to the hermaphrodite, funnel-form, five-cleft; to the females, scarcely apparent, almost none. *Stamina*: filamenta five, capillary, very small. *Antheræ* cylindrical, tubular. *Pistil*: germen ovate; style filiform, the length of the flower; stigma bifid. *Pericarp*: none. *Calix*: unchanged. *Seeds*: solitary, very short, oblong; down simple. **RECEPTACLE**, naked. **ESSENTIAL CHARACTER.** *Calix*: imbricate, cylindrical. *Florets*: female mixed with hermaphrodites. *Down*: simple. **RECEPTACLE**: naked.—Most of the plants of this genus are shrubby: the flowers are disposed commonly in corymbs.—The species are,

B A C

1. *Baccharis Ivæfolia*; *Peruvian Ploughman's Spikenard*. Leaves lanceolate, longitudinally tooth-serrate. The female florets with a trifid corolla, very abundant; hermaphrodites at the disk few, and five-cleft. This shrub is five or six feet high.—It is a native of America, flowering in July and August. It may be propagated by cuttings planted in a shady border, during any of the summer months; or by seeds sown on a common border in the spring. These seeds ripen well in this country, and if permitted to scatter on the ground, the plants will come up in the following spring. It is pretty hardy, and will live abroad in mild winters, if planted in a warm situation; but it is usually kept in the green house, and placed abroad in summer; it requires much water in warm weather.

2. *Baccharis Neriifolia*; *Oleander-leaved Ploughman's Spikenard*. Leaves lanceolate, serrate at the upper part

with one or two toothlets, about three feet high; trunk the thickness of the human arm.—This is difficult to propagate, for the cuttings with great difficulty take root; and as it rarely has shoots near the roots to lay down, in Holland they lay down the entire head of young plants, slitting the smaller branches in the same manner as is practised for Carnations, laying them into the ground, and forking them down to prevent their rising; these, when duly watered, put out roots in one year, when they may be taken off, and placed in small pots filled with light earth, and placed in the shade till they have taken new root: after which they may be placed in a sheltered situation in summer, but in winter must be kept within the protection of the green-house.

3. *Baccharis Arborea*. Leaves elliptic-lanceolate, quite entire, naked, petioled; height three feet; trunk the thickness of the human arm; seeds streaked. This is the largest of the genus.—Observed by Kœnig in woods on the island of Joanna.

4. *Baccharis Halmifolia*; *Sea Purslane-leaved Ploughman's Spikenard*, or *Groundsel Tree*. Leaves obovate, emarginate-crenate in the upper part. This is an herbaceous kind of shrub, six, seven, or eight feet high: its foliage continues green throughout the year, flowering in October, and is a native of Virginia, and other parts of North America. This sort may be propagated by cuttings, which should be planted in April or May, upon a shady border, and duly watered in dry weather, until they have taken root; and at Michaelmas, they will be fit to transplant where they are to remain: this will live in the open air, and is never injured by the cold of our ordinary winters, but severe frost will sometimes destroy it. It was cultivated in 1688 by Bishop Compton.

5. *Baccharis Dioscoridis*. Leaves broad, lanceolate, toothed, sessile, stipuled; stems shrubby, six feet high, weak, a little hairy, much branching, luxuriant.—Native of Egypt.

6. *Baccharis Indica*. Leaves obovate, toothletted, petioled; branches with raised streaks; corymb large, terminating.—Native of Ceylon, and the Cape of Good Hope.

7. *Baccharis Brasiliæna*. Leaves obovate, entire, scabrous, sessile, veined underneath; stem somewhat angular; down ferruginous.—Native of Brazil.

8. *Baccharis Fœtida*. Leaves lanceolate, serrate, toothed; corymbs leafy. This rises with a woody stem six or seven feet high.—It is a native of Carolina, and some other parts of North America. It may be propagated by cuttings, planted towards the end of May; if shaded and duly watered, they will put out roots in two months, when they should be potted, that they may be sheltered under a frame in winter.

9. *Baccharis Chinensis*. Leaves lanceolate, quite entire, tomentose beneath, petioled; peduncles many-flowered, axillary. An undershrub, three feet high, upright, simple, round; flowers yellow, oblong.—Native of China, near Canton.

Bacopa; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted: two of the parts oblong, concave, acute; the two inferior deflex, ovate, acute; the single superior one broader, roundish, unduluted. *Corolla*: one-petalled; tube short, towards the orifice a little enlarged; border five-parted; parts ovate-oblong, obtuse, equal, spreading. *Stamina*: filamenta five, inserted into the tube of the corolla; antheræ sagittate. *Pistil*: germen ovate, compressed, below incrusted by the calix growing to it; style short; stigma headed. *Pericarp*: capsule one-celled. *Seeds*: many, extremely small. ESSENTIAL CHARACTER. *Corolla*: with a short tube, spreading at top. *Stamina*: inserted into the tube of the corolla. *Stigma*: headed. *Capsule*: one-celled.—The only species known, is,

1. *Bacopa Aquatica*. This plant puts forth several cylindrical.

dris, succulent, knotty stems; leaves opposite, stem-clasping, or rather connate, thick, oblong, concave, sharp, smooth; flowers solitary, peduncled, alternate from the axils: below the calix there stands a pair of fleshy bractes on the long peduncle; corolla blue. It puts forth roots from the knots, both as it runs along the ground, and as it lies on the surface of the water.—Native of the island of Cayenne, on the borders of rivulets, flowering and fruiting in December. The French inhabitants call it *herbe aux brulures*, on account of its efficacy in curing burns.

Bactris; a genus of the class Monœcia, order Hexandria.—GENERIC CHARACTER. *Male Flower*. *Calix*: spathe universal, one-leaved; spadix branched; perianth one-leaved, three-parted, small; parts lanceolate, concave, coloured. *Corolla*: one-petalled, three-cleft; tube short; clefts ovate, acute, erect. *Stamina*: filamenta six, subulate, erect, of the length of the corolla, inserted into the middle of the tube; antheræ oblong, incumbent. *Female flowers*, few in the same spadix, intermixed with the male ones. *Calix*: spathe the same as in the males; perianth one-leaved, bell-shaped, three-toothed, sharp-pointed, coloured, very small, permanent. *Corolla*: one-petalled, erect, three-toothed, permanent. *Pistil*: germen ovate, large; style very short; stigma headed, obscurely three-cleft. *Pericarp*: drupe coriaceous, roundish, fibrous, succulent, sharp-pointed with the style. *Seed*: nut roundish, depressed on each side, marked on the sides with three holes; kernel solid. ESSENTIAL CHARACTER. *Male*. *Calix*: three-parted. *Corolla*: one-petalled, three-cleft. *Stamina*: six. *Female*. *Calix*: one-leaved, three-toothed. *Corolla*: one-petalled, three-toothed. *Stigma*: obscurely three cleft. *Drupe*: coriaceous.—The species are,

1. *Bactris Minor*. Fruit roundish; root creeping; flowers without scent, very slightly tinged with yellow; fruit dark purple, the size of a common cherry, containing an acid juice, of which the Americans make a sort of wine. They are also eaten raw, but are not pleasant. Canes are made of the stem, which are dark coloured, shining, jointed, and very light.—Native of Carthage in South America.

2. *Bactris Major*. Fruit ovate. This commonly grows to the height of twenty-five feet, and the trunk to two inches or more in diameter. Fruit the form and size of an egg, acuminate with the style, fibrous, succulent, covered with a dark purple coriaceous coat, of which the natives make a vinous liquor. The nut is large, of a dark colour, ovate-oblong, with an acuminate trifid apex, and three obscure holes, two above the middle, and the third higher; kernel oblong, blunt at both ends, cartilaginous, solid.—Native of Carthage in South America.

Bæckia; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, funnel-form, five-toothed, permanent. *Corolla*: petals five, roundish, patulous, inserted into the calix. *Stamina*: filamenta eight, of which six are equal, two solitary, very short, bent in; antheræ subovate, small. *Pistil*: germen roundish; style filiform, shorter than the corolla; stigma capitate. *Pericarp*: capsule globular, crowned, four-celled, four-valved. *Seeds*: roundish, angular on one side. ESSENTIAL CHARACTER. *Calix*: funnel-form, five-toothed. *Corolla*: five-petalled. *Capsule*: globular, four-celled, crowned.—The only species belonging to this genus, hitherto discovered, is,

1. *Bæckia Frutescens*. This is a shrub, which has the habit of Southernwood, with wand like branches, and opposite short simple twigs; leaves opposite, linear, sharp, smooth, quite entire; flowers axillary, solitary, on a naked peduncle

the length of the flower, much shorter than the leaves.—Native of China, and called there *tiangina*.

Bæobotrys; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth double; exterior three-leaved; leaflets roundish, concave, smaller; inferior one-leaved, bell-shaped, short, growing to the germen, five-cleft; clefts ovate, permanent, converging after flowering, and crowning the fruit. *Corolla*: one-petalled, tubular; tube very short; border five-cleft, erect; clefts rounded, very short. *Stamina*: filamenta five, very short, in the middle of the tube; antheræ heart-shaped. *Pistil*: germen globose, half superior; style cylindrical, very short, permanent; stigma obtuse, tuberculated. *Pericarp*: berry globose, somewhat dry, one-celled, growing to the calix. *Seeds*: several, angular, affixed to a columnar receptacle in the bottom of the berry. ESSENTIAL CHARACTER. *Corolla*: tubular, with a five-cleft border. *Calix*: double; outer two-leaved; inner one-leaved, bell-shaped. *Berry*: globose, one-celled, growing to the calix, many-seeded.—The only species hitherto discovered, is,

1. *Bæobotrys Nemoralis*. Native of the isle of Tanna, in the South Seas.

Ballota; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, salver-shaped, five-cornered, oblong, ten-streaked, erect, permanent, equal; mouth acute, patulous, plaited, five-toothed; involucre of linear leaflets under the whorls. *Corolla*: monopetalous, ringent; tube cylindrical, the length of the calix; upper lip erect, ovate, entire, crenate, concave; lower trifid, obtuse; the middle segment larger, emarginate. *Stamina*: filamenta four, the two shorter subulate, bending towards the upper lip, and shorter than it. Antheræ oblong, lateral. *Pistil*: germen quadrifid; style filiform, in the same situation and form with the *stamina*. Stigma slender, bifid. *Pericarp*: none. *Calix*: unchanged, fostering the seeds in its bosom. *Seeds*: four, ovate. ESSENTIAL CHARACTER. *Calix*: salver-shaped, five-toothed, ten-streaked. *Corolla*: upper lip crenate, concave.—The European sorts being common stinking weeds, are never introduced into gardens.—The species are,

1. *Ballota Nigra*; *Stinking or Black Horehound*. Leaves cordate, undivided, serrate; calices acuminate; corolla purple, twice the length of the calix; filamenta brown. It is a perennial hairy plant, with an acrid pungent smell; common in most parts of Europe, in waste places and hedges, flowering in July. It is recommended in hysterical cases. In Gothland, it is an universal remedy in disorders incident to cattle; but the Swedish plant is not supposed to be the same with ours. This, says Meyrick, is one of those neglected English plants, which are possessed of great virtues, though they are but little known, and still less regarded. An infusion of the green leaves, or a conserve made of the fresh-gathered tops is one of the best remedies for hypochondriacal and hysteric complaints. It likewise promotes the menses, and is good in low-spiritedness, and all the numerous train of nervous disorders. The flowers are sometimes found white.

2. *Ballota Alba*; *White-flowered Black Horehound*. Leaves cordate, undivided, serrate; calices subtruncate.—This has a pale stem and white corollas, with rounded cordate veined leaves.—It is a native of Sweden.

3. *Ballota Lanata*; *Woolly Black Horehound*. Leaves palmate, toothed; stem woolly. The stems are white with wool; corollas extremely hirsute, pale yellow, white on the outside.—It is a hardy plant, a native of Siberia, towards China.

4. *Ballota Sæveolens*; *Sweet-smelling Black Horehound*. Leaves cordate; spikes leafy; calices truncate; awns linear;

root annual; stem upright, shrubby at bottom, branched, hirsute; branches almost upright, villose. Browne says, that it commonly rises to the height of three or four feet; and that it is a very grateful cephalic and alexipharmic. It is a very odorous plant, and the people of St. Domingo use it in their warm baths.—A native of the West Indies. It requires the protection of a stove.

5. *Ballota Disticha*; *Betony-leaved Black Horehound*. Whorls halved, two-parted, half-spiked; stem pubescent, one to two feet high.—Native of the East Indies. It must be placed in a stove in England.

6. *Ballota Pilosa*. Leaves ovate, crenate, tomentose; whorls hairy; calices ten-toothed; stem perennial, four feet high, weak, streaked, hairy.—Native of Cochinchina. It will not live without a stove in this country.

Baltimora; a genus of the class Syngnesia, order Polygamia.—GENERIC CHARACTER. *Calix*: common cylindrical; leaflets seven, lanceolate, erect, the interior ones shorter. *Corolla*: compound, radiate; corollules hermaphrodite of the disk many; females of the ray five; proper of the hermaphrodites funnel-form, with a five-cleft tomentose border; of the females ligulate, ovate, trifid, the middle ones less. *Stamina*: in the hermaphrodite, filamenta five; antheræ cylindrical. *Pistil*: in the hermaphrodite, germen obscure, style short; stigma none. In the females, germen oblong, crowned with a toothed deciduous calicle; style filiform, very short; stigmas two, filiform, longer than the corollule. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodite, none; in the females three-sided, naked, gibbous at the top. *Receptacle*: chaffy. ESSENTIAL CHARACTER. *Calix*: cylindrical, many-leaved; ray of the corolla five-flowered. *Down*: none. *Receptacle*: chaffy.—One species only is yet known,

1. *Baltimora Recta*. An annual plant, with a stem two feet high, four-cornered, upright, green, with the sides deeply channelled, and the angles rugged; flowers yellow.—Native of Maryland, near Baltimore; it flowers in June and July.

Bambusa; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none, except glume-like bractes scattered, often three under each spikelet, oblong, pointed, concave, keeled unequal, shorter than the floscules, two opposite, the third leaning on the flat side of the spikelet; spikelets lanceolate, distichous, compressed, sharp, nearly five-flowered. *Corolla*: glume two-valved; valve inferior, oblong, ventricose, acuminate, towards the tip keeled and streaked; interior lanceolate, flat, with complicated margins, ciliate, a little longer than the inferior, and projecting from it. Nectary two-leaved, flat at the anterior side of the germen; leaflets ovate, acuminate, bearded at the tip, membranaceous. *Stamina*: filamenta six, capillary, almost the length of the corolla; antheræ paralleliped, two-cleft at the base. *Pistil*: germen oblong; style capillary, two-cleft; stigmas feathery. *Pericarp*: none. *Seed*: single, oblong.—For the rest, see *Arundo Bambos*, and *Nastus*.

Banara; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, six-parted, permanent; parts ovate. *Corolla*: petals six, roundish, concave, spreading, three times larger than the calix, inserted into the receptacle. *Stamina*: filamenta fifteen and more, capillary, length of the corolla, inserted into a glandule surrounding the germen; antheræ roundish. *Pistil*: germen somewhat globose, seated in a glandule; style filiform, of the height of the *stamina*; stigma headed. *Pericarp*: berry globose, but little succulent, one-celled, crowned by the permanent style. *Seeds*: numerous, very small, cornered, striated. ESSENTIAL CHARACTER. *Calix*:

six-parted, permanent. *Corolla*: six-petalled; germen seated on a glandule; stigma headed; berry globose, one-celled, many-seeded.—The following species only has hitherto found,

1. *Banara Guianensis*. This is a tree of ten feet or more in height, and about seven inches in diameter, with a grayish bark, and a whitish light wood. The corolla is yellow, and the berry black.—Native of the island of Cayenne, flowering in May, and bearing fruit in July.

Baneberry. See *Actæa*.

Banisteria; a genus of the class Decandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, very small, stiff underneath with tubercles, permanent; two melliferous glands under each division of the calix, except one, they are therefore eight in number. *Corolla*: petals five, orbiculate, very large, spreading, crenate; claws oblong linear. *Stamina*: filamenta ten, very small, coalescing at bottom; antheræ simple. *Pistil*: germina three, winged, coalescent; styles three, simple; stigmas obtuse. *Pericarp*: capsules three, running out into a long wing, one-celled, marked at the sides with small appendices, not gaping. *Seeds*: solitary, covered, toothed on the lateral edge. **ESSENTIAL CHARACTER.** *Calix*: five-parted, with melliferous pores at the base on the outside. *Petals*: roundish, with claws; stigmas leaf-shaped. *Seeds*: three, winged with membranes.—These plants, being all natives of hot countries cannot be preserved in England, unless they are kept in a bark-stove. They are propagated by seeds, which must be procured from the countries where they grow naturally. These seeds should be fully ripe when gathered, and put into sand or earth, in which they should be sent to England, otherwise they will lose their vegetative quality; for from a large parcel of these seeds, which were sent over in papers, as fresh as they could possibly arrive here, very few plants were raised, and those did not appear till the second year; therefore, when the seeds arrive, they should be immediately sown in pots; and if it happen in autumn or winter, the pots should be plunged into a hot-bed of tanner's bark where the heat is very moderate, and secured from frost and wet till spring, when they must be removed to a fresh hot-bed which will bring up the plants; but if they should not appear the first year, the pots should be preserved till the next spring, to see if the seeds will grow. When the plants come up, they must be put into separate pots, filled with light earth, and plunged into the bark-bed; after which they must be treated like other tender plants from the same countries.—The species are,

1. *Banisteria Angulosa*. Leaves sinuate-angular; corolla sulphur-coloured.—Native of the island of Dominick, where Plumier first discovered it, and also of Hispaniola.

2. *Banisteria Purpurea*. Leaves ovate; spikes lateral; seeds erect.—Native of the Caribbee Islands.

3. *Banisteria Laurifolia*. Leaves ovate-oblong, rigid, racemes terminal.—Native of Jamaica and Hispaniola.

4. *Banisteria Longifolia*. Leaves oblong, acuminate, rigid, shining; panicle terminating; branches spreading very much.—Native of the West Indies.

5. *Banisteria Bengalensis*. Leaves ovate-oblong, acuminate; racemes lateral; seeds spreading; corollas blue.—Native of the East and West Indies.

6. *Banisteria Dichotoma*. Leaves ovate; branches dichotomous; corolla of a golden scarlet colour, spreading.—First observed in the island of Martinico.

7. *Banisteria Fulgens*. Leaves subovate, tomentose underneath; racemes brachiata; peduncles umbelled.—Native of Jamaica and Barbadoes

8. *Banisteria Brachiata*. Leaves subovate; branches brachiata; seeds narrower within. The flowers are produced in loose spikes at the ends of the branches, are first of a gold colour, and fade to a scarlet; these are succeeded by slender thin seeds, and for the most part single.—Native of Carthagena

9. *Banisteria Aculeata*. Leaves pinnate; leaflets oblong, obtuse; flowers spiked; stem branching, prickly. The flowers grow in loose spikes at the end of the branches, and are succeeded by single seeds, as large as those of the greater Maple.—Native of Tolu.

10. *Banisteria Cœrulea*. Branches tubercled; leaves ovate-acute, coriaceous; racemes axillary; corolla blueish.—Native of Jamaica and Dominica.

11. *Banisteria Nitida*. Leaves ovate-oblong, quite entire, shining beneath; panicle terminating, leafy.—Native of Brazil.

12. *Banisteria Chrysophylla*. Branches tubercled; leaves ovate-acute, with a golden nap on the lower surface; wings very long.—Found near Rio Janeiro in Brazil.

13. *Banisteria Muricata*. Leaves ovate-acute, tomentose beneath; racemes axillary; capsules muricate.—Native of Peru.

14. *Banisteria Leona*. Branches tubercled; leaves ovate-acuminate, coriaceous; flowers paniced.—Native of America, and found also at Sierra Leone.

15. *Banisteria Ferruginea*. Leaves ovate-acuminate, ferruginous beneath; flowers paniced; bractes imbricate.—Native of Rio Janeiro, near St. Sebastian, in Brazil.

16. *Banisteria Emarginata*. Leaves ovate, subcordate, emarginate-cuspidate at the end, tomentose on the lower surface; flowers raceme-corymbed, terminating; corolla yellow.—Native of America.

17. *Banisteria Quapara*. Leaves ovate, tomentose beneath; flowers in corymbs; seeds erect; corolla yellow, with unequal petals; seeds lens-shaped.—Native of Guiana, on the borders of meadows, flowering in August.

18. *Banisteria Sinemariensis*. Leaves ovate, acuminate; flowers in corymbs, yellow; wings gradually widening. This is a shrub with a trunk five feet high, putting forth many climbing branches: the fifth petal is larger than the rest, and fringed.—Native of Guiana, on trees, by the sides of meadows and fields, flowering and fruiting in August.

19. *Banisteria Orbiculata*. Stem twining; leaves orbiculate, beneath tomentose and silky; petioles biglandular; gemina united; styles three; stigmas leafy, short.—Native of Jamaica, Guadaloupe, and St. Domingo.

20. *Banisteria Ciliata*. Leaves cordate-roundish, eared, smooth, ciliate.—Native of Brazil.

21. *Banisteria Auriculata*. Stem twining, slender; leaves subsagittate, smooth, with rounded lobes; flowers in umbels.—Native of Rio Janeiro.

22. *Banisteria Ovata*. Stem twining; leaves ovate, acute, quite entire; flowers in umbels; involucres stipuled; corolla red, or sulphur-coloured.—Native of the island of Dominick.

23. *Banisteria Palmata*. Stem twining; leaves palmate, tomentose beneath; petioles biglandular. The leaves are divided into five acute parts, the middle one longest.—Native of St. Domingo.

24. *Banisteria Sagittata*. Stem twining; leaves sagittate, large, tomentose; petioles biglandular. The leaves have one tooth on each side towards the tip.—Native of St. Domingo.

Banksia; a genus of the class Tetrandria, order Monogynia: named after Sir Joseph Banks, P. R. S. who first discovered it.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, four-cleft inferior. *Corolla*: one-petalled; tube cylindric, very short; horder very long, four-parted; parts linear,

lanceolate at the tip, internally hollowed by a little cavity, acute. *Stamina*: filamenta none; antheræ four, lanceolate, sessile in the cavity of the parts of the corolla. *Pistil*: germen superior, minute; style filiform, stiff, longer than the corolla; stigma pyramideate, acute. *Pericarp*: capsule ovate or globose, woody, one-celled, two-valved. *Seeds*: two, obovate, convex on one side, flat on the other, terminated by a very large membranaceous veinless wing. **ESSENTIAL CHARACTER.** *Calix*: four-cleft, inferior. *Corolla*: four-parted; tube very short; border very long, linear-lanceolate; antheræ sessile in the cavity of the parts of the corolla. *Capsule*: two-seeded, one or two celled, two-valved.—Some of the species of this genus have flowered and seeded in England. They have not yet been increased any other way but by seeds. These, and the plants in general from the South Seas, are hardy, considering their climate, and may be treated much in the same manner with the Cape plants. They covet abundance of air, and flourish best near the front of the dry-stove.—The species are,

1. *Banksia Serrata*; *Serrate-leaved Banksia*. Leaves linear, attenuated into the petiole, equally serrate, truncate at the end with a point. This is the most handsome species of the genus. The leaves are at the ends of the branches confluent, scattered, seven or eight inches long, narrow, smooth, coriaceous, flat, spreading much, surrounding the ament, which is very large, thick, columnar, obtuse, erect; flowers much spreading, ascending, the borders pubescent on the outside, and hoary.—Native of New South Wales.

2. *Banksia Integrifolia*; *Entire-leaved Banksia*. Leaves wedge-form, quite entire, white-tomentose underneath.—Native of the South Sea islands,

3. *Banksia Ericæfolia*; *Heath-leaved Banksia*. Leaves approximating acerose, truncate-emarginate, smooth. The leaves of this are very small.—Native of New South Wales.

4. *Banksia Dentata*; *Tooth-leaved Banksia*. Leaves oblong, attenuated into the petiole, curved, flexuose, toothed; teeth ending in a spinule, white underneath. The flowers in this species are smaller than in the others.—Native of New South Wales.

5. *Banksia Pyriformis*; *Pear-fruited Banksia*. Flowers solitary; capsules ovate, pubescent; leaves lanceolate, very entire, smooth.—Native of New South Wales.

6. *Banksia Gibbosa*; *Gibbous-fruited Banksia*. Flowers solitary; capsules ovate, gibbous, wrinkled; leaves columnar, pale green, smooth.—Native of New South Wales.

7. *Banksia Musculiformis*; *Muscle-fruited Banksia*. Flowers solitary; capsules ovate-conical, muscle-shaped, pointed, with tubercles on the outside; leaves obovate, emarginate.—Native of Amboyna.

8. *Banksia Spinulosa*; *Prickly-leaved Banksia*. Leaves linear-revolute, with a little sharp point, and with spinous denticulations towards the top.—Native of New South Wales.

Barbadoes Cherry. See *Malpighia*.

Barbadoes Gooseberry. See *Cactus Pereskia*.

Barbadoes Wild Olive. See *Bontia*.

Bark-beds. See *Hot-beds*.

Bark, Jesuit's. See *Cinchona*.

Barleria; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth four-parted, permanent; two opposite leaflets larger. *Corolla*: monopetalous, funnel-form, quinquefid, subequal; the fifth division deeper. *Stamina*: filamenta four, filiform, two very short, capillary. Antheræ oblong, the two lower withered. *Pistil*: germen ovate; style filiform, the length of the stamina; stigma bifid. *Pericarp*: capsule acute, flat-quadrangular, two-celled, two-valved, gaping elastically at the

claws; partition contrary. *Seeds*: two, compressed, roundish. **ESSENTIAL CHARACTER.** *Calix*: four-parted. *Stamina*: two, far less than the others. *Capsule*: quadrangular, bilocular, bivalvular, elastic without the claws. *Seeds*: two.—*Barlerias* being all natives either of the East Indies or South America, require the protection of the bark-stove.—The species are,

1. *Barleria Longifolia*. Spines of the whorls six-fold; leaves ensiform, very long, scabrous; flowers in whorls, axillary.—Native of the East Indies.

2. *Barleria Solanifolia*. Spines axillary; leaves lanceolate, toothletted; flowers blue, and more completely labiated than any of the other species.—Native of Panama. The roots of this species will continue three or four years, but after the second year the plants grow too rambling, and the lower parts of the branches being naked, are not so sightly as the young plants; therefore a succession of these should be raised and the old ones turned out. They are propagated by seeds, which will sow themselves in the pots which are near them in the stove, when the plants are once obtained; but where the seeds are received from abroad, they must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, and plunged into a hot-bed of tanner's bark, where they must constantly remain, and be managed in the same manner as other tender exotics from the same countries, giving them water frequently in summer, and letting the fresh air to them every day in warm weather, but in winter they should have less water, and be kept warm. They flower from June to November, and their seeds ripen soon after.

3. *Barleria Hystrix*. Spines axillary, twin, simple; leaves quite entire, lanceolate, ovate, smooth on both sides. The stem is wand-like, not firm.—Native of the East Indies.

4. *Barleria Prionitis*. Spines axillary, pedate, four-fold; leaves quite entire, lanceolate-ovate; stem herbaceous, round, stiff.—Native of the East Indies. It has flexible perennial stalks, which, if cut off during the summer, and made into lengths of six or eight inches, and planted in pots, plunging them into a hot-bed, and duly watered and shaded from the sun, will soon put out roots; when they may be planted each in a small pot, and plunged into the tan-bed in the stove; for although this sort may be kept in a dry-stove through the winter, yet the plants will not grow near so fast, nor will their leaves be so large, as those which are plunged into the bark. By this means the plants may be propagated in plenty; but as they rarely produce flowers in England, so two or three plants will be sufficient to maintain the species.

5. *Barleria Buxifolia*. Spines axillary, opposite solitary; leaves roundish, quite entire.—Native of Jamaica, and the East Indies. This will produce seed in England, provided the plants are kept in the tan-bed in the stove, and may therefore be propagated by seeds, which should be sown in the hot-bed; and the plants afterwards treated in the same manner as those of the fourth species.

6. *Barleria Noctiflora*. Spines axillary, branching; leaves lanceolate, quite entire, cuspidated; bractes ovate, scarious; tube elongated; flowers blue, and expanding during the night.—Observed near Tanjour in the East Indies.

7. *Barleria Cristata*. Leaves oblong, quite entire; two leaflets of the calix broader, ciliated, and two linear acute; stem round; corolla blue, with ovate lobes.

8. *Barleria Coccinea*. Unarmed: leaves ovate, toothletted, petioled; stem smooth, four feet high; flowers scarlet, in whorls at the joints, appearing from July till September.—Native of South America. See the fifth species.

9. *Barleria Pungens*. Unarmed: leaves ovate, acute, pungent; bractes ciliated.—Found at the Cape of Good Hope.

10. *Barleria Longiflora*. Unarmed: leaves ovate, silky; bractes cordate, scarious; corollas very long.—Observed on the mountains of St. Thomas in Malabar.

11. *Barleria Procumbens*. Unarmed: leaves lanceolate, crenate, hispid; heads terminating; flowers yellow.—Native of China, near Canton.

Barley. See *Hordeum*

Barnadesia; a genus of the class Syngenesia, order Polygamia Equalis.—GENERIC CHARACTER. *Calix*: common, somewhat ventricose, spreading at the tip, imbricate; scales imbricate, gradually longer from the base to the tip; the inferior or exterior ovate, closely imbricate, sharp, pungent; the superior or interior subulate, flat, spreading, pungent. *Corolla*: compound, rayed. Corollets hermaphrodite, tubular, very few, remote, in the disk lingulate, in a simple series, in the ray. Proper to the former, funnel-form; tube very short; border hairy, five-parted; parts erect, converging. Proper to the latter, ligulate, lanceolate, spreading at the base, incurved at the tip, and split, outwardly very hairy; tube longer than the calix. *Stamina*: filamenta five. Antheræ cylindric, tubular. *Pistil*: germen ovate; style filiform, longer than the stamina; stigma bifid; clefts spreading, ovate-rounded. *Pericarp*: none; calix converging. *Seeds*: very many, ovate, hairy; hairs reversed. *Down of the flowers of the disk*, bristly; rays subulate, stiff, broken backwards, naked, or covered with extremely minute hairs. *Of the radial flowers*, long, erect, spreading, many-rayed, feathery, soft. *Receptacle*: flat, villose, without chaff. ESSENTIAL CHARACTER. *Calix*: naked, imbricate, pungent. *Corolla*: radiate. *Down of the ray*, feathered; of the disk, bristly, broken backwards.—Of this genus the following species only has yet been discovered.

1. *Barnadesia Spinosa*. This is a shrub, with very smooth branches, set with a pair of thorns at their origin, which at first were stipules; they are patulous, brown, and smooth; leaves alternate, simple, ovate, quite entire, sharp, flat, veined, somewhat hairy on both sides, whitish underneath; petioles very short; stipules in pairs, small, subulate; flowers panicled, terminating; calix pubescent. The flower is singular, in having two sorts of down.—Native of South America.

Barrenwort. See *Epimedium*.

Barreria: a genus of the class Syngenesia, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-toothed, small. *Corolla*: one-petalled, five-parted; parts oblong, acute, convex beneath, concave above, with a double pit; the superior ovate, bifid, the wedge-shaped one trifid; excavated for the reception of the stamina. *Stamina*: filamenta five, ascending, linear, wider above, thick, triangular, bordered, curved. Antheræ erect, four-cornered, marginated, coalescing into the form of a mill-wheel; each, in the closed flower, answering together with the filamenta, to the pits of the two petals. *Pistil*: germen roundish; style short; stigma trifid. *Pericarp* and *Seeds*: not ascertained. ESSENTIAL CHARACTER. *Calix*: five-toothed, very small. *Corolla*: five-parted. *Style*: short. *Stigma*: trifid.—The only known species is,

1. *Barreria Guianensis*. This tree rises forty or fifty feet in height, and is two feet and a half in diameter; the bark is ash-coloured, and the wood is reddish-brown, hard, and compact: the flowers, which appear in November, are in small axillary spikes, alternate, and almost sessile.—Native of Guiana, in the extensive forests near the banks of the river Sinemari, fifty leagues from its mouth.

Barringtonia; a genus of the class Monadelphia, order

Polyandria.—GENERIC CHARACTER. *Calix*: perianth two-leaved, superior; leaflets roundish, concave, coriaceous, permanent. *Corolla*: petals four, equal, ovate, spreading, coriaceous, larger than the calix. Nectary conic, tubular, coating the base of the style, toothed at the tip; teeth several, unequal. *Stamina*: filamenta very many, monadelphous, (or conjoined from the very base into a cylinder seated on the receptacle,) capillary, longer than the corolla. Antheræ small, roundish. *Pistil*: germen inferior, turbinate; style filiform, length of the stamina; stigma simple. *Pericarp*: drupe large, ovate, conic quadrangular, crowned by the calix. *Seed*: nut long, ovate, outwardly wrinkled, fibrose, four-celled. *Kernels* ovate, wrinkled. ESSENTIAL CHARACTER. *Calix*: simple, two-leaved, superior, permanent. *Fruit*: a dry four-cornered drupe, inclosing a nut, one to four-celled.—The only known species is,

1. *Barringtonia Speciosa*; *Laurel-leaved Barringtonia*. This is a lofty tree, and the handsomest in the whole equinoctia flora, abounding with thick shady bunches of leaves, and large handsome purple and white flowers, every where mixed with them. The flowers open at night, and fall at sun-rise: the birds pluck them off, and the ground about these trees is perfectly covered with them. The seed mixed with bait, inebriates fish in the same manner as the *Coculus indicus*, &c.—It grows within the tropics, especially on the shores of the ocean, and at the mouths of rivers in the East Indies, from the southern coasts of China, through the Molucca isles to Otaheite, and the other Society Isles, the Friendly Isles, &c. It is cultivated in the governor's garden at the island of St. Helena.

Bartsia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, permanent; mouth obtuse, two-lobed; lobes emarginate, coloured at the top. *Corolla*: monopetalous, ringent; upper lip erect, slender, entire, longest; lower reflex, trifid, obtuse, very small. *Stamina*: filamenta four, bristle-shaped, the length of the upper lip; two somewhat shorter. Antheræ oblong, approximating under the top of the upper lip. *Pistil*: germen ovate; style filiform, longer than the stamina; stigma obtuse, nodding. *Pericarp*: capsule ovate, compressed, acuminate, two-celled, two-valved; partition contrary to the valves. *Seeds*: numerous, angular, small. ESSENTIAL CHARACTER. *Calix*: two-lobed, emarginate, coloured. *Corolla*: coloured less than the calix; upper lip longest. *Capsule*: two-celled.

1. *Bartsia Coccinea*; *Red Bartsia*. Leaves alternate, linear, two-toothed on each side; capsule elastic.—This most beautiful plant has a stem entirely simple: it has been found in Maryland, Virginia, and New York.

2. *Bartsia Pallida*; *Pale-flowered Bartsia*. Leaves alternate, lanceolate, quite entire; floral leaves ovate, toothed; root fibrous; stem round, simple, streaked; corolla purple.—Native of Siberia and Hudson's Bay.

3. *Bartsia Viscosa*; *Viscid Bartsia*, or *Yellow Marsh Eye-bright*. Leaves serrate, uppermost alternate; flowers distant, lateral; corolla yellow; stem a foot high, upright, cylindric, simple, hirsute. The whole plant is clammy.—It is an annual, native of France, Italy, and Britain; in the marshes of Cornwall, Devonshire, Lancashire, and Staffordshire; and of Argyleshire in Scotland; flowering in July and August.

4. *Bartsia Alpina*; *Alpine Bartsia*. Leaves opposite, cordate, obtusely serrate; antheræ hairy; stem simple, six or seven inches high, hard, villose, obtusely quadrangular; corollas of a violet purple, thrice as long as the calix.—Native of the mountains of Lapland, Switzerland, Savoy, Monte Baldo, and near Orton in Westmoreland.

5. *Bartsia Gymnandria*. Two-stamined; leaves radical, twofold, petioled; stem mostly two-leaved, three or four inches high, round, smooth, simple; one spiked; spike linear; obtuse; whorls bracted, collected; corolla pale blue.—It grows within the arctic circle on the north side of the frozen rocks in Kamptschatka, where there is no other vegetation.

6. *Bartsia Odontites*; *Red Bartsia*. Leaves lanceolate, serrate, the upper alternate; flowers in racemes, inclining to one side; corolla rose-coloured; antheræ smooth; root fibrous, annual.—Common in meadows and pastures, flowering in July.

Basella; a genus of the class Pentandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: seven-cleft, pitcher-shaped, the two outer divisions broader, one within the rest, converging above, fleshy at the base. *Stamina*: filamenta five, subulate, equal, fastened to the corolla, and shorter than it. *Antheræ* roundish. *Pistil*: germen superior, subglobular; styles three, filiform, the length of the stamina; stigmas oblong, on one side of the tops of the styles. *Pericarp*: corolla permanent, closed, fleshy, counterfeiting a berry. *Seed*: single, roundish. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: seven-cleft; two opposite divisions shorter, at length berried. *Seed*: one.—These plants are propagated by seeds, which should be sown on a hot-bed in the spring, and when they are fit to remove, they should be each planted in a separate pot filled with rich earth, and plunged into the tan-bed, where they must be treated in the same manner as other tender exotics. They may also be propagated by cuttings, which should be laid to dry a day or two after they are taken from the plants, before they are planted, that the wound may heal; otherwise they will rot. These cuttings should be treated in the same manner as the seedling plants; but as these plants rise so easily from seed, it is seldom they are propagated any other way; because they are plants of short duration. They climb to a considerable height, and send forth a great number of branches, so that they should have a place near the back of the stove, where they may be trained up to a trellis, or fastened to the back of the stove, otherwise they will twist themselves about whatever plants stand near them, and be very injurious to the other plants; whereas, when they are regularly trained to a trellis, they will have a good effect in adding to the variety. They flower from June till autumn, and the seeds ripen in September and December.—The species are,

1. *Basella Rubra*; *Red Malabar Nightshade*. Leaves flat; peduncles simple. The flowers of this plant have no great beauty, but the plant is preserved for the odd appearance of the stalks and leaves.—It is a native of the East Indies, Amboyna, Japan, &c. A beautiful colour is drawn from the berries; but when used for painting, does not continue very long, but changes to a pale colour. It is thought, however, this beautiful colour might be fixed, so as to become very useful; for the juice of these berries has been used for staining calico's in India.

2. *Basella Alba*; *White Malabar Nightshade*. Leaves oblong and flaccid. The stalks, flowers, and fruit, are smaller than those of the first species.—Native of China and Amboyna.

3. *Basella Lucida*; *Shining Malabar Nightshade*. Leaves subcordate; peduncles crowned, branching.—Native of the East Indies.

4. *Basella Nigra*; *Black Malabar Nightshade*. Leaves round-ovate, alternate, thick, smooth, entire, petioled; spikes lateral; stem perennial, twining, slender, round, succulent, branched; flowers purple and white, lateral, few, in long solitary spikes.—This is a native both of China and Cochinchina, in the hedges and fences of their gardens.

Basil. See *Ocimum* and *Clinopodium*.

Bassia; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved; leaflets coriaceous, ovate, permanent. *Corolla*: monopetalous, bell-shaped; tube inflated, ovate, fleshy; border shorter than the tube, eight-parted; divisions ovate, almost upright. *Stamina*: filamenta sixteen, eight below the jaws, and eight in the middle of the tube. *Antheræ* linear, sagittate, acute, villose on the inside, shorter than the corolla. *Pistil*: germen superior, ovate; style subulate, twice as long as the corolla; stigma acute. *Pericarp*: drupe fleshy, milky. *Seeds*: nuts five, oblong, three-cornered. **ESSEN. CHAR.** *Calix*: four-leaved. *Corolla*: eight-cleft; tube inflated. *Stamina*: sixteen. *Drupe*: five-seeded.—The species are,

1. *Bassia Longifolia*. Leaves ovate-lanceolate; peduncles axillary. This is a lofty tree, with the outmost branches recurved, thickish, and covered with a gray down.—Native of Malabar and Ceylon.

2. *Bassia Dubia*. Seed large, half-moon shaped, flattened like a lens, smooth, shining, of a dark chestnut colour, except an oblong rugged umbilical area, which is pale, and almost white. The shell is thick, stony, and very hard.—Native country not ascertained.

3. *Bassia Obovata*. Leaves obovate; peduncles heaped, terminating.—Native of the isle of Tanna in the South Seas.

Bassovia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, permanent, five-parted; parts ovate, acute. *Corolla*: one-petalled; tube very short; border five-cleft, spreading; clefts ovate, acute, larger than the calix. *Stamina*: filamenta five, inserted in the tube of the corolla, and opposite to its clefts. *Antheræ* ovate. *Pistil*: germen ovate, sitting on a glandule; style short; stigma thickish, obtuse. *Pericarp*: berry ovate, knobbed. *Seeds*: very many, kidney-shaped, girt with a membrane, nestling in a pulp. **ESSENTIAL CHARACTER.** *Corolla*: five-cleft, spreading, with a very short tube. *Berry*: ovate, knobbed, with many seeds.—The only species known, belonging to this genus, is,

1. *Bassovia Sylvatica*. Stems herbaceous, three or four feet high, branched; leaves alternate, ovate, acute smooth, quite entire, on a petiole about an inch in length; the largest are ten inches long, and four and a half broad; flowers in axillary corymbs, green, and very small.—Native of Guiana, in wet forests, flowering and fruiting in June.

Batis; a genus of the class Diœcia, order Triandria.—**GENERIC CHARACTER.** *Male.* *Calix*: ament pyramidal; scales one-flowered, four-fold, imbricate. *Corolla*: none. *Stamina*: filamenta four, erect, longer than the scales of the ament. *Antheræ* oblong, twin, incumbent. *Female*, on a separate plant. *Calix*: ament common, fleshy, containing some floscules conglomerated into an ovate quadrangular body; involucre two-leaved. *Corolla*: none. *Pistil*: germen quadrangular, fastened to the ament; style none; stigma two-lobed, obtuse, villose. *Pericarp*: berry conjoined with the rest, one-celled. *Seeds*: four, triangular, acuminate. **ESSENTIAL CHARACTER.** *Male*: ament four-fold, imbricate. *Calix* and *Corolla*: none. *Female*: ament ovate; involucre two-leaved. *Calix* and *Corolla*: none. Stigma two-lobed, sessile. Berries conjoined, four-seeded.—The only known species is,

1. *Batis Maratima*. This is a shrub about four feet high; stems brittle, round, ash-coloured; fruits yellow, or greenish-yellow. The whole plant is very salt to the taste; and it is burnt for barilla at Carthage, &c.—Native of the Caribbee islands, and the neighbouring continent. It is very common in all the salt-marshes on the south side of Jamaica.

Bauhinia; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth oblong, gaping longitudinally on the lower side, reclining on the other, gaping also five ways at the base, with five cohering leaflets above, deciduous. *Corolla*: petals five, oblong, waved with attenuated reflected tops, expanding; the lower ones a little larger, the upper one more distant, all with claws placed on the calix. *Stamina*: filamenta ten, declining shorter than the corolla; the tenth much the longest. *Antheræ* ovate, always on the tenth, seldom on the rest. *Pistil*: germen oblong, sitting on a pedicle; style filiform, declining; stigma obtuse, rising. *Pericarp*: legume long, subcolumnar, one-celled. *Seeds*: many, roundish, compressed, placed according to the length of the legume. **ESSENTIAL CHARACTER.** *Calix*: five-cleft, deciduous. *Petals*: expanding, oblong, with claws, the upper one more distant, all inserted into the calix.—These plants being all natives of hot countries, will not thrive in England unless they are kept in the bark-stove. They are propagated by seed, which must be procured from the countries where they grow naturally, for they do not perfect their seeds in England. As these plants frequently flower in winter, they deserve a place in the stove.—The species are,

1. *Bauhinia Scandens*; *Climbing Mountain Ebony*. Stem cirrhiferous; rising with many slender stalks, which put out tendrils, and fasten themselves to the neighbouring trees.—It is a native of both Indies, but has not produced flowers in England. The flowers are at first whitish, but turn to a yellowish colour.

2. *Bauhinia Aculeata*; *Prickly-stalked Mountain Ebony*. An erect inlegant shrub; with the trunk and branches prickly; leaves roundish, with two roundish blunt lobes, nine-nerved, prickly. It rises to the height of sixteen or eighteen feet in Jamaica, where, as well as in the other sugar islands, it grows plentifully. The stalks are terminated by several long spikes of yellow flowers, which are succeeded by bordered pods, about three inches long, containing two or three swelling seeds; these pods are glutinous, and have a strong balsamic scent, as have also the leaves when bruised; whence, from its strong odour, the Americans call it the Indian Savin-tree.

3. *Bauhinia Divaricata*; *Dwarf Mountain Ebony*. Leaves smooth; lobes divaricated, acute, two-nerved; petals lanceolate. This is a low shrub, seldom rising more than five or

six feet high, dividing into several branches. Flowers in a simple upright raceme; corolla white. The flowers have a very agreeable scent, appear most part of the summer, and are one of the greatest beauties of the hot-house. The pods are taper, about four inches long, and contain four or five dark-coloured seeds.—It flowers from June till September, and grows naturally in great plenty on the north side of the island of Jamaica.—This sort has several times produced pods in the Chelsea garden, but they have never come to maturity. The seeds should be brought over in their pods; which will preserve them good. These must be sown in pots filled with light fresh earth, and plunged into a moderate hot-bed of tanner's-bark; if the seeds be good, the plants will come up in about six weeks, and in a month after will be fit to transplant, when they should be carefully shaken out of the seed-pod, so as not to injure the roots, and each planted into a separate small pot filled with light loamy earth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root; after which they should have fresh air admitted to them every day in warm weather. In the autumn they must be placed in the bark-stove, and treated in the same way as other tender exotics, giving them but little water in winter.

4. *Bauhinia Ungulata*. Leaves ovate; lobes parallel; stem smooth, dividing into many small branches, terminated by loose bunches of white flowers.—Native of America.

5. *Bauhinia Variegata*; *Variogated Mountain Ebony*. Calices one-leaved, bursting; petals sessile, ovate; lobes of the leaves ovate obtuse. The flowers are large, and grow in loose panicles at the extremity of the branches, of a purplish red colour, marked with white, and the bottom yellow.—It grows naturally in both Indies.

6. *Bauhinia Purpurea*; *Purple Mountain Ebony*. Leaves subcordate, two-parted, rounded, tomentose underneath. A tall tree, The corolla is of a very red purple.—Native of the East Indies, where it flowers the whole year.

7. *Bauhinia Tomentosa*; *Downy Mountain Ebony*. Leaves cordate; lobes semiorbiculate, tomentose. Flower yellowish-white scentless.—Native of the East Indies.

8. *Bauhinia Acuminata*; *Sharp-leaved Mountain Ebony*. Leaves ovate; lobes acuminate, semioval; flowers bell-shaped, pure white.—Native of the East Indies.

9. *Bauhinia Marginata*. Stem prickly; leaves cordate with round lobes, tomentose underneath. The flowers grow at the extremity of the branches, two or three together, large, and of a dirty white colour. Native of New Spain.

10. *Bauhinia Rotundata*. Stem prickly; leaves subcordate, two-parted, rounded; flowers scattered, large, and white.—Native of Carthage in New Spain.

11. *Bauhinia Aurita*; *Long-eared Mountain Ebony*. Leaves subtransverse at the base; lobes lanceolate, projected, three-nerved; petals lanceolate.—Native place unknown. It flowers in September.

12. *Bauhinia Porrecta*; *Smooth Broad-leaved Mountain Ebony*. Leaves cordate; lobes projected, acute, three-nerved; petals lanceolate. This tree rises to about fifteen feet in height, with several straight trunks. The wood is very hard, and veined with black; whence its name of Ebony.—It grows on the hills in Jamaica, and flowers in July.

13. *Bauhinia Candida*; *White-leaved Mountain Ebony*. Leaves cordate, pubescent underneath; lobes ovate, obtuse; calices attenuated upwards, and elongated.—It flowers in May and June; and is a native of the East Indies.

Begonia; a genus of the class *Monœcia*, order *Polyandria*.

—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: none. *Corolla*: petals four (in *Begonia Octopetala* six to nine) of which two opposite ones are larger, commonly roundish (in *Begonia Ferruginea* all nearly equal, oblong.) *Stamina*: filamenta numerous (fifteen to one hundred) inserted into the receptacle, very short, sometimes united at the base. *Antheræ* oblong, erect. *Female Flowers*, usually on the same common peduncles with the males. *Calix*: none. *Corolla*: petals in most species five, in some six, in others perhaps four, commonly unequal. *Pistil*: germen inferior; three-sided, in very many winged; styles in most three, bifid; stigmas six. *Pericarp*: capsule in most three-cornered, winged, three-celled, opening at the base by the wings; some are two-celled, and others perhaps one-celled. **ESSENTIAL CHARACTER.** *Male.* *Calix*: none. *Corolla*: many petalled. *Stamina*: numerous. *Female.* *Calix*: none. *Corolla*: many-petalled, superior. *Capsule*: winged, many-seeded.—The plants of this genus increase readily by cuttings; and if kept in the bark-stove prove highly ornamental, being much esteemed, both for the beauty of the flowers and the singularity of the leaves. Where there is no bark-stove, they will be found to do very well over the flue of the dry-stove.—The species are as follows:

1. *Begonia Nitida*. Shrubby, erect; leaves very smooth, unequally cordate, obscurely toothed; largest wing of the capsule roundish; corolla flesh or rose coloured. It is an elegant shrub, flowering here from May till December.—Native of Jamaica.

2. *Begonia Isoptera*. Caulescent; leaves smooth, semicordate, obscurely toothed; wings of the capsule almost equal, parallel; seeds numerous, small.—Native of Java.

3. *Begonia Reniformis*. Caulescent; leaves kidney-shaped, angular, toothed; the largest wing of the capsule acute-angled, the others parallel, very small.—Native of Brazil, in the shady clefts of the rocks.

4. *Begonia Erminia*. Caulescent; leaves cordate, acuminate, serrate; the largest wing of the capsule sickle-shaped, the rest obliterated.—Native of Madagascar, on stones and rocks by brooks.

5. *Begonia Crenata*. Caulescent; leaves unequally cordate, roundish, obtuse, crenate-toothed; capsules two-celled; flowers pale red.—Native of the island of Salsette in the East Indies, on walls and rocks.

6. *Begonia Tenuifolia*. Caulescent; leaves unequally cordate, ovate, acute-angular, obscurely toothed; capsules two-celled.—Native of Prince's Island, near Java.

7. *Begonia Ferruginea*. Caulescent; leaves unequally cordate, toothed; petals of the male flower oblong, nearly equal; flowers blood red, nodding.—Found in New Granada.

8. *Begonia Grandis*. Caulescent; leaves unequally cordate, angular, serrate; wings of the capsule a little unequal; male corolla purple.—Native of Japan.

9. *Begonia Macrophylla*. This is two feet high, entirely smooth; female flowers five petalled.—A native of the islands in the West Indies.

10. *Begonia Acutifolia*. Caulescent; leaves semicordate, angular, toothed; the largest wing of the capsule obtuse-angled, the others acute-angled.—Native of Jamaica.

11. *Begonia Acuminata*. Caulescent; leaves hispid, semicordate, acuminate, unequally toothed; the largest wing of the capsule obtuse-angled, the others acute-angled.—Found in the Blue Mountains in Jamaica.

12. *Begonia Humilis*. Caulescent, upright; leaves hispid, semicordate, doubly serrate; wings of the capsule rounded, a little unequal.—Native of the island of Trinidad.

13. *Begonia Hirsuta*. Caulescent; leaves hispid, semicordate, doubly serrate; the largest wing of the capsule obtuse-angled, the others parallel and very small; corolla white.—Observed on the rocks of Guiana, in South America.

14. *Begonia Urticæ*. Caulescent, radicans; leaves hispid on both sides, unequally ovate, doubly serrate; capsules three-horned at the base; flowers usually in pairs, a male with a female; males blood-red; no stamina; no rudiment of a pistil.—Found by Mutis in New Granada.

15. *Begonia Scandens*. Scandent, radicans; leaves ovate-roundish, obscurely-toothed; the largest wing of the capsule obtusely angled, the others parallel and very small.—Native of Guiana, of Jamaica, and of the Isle of France.

16. *Begonia Tuberosa*. Creeping; leaves unequally cordate, angular, toothed; wings of the capsule parallel.—Native of Amboyna, the Moluccas, and Celebes.

17. *Begonia Rotundifolia*. Creeping; leaves reniform, roundish, crenate; stems thick, cylindric, naked, with small permanent stipules, between which they are marked with scars from the fallen leaves. The leaves are slightly crenate, green, and shining above, white beneath, on pretty long petioles. From the end of each stem arises a peduncle, or rather scape, longer than the leaves, bearing an umbel-shaped panicle of red monœcous flowers at the top.—Native of South America, on rocks and trees.

18. *Begonia Nana*. Stemless; leaves lanceolate; scape with about two flowers.—Native of Madagascar, on rocks and trunks of trees.

19. *Begonia Tenera*. Stemless; leaves unequally cordate; flowers umbelled.—Native of Ceylon.

20. *Begonia Diptera*. Stemless; leaves unequally cordate; peduncles dichotomous: one wing of the capsule very large, another narrow, and the third obscure.—Native of the island of Joanna, in shady places, by the sides of mountains.

21. *Begonia Octopetala*. Stemless; leaves cordate, five-lobed; peduncles dichotomous; root tuberous, viscid, purple within.—Found on the mountains of Lima.

22. *Begonia Malabarica*. Stems herbaceous; peduncles axillary, short, subtriflorous; fruits berried.—Native of Malabar.

23. *Begonia Repens*. Stems creeping, rooting at the joints; leaves one-eared; peduncles axillary, long, many-flowered.—Native of St. Domingo.

Bejario; a genus of the class *Dodecandria*, order *Monogynia*.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, gibbous downwards, subventricose, seven-cleft; divisions subequal, ovate, acute, converging, small; the outer ones broader, permanent. *Corolla*: petals seven, oblong, broader above, obtuse, patulous, inserted into the receptacle. *Stamina*: filamenta fourteen, subulate, rather shorter than the corolla, alternately less. *Antheræ* oblong, incumbent. *Pistil*: germen superior; style columnar, middle-sized, permanent; stigma thickish, seven-striated. *Pericarp*: berry juiceless, seven-cornered, depressed, umbilicate, seven-celled.

Seeds: numerous, columnar-oblong, imbricate. *ESSEN. CHAR.*
Calix: seven-cleft. *Petals*: seven. *Stamina*: fourteen. *Berry*: seven-celled, many-seeded.—The species are,

1. *Bejaria Æstuans*. Leaves lanceolate; flowers in racemes. This is a shrub, twelve feet in height, with roundish spreading branches; corolla flesh-colour.—Native of Mexico.

2. *Bejaria Resinosa*. Leaves ovate; flowers heaped; corolla purple, very resinous or viscid.—Found in New Granada.

Belladonna. See *Amaryllis* and *Atropa*.

Bell-flower. See *Campanula* and *Canarina*.

Bellis; a genus of the class Syngenesia, order Polygamia Superflua.—*GENERIC CHARACTER.* *Calix*: common hemispheric, upright; leaflets ten to twenty, in a double row, lanceolate, equal. *Corolla*: compound, radiate; corollules hermaphrodite, tubular, numerous in the disk; female ligulate, more in number than the leaves of the calix in the ray. Proper of the hermaphrodite funnel-form, five-cleft; of the female ligulate, lanceolate, scarcely three-toothed. *Stamina*: of the hermaphrodite; filamenta five, capillary, very short. *Antheræ* cylindric, tubular. *Pistil*: germen ovate; of the hermaphrodite, style simple; stigma emarginate: of the female, style filiform; stigmas two, patulous. *Pericarp*: none. *Calix*: unchanged. *Seeds*: solitary, obovate, compressed; down none. *Receptacle*: naked, conical. *ESSEN. CHAR.* *Calix*: hemispheric, with equal scales. *Seeds*: ovate, with no down. *Receptacle*: naked, conical.—The species are,

1. *Bellis Perennis*; *Perennial* or *Common Daisy*. Scape naked. It is a native of most parts of Europe, in pastures, flowers almost all the year, and shuts up very close every night, and in wet weather.—The taste of the leaves is somewhat acrid, notwithstanding which, it is used in some countries as a pot-herb. The roots have a penetrating pungency. It is ungrateful to cattle, and even to geese; although it occupies a large share of pasture lands, to the exclusion of grass and profitable herbs. It has been much recommended as excellent for fresh wounds, externally, and against inflammatory disorders, &c. internally; but it is now wholly out of use. Meyrick, however, recommends a strong decoction of the roots, as an excellent medicine in scorbutic complaints; but says, the use of it must be continued for a considerable length of time before its effects will appear. Some persons give the roots, boiled in milk, to keep puppies from growing; but they have no such effect.—The varieties of this species are: the Double White, Red, White, and Red-striped; Variegated, Scarlet, and Pied; Double-quilled, or with fistular florets; Double Cock's-comb-shaped, white, red, and speckled; Proliferous, Childing, or Hen-and-Chicken Daisy. The common wild Daisy being a troublesome weed in pasture lands, and the lawns and grass walks in gardens, is never cultivated. The Garden Daisies flower in April and May, when they make a pretty variety, being intermixed with plants of the same growth; they should be planted in a shady border, and a loamy soil, without dung, in which they may be preserved without varying, provided the roots are transplanted and parted every autumn; which is all the culture they require, except keeping them clear from weeds. These were formerly planted for edgings to borders, but they are very unfit for this purpose, because, where they are fully exposed to the sun, they frequently die in large patches, whereby the edgings become bald in many places.

2. *Bellis Annua*; *Annual Daisy*. Stem somewhat leafy. This is a low annual plant, seldom rising more than three inches high, with an upright stalk, hairy leaves on the lower part, but the upper part naked, and supporting a single flower like that of the Common Daisy, but smaller.—Native of Sicily, Spain, about Montpellier, Verona, and Nice.

VOL. 1.—14.

Bellium; a genus of the class Syngenesia, order Polygamia Superflua.—*GENERIC CHARACTER.* *Calix*: common simple, with very many equal boat-shaped leaflets. *Corolla*: compound, radiated; in the ray female, ten or twelve; in the disk hermaphrodite, very many: proper of the hermaphrodite funnel-shaped, quadrifid, erect; of the females, elliptic-emarginate, ligulate. *Stamina*: in the hermaphrodite, filamenta, four, short. *Antheræ* cylindric. *Pistil*: in the hermaphrodite, germen turbinate; style filiform; stigma bifid, oblong; in the females, germen turbinate; style very short; stigma bifid, minute. *Pericarp*: none; calix unchanged. *Seeds*: turbinate; crown chaffy, eight-leaved, rounded; down with eight single awns. *Receptacle*: naked, conic. *ESSENTIAL CHARACTER.* *Calix*: with equal leaflets. *Seeds*: conic, with a chaffy eight-leaved crown, and awned down. *Receptacle*: naked.—The species are,

1. *Bellium Bellioides*. Scape naked, filiform. It has the habit of the Daisy, but differs essentially from it in having a down to the seed: ray white; disk yellow.—Native of Italy, about Rome, and in the island of Majorca.

2. *Bellium Minutum*. Stem leafy. This is one of the minutest of plants; stem capillary, an inch in length; the whole plant smooth and ascending.—Native of the Levant.

Bellonia; a genus of the class Pentandria, order Monogynia.—*GENERIC CHARACTER.* *Calix*: perianth one-leaved, superior, semiquinquefid, permanent; divisions lanceolate, acute. *Corolla*: monopetalous, wheel-shaped; tube very short; border flat, semiquinquefid, obtuse, large. *Stamina*: filamenta five, subulate, erect, very short. *Antheræ* erect, convergin, short. *Pistil*: germen inferior; style subulate, straight, longer than the stamina; stigma acute. *Pericarp*: capsule turbinate, ovate, wrapped up in the calix, and beaked with its converging divisions, one-celled. *Seeds*: numerous, roundish, small. *ESSENTIAL CHARACTER.* *Corolla*: wheel-shaped. *Capsule*: one-celled, inferior, many-seeded, beaked with the calix.—The species are,

1. *Bellonia Aspera*. Leaves ovate-serrate: flowers corymbed, terminating. This is a shrub ten or twelve feet in height, from which issue many lateral branches.—Common in the warm islands of America.

2. *Bellonia Spinosa*. Thorny: leaves ovate, angular, tooth-serrate; peduncles axillary, one-flowered.—Discovered by Swartz in Hispaniola.

Benjamin Tree. See *Laurus*.

Bennet Herb. See *Geum*.

Bent Grass. See *Agrostis*.

Berberis; a genus of the class Hexandria, order Monogynia.—*GENERIC CHARACTER.* *Calix*: perianth six-leaved, patulous; leaflets ovate, with a narrower base, concave, alternate, smaller, coloured, deciduous. *Corolla*: petals six, roundish, concave, erect, expanding, scarcely larger than the calix. Nectary, two small roundish coloured bodies, fastened to the base of each petal. *Stamina*: filamenta six, erect, compressed, obtuse. *Antheræ* two, fastened on each side to the top of the filamenta. *Pistil*: germen cylindric, the length of the stamina; style none; stigma orbiculate, broader than the germen, surrounded with a sharp edge. *Pericarp*: berry cylindric, obtuse, umbilicated with a point, one-celled. *Seeds*: two, oblong, cylindric, obtuse. *ESSENTIAL CHARACTER.* *Calix*: six-leaved. *Petals*: six, with two glands at the claws. *Style*: none. *Berry*: two-seeded.—The species are,

1. *Berberis Vulgaris*; *Common Barberry*. Peduncles racemed; spines triple. The Common Barberry is a shrub, rising to the height of eight or ten feet, with stems upright and branched, smooth, and slightly grooved, brittle, with a white

pith, and covered with an ash-coloured bark; flowers towards the ends of the branches in pendulous racemes; berries first green, but when ripe changing to a fine red colour.—Native of the eastern countries, and now of most parts of Europe, in woods, coppices, and hedges. It is found in a chalky soil in England, particularly about Saffron-Walden in Essex. The flowers appear in May, and the fruit ripens in September. The varieties of this species are not worth enumerating. The leaves of this shrub are gratefully acid: the smell of the flowers is offensive when near, but pleasant at a certain distance: the berries are so very acid that birds seldom touch them. The Barberry is cultivated for the sake of the fruit, which are pickled, and used for garnishing dishes, and being boiled with sugar, form a most agreeable rob or jelly; they are used likewise as a sweetmeat, and in sugar-plums or comfits. The roots boiled in lee, yield a yellow colour; and in Poland they dye leather of a fine yellow colour with the bark of the root. The inner bark of the stems will also dye linen of a fine yellow, with the assistance of alum. Cows, sheep, and goats, are said to eat it; horses and swine, to refuse it. The fruit of the Barberry is considered as a mild restraining acid, agreeable to the stomach, and of efficacy, like other vegetable acids, in hot bilious disorders, and in a putrid disposition of the humours. According to Prosper Alpinus, the Egyptians employed a diluted juice of the berries in ardent and pestilential fevers. Their method is to macerate them in about twelve times their quantity of water, and let them stand for about twenty-four hours, and then to add a little Fennel-seed. The liquor is then pressed out and strained, and sweetened with sugar, or syrup of citrons, roses, &c. and given plentifully as a drink. A concrete, similar to cream of tartar, may be obtained from the juice, by mixing it with Lemon juice, in the proportion of two pounds of Barberry juice, and two ounces of Lemon juice, and digesting them in a sand-heat for two days, and then gently evaporating the filtered liquor to one half, and setting it in a cellar for some days. The tartar incrustates the sides of the vessel, and is a grateful medicine in febrile disorders: in fact, it is the essential salt of the Barberry. The berries of this shrub are also made into an agreeable jelly, by boiling them with an equal weight of fine sugar to a proper consistence, and then straining it. As the leaves are also acid, they have been sometimes employed for the same purposes as the fruit, and have been introduced as an ingredient in salads. The celebrated naturalist, Mr. Ray, successfully employed the inner yellow bark, which is austere and bitterish, in the form of a decoction, as a gentle purgative in the jaundice. It is also said to be a good lotion for the itch, and other cutaneous eruptions. Insects of various kinds are remarkably fond of the Barberry flowers. Linneus observed long since, that when bees, in search of honey, touch the filaments, they spring from the petal, and strike the antheræ against the stigma, and thereby explode the pollen. The purpose which this curious contrivance of nature is intended to answer is evident: in the original position of the stamina, the antheræ are sheltered from rain by the concavity of the petals; thus probably they remain, till some insect, coming to extract honey from the base of the flower, thrusts itself between the filaments, and almost unavoidably touches them in the most irritable part; thus the impregnation of the germen is performed; and as it is chiefly in fine sunny weather that insects are on the wing, the pollen is also in such weather most fit for the purpose of impregnation.—It is generally propagated by suckers, which are put out in great plenty from the roots: but these plants are very subject to send out suckers in greater plenty than those which are propagated by layers; therefore the latter

method should be preferred. The best time for laying down the branches is in autumn, and the young shoots of the same year are the best; these will be well rooted by the next autumn, when they may be taken off, and planted where they are designed to remain. When this plant is cultivated for its fruit, it should be planted single, (not in hedges, as was the old practice,) and the suckers every autumn taken away, and all the gross shoots pruned out; by this method the fruit will be much fairer, and in greater plenty. A few of these shrubs may be allowed to have place in wildernesses, or plantations of shrubs, where they will make a pretty variety; but they should not be planted in great quantities near walks, because their flowers emit a very strong disagreeable odour.

2. *Berberis Cretica*; *Cretan*, or *Box-leaved Barberry*. Peduncles subumbelled; spines triple. This never rises more than three or four feet high in England. It flowers in April and May, but is not succeeded by fruit.—Native of Crete or Candia, and also of Japan. This sort may be propagated by laying down the branches in the same manner as the first species; but when the young plants are taken off, they should be planted in pots, and sheltered under a frame in winter, till they have obtained strength, when they may be turned out of the pots, and planted in a warm situation.

Bergera; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, very small, acute, spreading, permanent. *Corolla*: petals five, oblong, bluntish, spreading. *Stamina*: filamenta ten, live alternately shorter. *Antheræ* round. *Pistil*: germen roundish, superior; style filiform; club-shaped; stigma turbinate, shining, with transverse grooves. *Pericarp*: berry subglobular, one-celled. *Seed*: two. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Berry*: subglobular, one-celled, with two seeds.—The only species hitherto discovered is,

1. *Bergera Koenigii*. This a very leafy tree, with the bark of Alder.—Native of the East Indies.

Bergia; a genus of the class Decandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, spreading; leaflets lanceolate, permanent. *Corolla*: petals five, oblong, spreading, the length of the calix. *Stamina*: filamenta ten, bristle-shaped, of middling length. *Antheræ* roundish. *Pistil*: germen roundish, superior; styles five, very short, approximating; stigmas simple, permanent. *Pericarp*: capsule simple, subglobular, mucronate, with five little swellings, five-celled, five-valved; valves ovate, flat, opening along the furrows, permanent, spreading very widely. *Seeds*: numerous, minute. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Capsule*: one, globular, with swellings, five-celled, five-valved; valves resembling petals. *Seeds*: very many.—The species are,

1. *Bergia Capensis*. Leaves lanceolate, or elliptic; flowers in whorls.—A native of Tranquebar in the East Indies.

2. *Bergia Glomerata*. Leaves obovate, crenulate; flowers glomerate.—Native of the Cape of Good Hope.

Bertiera; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth turbinate, five-toothed. *Corolla*: one-petalled; tube short; mouth villose; border five-cleft; clefts ovate, acute, spreading. *Stamina*: filamenta five, very short, inserted into the tube beneath the orifice. *Antheræ* linear, erect. *Pistil*: germen roundish, inferior, crowned by a gland; style filiform; stigma two-plated. *Pericarp*: berry globose, crowned by the teeth of the calix, two-celled. *Seeds*: very many, roundish, affixed to the dissepiment. ESSENTIAL CHARACTER. *Calix*: turbinate, five-toothed. *Corolla*: tube short, with a

villose mouth. *Berry*: globose, inferior, two-celled, many-seeded.—The only known species is,

1. *Bertiera Guianensis*. This is a shrub six or seven feet in height, the thickness of the human arm; branches opposite, knotty tomentose.—Found in the wood of Aurora in Guiana, flowering and fruiting in the month of June.

Besleria; a genus of the class Didymia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, acuminate, erect, loose, with reflected tips. *Corolla*: monopetalous, ringent; tube the length of the calix, roundish, gibbous on one side at the base, and at the top; border five-cleft; divisions roundish, the lowermost largest, the two upper less divided. *Stamina*: filamenta four, within the tube of the corolla, of which two are a little shorter. *Antheræ* oblong, twin, hanging down on each side. *Pistil*: germen globular, sitting on a glandular body, which embraces it and is permanent, cordate where the corolla is gibbous; style subulate, erect; stigma bifid, obtuse. *Pericarp*: berry subglobular, one-celled; partition two opposite semiovalate laminas. *Seeds*: numerous, round, very small, nestling, fixed to the inner surface of the berry. ESSENTIAL CHARACTER. *Calix*: five-parted. *Berry*: subglobular, many-seeded.—These plants grow naturally in the warm countries. The seeds should be sown on a hot-bed, early in the spring, and when the plants are come up half an inch high, they should be each transplanted into a small pot filled with light fresh earth, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root, after which time they should have air and water in proportion to the warmth of the season, and the heat of the bed in which they are placed. When the plants have filled these small pots with their roots, they must be shaken out, the roots trimmed, and put into large ones, filled with light fresh earth, and treated as before. In the second year they will flower.—The species are,

1. *Besleria Melittifolia*. Peduncles branching; leaves ovate.—Native of South America.

2. *Besleria Lutea*. Peduncles simple, crowded; leaves lanceolate.—Native of Martinico, Jamaica, &c.

3. *Besleria Cristata*. Peduncles simple, solitary; calices serrate-erect; corolla yellow.—Native of woods and moist mountains in Martinico.

4. *Besleria Bivalvis*. Stem herbaceous, long, creeping, hairy, round; calices bivalve, torn.—Observed at Surinam.

5. *Besleria Biflora*. Peduncles two-flowered; involucre caducous, inflated; leaves ovate, quite entire.—Native of the island of Otaheite.

6. *Besleria Cymosa*. Peduncles cymed; pedicels with little bractes; leaves ovate, crenate.—Native of the island of Tanna.

Beta; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, concave, permanent; divisions ovate-oblong, obtuse. *Corolla*: none. *Stamina*: filamenta five, subulate, opposite to the leaves of the calix, and of the same length with them. *Antheræ* roundish. *Pistil*: germen in a manner below the receptacle; styles two, very short, erect; stigmas acute. *Pericarp*: capsule within the bottom of the calix, one-celled, deciduous. *Seed*: single, kidney-form, compressed, involved in the calix. ESSENTIAL CHARACTER. *Calix*: five-leaved, *Corolla*: none. *Seed*: kidney-form, within the substance of the base of the calix.—The species are,

1. *Beta Vulgaris*; *Red Garden Beet*. Flowers heaped; leaflets of the calix toothed at the base.—There are many seminal varieties; for the Beet is very subject to change and to degenerate in our climate. It is a native of the sea-coast

of the southern parts of Europe. The roots of Red Beet are boiled, sliced, and eaten cold, by themselves, or in salads; are used as garnish to dishes, and as a pickle. The green-leaved sort is most esteemed; the roots being the largest and tenderest. Martial has justly marked the Beet for its fatuity. It is said to be prejudicial to the stomach, and to afford little nourishment: taken in quantity, it tends to loosen the belly. The juice both of the roots and leaves is said to be a powerful errhine, occasioning a copious discharge of mucus, without provoking sneezing. A good sugar may be obtained from the juice of the fresh roots.—This species is frequently sown with Carrots, Parsnips, or Onions, by the kitchen-gardeners near London, who draw up their Carrots or Onions when they are young, whereby the Beets obtain room to grow, when the other crops are gathered; but if the other crops are not removed in time, it will be better to sow them separately. This sort requires a deep light soil; for, as their roots run deep in the ground, so in shallow ground they will be short and stringy. The seeds should be sown in March, but the plants should not be left nearer than a foot apart, or in good land a foot and a half, for the leaves will cover the ground at that distance. The roots will be fit for use in the autumn, and continue good all the winter; but in the spring, when they begin to shoot, they will be hard and stringy: a few roots may be left for seed, or some of the fairest roots transplanted to a sheltered spot of ground, where they may be defended from strong winds, which frequently break down their stalks, if they are not well supported, especially when the seeds are formed; which, becoming heavy as they increase in bulk, are apt to weigh down the tender stalk upon which they grow. The seed will ripen in September, when the stalks should be cut off, and spread on mats to dry, and afterwards threshed out and cleared, and put up in bags for use.

2. *Beta Cicla*; *White Garden Beet*. Flowers threefold; leaflets of the calix unarmed at the base. The lower leaves of this sort are thick and succulent, and their footstalks are broad: for these it is cultivated; the leaves being boiled as Spinach, or put into soups, and the stalks and midrib of the leaf being eaten as Asparagus: it affords both food and medicine.—The juice of the fresh root is an excellent remedy for the head-ache, and that species of the tooth-ache in which the whole jaw and side of the face is affected. The method of using it, is to snuff it up the nose in order to provoke sneezing, and a discharge of humours from the head and parts adjacent.—This sort is commonly sown by itself, and not mixed with other crops. It must be sown in the beginning of March, upon an open spot of ground, that is not very moist; the seeds should be sown thinly, because the plants require room to spread; for when they are too close, the leaves, being small and full of fibres, will be unfit for the purposes designed. When the plants have put out four leaves, they should be hoed, as is practised for Carrots, carefully cutting up all the weeds, and also the plants where they are too near each other, leaving them at least four inches asunder: if this be done in dry weather, all the present weeds will be destroyed; but as young weeds will soon appear, in three weeks or a month's time the ground should be a second time hoed over, to cut up the weeds, and thin the plants to a greater distance; for by this time they will be past danger, and should not be left nearer than six inches.—A large variety of this has been introduced from abroad, under the titles of *Mangel Wurzel*, *Racine de Disette*, *Root of Scarcity*. It is much cultivated on the continent, both in the fields and gardens. Its qualities, and the quantity of its produce, have been much magnified, like most other newly introduced

things. The leaf and root are said to be excellent food for man and beast, not liable to be affected by drought, or to destruction from insects. The leaves are twelve or fifteen inches broad or more, and of proportionable length, and may be gathered every fortnight during the season. The roots weigh from ten to twenty pounds; they have an earthy taste, and are mawkishly sweet, either boiled, fried, or in salad. The young, thick, fleshy stalks, divested of the leafy part, peeled or scraped, then boiled and served up with butter, are tender, and agreeably tasted; as are also the leaves, to boil occasionally as Spinach and other small greens.

3. *Beta Maritima*; *Sea Beet*. Flowers double, or twin; leaflets of the calix even, not toothed.—It is a native of Holland; and is also found plentifully about Nottingham, and on the sea-coast, and in the salt marshes of Great Britain.

4. *Beta Patula*; *Spreading Beet*. Flowers heaped; all the leaves linear-lanceolate; branches divaricated. It flowers in August.—Native of the island of Madeira.

Betel, or *Bette*. See *Piper*.

Betonia; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, cylindrical, five-toothed, awned, permanent. *Corolla*: monopetalous, ringlet; tube bent in, cylindrical; upper lip roundish, entire, flat, erect; lower trifid; middle division broader, roundish, emarginate. *Stamina*: filamenta four, subulate, the length of the throat; two shorter, inclined to the upper lip. *Antheræ* roundish. *Pistil*: germen four-parted; style, form, situation, and size of the stamina; stigma bifid. *Pericarp*: none. *Calix*: fostering the seeds in its bosom. *Seeds*: four, ovate. ESSENTIAL CHARACTER. *Calix*: awned. *Corolla*: upper lip ascending, flattish; tube cylindrical.—They may be propagated by seeds, or by parting the roots. They require a shady situation and a moist stiff soil. The best time to transplant and separate the roots, is in autumn; but the seeds should be sown in the spring, upon a shady border, and they will require no other care but to keep them clean from weeds, and to thin them where they are too close.—The species are,

1. *Betonia Officinalis*, *Wood Betony*. Spike interrupted; helmet of the corolla entire; middle division of the lower lip emarginate; calices smoothish. There are two varieties of this species.—Betony, says Linneus, was formerly much used in medicine; but it is discarded from modern practice. When fresh, it intoxicates; the leaves when dry excite sneezing: sheep eat it, but goats refuse it. The leaves and flowers, according to Lewis, have an herbaceous, roughish, and somewhat bitterish taste, with a weak aromatic flavour. An infusion or light decoction of them may be drunk as tea; or a saturated tincture, in rectified spirits, may be given in laxity and debility of the viscera. The sneezing quality of the dried leaves seems to be merely owing to the rough hairs on them. The roots are bitter, and very nauseous: in a small dose they vomit and purge violently. Meyrick informs us, that many people have been cured of inveterate head-aches, which resisted every other remedy, by daily breakfasting on a tea made of the leaves and tops of this herb: he says, the dried leaves are often smoked as tobacco, in disorders of the head and stomach, and that the young leaves, beaten into a conserve, are beneficial in the jaundice, falling-sickness, palsy, gout, and dropsy; as also in colds; coughs, wheezing, shortness of breath, and sharp defluxions on the lungs. A strong decoction of the plant kills worms, removes obstructions, takes away stitches and other pains in the back and sides, and eases the colic. Bruised, and applied to green wounds, it quickly heals them, and draws thorns, splinters, and other bodies, out of the flesh. It is a native of woods, heaths, and

pastures, among bushes; flowering from the beginning of July to September.

2. *Betonia Orientalis*; *Oriental Betony*. Spike entire, middle division of the lip of the corolla quite entire.—First discovered in the Levant.

3. *Betonica Alopecuros*; *Fox-tail Betony*. Spike leafy at the base; helmet of the corolla bifid.—Native of the mountains of Savoy, Piedmont, Austria, Carniola, Silesia, and Provence.

4. *Betonica Hirsuta*; *Hairy Betony*. Spike leafy at the base; helmet of the corolla entire.—Native of the Alps, Appenines, and Pyrenees.

5. *Betonica Heraclea*. Spike with woolly calices; teeth filiform; leaves lanceolate, naked; stem and leaves almost smooth; enollas yellow.—Native of the Levant.

6. *Betonica Stricta*; *Danish Betony*. Spike oblong; helmet of the corolla entire; middle division of the lower lip notch-waved; calices hairy.—Native of Denmark.

7. *Betonica Incana*; *Hoary Betony*. Spike interrupted; helmet of the corolla bifid; middle division of the lower lip notched; tube tomentose, bent in.—Native of Italy.

Betula; a genus of the class Monoccia, order Tetrandria.—GENERIC CHARACTER. *Male flowers*, in a cylindrical ament. *Calix*: ament imbricate on every side, loose, cylindrical; consisting of three flowered scales, in each of which are two very minute scales, placed at the sides; three equal floscules, fixed to the disk of each scale of the calix. Perianth in each one-leaved, small, entire, three or four parted; divisions ovate, obtuse. *Corolla*: none. *Stamina*: filamenta to each four, very small. *Antheræ* twin. *Female flowers*, in an ament of the same plant. *Calix*: ament cylindrical or roundish, imbricate, with two-flowered scales. *Corolla*: none. *Pistil*: germen proper, ovate, compressed, very small, two-seeded; styles two, setaceous; stigmas simple. *Pericarp*: none. Ament under each scale cherishing the seeds of two florets. *Seeds*: solitary, ovate. ESSENTIAL CHARACTER. *Male*. *Calix*: one-leaved, three-cleft, three-flowered. *Corolla*: four-parted. *Female*. *Calix*: one-leaved, subtrifid, two-flowered. *Seed*: with a winged membran on each side.—The species are,

1. *Betula Alba*; *Common Birch Tree*. Leaves ovate, acuminate, serrate. This tree is known at first sight by the silvery colour of its bark: it is of a middling or rather inferior size among other forest trees. The wood of Birch is very white; women's shoe-heels and pattens, and packing cases, are made of it. It is planted along with hazel, to make charcoal for forges. In the northern parts of Lancashire they make a great quantity of besoms with the twigs, for exportation. The bark is of great use in dyeing wool yellow, and particularly in fixing fugacious colours. For this purpose it is best to use it dry, and to disbark trees of eighteen or twenty years' growth, at the time when the sap is flowing. The trees should stand, and be cut down the following winter. The black American Birch may be applied equally well to the same purpose. The Highlanders of Scotland use the bark for tanning leather, and for making ropes; and sometimes they burn the outer rind instead of candles. With the fragments dexterously braided, the Laplanders make themselves shoes and baskets; they use large thick pieces, set out with a hole in the middle to fit the neck, for a surtnut to keep off the rain. The Russians, Poles, and Norwegians, cover their houses with it, laying turf three or four inches thick over. In Kamtschatka they make hats and drinking cups of it. The wood was formerly used by the Scotch Highlanders for their arrows; but now by the wheelwright, and for most rustic implements; by the turner, for trenchers, bowls, ladles, &c.

and when of a proper size, it will make tolerable gates, rails, &c. In France, it is generally used for wooden shoes. It affords good fuel, some of the best charcoal; and the soot is a good lamp-black for printers' ink. The small branches serve the Highlanders for hurdles and side fences to their houses. Moxa is made of the yellow fungous excrescences of the wood, which sometimes swell out from the fissures. The leaves afford good fodder to horses, cows, sheep, and goats. The seeds are the favourite food of the siskin, or aberdevine; and the tree also furnishes food for a variety of insects.—The vernal sap of the Birch-tree is well known to have a saccharine quality, and to make a wholesome diuretic wine. In order to obtain this juice, in the beginning of March, while the sap is rising, and before the leaves shoot out, bore holes in the bodies of the largest trees, and put fossets therein, made of Elder sticks with the pitch taken out, setting vessels under to receive the liquor. If the tree be large, you may tap it in four or five places at a time; and thus from several trees you may draw several gallons of juice in a day. If you do not obtain enough in one day, bottle up close what you have; until you have extracted sufficient for your purpose; but the sooner it is boiled, the better. Boil the saps long as any scum rises, skimming it all the time. To every gallon of liquor put four pounds of sugar, and boil it afterwards half an hour, skimming it well; then put it into an open tub to cool, and when cold, turn it into a cask; when it has done working, bung it up close, and keep it three months; then either bottle it off, or draw it out of the cask when it is a year old.—This juice is an excellent medicine against the scurvy, and other similar disorders. It removes obstructions, promotes urine, and, if taken pretty freely, loosens the belly. Fermented with yeast, it yields a vinous liquor, which is far from being unpleasant, and is said to be good for the stone and gravel. The leaves and bark of the tree, resolve, clean, and resist putrefaction. A decoction of them may be advantageously employed to bathe cutaneous eruptions with, and is also serviceable in the dropsy.—This tree deserves to be planted in parks and ornamental woods; to increase the variety, and its fragrant smell after rain justly entitles it to a place in the wilderness. The stem being straight, the bark smooth and white, and the foliage neat, the Birch has a picturesque appearance, when properly placed in ornamental plantations; either in the openings here and there, to show the foliage and hanging down of the twigs; or within, to display its silvery bark through the gloom. Though it is in the lowest esteem as a timber tree, it may yet deserve to be cultivated, not merely as an ornament, but for its various uses; especially as it will grow to advantage upon barren land, where better trees will not thrive: it will flourish in moist spongy land, or in dry gravel and sand, where there is little surface; upon ground which produced nothing but moss, these trees have succeeded so well as to be fit to cut in ten years after planting, when they have been sold for nearly ten pounds the acre standing, and the after-produce has been considerably increased; and as the woods near London have been grubbed up, the value of these plantations has advanced in proportion: therefore those persons who are possessed of such poor land, cannot employ it better than by planting it with these trees, especially as the expense of doing it is not great. The best method to cultivate it, is to furnish yourself with young plants from the woods where they naturally grow; but in places where there are no young plants to be procured, they may be raised from seeds, which should be carefully gathered in the autumn, as soon as the scales under which they lodge begin to open, otherwise they will soon fall out and be lost: the seeds being small, should not be buried deep in the ground,

a quarter of an inch is sufficient. They should be planted in autumn, or from the middle of October till the middle of March, in the shade, where they will thrive better than when they are exposed to the full sun; for in all places where there are any large trees, the seeds fall, and the plants come up well without care; so that if the young plants are not destroyed by cattle, there is generally plenty of them in all the woods where there is any of these trees. If the plants take kindly to the ground, they will be fit to cut in about ten years; and afterwards they may be cut every seventh or eighth year, if they are designed for the broom-makers only; but where they are intended for hoops, they should not be cut oftener than every twelfth year. The expense of making these plantations, in places where the young plants can be easily procured, will not exceed forty shillings per acre, and the after-expense of clearing, about twenty shillings more; so that the whole will not be more than three pounds; and if the land so planted be of little value, the proprietor cannot make better use of his money; for when the wood is cut, it repays the expense with interest, and a perpetual stock upon the ground.—The several varieties of this species are of too trifling a nature to be here enumerated.

2. *Betula Nigra*; *Black Virginia Birch-tree*. Leaves rhomb-ovate, acute, doubly serrate, pubescent underneath, entire at the base; scales of the strobiles villose; segments linear equal. Although this species has been hitherto propagated chiefly for ornamental plantations, it is to be hoped that it will be admitted among our forest trees, for it is equally hardy with the European White Birch, and attains to a much greater size, growing upwards of sixty feet high, and thriving on the most barren ground, and may be cultivated to great advantage in England, in the same manner as the first species; which see.—There are several varieties of this species, differing in the colour, size of the leaves, and shoots; such as the Broad-leaved Virginia, the Poplar-leaved Virginia, the Paper Birch, Brown Birch, &c.

3. *Betula Lenta*; *Canada Birch*. Leaves cordate oblong, acuminate, serrate. It grows to sixty feet or more in height. The liquor flowing from its wounds is used by the inhabitants of Kamtschatka without previous fermentation; with the wood they build sledges and canoes; and they convert the bark into food by stripping it off when green, and cutting it into long narrow pieces, like vermicelli, drying it, and stewing it with their caviar.—Of this species, which is propagated in the same manner as the first, there are also several varieties not worth noticing.

4. *Betula Nana*; *Smooth Dwarf Birch*. Leaves orbiculate, crenate, or circular, scolloped. This is an upright shrub, seldom above two or three feet high; trunk hard and stiff, with a roughish bark, like that of the Elm, of a russet or blackish purple colour. It flowers in May, and is a native of the northern parts of Europe.—This plant, the leaves of which, according to Linneus, dye a better yellow than the common Birch, is of signal use in the economy of the Laplanders; the branches furnishing them with their bed, and their chief fuel. The seeds are the food of the ptarmigan, which makes so considerable a part of their sustenance. The moxa is also prepared from it, which the Laplanders consider as an efficacious remedy in all painful diseases.

5. *Betula Pumila*; *American or Hairy Dwarf Birch*. Leaves obovate, crenate.—It is a native of North America, cultivated only in the gardens of the curious.

6. *Betula Alnus*; *Alder*. Peduncles branched; leaves roundish, wedge-form, very obtuse, glutinous; axils of the veins villose underneath. Though this species appears generally as a shrub, it will grow to a considerable tree, thirty-five

or forty feet in height.—It is a native of Europe, from Lapland to Gibraltar, and of Asia, from the White Sea to mount Caucasus, in wet and boggy grounds, and on the banks of rivers; flowering with us in March and April. There are many varieties, of which our limits will not admit; but there is a long-leaved Alder from America, which grows to thirty feet in height, and merits a place in all plantations. The branches are slender, smooth, numerous, and dark-brown, or purple; the leaves are long, and free from the clamminess of the common sort: they sometimes continue on the tree even in December, and it has then the appearance of an evergreen.—The wood of the Alder is valuable for piles, pipes, pumps, sluices, and in general for all works intended to be constantly under water. It is said to have been used under the Rialto at Venice; and we are told that the morasses about Ravenna were piled with it, in order to lay the foundations for building upon. In Flanders and Holland, it is raised in abundance for this purpose. It serves also many domestic and rural uses, as for cart wheels, spinning-wheels, milk-vessels, bowls, spoons, small trays, trenchers, and other turnery ware, troughs, handles of tools, clogs, pattens, and wooden heels. The roots and knots furnish a beautiful veined wood for cabinets. The Scotch Highlanders often make chairs with it, which are very handsome, and the colour of Mahogany. The wood that has lain in bogs, is black like Ebony. It is very generally planted for coppice wood, to be cut down every ninth or tenth year for poles; and the branches make good charcoal. The bark is used by tanners and leather-dressers; also by fishermen for their nets. This, and also the young shoots, dye yellow, and, with a little copperas, a yellowish gray, very useful in the demi-tints and shadows of flesh in tapestry. The shoots cut in March will dye a cinnamon colour; and a fine tawny, if they be dried and powdered. The fresh wood yields a dye the colour of rappee-snuff. The catkins dye green. The bark is used as a basis for blacks; an ounce of it dried and powdered, boiled in three quarters of a pint of water, with an equal quantity of logwood, with solution of copper, tin, and bismuth, six grains of each, and two drops of solution of iron vitriol, will dye a strong deep *boue de Paris*. The leaves have been sometimes employed in tanning leather. The Laplanders chew the bark, and dye their leather garments red with their saliva.—The whole tree is very astringent. Motherby says, a decoction of the bark of the Alder has been often known to cure agues, and is frequently used by country people, to repel inflammatory tumors in the throat, and parts adjacent. According to Tournefort, the peasants on the Alps are frequently cured of rheumatic complaints, by being covered with bags full of the heated leaves. The bark possesses a considerable degree of astringency, and a decoction of it may be advantageously employed to bathe the swellings and inflammations. It dyes woollen of a reddish colour, and, with the addition of copperas, black. The Alder makes good hedges by the sides of streams and ditches, and in all wet morassy soils, and serves to keep up the banks; but if it be planted in a low meadow, it is said that the ground surrounding it will become boggy; whereas, if Ash be planted, the roots of which penetrate a great way, and run near the surface, the ground will become firm and dry. The shade of Alder seems to be no material impediment to the growth of grass. The boughs cut in summer, spread over the land, and left during the winter to rot, are found to answer as a manure, clearing the ground in March of the undecayed parts, and then ploughing it. The fresh-gathered leaves are covered with a glutinous liquor, in which fleas are said to entangle themselves, as birds do in lime. Linnaeus says, that horses, cows, sheep, and goats, eat it, but

that swine refuse it. The tongues of horses feeding upon it are turned black, and it is supposed by some persons not to be wholesome for them.—The Alder delighting in a very moist soil, where few other trees will thrive, is a great improvement to such lands. It is propagated by layers, cuttings, or truncheons about three feet in length. The best time for planting truncheons is in February, or the beginning of March; they should be sharpened at one end, and the ground should be loosened with an iron crow before they are thrust into it, that the bark may not be torn off. They must be planted at least two feet deep, to prevent their being blown out of the ground by strong winds, after they have made their shoots. The plantations should be cleared at first of tall weeds; but when the trees have made good heads, they will require no farther care. If you raise them by layers, this operation must be performed in October, and by the October following they will have taken root sufficiently to be transplanted. They should be set at least a foot and a half deep in the ground; and their tops must be cut off to about nine inches above the surface, which will occasion them to shoot out many branches. In planting Alders for coppices, it is much better to raise them from young trees than from truncheons. To obtain a quantity of these, plant suckers, and head them down for stools; lay the shoots in the succeeding autumn, and in twelve months they will have taken root; then remove and plant them in rows; in one or two years, they may be planted where they are to remain. If the coppice is to be on boggy or watery ground, they may be removed from the nursery, and planted three feet asunder in holes previously prepared. There they may stand six or seven years, when half the trees may be taken away, and the rest cut down for stools. Every ninth or tenth year will afford a fall for poles. These trees will thrive exceedingly on the sides of brooks, and may be cut for poles every sixth year. The banks of rivers may be secured by placing truncheons very close, and cross-wise. Their leaves being large, and of a deep green, they will add much to the beauty of aquatic plantations.

7. *Betula Incana; Hoary Alder.* Peduncles branched; leaves roundish, elliptic, acute, pubescent underneath; axils of the veins naked; stipules lanceolate. This species is totally distinct from the common Alder; it never attains the size of that, and is commonly shrubby; the trunk is scarcely thicker than a man's arm, the wood white, and of a close texture.—It grows naturally in dry sandy soils, and may perhaps be cultivated with the Birch, where land is of little value, as an under-wood, and may be propagated either by layers or cuttings, as well as by seeds, where they can be obtained.—Native of the alpine and subalpine parts of Switzerland, of Dauphiny, of eastern Siberia, and of the islands beyond Kamtschatka.

8. *Betula Populifolia; Poplar-leaved Birch.* Leaves deltoid, drawn out to a long point, unequally serrate, very smooth; the scales of the strobiles having roundish side-lobes; petioles smooth.—Native of North America.

9. *Betula Papyracea; Paper Birch.* Leaves ovate, acuminate, doubly serrate; veins hirsute underneath.—Native of North America.

10. *Betula Excelsa; Tall Birch.* Leaves ovate, acute, serrate; scales of the strobiles having the side-lobes rounded; petioles pubescent, shorter than the peduncle.—Native of North America.

11. *Betula Oblongata; Turkey Alder.* Peduncles branched; leaves oval, somewhat obtuse, glutinous; the axils of the veins marked underneath.—This is very common in Austria and Hungary.

12. *Betula Serrulata; Notched-leaved Alder.* Peduncles

branched; leaves obovate, acute; veins and their axils villose underneath; stipules oval, obtuse.—Native of Pennsylvania.

13. *Betula Crispa*; *Curled-leaved Alder*. Peduncles branched; leaves ovate, acute, somewhat waved; veins hairy underneath; axils naked; stipules roundish, ovate.—Native of Newfoundland and Hudson's Bay.

14. *Betula Daurica*. Leaves ovate, acuminate, serrate, hairy on the nerve. This species, when young, is scarcely to be distinguished from our common Birch, except by the leaves: it does not grow so tall, and the trunk does not exceed a foot in diameter: the wood is hard, yellower than that of the common sort, and in old trees marbled with brown and gray towards the middle: it is tougher, and therefore more fit for the use of the wheelwright: it is also used for making charcoal.—Native of Dauria.

15. *Betula Fruticosa*. Leaves rhomboid-ovate, equally serrate, smooth.—It abounds in marshes, and on rocky mountains, and in the cold subalpine regions of eastern Siberia, especially towards the lake Baikal.

Bidens; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common imbricate erect; leaflets often equal, oblong, channelled, concave. *Corolla*: compound uniform, tubular; corollules hermaphrodite, tubular; proper one-petalled, funnel form, border five-cleft erect. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: germen oblong; style simple, the length of the stamina; stigmas two, oblong, reflex. *Pericarp*: none. *Calix*: unchanged. *Seed*: solitary, obtuse-angular; down with two or more awns, oblong, straight, acute, rough-hooked backwards. *Receptacle*: flat, chaffy; chaffs deciduous, flattish. ESSENTIAL CHARACTER. *Calix*: imbricate. *Corolla*: sometimes, but seldom, with a floscule or two in the ray. *Seed*: crowned with erect scabrous awns. *Receptacle*: chaffy.—The species are,

1. *Bidens Tripartita*; *Trifid Water Hemp Agrimony*, or *Bur Marygold*. Leaves trifid; calices somewhat leafy; seeds erect; root annual; stem one to three feet high.—This plant dyes a deep yellow: the yarn or thread must be first steeped in alum-water, then dried and steeped in a decoction of the plant, and afterwards boiled in the decoction. The seeds have been sometimes known to destroy gold fish by adhering to their gills and jaws. As it is found by a chemical analysis to possess much the same qualities as *Verbesina acmella*, it is probable that it might have the same good effects in expelling the stone and gravel: it grows readily in wet situations.

2. *Bidens Minima*; *Nodding Bur Marygold*. Leaves lanceolate, sessile; flowers and seeds erect.—This, like the first species, prospers in a wet soil.

3. *Bidens Nodiflora*; *Sessile-flowered Bidens*. Leaves oblong, quite entire, one-toothed; stem dichotomous; flowers solitary, sessile; annual.—Native of the East Indies. It must be sown upon a moderate hot-bed in the spring, and afterwards treated like other hardy annual plants, planting them into the full ground the latter end of May. They will flower in June, soon after which the plants decay.

4. *Bidens Tenella*. Leaves linear; peduncles capillary; calices mostly four-leaved; seeds erect, five-fold.—It is an annual, a native of the Cape of Good Hope, and must be cultivated in the same manner as the preceding species.

5. *Bidens Cernua*; *Drooping Water Hemp Agrimony*, or *Bur Marygold*. Leaves lanceolate, stem-clasping; flowers nodding, yellowish-green; seeds erect; root annual.—Native of most parts of Europe. Found at Ditchingham in Norfolk, and Tarporley in Cheshire; it is frequent in Ireland. It flourishes in wet situations.

6. *Bidens Frondosa*; *Smoothed-stalked Bidens*. Leaves pin-

nate, serrate, marked with lines, smooth; seeds erect; calices leafy; stem polished, three feet high.—It grows naturally in Virginia, Maryland, and Canada, where it is often a troublesome weed. It is easily propagated by seeds sown in the spring, in an open situation, where, if they be permitted to scatter, the plants will come up the following spring. Two or three of them may be transplanted where they are to grow, and, after they are rooted, will require no further care.

7. *Bidens Pillosa*; *Hairy Bidens*. Leaves pinnate, somewhat hairy; stem with bearded joints; calices with a simple involucre; seeds diverging.—Native of America, and the island of Tongataboo in the South Seas. See the third species.

8. *Bidens Bipinnata*; *Hemlock-leaved Bidens*. Leaves bipinnate, gashed; calices involucred; corollas half radiated; seeds diverging. Annual.—Native of Virginia. For its cultivation, see the sixth species.

9. *Bidens Nivea*; *Snowy Bidens*. Leaves simple, cordate-ovate, acuminate; branches trichotomous, serrate; flowers hemispherical; peduncles elongated.—Native of Jamaica, in elevated pastures, and on the sea-coast of the southern parts. It is propagated by seeds, which should be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pot, plunged into a fresh hot-bed, and treated as other tender plants from the same hot countries: in autumn, they must be placed in the bark-stove, and will generally live some years with management.

10. *Bidens Verticillata*. Leaves oblong, entire, lower ones entire, upper ones opposite; flowers verticilled.—Native of Vera Cruz in South America. For the cultivation of this plant, see the preceding species.

11. *Bidens Scandens*. Leaves opposite, ovate, acuminate, serrate; stem climbing, shrubby; flowers panicled, ovate.—Native of the cooler mountains of Jamaica, and of Vera Cruz. See the ninth species.

12. *Bidens Bullata*; *Various-leaved Bidens*. Leaves ovate, serrate; lower ones opposite, upper ones ternate, the middle larger.—Native of America, found also wild in Italy. See the third species.

13. *Bidens Hirsuta*. Leaves opposite, ovate-lanceolate, entire, tomentose-hirsute; stem climbing, shrubby; peduncles opposite, diverging, many-flowered; annual.—Native of Jamaica. See the ninth species.

14. *Bidens Odorata*. Stem four-cornered, branching very much; leaves connate, bipinnate; pinnules wedge-trifid, smooth; seeds rugged.—It is a native of Mexico. See the ninth species.

Bignonia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, erect, cup-form, five-cleft. *Corolla*: monopetalous, campanulate; tube very small, the length of the calix; throat very long, ventricose beneath, oblong-campanulate; border five-parted, the two upper divisions reflex, lower patulous. *Stamina*: filamenta four, subulate, shorter than the corolla; two longer than the other two. Antheræ reflex, oblong, as it were doubled. *Pistil*: germen oblong; style filiform, situation and form of the stamina; stigma capitate. *Pericarp*: silique two-celled, two-valved; partition membranaceous, parallel, thickened at the sutures. *Seeds*: very many, imbricate, compressed, membrane-winged on both sides. ESSENTIAL CHARACTER. *Calix*: five-cleft, cup-form. *Corolla*: throat bell-form, five-cleft, ventricose beneath. *Silique*: two-celled. *Seeds*: membrane-winged.—These are exotic trees or shrubs, and may be raised from seeds sown on a moderate hot-bed in the spring. They should be soon inured to the open air, to prevent their being drawn up weak. They may

also be increased by cuttings, and some of them by layers.

—The species are,

1. *Bignonia Catalpa*; *Common Catalpa Tree*. Leaves simple, cordate; stem erect; seeds winged with membranes. A deciduous tree, with a smooth brown bark, thirty or forty feet high; with lateral branches; ovate-leaves; and the flowers in branching panicles, of a dirty white colour, with purple spots, and faint stripes of yellow inside.—The branches dye wool a kind of cinnamon colour. Thunberg mentions, that the Japanese lay the leaves on parts of the body affected with pains, supposing them to be beneficial to the nerves; and that a decoction of the pods is esteemed useful in the asthma.—The seeds of this tree are usually imported from South Carolina. The seedling plants should be placed abroad in the beginning of June, in a sheltered situation, till autumn, when they should be placed under a common frame, to screen them from frost in winter; but in mild weather they must be fully exposed to the open air. The following spring they may be taken out of the pots, and planted in a nursery-bed in a warm situation, where they may remain two years to get strength, and be afterwards planted where they are designed to remain. These plants, when young, are frequently injured by frost, for they shoot pretty late in autumn, so that the early frosts often kill the extremity of their branches; but as the plants advance in strength, they become more hardy, and are seldom injured but in very severe winters. It is late in the spring before the leaves come out, which has often caused persons to believe they were dead, and some have been so imprudent as to cut them down on that supposition, before the tree was well known. This tree may also be propagated by cuttings, which should be planted in pots in the spring, and plunged into a moderate hot-bed, observing to shade them from the sun in the middle of the day, and refresh them occasionally with water. In about six weeks these will have taken root, and made shoots above, so should have plenty of air admitted to them, and be hardened by degrees to bear the open air. They must be treated in the same manner as the seedling plants, and the spring following planted out into a nursery-bed, as is before directed. The *Catalpa* delights in a rich moist soil, where it will make great progress, and in a few years produce flowers.

2. *Bignonia Tomentosa*. Leaves simple, cordate, tomentose beneath; flowers axillary, paniced.—Native of Japan.

3. *Bignonia Sempervirens*; *Carolina Yellow Jasmine*. Leaves simple, lanceolate; stem twining, rising to a considerable height on the neighbouring plants.—It grows naturally in South Carolina, where it spreads over the hedges, and at the season of flowering; perfumes the air to a great distance; also sparingly in Virginia. The inhabitants call it *Yellow Jasmine*, probably from the sweet odour of its flowers.—The young plants are impatient of cold, so must be sheltered in the winter until they have obtained strength, when they should be planted against a warm wall, and in winter protected from frost by a covering of mats, and the ground about their roots covered with tan.

4. *Bignonia Unguis*. Leaves conjugate; tendril very short, bowed, three-parted.—Native of the West Indies. It will live in the open air, if planted against a wall that has a south aspect, and sheltered in very severe frost.

5. *Bignonia Aequinoctialis*. Leaves conjugate, cirrhose; leaflets ovate-lanceolate; peduncles two-flowered; siliques linear.—Native of New Spain. See the fourth species.

6. *Bignonia Paniculata*. Leaves conjugate, cirrhose; leaflets cordate-ovate; flowers racemed; peduncles three-flowered.—Native of South America. It will not thrive in this country, except kept in the bark-stove.

7. *Bignonia Crucigera*. Leaves conjugate, cirrhose; leaflets cordate; stem muricated.—Native of Campeachy. See the preceding species.

8. *Bignonia Capreolata*; *Four-leaved Trumpet-flower*. Leaves conjugate, cirrhose; leaflets cordate-lanceolate; bottom leaves simple.—Native of Virginia and Carolina. See the sixth and twelfth species.

9. *Bignonia Pubescens*. Leaves conjugate, cirrhose; leaflets cordate-ovate, pubescent beneath.—It grows naturally in Virginia, and several other parts of America. When this sort is planted in the full ground against a wall, the roots should be covered in autumn with some old tanner's bark, to keep out the frost in winter; and in very severe frost, the branches should be covered with mats.

10. *Bignonia Triphylla*; *Three-leaved Trumpet-flower*. Leaves ternate; leaflets ovate, acuminate; stem shrubby, erect.—Native of South America. See the sixth species.

11. *Bignonia Pentaphylla*; *Hairy Five-leaved Trumpet-flower*. Leaves digitate; leaflets quite entire, obovate.—Native of Jamaica. See the sixth species.

12. *Bignonia Leucoxylon*; *Smooth Five-leaved Trumpet-flower*, *White Wood*, or *Tulip-flower*. Leaves digitate; leaflets quite entire, ovate, acuminate. It rises with an upright stem forty feet high.—Native of Jamaica. It will take root from cuttings planted during summer in pots, and plunged into a bark-bed: the wood is very hard and white.

13. *Bignonia Radiata*; *Roy-leaved Trumpet-flower*. Leaves digitate; leaflets pinnatifid; stem three inches high; corolla pale yellow.—Native of very dry sand in Peru.

14. *Bignonia Radians*; *Rooting or Ash-leaved Trumpet-flower*. Leaves pinnate; leaflets gashed; stem with rooting joints; flowers at the ends of the new shoots, in large bunches, with long swelling tubes, shaped like a trumpet: corolla of an orange colour, opening at the beginning of August. Native of Carolina.—This kind is hardy enough to thrive in the open air; but as the branches trail, they must be supported; it is therefore usually planted against walls or buildings, where, if the branches have room, it will spread to a great distance, and rise very high, forty or fifty feet; it is therefore very convenient for covering unsightly buildings. It may also be trained up against the stems of trees, where, by proper management, it will make a fine appearance when in flower. It is propagated by seeds, but the young plants, so raised, do not flower in less than seven or eight years; therefore those which are propagated by cuttings, or layers from flowering plants, are most esteemed, because they will flower in two or three years after planting. The culture necessary for these plants, after they are established, is to cut away all the small weak shoots of the former year in winter, and shorten the strong ones to about two feet long, that young shoots may be obtained for flowering the following summer. These plants are of long duration.

15. *Bignonia Stans*; *Branching-flowered Trumpet-flower*. Leaves pinnate; leaflets serrate; stem erect, firm; flowers racemed, yellow, with red lines in the inside of the tube.—Native of all the sugar islands in the West Indies, chiefly in a dry rocky or gravelly soil. It is propagated by seeds sown on a hot-bed, and the plants afterwards transplanted into separate small pots, filled with light fresh earth, and plunged into a fresh hot-bed; in the autumn they must be removed into the bark-stove, and during the winter should have but little water, and in summer refreshing them with it sparingly. The plants should constantly remain in the bark-stove, and be treated in the same manner as other tender plants from hot countries. The third year from the seed they will flower, but they do not produce seeds in England.

Bugloss, or Garden Alkanet

16. *Bignonia Grandiflora*. Leaves pinnate; leaflets ovate, acuminate, serrate; stem twining; calix semiquinquefid; corolla purple, the size of a rose.—Native of Japan.

17. *Bignonia Chelonoides*. Leaves unequally pinnate; leaflets ovate, quite entire, acuminate, pubescent; corollas bearded with the rudiment of a fifth stamina. This is a large tree, with a whitish ash-coloured bark. The fresh flowers, immersed in water, give it a pleasant odour; and in the East Indies, of which it is a native, they sprinkle it over the temples in a morning, to correct the stagnant air.

18. *Bignonia Spathacea*. Leaves unequally pinnate; leaflets ovate, rough with hairs; calix one-leaved, spotted; corolla salver-shaped.—A large tree, native of Malabar, Java, and Ceylon, in woods near waters.

19. *Bignonia Peruviana*. Leaves decomposed; leaflets gashed; stem with tendrils at the joints. This species climbs by tendrils, which come out from the joints of the branches. Native of America.

20. *Bignonia Indica*; *Indian Trumpet-flower*. Leaves bipinnate; leaflets quite entire, ovate, acuminate. This is a large tree, with ascending branches.—Native of the East Indies, and Cochinchina.

21. *Bignonia Cœrulea*. Leaves bipinnate; leaflets lanceolate, entire.—Native of the Bahamas.

22. *Bignonia Longissima*; *Waved-leaved Trumpet-flower*. Leaves simple, oblong, acuminate; stem erect; seeds woolly. This beautiful tree, forty feet high, is now cultivated in many parts of Jamaica, especially in the low lands and savannas, where it grows to a considerable size, and is generally looked upon as an excellent timber-tree. Its numerous flowers, and slender siliques, add a peculiar grace to its growth.—Native of the West Indies.

23. *Bignonia Echinata*; Climbing; lower leaves ternate, upper bijugous cirrhose; fruits echinate. This is a rambling shrub, climbing to the tops of trees, by its very long and numerous branches; corolla flesh-coloured.—Native of the West Indies, Carthage, and Guiana.

25. *Bignonia Pentandra*. Leaves bipinnate; stamina five, with two antheræ on each; calix fleshy coloured, five-toothed.—Native of Cochinchina, near rivers.

25. *Bignonia Alliacea*. Leaves conjugate; leaflets elliptic, entire, coriaceous; peduncles five-flowered, axillary; calices entire. This plant obtained its trivial name from the strong scent of Garlic, which betrays it from afar.—It is a native of the West Indian islands, and the forests of Cayenne and Guiana.

26. *Bignonia Cassinoides*. Leaves simple, elliptic, coriaceous; raceme terminating; corolla large, smooth, two inches in diameter.—Native of Rio Janeiro.

27. *Bignonia Bijuga*. Leaves abruptly pinnate, bijugous; leaflets elliptic, quite entire; branches alternately compressed above, covered with an ash-coloured bark, and smooth; raceme terminating.—Native of Madagascar.

Birthwort. See *Aristolochia*.

Biscutella; a genus of the class Tetradynamia, order Siliculosa.—GENERIC CHARACTER. *Calix*: perianth four-

leaved; leaflets ovate, acuminate, gibbous at the base, coloured, deciduous. *Corolla*: four-petalled, cruciform; petals oblong, obtuse, spreading. *Stamina*: filamenta six, the length of the tube of the corolla, two opposite shorter; antheræ simple. *Pistil*: germen compressed, orbiculate, emarginate; style simple, permanent; stigma obtuse. *Pericarp*: silicle erect, compressed, flat, semibifid, with roundish lobes, two-celled; partition lanceolate, ending in a rigid style; cells two-valved, affixed to the partition, on its straight margin. *Seeds*: solitary, roundish, compressed, in the middle of the cell. ESSENTIAL CHARACTER. Silicle compressed, flat, rounded above, and below two-lobed. *Calix*: leaflets gibbous at the base.—They are all annual plants, except the last, which perish soon after they have perfected their seeds. These should be sown either in spring or autumn, upon a border of light earth, in an open situation, where they are to remain. Those sown in autumn will come up in about three weeks, and will live through the winter without any protection, and flower earlier the following summer, whereby good seeds may be always obtained; whereas, those which are sown in the spring, in bad seasons decay before their seeds are ripe. The autumnal plants flower in June, and the spring plants in July, and their seeds ripen about six weeks after: if these are permitted to scatter, there will be plenty of young plants produced without any care. They require no further culture, but to keep them clean from weeds, and to be thinned where they are too close, leaving them eight or nine inches asunder.—The species are,

1. *Biscutella Auriculata*; *Ear-podded Buckler Mustard*. Calices gibbous on each side with the nectary; silicles running into the style; flowers in panicles, pale yellow.—Native of the south of France and Italy.

2. *Biscutella Apula*; *Spear-leaved Buckler Mustard*. Silicles scabrous; leaves lanceolate, sessile, serrate. It flowers in June and July.—Native of Italy.

3. *Biscutella Lyrata*. Silicles scabrous; leaves lyrate.—Native of Spain and Sicily.

4. *Biscutella Coronopifolia*. Silicles smooth; leaves toothed, rough with hairs.—It is found in dry barren places in Spain, Italy, and Germany.

5. *Biscutella Lævigata*; *Smooth Buckler Mustard*. Silicles smooth; leaves lanceolate-serrate. Flowers in June and July.—Native of Italy and Austria.

6. *Biscutella Sempervirens*; *Shrubby Buckler Mustard*. Silicles somewhat scabrous; leaves lanceolate, tomentose. This is a very distinct species.—Native of Spain.

Biserrula; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, erect, semiquinquefid; teeth subulate, equal, the two upper ones more remote. *Corolla*: papilionaceous; banner larger, reflected on the sides, ascending, roundish; wings ovate-oblong, free, shorter than the banner; keel the length of the wings, obtuse, ascending. *Stamina*: filamenta diadelphous, (simple and nine-cleft,) ascending at their tips, inclosed within the keel; antheræ small. *Pistil*: germen oblong, compressed; style subulate, ascending; stigma simple. *Pericarp*: legume large, linear, flat, two-celled; partition contrary to the valves. *Seeds*: very many, kidney-form, compressed.—ESSENTIAL CHARACTER. Legume two-celled, flat; partition contrary.—The only known species is,

1. *Biserrula Pelecinus*; *Bastard Hatchet Vetch*.—This is an annual plant, which grows naturally in Italy, Sicily, Spain and the south of France. It sends out many angular stalks, which trail on the ground, subdivided into many branches, with long winged leaves, composed of many pairs of leaflets terminated by an odd one; these are heart-shaped: towards

the upper part of the branches come out the peduncles, which sustain several small purplish flowers.—It is propagated by seeds, which in this country should be sown in the autumn, on a bed of light earth, where the plants will come up in about three weeks, and will live in the open air very well. These should be sown where they are designed to remain, or transplanted very young; for when they are large they will not bear removing. When the plants are come up, they will require no other care but to keep them clean from weeds; and where they are too near, they should be thinned to about a foot distance from each other. They flower in June, and the seeds ripen in September.

Bishop's Weed. See *Anni*.

Bitter Vetch. See *Orobus*.

Bitterwort. See *Gentiana*.

Bixa; a genus of the class Polyandria, order Monogynia.—

GENERIC CHARACTER. *Calix*: perianth five-toothed, very small, obtuse, flat, permanent. *Corolla*: double, outer with petals five, oblong, equal, large, more rude; inner with five petals like the outer, but thinner. *Stamina*: filamenta numerous, setaceous, shorter by half than the corolla; antheræ erect. *Pistil*: germen ovate; style filiform, the length of the stamina; stigma parallelly bifid, compressed. *Pericarp*: capsule ovate-cordate, compressed, fenced with bristles, bivalve, gaping at the angles, one-celled, with an inner bivalve membrane. *Seeds*: numerous, turbinate, with a truncated navel, berried. *Receptacle*: linear, longitudinal, fastened to the middle of the valves. **ESSENTIAL CHARACTER.** *Corolla*: ten-petalled. *Calix*: five-toothed. *Capsule*: hispid, bivalve.—The only known species is,

1. *Bixa Orellana*; *Arnotto*, or *Arnottia*. This shrub rises with an upright stem to the height of eight or ten feet, sending out many branches at the top, forming a regular head. The name of this plant is variously spelt in England, as *arnotto*, *arnotta*, *anotta*, *anato*, *anoto*, *annotto*. The drug called *terra orellana*, or *orleana*, *roneou*, or *arnotto*, is thus prepared from the red pulp which covers the seeds. The contents of the fruit are taken out and thrown into a wooden vessel, where as much hot water is poured upon them as is necessary to suspend the red powder or pulp; and this is gradually washed off with the assistance of the hand, or of a spatula or spoon. When the seeds appear quite naked, they are taken out, and the wash is left to settle; after which the water is gently poured away, and the sediment put into shallow vessels, to be dried by degrees in the shade. After acquiring a due consistence, it is made into balls or cakes, and set to dry in an airy place, until it is perfectly firm. Some persons first pound the contents of the fruit with wooden pestles, then covering them with water, leave them to steep six days: this liquor being passed through a coarse sieve, and afterwards through three finer ones, is again put into the vat or wooden vessel, and left to ferment a week. It is then boiled until it is pretty thick, and when cool it is spread out to dry, and then made up into balls, which are usually wrapped up in leaves.—*Arnotto*, of a good quality, is of the colour of fire, bright within, soft to the touch, and dissolves entirely in water. It is reputed to be cooling and cordial, and is much used by the Spaniards in their chocolate and soups, both to heighten the flavour, and to give them an agreeable colour. It is esteemed good in bloody fluxes, and disorders of the kidneys: mixed with lemon-juice and a gum, it makes the crimson paint with which the Indians adorn their persons. It was formerly used by dyers to form the colour called *aurora*; but at present it is not held in such estimation as a dye, though it still maintains its ground with painters. *Arnotto* is well known to be the drug which

is used for dyeing cheese in Gloucestershire, under the name of cheese-colouring. It is used in Holland for colouring butter. The bark makes good ropes for the common plantation uses in the West Indies; and pieces of the wood are used by the Indians to procure fire by friction.—It is propagated by seeds, and may be cultivated with great ease. It is planted in many parts of Jamaica, Barbadoes, Cayenne, &c. in rich soils and shady situations, shooting luxuriantly near rivulets. The seed should be sown in a small pot, filled with light rich earth, and plunged into a hot-bed of tanner's bark, where, if the bed be of a proper temperature of heat, the plants will appear in about a month after: when these are about an inch high, they should be taken out of the pot, and carefully separated, so as not to tear off their tender roots, and each replanted in a small pot filled with some rich light earth, and plunged into a fresh hot-bed of tanner's bark, observing to shade them every day until they have taken new root; after which they must be treated as other tender plants from the same country.

Blackberry. See *Rubus Fruticosus*.

Blackburnia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth very short, four-toothed, inferior; teeth short, acute, horizontal. *Corolla*: petals four, elliptic. *Stamina*: filamenta four, subulate, rather shorter than the petals; antheræ heart-shaped, erect. *Pistil*: germen conic; style filiform, erect, length of the stamina; stigma simple. *Pericarp*: berry. *Seed*: single. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Petals*: four, elliptic. *Antheræ*: heart-shaped. *Germen*: conic. *Stigma*: simple. *Pericarp*: berry with a single seed.—The only known species is,

1. *Blackburnia Pinnata*. Leaves alternate, abruptly pinnate, with two or three pairs of leaflets, which are opposite, oblique, ovate, quite entire, and very smooth; panicles axillary, small.—Native of Norfolk Island.

Bladder Nut. See *Staphylea*.

Bladder Sena. See *Colutea*.

Bladhia: a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, very short, permanent, five-parted; parts ovate, concave, spreading, torn, subserrate. *Corolla*: one-petalled, wheel-shaped, five-parted; parts ovate, obtuse, spreading. *Stamina*: filamenta five, very short; antheræ heart-shaped, acute, converging into a cone, shorter than the corolla. *Pistil*: germen superior; style filiform, longer than the corolla; stigma simple, acute. *Pericarp*: berry globose, crowned by the permanent style, one-celled. *Seed*: single, globose, involved in a membrane. **ESSEN. CHAR.** *Corolla*: wheel-shaped, deciduous. *Berry*: containing one arilled seed.—These plants are all natives of Japan.—The species are,

1. *Bladhia Japonica*. Leaves serrate, smooth; corolla white, sweet-smelling.

2. *Bladhia Villosa*. Leaves serrate, villose; stem filiform, almost erect, tomentose a finger's length.

3. *Bladhia Crispa*. Leaves oblong, curled, smooth; stem round, smooth, a span or more in height; berry red, the size of a pea.

Blaria; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four parted; leaflets linear, erect, a little shorter than the corolla, permanent. *Corolla*: monopetalous, campanulate; tube cylindrical, the length of the calix, pervious; border small, four-cleft; divisions ovate, reflex. *Stamina*: filamenta four, setaceous, the length of the tube, inserted into the receptacle; antheræ oblong, compressed, erect, obtuse, emarginate. *Pistil*: germen four-cornered, short; style setaceous, much

longer than the corolla; stigma obtuse. *Pericarp*: capsule obtuse, quadrangular, four-celled, gaping at the angles. *Seeds*: some roundish. **ESSENTIAL CHARACTER.** *Calix*: four-parted. *Corolla*: four-cleft. *Stamina*: inserted into the receptacle. *Capsule*: four-celled, many-seeded.—These are all shrubs, inhabitants of the Cape; requiring the same shelter and treatment with other Cape plants, in the dry-stove; and may be increased by cuttings, like the *Ericas* or *Heaths*, which they much resemble.—The species are,

1. *Blæria Ericoides*; *Heath-leaved Blæria*. Antheræ awnless, standing out; calices four-leaved; bractes the length of the calix; leaves in fours, oblong, acrose, hairy, imbricate. It is about the height of common *Heath*.

2. *Blæria Ciliaris*; *Ciliated Blæria*. Flowers in a head; calices ciliate, by the whiteness of which the plant is also readily known.

3. *Blæria Articulata*; *Jointed-leaved Blæria*. *Stamina* protruded, two-parted; corollas cylindric.—This is a distorted shrub, about the stature of common *Heath*.

4. *Blæria Purpurea*; *Purple-flowered Blæria*. *Stamina* included, two-parted; corollas oblong, straight; flowers terminating, aggregate; peduncles erect.

5. *Blæria Pusilla*; *Dwarf Blæria*. Flowers scattered, corollas funnel-form: this must be cautiously distinguished from the *Heaths*.

6. *Blæria Muscosa*; *Moss-leaved Blæria*. Antheræ awnless, almost standing out; calices one-leaved, hairy; corollas bell-shaped, hairy in the upper part; flowers axillary; stigmas peltate. It flowers from June till August.

Blakea; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth of the fruit inferior, six-leaved; leaflets ovate, concave, expanding, the size of the flower; perianth of the flower superior; margin quite entire, hexangular, membranaceous. *Corolla*: petals six, ovate, expanding, equal. *Stamina*: filamenta twelve, subulate, erect; antheræ triangular, depressed, concatenated into a ring. *Pistil*: germen inferior, obovate, crowned with the margin of the calix; style subulate, the length of the flower; stigma acute. *Pericarp*: capsule obovate, six-celled. *Seeds*: very many. **ESSENTIAL CHARACTER.** *Calix*: inferior six-leaved; superior entire. *Petals*: six. *Capsule*: six-celled, many-seeded.—These trees have not been cultivated in Europe.—The species are,

1. *Blakea Trinervia*. Two caliced: leaves nerveless, very finely striated across, oblong-ovate, petioled, opposite. Flowers opposite, solitary. It grows generally to the height of ten or fourteen feet. It is certainly one of the most beautiful productions of America. It supports itself for a time by the help of some neighbouring shrub or tree, but it grows gradually more robust, and at length acquires a pretty moderate stem, which divides into many weakly declining branches, well supplied on all sides with beautiful rosy blossoms. It thrives best in the West Indies, on the sides of ponds or rivulets; and when planted in gardens, where it makes a very elegant appearance, it ought to be supported while it is young and weakly.—Native of cool moist places, in Jamaica.

2. *Blakea Triplinervia*. Uncaliced. This tree grows to the height of sixteen feet. Leaves triple-nerved, opposite, petioled, six or seven inches long, ribbed underneath, and having a nerve running along the edge; peduncles three-flowered; seeds minute. The fruit is of a yellow colour, and sapid.—It is a native of Surinam, and also of Guiana, where it flowers and fruits in May.

Blasia; a genus of the class Cryptogamia, order Algæ, or Flags.—The only species yet brought to light is,

1. *Blasia Pusilla*; *Dwarf Blasia*. It grows on the sides

of ditches and brooks, and in moist shady places in a sandy soil, in many parts of Europe.—It is found with us on Hounslow Heath, also near Manchester and Halifax.

Blechnum; a genus of the class Cryptogamia, order Filices, or Ferns.—**GENERIC CHARACTER.** Fructifications disposed in two lines, approaching to the rib of the frond, and parallel.—These ferns are natives of warm or hot countries, and require protection. They are increased by parting the roots.—The species are,

1. *Blechnum Occidentale*; *South American Blechnum*. Fronds pinnate; pinnae lanceolate, opposite, emarginate at the base.—Native of the West India islands, and the continent of South America.

2. *Blechnum Orientale*; *Chinese Blechnum*. Fronds pinnate, three feet long; pinnae linear, alternate.—Found in China, and also in the Society Isles.

3. *Blechnum Australe*; *Cape Blechnum*. Fronds pinnate; pinnae subsessile, cordate-lanceolate, quite entire, the lowest opposite.—Native of the Cape of Good Hope.

4. *Blechnum Virginicum*; *Virginian Blechnum*. Fronds pinnate; pinnae multifid.—Native of Virginia and Carolina.

5. *Blechnum Japonicum*; *Japanese Blechnum*. Frond bipinnatifid; pinnules ovate, obtuse, serrated.—Native of Japan.

6. *Blechnum Radicans*; *Rooted-leaved Blechnum*. Fronds bipinnate; pinnae lanceolate-crenulated; the lines of fructification interrupted.—Native of Virginia and Madeira.

*Blight*s. There is nothing so destructive to a fruit-garden as blights; nor is there any thing in the business of gardening which requires more of our serious attention, than the endeavouring to prevent or guard against this great enemy of gardens.—1. Blights are often caused by a continued dry easterly wind for several days together, without the intervention of showers or any morning dew, by which the perspiration in the tender blossoms is stopped, so that in a short time their colour is changed, and they wither and decay; and if it so happen that there is a long continuance of the same weather, it equally affects the tender leaves; for their perspiring matter is hereby thickened and rendered glutinous, closely adhering to the surface of the leaves, and becomes a proper nutriment to those small insects, which are always found preying upon the leaves and tender branches of fruit-trees whenever this blight happens: but it is not these insects which are the first cause of blights, as has been imagined by some; though it must be allowed that whenever these insects meet with such a proper food, they multiply exceedingly, and are instrumental in promoting the distemper; so that many times when the season proves favourable to them, and no proper care has been taken to prevent their mischief, it is surprising to think how whole walls of trees have suffered by this infection. The best remedy yet known for this distemper, is gently to wash and sprinkle over the trees from time to time with common water, that is, such water as has not had any thing steeped in it; and the sooner this is done after danger is apprehended, the better; and if the young and tender shoots seem to be much infected, wash them with a woollen cloth so as to clear them, if possible, from all this glutinous matter, that their respiration and perspiration may not be obstructed, and if some broad flat pans or tubs of water be placed near the trees, that the vapours exhaled from the water may be received by the trees, it will keep their tender parts in a ductile state, and greatly help them: but whenever this operation of washing the trees is performed, it should be early in the day, that the moisture may be exhaled before the cold of the night comes on, especially if the nights be frosty: nor should it be done when the sun shines very hot upon the wall, which

would be subject to scorch up the tender blossoms.—2. Another cause of blights in the spring is, sharp hoary frosts, which are often succeeded by hot-sunshine in the day time: this is the most sudden and certain destroyer of fruits that is known; for the cold of the night starves the tender parts of the blossoms, and the sun rising hot upon the walls before the moisture is dried from the blossoms, (which being in small globules, collects the rays of the sun,) a scalding heat is thereby acquired, which scorches the tender flowers, and other parts of plants. The method to prevent this mischief is, to cover the walls carefully with mats, canvass, or reeds, fastened so as not to be disturbed by the wind, and suffered to remain on during the night, but taken off every day when the weather permits. Although this method is thought by some to be of little service, (and may be really prejudicial, if the trees be too long covered, or incautiously exposed,) yet when this covering is conducted properly, it frequently proves a great protection to fruit-trees; and if the covering be fixed near the upper part of a wall, and be fastened to pulleys, so as to be drawn up or let down occasionally, the operation will be easy, and the success will sufficiently repay the trouble.—3. But there is another sort of blight that sometimes happens later in the spring, namely, in April or May, which is often very destructive to orchards and open plantations; against which we know not any remedy. This is called a fire-blast, which in a few hours has not only destroyed the fruit and leaves, but many times parts of trees, and sometimes entire trees, have been killed by it. This is supposed to be effected by volumes of transparent flying vapours, which among the many forms they revolve into, may sometimes approach so near to a hemisphere or hemicylinder, either in the upper or lower surfaces, as thereby to make the beams of the sun converge enough to scorch the plants or trees they fall upon, in proportion to the greater or less convergency of the sun's rays. Against this enemy there is no guard, nor any remedy to cure it: but as this more frequently happens in close plantations, where the stagnating vapours from the earth, and the plentiful perspirations from the trees, are pent in for want of a free air to dissipate and dispel them, (which are often observed in still weather to ascend in so plentiful a manner as to be seen with the naked eye, but especially with reflecting telescopes, so as to make a clear and distinct object become dim and tremulous,) than in those which are planted at a greater distance, or are not surrounded with hills or woods; this directs us in the first planting of kitchen-gardens and orchards, that we should allow a greater distance between the trees, and make choice of clear healthy situations, that the air may freely pass between the trees, to dissipate those vapours before they are formed into such volumes; whereby the circumbient air will be clear, and less subject to injuries, as also the fruits which are produced in this clearer air will be much better tasted than those that are surrounded with a thick rancid air; for as fruits are often in a respiring state, they are consequently, by imbibing a part of these vapours, are rendered crude and ill-tasted, which is often the case with a great part of our fruits in England.—4. But that blights are frequently no more than an inward weakness or distemper in trees, will evidently appear, if we consider how often it happens, that trees against the same wall, exposed to the same aspect, and equally enjoying the advantages of sun and air, with every other circumstance which might render them equally healthy, yet very often are observed to differ greatly in their strength and vigour; and indeed we generally find the weak trees to be blighted, when the vigorous ones in the same situation shall escape very well; which must therefore, in a great measure, be ascribed

to their healthy constitution. This weakness, therefore, in trees, must proceed either from the want of a sufficient supply of nourishment to maintain them in perfect vigour, or from some ill qualities in the soil where they grow; or perhaps from some bad qualities in the stock, or inbred distemper of the buds or scions, which they had imbibed from their mother-tree, or from mismanagement in the pruning, &c. all which are productive of distempers in trees, and of which they are with difficulty cured. Now if this is occasioned by a weakness in the tree, we should endeavour to trace out the true cause: first, whether it has been occasioned by ill management in the pruning, which is too often the case; for how common is it to observe peach-trees trained up to the full length of their branches every year, so as to be carried to the top of the wall in a few years after planting, when at the same time the shoots for bearing have been so weak, as scarcely to have strength to produce their flowers; but this being the utmost of their vigour, the blossoms fall off, and many times the branches decay, either the greatest part of their length, or quite down to the place where they were produced; and this, whenever it happens to be the case, is ascribed to a blight. Others there are, who suffer their trees to grow just as they are naturally disposed, during the summer season, without stopping shoots, or disburdening their trees of luxuriant branches; by which means two, three, or four shoots shall exhaust the greatest part of the nourishment of the trees all the summer; which shoots, at the winter pruning, are entirely cut out; so that the strength of the tree was employed only in nourishing useless branches, while the fruit-branches are thereby rendered so weak as not to be able to preserve themselves. (See *Amygdalus*.) But should the weakness of the tree proceed from an inbred distemper, it is the better way to remove the tree at first, and, after renewing the earth, plant a new one in its place. Or if your soil be a hot burning gravel or sand, in which your peach-trees are planted, you will generally find this to be the case, after their roots have got beyond the earth of your borders; for which reason it is much more adviseable to dig them up and plant Grapes, Figs, Apricots, or any other sort of fruit which may do well in such a soil, rather than to be annually disappointed of your hopes; for by a variety of experiments, it has been found that Apricots attract and imbibe moisture with a much greater force than Peaches and Nectarines, and consequently are better able to extract the nutritive particles from the earth, than the others which require to be planted in a generous soil, capable of affording them a sufficiency of nourishment without much difficulty: and it is in such places we often see Peaches do wonders, especially if assisted by art; but as for the Vine and Fig-tree, they perspire very slowly, and are very often in an imbibing state, so that a great part of that fine racy flavour, with which their fruits abound when planted in a dry soil, is probably owing to those refined aerial particles, which are collected when in a state of respiration; and therefore as these trees delight not in drawing much watery nourishment from the earth, so they will better succeed in such a soil, than in one that is more generous: we should therefore always endeavour to suit the particular sorts of fruits to the nature of our soil, and not pretend to have all sorts of good fruit in the same ground.

Blitum; a genus of the class Monandria, order Digynia. —GENERIC CHARACTER. *Calix*: perianth three-parted, spreading, permanent; divisions ovate, equal, two more gaping than the other. *Corolla*: none. *Stamina*: filamenta setaceous, longer than the calix, within the middle division, erect; antheræ twin. *Pistil*: germen ovate, acuminate; styles two, erect, gaping, the length of the stamen; stigmas simple.

Pericarp: capsule very thin, (rather the crust of the seed,) ovate, a little compressed, contained within the calix, now become a berry. *Seed*: single, globular, compressed the size of the capsule. **ESSENTIAL CHARACTER.** *Calix*: trifid. *Petals*: none. *Seed*: one, with a bearded calix.—This genus consists of annual plants, which will drop their seeds if permitted, and the plants will come up in plenty the following spring; or if the seeds of either of the sorts are sown in March or April upon a bed of common earth, in an open situation, the plants will come up in a month or six weeks after; and if they are to remain in the place where they are to be sown, will require no other care but to keep them clear from weeds, and to thin them out, so as to leave them six or eight inches apart; and in July the plants will begin to shew their berries, when they will make a pretty appearance. When the plants are designed to be removed, they should be transplanted before they shoot up their flower-stems, for they will not bear transplanting well afterwards; and if they are planted in pots, they will require to be duly watered in dry weather: as the flower-stems advance, they should be supported by sticks, or the branches will fall to the ground when the berries are grown rather large and weighty.—The species are,

1. *Blitum Capitatum*; *Berry-headed Strawberry Blite*. Heads spiked, terminal. This is about two feet high; the flowers on the upper part issuing in small heads at every joint: when the flowers are past, these heads swell to the size of Wood Strawberries, when ripe having the same appearance, and full of purple juice, which stains the hands, and was formerly much used for colouring in cookery. Commonly called Strawberry Blite, Strawberry Spinach, or Bloody Spinach, and by some Berry-bearing Orach.—Native of Switzerland, the Grisons, Austria, the Tyrol, Spain, and Portugal.

2. *Blitum Virgatum*; *Slender-branched Strawberry Blite*. Heads scattered, lateral. It seldom exceeds a foot high.—Native of the south of France, Spain, Italy, and Tartary.

3. *Blitum Tataricum*. Leaves triangular, sharply-toothed; heads simple, lateral.

4. *Blitum Chénopodioides*. Heads in whorls, juiceless.—Native of Tartary, now in Sweden.

Blood Flower. See *Hémánthus*.

Bloodwort, or Bloody Dock. See *Rumex*.

Blue-Bottle. See *Centaurea*.

Bocconia; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth two-leaved, ovate, obtuse, concave, caducous. *Corolla*: none. *Stamina*: filamenta twelve, very short; antheræ linear, very large, the length of the calix. *Pistil*: germen roundish, contracted both ways, large, pedicelled; style one, bifid; stigmas simple, reflex. *Pericarp*: capsule subovate, attenuated to each end, compressed, one-celled, two-valved; valves coriaceous, gaping from the base, the annular suture continuing, crowned with the style. *Seed*: one, globular, the base involved in a pulp, fixed to the bottom of the capsule. **ESSENTIAL CHARACTER.** *Calix*: two-leaved. *Corolla*: none. *Style*: bifid. *Berry*: dry, one-seeded.—The species are,

1. *Bocconia Frutescens*; *Shrubby Bocconia, Tree Celandine, or Parrot-weed*. It is a shrub, rising to the height of ten or twelve feet, with a straight trunk, as large as a man's arm, covered with a white smooth bark, and branched towards the top. The trunk is hollow, filled with a pith like the Elder. It abounds in all its parts with a thick yellow juice, like Celandine. The singular beauty of this plant renders it worthy of a place in every curious collection. The juice is acid, and is employed in the West Indies to take off tetter and warts.—Native of Mexico and the West India

islands.—It is propagated by seeds, which should be sown in a pot filled with light fresh earth, early in the spring, and plunged into a hot-bed of tanner's bark, observing to water it now and then gently, otherwise the seeds will not grow. When the plants are come up, they should be each transplanted into separate small pots, filled with light sandy earth, and plunged into the hot-bed again, observing to shade the glasses in the heat of the day, until the plants have taken root. They must be sparingly watered while young; for the stems being very tender and full of juice, will rot if they receive too much moisture; but after their stems are become woody, they will require it often, especially in hot weather, when also they should have a large share of air. In two months, they will have filled these small pots with their roots; therefore they should be taken out, and planted into pots one size larger, filled with light fresh earth, and plunged into the bark-stove, where they should have a good share of fresh air in warm weather.

2. *Bocconia Cordata*. Leaves cordate, a little lobed; panicl elongated, with single branches; calix white; stamina about twenty-four; style none; stigma bilamellated, sessile.—Native of China.

Boehmeria; a genus of the class Monœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male flowers*, on the same plant with the Female, either distinct or mixed. *Calix*: perianth one-leaved, four-parted to the base: parts lanceolate, acute, somewhat erect, coloured. *Corolla*: none. *Nectary*: none. *Stamina*: filamenta four, longer than the calix, subulate, upright; antheræ roundish, ovate. *Pistil*: a rudiment, or none. *Female flowers.* *Calix*: none; but numerous, crowded, ovate, acuminate scales. *Corolla*: none. *Pistil*: germen ovate, between each scale, compressed: style filiform, erect, permanent; stigma simple, pubescent. *Pericarp*: none. *Seed*: roundish, compressed, margined. **ESSENTIAL CHARACTER.** *Male.* *Calix*: four-parted. *Corolla*: none. *Female.* *Calix*: none, but crowded scales; between each germen, obovate. *Style*: single. *Seed*: single, compressed.—The species are,

1. *Boehmeria Caudata*. Leaves opposite, ovate, acute, serrate; racemes very long, pendulous; flowers diœcous; stem suffruticose. A shrub, 11 or 12 feet high.—Native of Jamaica.

2. *Boehmeria Littoralis*. Leaves opposite, obovate-lanceolate, serrate; flowers conglomerate, axillary, monœcous, mixed; stem herbaceous, four-cornered.—Native of Hispaniola.

3. *Boehmeria Cylindrica*. Leaves opposite, ovate, acuminate, serrate; racemes spiked, axillary, erect, simple. Annual.—Native of North America, and Jamaica.

4. *Boehmeria Ramiflora*. Leaves alternate, broad-lanceolate, acuminate, serrate, wrinkled; flowers aggregate, axillary and lateral, monœcous, distinct; males three-stamined. A shrub, eight feet high.—Native of the West India islands.

5. *Boehmeria Hirta*. Leaves alternate, ovate, acute, serrate, hirsute; flowers monœcous, heaped, axillary, mixed.—Native of Jamaica.

Boerhavia; a genus of the class Monandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth oblong, tubular and angular, placed beneath the corolla, with a contracted entire mouth, permanent. *Corolla*: one-petalled, bell-shaped, upright, bluntly five-cleft, plaited, seated on the calix. *Nectary*: fleshy, subcylindric, with a toothletted mouth, surrounding the base of the germen. *Stamina*: filamenta, one, two, or three, inserted into the edge of the nectary, between the toothlets, capillary at bottom, within the calix, more slender, upright, about the length of the corolla; antheræ twin, globular. *Pistil*: germen roundish, pedicelled, the pedicel surrounded by the nectary; style filiform,

twisted, the height of the stamina; stigma capitate. *Pericarp*: none. *Calix*: enlarged, closed, incrusting the seed. *Seed*: one, oblong, obtuse-angular. **ESSENTIAL CHARACTER.** *Calix*. small, entire. *Corolla*: one-petalled, bell-shaped, plaited. *Seed*: one, naked, inferior. *Stamina*: one, two, or three.—The species are,

1. *Boerhavia Erecta*; *Upright Hogweed*. Stem erect, smooth; flowers two-stamined.—This was discovered at Vera Cruz, and in the Society Isles: it is an annual plant.

2. *Boerhavia Diffusa*; *Spreading Hogweed*. Stem smooth and even, diffused; leaves ovate. The flowers, in corymbose heads, are purple, have only one stamen, and a twin antheræ.—Native of both Indies.

3. *Boerhavia Hirsuta*. Stem diffused, pubescent; leaves ovate, repand; flowers in heads, scarlet.—Native of Jamaica.

4. *Boerhavia Scandens*; *Climbing Hogweed*. Stem erect; flowers two-stamined, in umbels, green; leaves cordate, acute.—Native of Jamaica, especially about Spanish Town.

5. *Boerhavia Repens*. Stem creeping.—Native of Nubia.

6. *Boerhavia Angustifolia*. Leaves linear, acute.—Native place unknown.

7. *Boerhavia Tetrandria*. Stem creeping; flowers four-stamined.—Native of the Society Isles.

8. *Boerhavia Adscendens*. Leaves oblong-ovate, somewhat fleshy; flowers panicled; peduncles two-flowered; stem ascending.—Native of Guinea.

9. *Boerhavia Plumbaginea*. Leaves subcordate, orbiculate-ovate, pubescent beneath; flowers in umbels; corolla pale rose colour.—Native of Spain.

Bog-Berry. See *Vaccinium*.

Bog-Rush. See *Schanus*.

Boletus, is characterised by Linneus as a horizontal Fungus, porous, or punched with lobes underneath. In the *Systema Naturæ*, 14th edition, only twenty-one species are recited; eleven of which are parasitical and stemless, the rest are stipitated. Mr. Hudson has thirteen species, five of which are not in Linneus, but chiefly from Schœffer, who has a vast many others not noticed by Linneus.—From the *Boletus Ignarius* is prepared the Amadon, commonly used on the continent for tinder, to receive the spark struck from the steel by the flint; and the Agaric, for stopping hæmorrhages in amputation.

Boltonia; a genus of the class Syngenesia, order Polygamia Superflua.—**GENERIC CHARACTER.** *Calix*: common, flattish, imbricate, with somewhat equal, linear, sharp scales. *Corolla*: compound, radiate; corollets, hermaphrodite, tubular, numerous in the hemispheric disk; females, several in the ray. Proper of the hermaphrodite, funnel-form, five-cleft; female, linear, entire. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*, in the hermaphrodites: germen oblong; style filiform, length nearly of the hermaphrodite; stigmas two, revolute. *Pericarp*: none. *Calix*: unchanged. *Seed*, in the hermaphrodites, solitary, compressed, crowned, with a five-toothed margin: in the females, extremely similar. *Receptacle*: naked, hemispheric. **ESSENTIAL CHARACTER.** *Calix*: common subimbricate, with linear scales. *Corolla*: radiate. *Germina*: compressed, vertical. *Down*: obscurely toothed, two-horned. *Receptacle*: honey-combed.—The species are,

1. *Boltonia Asterioides*; *Starwort-flowered Boltonia*. Leaves quite entire.—Native of South America.

2. *Bombax Glastifolia*; *Glaucous-leaved Boltonia*. Lower leaves serrate.—Native of South America.

Bombax; a genus of the class Monadelphica, order Polyanthia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, tubular, campanulate, permanent; mouth three or five cleft,

obtuse, erect. *Corolla*: five-parted, spreading; segments oblong, concave. *Stamina*: filamenta five or more, subulate, the length of the corolla, connate at the base; antheræ oblong, bent in, incumbent. *Pistil*: germen roundish; style filiform, the length of the stamina; stigma capitate, five-toothed. *Pericarp*: capsule large, turbinate, oblong, five-celled, five-valved; valves woody. *Seeds*: very many, round, woolly. *Receptacle*: columnar, five-cornered, forming the partitions. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Stamina*: five or more. *Capsule*: woody, five-celled, five-valved. *Seeds*: woolly. *Receptacle*: five-cornered.—The plants of this genus are all tender, and will not thrive in the open air in England. *Bombax*, or silk-cotton, is propagated by seeds, which must be sown on a hot-bed in the spring; if the seeds are good, the plants will appear in a month, and will be strong enough to transplant in a month after, when they should be each planted in a small pot, filled with fresh lousy earth, and plunged into a moderate hot-bed of tanner's bark, being careful to shade them from the sun till they have taken fresh root; after which they should have a large share of fresh air admitted to them when the weather is warm, to prevent them from being drawn up weak; they must also be frequently refreshed with water, which must not be given in large quantities. In this bed they remain till autumn, provided there be room for the plants under the glasses. In the autumn they must be removed into the bark-stove, where they must constantly remain, being too tender to thrive in this country in any other situation. In winter they must have but little wet, especially if they cast their leaves; but in the summer they should be frequently refreshed with water, and in warm weather must have plenty of fresh air admitted to them. With this management the plants will make great progress, and in a few years will reach the glasses on the top of the stove. They form an agreeable variety in a large stove, where they have room to grow, their leaves having a different appearance from most other plants.—The species are,

1. *Bombax Pentandrum*. Flowers five-stamined; leaves in sevens. A tree, sixty or eighty feet high. Bark greenish, smooth, easily separating from the wood; branches near the summit pendent; leaves on long peduncles; flowers in a simple umbel; petals five, white and velvety without, smooth, concave, and of a purple or delicate rose colour within; fruit half a foot long, shaped like a cucumber, very slender at its base; seeds oval, with a sharpish point, enveloped with a great quantity of short dark cotton, which is not spun, but used for stuffing pillows, mattresses, &c.—Native of both Indies.

2. *Bombax Ceiba*. Flowers many-stamined; leaves quinate. The canoes now made in the West Indies from this tree frequently carry from fifteen to twenty hogsheads of sugar, from six to twelve hundred weight each; the average about twenty-five tons burden. When sawn into boards, and then well saturated with lime-water, the wood bears exposure to the weather many years; it is also formed into laths for roofs, curing-pots, and hogshead-heading. When the tree decays, it becomes a nest for the *Macaca* beetle, the caterpillar of which, gutted and fried, is esteemed by many persons one of the greatest delicacies. The down which is enclosed in the seed-vessels is seldom used, except by the poorer inhabitants to stuff pillows or chairs; and it is generally thought unwholesome to lie upon.—It is a native of both Indies; and some modern writers have affirmed, that there are trees of the silk-cotton now growing in the West Indies, so large as not to be fathomed by sixteen men, and so tall that an arrow cannot be shot to their top.

3. *Bombax Heptaphyllum*. Flowers many-stamined; leaves sevenfold. This tree grows to the height of fifty feet

before it branches, and is eighteen feet in thickness.—It abounds in Malabar, and is also a native of America.

4. *Bombax Gossypium*. Leaves five-lobed, acuminate, tomentose underneath. A large tree, with green, nearly smooth bark.—Native of the coast of Coromandel; and the Spanish West Indies, where the inhabitants spin the down enclosed in the pods, which is of a fine purple colour, and work it into garments, which they wear without dyeing.

Bonnetia; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted; parts concave, acute, two larger. *Corolla*: petals five, ovate, somewhat obtuse, concave, longer than the calix; of which the three smaller are upright; the two larger declinate, gaping. *Stamina*: filamenta very many, inserted into the receptacle, shorter than the corolla, dilated at the tip; antheræ oblong, tetragonal. *Pistil*: germen oblong, superior; style length of the germen, incurved; stigma three-lobed. *Pericarp*: capsule oblong, three-celled, three-valved; valves sharp-pointed. *Seeds*: very many, small, oblong, involved in a coloured membrane, affixed to the three-sided receptacle. ESSENTIAL CHARACTER. *Calix*: five-parted, two parts larger. *Corolla*: five-petalled, three smaller upright, two larger declinate. *Capsule*: oblong, three-celled, three-valved, many-seeded.—The only known species is,

1. *Bonnetia Palustris*, which grows in marshy places in Cayenne and Guiana. It is a tree of about 15 feet high, and seven or eight inches in diameter; branching chiefly towards the top. The branches are upright in their growth; the leaves are alternate, smooth, ovate, and entire; the flowers are borne on terminal spikes, and of a purple colour. In its native climate it flowers in August, and ripens its seeds in October.

Bontia; a genus of the class Didymia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted; leaflets blunt, upright, permanent. *Corolla*: one-petalled, ringent; tube long, cylindric; border gaping; upper lip upright, emarginate; lower revolute, semitrifid, the size of the upper. *Stamina*: filamenta four, subulate, bending to the upper lip, the length of the corolla, two higher; antheræ simple. *Pistil*: germen ovate; style simple, situation and length of the stamina; stigma bifid, blunt. *Pericarp*: drupe ovate, with the top oblique. *Seed*: nut-oval, one-celled, germinating. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: two-lipped, lower lip three-parted, revolute. *Drupe*: ovate, one-seeded, with the end oblique.—The only known species is,

1. *Bontia Daphnoides*; *Barbadoes Wild Olive*. Leaves alternate; peduncles one-flowered. A shrub, four or five feet high; leaves rather stiff, lanceolate, smooth; flowers yellowish, with a line of dusky purple across the lower lip, axillary, single, or in pairs; tube and lower lip hairy.—Birds grow fat upon the fruit, but unless the entrails are taken out as soon as they are killed, the flesh becomes too bitter to be eaten.—This plant is greatly cultivated in Barbadoes, for making hedges, than which there is not any thing more proper for those hot countries, it being an evergreen and of quick growth. From cuttings planted in the rainy season, when they have immediately taken root, there has been a complete hedge, four or five feet high, in eighteen months: and as this will very well bear cutting, it is formed into a very close thick hedge, which makes a beautiful appearance. In Europe, it may be raised from seeds, which should be sown on a hot-bed early in the spring, that the plants may acquire sufficient strength before winter. When they are come up, they must be transplanted out, each into a separate half-

penny pot, filled with light fresh earth, and plunged into a moderate hot-bed of tanner's bark, observing to water and shade them until they have taken root; after which they must have a large share of air in warm weather, and be often refreshed with water. In winter they must be placed in the stove, where they should have a moderate degree of warmth, and but little water during that season. In summer they must have a great share of air, but will not do well if exposed abroad, especially in cold summers; so that they should remain in the stove among plants which require a great share of air, which may be admitted by opening the glasses in very hot weather. They may also be propagated by cuttings, which should be planted in summer.

Borago: a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, permanent. *Corolla*: monopetalous, rotate, length of the calix; border five-parted, flat; throat crowned with five emarginate obtuse prominences. *Stamina*: filamenta five, subulate, converging; antheræ oblong, fixed to the inside of the filamenta in the middle, converging. *Pistil*: germen four; style filiform, longer than the stamina; stigma simple. *Pericarp*: none. *Calix*: larger, inflated. *Seeds*: four, roundish, wrinkled, keeled outwards at the top, globular at the base, inserted longitudinally into a hollow receptacle. ESSENTIAL CHARACTER. *Corolla*: rotated; throat closed with rays.—The species are,

1. *Borago Officinalis*; *Common Borage*. All the leaves alternate; calices spreading. Stem about a foot and a half high, branched, hollow, succulent, cylindric; leaves large, wrinkled, deep green; flowers terminating, blue, flesh-coloured, or white. The whole plant of *Common Borage* is rough, with white, stiff, prickly hairs; flowering from May till August. It came originally from Aleppo, but is now naturalized in most parts of Europe; where it is scarcely biennial. In England we frequently find it on dunghills and heaps of rubbish.—It was formerly in great request, being reckoned one of the four cordial flowers. Very light, surely, (says an ingenious author,) were those sorrows which could be so driven away. The whole herb is succulent, and very mucilaginous, having a peculiarly faint smell when bruised: the juice affords a true nitre: the plant is now seldom taken inwardly, except as an ingredient in cool tankards: the young tender leaves may be used in salads, or as a pot herb. A water, distilled from the flowers of this plant, was formerly in great esteem as a cordial and strengthener, but is very little regarded at present. It is, however, of a remarkably cooling nature, and consequently may be used with success, in inflammations of the eyes externally, and inwardly in burning fevers. The juice is good in obstinate coughs, catarrhs, hoarseness, and defluxions on the lungs: the flowers made into a conserve, are said to be good in putrid malignant fevers, and hypochondriacal complaints; likewise to remove obstructions, and cure the jaundice. This is a hardy annual plant, which, if permitted to scatter its seeds, the plants will come up in plenty without care; the seeds may also be sown either in spring or autumn, but the latter season is preferable, on a spot of open ground where the plants are designed to remain: when the plants have obtained a little strength, the ground should be hoed to destroy the weeds, and the plants must be cut up where they are too near each other, leaving them eight or ten inches asunder: after this they require no farther care, unless the weeds should come up again; then the ground should be a second time hoed over to destroy them, which, if well performed, and in dry weather, will clear the ground from weeds, so that it will require no more clearing till the *Borage* is decayed. The plants which are raised in the

autumn, will flower in May ; but those which are raised in the spring, will not flower till June.

2. *Borago Indica* ; *Indian Borage*. Leaves of the ramifications opposite, stem-clasping ; peduncles one-flowered. An annual plant, rarely rising a foot high.—Native of the East Indies. The seeds of this, and the third and fourth species, should be sown upon a hot-bed in March, and when the plants are strong enough to be removed, they should be each planted in a small pot filled with light earth, and plunged into a new hot-bed to bring them forward, otherwise they will not perfect their seeds in this country ; but in hot weather they must have a great share of air, otherwise they will draw up weak, and fail before the seeds are ripe.

3. *Borago Africana* ; *African Borage*. Leaves of the ramifications petiolate ; peduncles many-flowered ; corolla small ; blue, yellow within, with five purplish spots.—Native of the Cape of Good Hope. See the second species.

4. *Borago Zeylanica* ; *Ceylon Borage*. Branch-leaves alternate, sessile ; peduncles one-flowered ; calices earless.—Native of the East Indies. See the second species.

5. *Borago Orientalis* ; *Oriental Borage*. Calices shorter than the tube of the corolla ; leaves cordate.—Native of the country about Constantinople. It is perennial ; and is easily propagated by the root, which may be parted in the autumn ; it should have a dry soil and a warm situation, for as the flower-stalks appear early in the spring, when they are much exposed, they are often killed by the frost : if it be planted in dry rubbish, it will not grow too luxuriant, nor be in danger of suffering by the frost.

6. *Borago Longifolia*. Leaves linear-lanceolate, sessile, alternate ; calix very hairy at the base.—Native of Barbary.

Borassus ; a genus of Palms (see the Appendix, *Palmae*, of Linneus).—GENERIC CHARACTER. *Male*, *Anpana*. *Calix* : spathe universal, compound ; spadix amentaceous, imbricate ; perianth proper, three-leaved ; leaflets ovate, concave. *Corolla* : none. *Stamina* : filamenta six, thickish ; antheræ thicker, striated. *Femate*, *Curimpàna*, on a different plant. *Calix* : spathe and spadix as in the male ; perianth proper, three-leaved, permanent ; leaflets roundish, obtuse. *Corolla* : petals three, roundish, small, acute, permanent. *Pistil* : germen roundish ; styles three, small ; stigmas simple. *Pericarp* : berry (drupe) roundish, obtuse, rigid, one-celled. *Seeds* : three, subovate, compressed, distinct, filamentose. ESSENTIAL CHARACTER. *Corolla* : three-parted. *Male*. *Stamina* : six. *Female*. *Styles* : three. *Drupe* : three-seeded.—The only known species is,

1. *Borassus Flabelliformis*. Fronds palmate, plaited, cowed ; stipes serrate. This tree is twenty-five or thirty feet in height, two feet thick at bottom, and one at top. The fruit is the size of a child's head. A wine and sugar are made from the sap of this palm.—It is a native of Ceylon, the coast of Coromandel, and Java.

Borbonia ; a genus of the class Didelphia, order Decandria.—GENERIC CHARACTER. *Calix* : perianth one-leaved, semiquinquefid, turbinate, half the length of the corolla ; divisions lanceolate, acuminate, rigid, pungent, subequal, the lowest longer than the rest. *Corolla* : pentapetalous, papilionaceous, hirsute on the outside ; banner reflected, obtuse, claw the length of calix ; wings semicordate, a little shorter than the banner ; keel two-petalled, lunulate, obtuse. *Stamina* : filamenta nine, united into a cylinder, gaping longitudinally above, rising at the ends ; antheræ small. *Pistil* : germen subulate ; style very short, ascending ; stigma obtuse, emarginate. *Pericarp* : legume roundish, acuminate, one-celled, mucronate, with a spine. *Seed* : kidney-form. ESSENTIAL CHARACTER. *Calix* : acuminate spiny.

Stigma : emarginate. *Legume* : mucronate.—The method of propagating these plants, in the country, has been that of laying down their shoots ; but these are commonly two years before they put out roots fit to be separated from the old plant. In laying these down, the joint which is laid in the ground should be slit upward, as is practised in laying carnations, and the bark of the tongue at bottom taken off. The best time is the beginning of September. But where good seeds can be procured, that is the more eligible method of propagating the plants ; for those raised from the seeds make the straightest plants, and are quicker of growth. They should be sown in pots filled with light loamy earth, as soon as they are received ; if it happens in the autumn, the pots should be plunged into an old bed of tanner's bark, under a frame, where they may remain all the winter, being careful that they are secured from frost, and have not much wet. In the spring, the pots should be plunged into a hot-bed, which will bring up the plants in five or six weeks. When these are fit to remove, they should be each planted into a small separate pot, filled with the like loamy earth, and plunged into a moderate hot-bed, observing to shade them until they have taken fresh root, as also to refresh them with water as they may require it. After this they must by degrees be inured to the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy the air and sun. During the winter season, these plants must be sparingly watered ; but in summer, when they are placed abroad, they will require to be frequently refreshed, but must not have too much water given them at each time. These plants make a pretty variety in the green-house in winter, and as they do not require any artificial heat to preserve them, they are worthy of a place in every garden where there is a convenience for keeping them. They are all natives of the Cape of Good Hope.—The species are,

1. *Borbonia Ericifolia*. Leaves sublinear, acute, villose ; heads terminal ; flowers yellow, small.

2. *Borbonia Lævigata*. Leaves lanceolate, nerveless, smooth ; involucre and calices rough with hairs.

3. *Borbonia Trinervia*. Leaves lanceolate, three-nerved, quite entire.

4. *Borbonia Lanceolata* ; *Spear-leaved Borbonia*. Leaves lanceolate, many-nerved, quite entire. It flowers in August and September.

5. *Borbonia Cordata*. *Heart-leaved Borbonia*. Leaves cordate, many-nerved, quite entire.

6. *Borbonia Crenata* ; *Notch-leaved Borbonia*. Leaves cordate, many-nerved, toothletted.

Bosea ; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix* : perianth, five-leaved, equal ; leaflets roundish, concave, erect, thinner at the edge. *Corolla* : none. *Stamina* : filamenta five, subulate, longer than the calix ; antheræ simple. *Pistil* : germen ovate-oblong, cuspidate ; style none ; stigma two. *Pericarp* : berry-globular, one-celled. *Seed* : one, round, acuminate. ESSENTIAL CHARACTER. *Calix* : five-leaved. *Corolla* : none. *Berry* : one-seeded.—The only species is,

1. *Bosea Yervamora* ; *Golden-rod Tree*. Leaves simple, alternate, petioled, ovate, pointed, entire, smooth, with fine purple nerves ; flowers reddish, in loose axillary racemes. This is a pretty strong woody shrub, with a stem as large as a middling person's leg.—It is a native of the Canary Islands ; and has also been since found in some of the British West India Islands.

Box-Thorn. See *Lycium*.

Box-Tree. See *Buxus*.

Brabeium: a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Calix*: ament pubescent, with ovate, obtuse, three-flowered scales. *Corolla*: one-petalled, funnel-form, four-parted, deciduous; divisions linear, obtuse, rolled back at the top, deciduous. *Stamina*: filamenta four, capillary, inserted into the base of the segments of the corolla, and scarcely so long as that; antheræ small, gaping on the sides. *Pistil*: germen very small, villose; style filiform, longer than the stamina, somewhat thicker at the top; stigma simple. *Pericarp*: drupe very dry, roundish, villose. *Seed*: nut-globular. *Male Flowers on the same tree.* *Calix*: ament as in the hermaphrodites. *Corolla*: one-petalled, funnel-form, four or five cleft; clefts oblong, revolute. *Stamina*: filamenta four or five, inserted into the throat, of a middling length; antheræ oblong, fastened to the inside of the filamenta, except at the tip. *Pistil*: germen none; style filiform, of a middling length; stigmas two, erect. ESSENTIAL CHARACTER. *Hermaphrodite*: scales of the ament. *Corolla*: four-parted, revolute above. *Stamina*: four. *Pistil*: one. *Drupe*: roundish. *Seed*: globular. *Male*: scales of the ament. *Corolla*: four or five parted. *Stamina*: four, inserted into the throat; style bifid, abortive.—The only known species is,

1. *Brabeium Stellulifolium*; *African Almond*.—Native of the Cape of Good Hope, where it becomes a tree of middling growth; but in Europe it seldom exceeds nine feet high. It is difficult to propagate this tree by layers, which are often two years before they make roots strong enough to be taken from the old plants; when the branches are laid down, it will be a good method to slit them at a joint, as is practised in laying Carnations; which will promote their taking root. They must have but little water, especially in winter, for as the young shoots are chiefly pith within, they are very apt to rot with much moisture. The best time to make the layers is in April, just as the plants are beginning to shoot: and they must always be of the former year's growth. The plants must have a good green-house in winter; but in summer they should be set abroad in a sheltered situation, where they will thrive, and annually produce flowers in the spring, making a pretty variety among exotic plants.

Bradleja; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Male Flower.* *Calix*: none. *Corolla*: petals six, ovate, concave, spreading, nearly equal. *Stamina*: filamenta three, extremely minute; antheræ cylindrical, erect, formed of three united twin antheræ, tipped at the point with a cusp or spearlet. *Female Flowers.* *Calix*: none. *Corolla*: one petalled, six parted, inferior, three of the parts interior. *Pistil*: germen globose, six-furrowed, superior; style none; stigmas six to eight, very small, converging. *Pericarp*: capsule depressed, round, twelve-streaked, six-celled, six-valved, gaping. *Seed*: solitary, somewhat globose. ESSENTIAL CHARACTER. *Male.* *Calix*: none. *Corolla*: petals six, nearly equal; filamenta three, with three twin antheræ. *Female Calix*: none. *Corolla*: six-parted, three parts interior; germen superior, with six to eight stigmas. *Capsule*: six-celled, six-valved. *Seed*: solitary.—The species are,

1. *Bradleja Sinica*; *Chinese Bradleja*. A shrub, with leaves resembling the Annona, but not of a lucid surface.

2. *Bradleja Zeylanica*. A Ceylonese shrub.

3. *Bradleja Glochidion*. A tree which grows in the islands of the Southern or Pacific ocean.

Brassica: a genus of the class Tetradymania, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-

leaved, erect, a little converging; leaflets lanceolate-linear, concave-channelled, gibbous at the base, erect, parallel, deciduous. *Corolla*: cruciform; four-petalled; petals subovate, flat, expanding, entire, gradually lessening into claws nearly the length of the calix; nectareous glands four, ovate, of which one on each side between the shorter stamina and the pistil, and one on each side between the longer stamina and the calix. *Stamina*: filamenta six, subulate, erect, of these two opposite ones are of the length of the calix, and four longer; antheræ erect, acuminate. *Pistil*: germen columnar, the length of the stamina; style short, the thickness of the germen; stigma capitate, entire. *Pericarp*: silique long, somewhat like the shaft of a column, but flattened on both sides; partition with a prominent columnar top, two-celled, two-valved; valves shorter than the partition. *Seeds*: many, globular. ESSENTIAL CHARACTER. *Calix*: erect, converging. *Seeds*: globular. A gland between the shorter stamina and the pistil, and between the longer and the calix.—The species are,

* *Siliques slender, four-angled, with a short permanent Style.*

1. *Brassica Orientalis*; *Perfoliate Cabbage*. Stem-leaves cordate, stem-clasping, smooth; root-leaves scabrous, quite entire; siliques four-cornered; root spindle-shaped, small, white.—Native of corn-fields and cliffs in the Levant, about Montpellier; in Germany, Switzerland, Austria, Carniola, Piedmont, &c. In England it is found near Harwich; Bardsey, near Orford, Suffolk; Godstone, and Maresfield, Sussex. Annual, flowering in June.—This, with the second, third, fourth, and fifth species, may be propagated by sowing their seeds on a bed of light earth, early in the spring, in the place where they are designed to remain, for they do not bear transplanting well. When the plants are come up pretty strong, they should be so thinned as to leave them four or five inches apart, and they must be constantly kept clear from weeds. They will flower in June, and ripen seed in the beginning of August. If these be permitted to fall, the plants will come up, and maintain themselves without any further care. They are cultivated merely for curiosity.

2. *Brassica Austriaca*; *Austrian Cabbage*. Leaves cordate, stem-clasping, smooth, all quite entire; siliques four-cornered, striated, erect.—Native of Austria. It is a biennial plant. For its culture and propagation, see the preceding.

3. *Brassica Campestris*; *Yellow Field Cabbage*. Root and stem slender; stem-leaves uniform, cordate, sessile. Root annual; corolla yellow, never white.—For its culture and propagation, see the first species.

4. *Brassica Arvensis*; *Purple Field Cabbage*. Leaves stem-clasping, spatulate, repand; the upper cordate, quite entire. Perennial.—Native of corn-fields in the south of Europe. For its culture and propagation, see the first species.

5. *Brassica Alpina*: *Alpine Cabbage*. Stem-leaves cordate, sagittate, stem-clasping; radical leaves ovate; petals erect.—Native of Germany and Sweden. For its culture and propagation, see the first species.

** *Siliques with a cylindrical, rather obtuse Style.*

6. *Brassica Napus*; *Wild Cabbage, Rape, or Navew*. Root caulescent, fusiform. The roots when cultivated may be eaten, but have a stronger taste than the Turnip. It is much cultivated in the Isle of Ely, and some parts of England, under the title of Rape or Cole-seed; and in some parts of England for its seed, from which the rape-oil is drawn; and for feeding cattle. The residue, after the oil is expressed, is called oil-cake or rape-cake. It is a very efficacious manure, and is sold at from four to six pounds per ton. It is not this but the lint-cake, or residuum of Flax-seed, used in making linseed oil, that is used in fattening beasts. It grows among

corn, and on ditch-banks.—When it is cultivated for feeding cattle, it should be sown about the middle of June. The ground should be prepared in the same manner as for Turnips; the quantity of seeds for an acre of land is from six to eight pounds, and as the price of the seeds is not great, it is better to allow eight pounds; for if the plants are too close in any part, they may be easily thinned when the ground is hoed. When the plants have put out six leaves, they will be fit to hoe, which must be performed in the same manner as is practised for Turnips, with this difference only, of leaving these much nearer together; for as they have fibrous roots and slender stalks, they do not require near so much room. They should be hoed a second time, five or six weeks after the first, which, if well performed in dry weather, will entirely destroy the weeds, and they will require no further culture. By the middle of November these will be grown large enough for feeding, when, if there is a scarcity of fodder, this may be either cut or fed down; but where there is not an immediate want of food, it had better be kept as a reserve for hard weather, or spring seed, when there may be a scarcity of other green food. If the heads are cut off, and the stalks left in the ground, they will shoot again early in the spring, and produce a good second crop in April, which may be either fed off, or permitted to run to seed, as is the practice where this is cultivated for the seeds: but if the first is fed down, there should be care taken that the cattle do not destroy their stems, or pull them out of the ground. As this plant is so hardy as not to be destroyed by frost, it is of great service in hard winters for feeding ewes; for when the ground is so hard frozen that Turnips cannot be taken up, these plants may be cut off for a constant supply. In several places an acre of land, sown with this seed, has produced as much food as almost two acres of Turnips; and this will afford late food, after the Turnips are run to seed: one acre will produce as much as, at a moderate computation, will sell for five pounds, clear of charges. Partridges, pheasants, turkeys, and most other fowls, are very fond of this plant; so that wherever it is cultivated, if there are any birds in the neighbourhood, they will constantly lie among these plants. The seeds are sown in gardens for winter and spring salads, as it is one of the small salad herbs.—Cole or Rape is sometimes sown on fallow like Turnips, sometimes on the stubble of an arable crop: it requires good land; very stiff clay does not suit it, and poor land is wholly unfit; but on the sward of old grazing grounds, on fen and marsh lands, it generally turns out the most profitable crop for seed, either immediately, or after Flax. On old pastures the turf is pared and burnt, and the ashes are spread generally with a mixture of lime. The seed is sown in July, early enough to get a strong leaf, and late enough to prevent its running up to stem the first autumn; the quantity of one gallon to an acre, generally on one ploughing, and brushed in with a thorn-harrow. The crop is seldom hoed or weeded. The vacant patches are filled up in October with plants from those parts which are over-stocked; this work is done by women: the plants seldom fail, but they ripen later than the others. When a large piece fails, the plough is sometimes used in transplanting; the expense, four shillings an acre; namely, eight women at sixpence a day. In the common method of culture, the whole tribe of biennial weeds have time to establish themselves before winter; and the crop not being reaped until July or August following, they have time to mature and shed their seed. The grasses and strong-rooted weeds of every kind, gain possession of the soil; which also gets out of tilth, by lying so long without ploughing. One ploughing in autumn would extirpate the biennial weeds, check the

grasses and strong-rooted weeds, and preserve the soil in tillage. Draw from the first land sufficient plants for the last land, and bury the roots in a vacant place until wanted. Plough the first land, burying the weeds and the refuse Rape, and stock it at the same time with plants drawn from the second land. The first land being finished, supply the second with plants from the third, and so on, furnishing the last land with the plants in reserve. Thus the entire piece would have prime plants, equal in strength and regular in distance; the soil would be evenly occupied, and the crop would ripen equally; the hoe, and even the horse-hoe, might be used between the rows; and the foulest crop which farmers have to deal with, might, at a small expense, be rendered a fallow crop of the first estimation. In this management, the first or seed ploughing ought to be very shallow across the ridges; and the second or transplanting ploughing should be across the first; gathering up the ridges dry against winter. A manured fallow, a rich Wheat stubble, or other land sufficiently clean and in heart, might be planted in a similar manner; raising plants for this purpose in a detached seed-bed.—Rape is generally ripe in July, and is considered as fit for cutting when the forwardest of the seed has begun to turn black. It is cut with sickles, and laid in broad thin heaps upon the tops of the stubble, which is generally cut about a foot high, or as high as the lower branches will allow. It lies until the sap is pretty well dried out of the greenest pods, and the ripest are ready to open, and is commonly threshed in the field upon a cloth. It would be far better, however, to bind, shock, and carry it into the barn, threshing it when markets and convenience require. When Rape succeeds Flax, the ground is cleared of weeds as soon as convenient: it is then ploughed four or five inches deep, and from half a peck to a peck of seed, according to the richness of the soil, is sown from a week before to a week after Michaelmas; it is usually well harrowed in, and if it grows into rough leaf before winter, it is considered as better than growing more, which would place it in danger of being destroyed by frost; no weeding takes place, and the crop will be ready about the middle of July. It is reaped, and laid on the ground in single handfuls, and when dry, it is carried to the threshing-floor, on sledges covered with sail-cloth. The crop is from three to seven quarters on an acre. The seed lost in reaping and getting in, produces a crop of green food for sheep, which is fed off early enough to prepare the ground for a second crop of Flax. This straw is sold at two shillings an acre, to persons who burn it on the spot for the ashes. For immediate profit, and on old pastures broken up, Rape or Cole may be thus cultivated for seed; but on stubbles or fallows it answers better to feed it off with sheep, (the fat ones going over it once, and afterwards the lean or store sheep following,) in the autumn, but particularly in the spring, when there is frequently a scarcity of green food: this is an excellent preparation for either Wheat or Barley. It succeeds best on a deep soil, with good manure, and deep ploughing, and does best after Beans, Barley, Oats, or Wheat; it is sometimes sown after Turnips or Cabbages, which cannot be a right practice.—When sown on a fallow, the land should be ploughed up soon after Christmas, and lie till the end of March; it should then be ploughed a second time, harrowed down, and a coat of manure laid on, as for Turnips; when this is spread, the land should be crop-ploughed, and got into fine tilth by the end of June. The first rain after this, the seed should be sown, from two to four quarts an acre, according to circumstances, in the same manner with Turnips, and the land be lightly harrowed and rolled: the crop should be hoed, as above directed, and the vacant places filled up in October: many persons omit the hoeing entirely,

when it is intended only for feeding. Colesced being an exhauster of land, should not be repeated oftener than every seventh year, and not so often when cultivated for the seed.

7. *Brassica Rapa*; *Turnip*. Root caulescent, orbicular, depressed, fleshy. The variations of Turnip are chiefly in the root, and arise from the different soils, situations, and modes of cultivation. The general use of this root, for the table and feeding of cattle, is well known; and it has been a considerable improvement of light lands, particularly in the county of Norfolk, whence other counties have derived the culture. Skillful farmers prefer the large green-topped Turnip, because the roots grow to a large size, and continue much longer good; it also grows above ground more than any of the others, which renders it preferable for feeding cattle; and being the softest and sweetest, even when very large, it is most esteemed for the kitchen. In very severe winters, however, this is in greater danger of suffering by frost, than those whose roots lie deeper, especially if the ground be not covered with snow; for when the roots are alternately frozen and thawed, they rot sooner than those which are more covered and less tender. Roots of this sort have been boiled when more than a foot in diameter, and ate as sweet and tender as any of the smallest that could be found. The next in goodness to the green-topped, is the red or purple topped Turnip, which will also grow large, and be extremely good for some time; but the roots will become stringy much sooner than the others. The long-rooted, the yellow, and the black rooted Turnips, are now rarely cultivated except for the sake of variety, none of them being so good for the table or seed, as the red and green topped sorts. The early Dutch Turnip is chiefly sown in the spring, to supply the table before the others can be procured; and when drawn off young, this sort is tolerably good, but if the roots be left to grow large, they become stringy, rank, and unfit for use. The French Turnip is not much cultivated in England, but in France and Holland it is in great esteem, especially for soups, in which, being small, the roots are boiled whole; they must be used whilst they are young, otherwise they are rank and stringy.—Turnip roots are reputed to relax the bowels, and to sweeten the blood; to be fruitful to pregnant and hysteric women, and to all who are subject to flatulencies. The juice, well fermented, affords by distillation an ardent spirit. The rind is acrimonious. The tender tops boiled, are frequently eaten in the spring as greens with meat.—Although the practice of sowing Turnips for feeding cattle was evidently known to the ancients, it has only been of late adopted in Europe. The Turnip delights in a light, sandy, loamy soil; in a rich soil the roots grow rank, and are sticky, but if it be moist, they will thrive better in summer, especially in fresh land, where they are always sweeter than upon an old worn-out or rich soil. In field culture, a deep sand, such as has adhesion enough to make it of the value of from 5s. to 10s. an acre, is the best. If the land be wet or stiff, such as yield good Wheat crops, the culture may not be advantageous, especially if used, as it should be, as a preparation for Barley; on such soil it would shorten the crop at least two or three coombs an acre. Even blowing sands of 3s. 6d. or 2s. 6d. an acre, are to be preferred; for these, when folded, if the season should happen to be wet, yield profitable crops: indeed such lands are to be farmed no other way; for if no Turnips are gained, no corn can be had, and a mere sheep walk is then the only use that can be made of them. Where a farmer has no proper soil for Turnips, it is more prudent to give up the winter-feeding of more cattle than his hay and straw will do for, unless he can depend on buying Turnips, which may sometimes be advantageous, and

sometimes the contrary. The first earth or ploughing for Turnips should be given before Christmas, or certainly not later, and should be of a common staple depth; unless the land is foul, in which case it should be ploughed very shallow, in two-furrow ridges, and the second time to the full depth, but it should never be ploughed in wet weather. This second earth, for which frequently the farmer has not leisure, should be given before the spring seed-time, and will be very useful; for if there should be any spire or spear grass (quick, quich, or couch) in the-hand, that pernicious weed is too apt to get a hold before Barley sowing is over. Immediately after the Barley is in the ground, the third earth should be given, this will be in May; the fourth, about the second week in June; and the fifth, or seed-earth, about the latter end of the same month; unless the soil be subject to the mildew, in which case old Midsummer, the first week in July, will be full soon enough; and let it be observed, that harrowing with every earth is very necessary, for the surface should always be kept in fine friable order, that the seed-weeds may grow; whereas, if this be omitted till the seed-earth, they will then be grown so powerful as to smother many of the young plants. On a light dry soil, the Turnip-root is in a degree necessary; but where land will remain in grass, and where other arable crops are more certain and productive, it is less essential to good husbandry: in particular situations, however, under proper management, it may frequently be useful, and may be occasionally practised, on a small scale, in almost every situation. It may be very acceptable, therefore to give the proper tillage of the Turnip crop on rich retentive soils. If the land be foul, or if early sowing be proposed, break up in autumn, by a rice-balk or half-ploughing across the lands, gathering a bont in each interfurrow, and opening the cross trenches in order to lay the soil as dry as possible during the winter: but if the land be tolerably clean, and early sowing be not wanted, break up in the spring, in order that the roots and stems of grasses, &c. may remain in an undigested state, and assist in rendering a closely-textured soil loose, and fit to receive the weakly fibres of the seedling Turnips: cross, and give the first stirring (the third ploughing) without previous harrowing; and if the root-weeds be not yet subdued, give a fourth ploughing before the harrows be suffered to come upon the land. Spread dung which is in a middle state on the rough plit; if too long and strawy, it is pulled up by the harrows, and if wholly digested, it loses the valuable quality of rendering this retentive soil loose and open. As the dung is spread, harrow and roll, until the surface be perfectly reduced, and in this state let it lie until the seed-weeds have vegetated. Turn under the weeds, and manure, by a mean depth, or somewhat shallow ploughing; if not, harrow and roll, letting another crop of seed-weeds spend themselves; remembering that the stronger the seed-weeds are before they are ploughed under, the fitter the soil will be for the reception of the seedling Turnips, especially if it be of a tenacious quality. Harrow immediately the plit of the seed-ploughing with rough harrows, in order to give a uniform looseness to the surface, as well as that the seed may be buried at a uniform depth. Sow, and immediately cover with one full tine of a pair of light harrows, and, if possible, with the horses trotting. For a crop to be eaten off in autumn, sow, in June, the *Tankard* or *Pudding* Turnip, which has a rapid growth, but standing high above the ground, cannot bear the winter. For winter and spring feed, sow the common *White Loaf* in July; if these miscarry, or if stubble Turnips be attempted, sow in August the *Stone* Turnip, a small, hard, sweet root, which stands the winter with singular hardihood. In a common season, sow two pounds

of seed on an acre, all upon the same surface ; for perhaps the nearer the plants come up, the less danger there is of their being wholly cut off by insects ; but if these are known to be in force, or if any doubt arise, either as to the quality of the seed or the season, sow at least three pounds of seed to an acre ; if the soil lie in broad rough lands, plough one, two, or even three bounts in each interfurrow, according to the width, height, and wetness of the lands, as soon as the seed-weeds have done vegetating ; and if any root-weeds appear to be alive on the surface, or being dead, if any are likely to impede the hoe, pick them off, and cast them upon the intervals. If the first sowing miscarry, and the failure be fully ascertained, before the weeds have got too strong to be got out with rough harrows, harrow only before re-sowing ; but if the weeds have got fast hold of the soil, or if the season be too moist to obtain the intention by harrowing alone, plough a mean depth, and harrow, sow, and cover as before. On such soils the Turnips cannot be fed off the lands without injury, even by sheep ; nor can they well be carted off, except in light broad wheeled carts, or on sledges : they may, however, be useful in stall-feeding bullocks, or given to sheep on a sound piece of pasture.—Another method has been practised lately in cultivating Turnips ; which is, by sowing the seed in rows, with the drilled plough. In some places the rows have been sown three feet asunder, in others four, in some five, and some six. The latter has been commended by skilful persons as the most proper distance, for although the intervals are so large, yet the crop produced on an acre has been much greater than upon the same quantity of land where the rows have been but half this distance ; and upon all the fields which have been cultivated for Turnips, the crops have greatly exceeded those which have been hand-hoed. In a trial which was made of these two methods of husbandry, the same field was divided into different lands, which were alternately sown in broadcast ; the latter were hoed by hand in the common method, and the other cultivated by the hoeing plough ; and when the roots were fully grown, an equal quantity of land, which had been sown in different methods, was measured, and their roots drawn up and weighed ; and those roots which had been cultivated by the plough, were so much larger than the other, that the crop of one acre weighed a ton and a half more than that of an acre in the other husbandry.—When the Turnips are sown in drills, they will require to be hoed by hand, to separate and cut out the plants when they are too near together in the rows, as also to cut up the weeds between the plants, where the plough cannot reach them. If this is carefully performed, the ploughing of the intervals will encourage the growth of the roots, by thus stirring the ground, and prepare it much better for the crop of Barley, or whatever else is sown the following spring. This method of culture may be supposed to be more expensive than that commonly practised by those unacquainted with it ; but those who have made trial of both, find the horse-hoeing to be much the cheapest, and by far the best, for the labourers who are employed in hand-hoeing Turnips, are very apt to hurry over their work, so that half the weeds are left growing, and the plants are seldom singled out so well as they should be ; nor are they curious enough to distinguish the Charlock (which is one of the most common weeds in arable land) from the Turnips ; so that about the middle of September, it is very common to see the fields of Turnips full of the yellow flowers of the Charlock. Now, in the horse-hoeing, all the weeds in the intervals will be entirely destroyed, or if a few plants of Charlock in the rows should be overlooked, they may be easily drawn out afterwards, and by this method the land will be sooner

and better cleared from weeds. The above advantages of drilling Turnips have been confirmed from subsequent observations and experiments : the spaces between the rows will be hoed in half the time that would be required if sown in the common way ; and when they come to be set out at proper distances in the rows, the superfluous plants may be cut out in one-third of the time usually required, and that by women and children, which is a considerable advantage, when the hoeing is to be done in the busy time of harvest. It is not the practice, nor does it seem to be any advantage, to set out the rows at a greater distance than from seven to eight, or ten to twelve inches. The difference in weight, on a given quantity of land, appears also to be considerably to the advantage of the drill culture, to the amount of one ton, three, four, or twelve hundreds ; two tons, five hundred ; and even three tons. The principal advantage seems to consist in depositing the seed at a proper depth in the soil, namely, about two inches, where there is moisture, which in a dry season will send the plants up in a few days ; whereas, when they are sown broadcast in a time of drought, the seed may remain for several weeks waiting for rain to make them vegetate ; but the seed being all deposited at the same depth, will vegetate at the same time, and by getting into the rough leaf sooner, will stand a better chance of escaping the fly.—No Turnips, and consequently no Barley after them, can be had without dung, and the crop in a great measure depends upon the quantity of it. The dependence for manure is chiefly on the fold or farm-yard, usually both. Of farm-yard dung, or else muck, that is, dung mixed with mould, marl, &c. not less than twelve loads should be spread on an acre, such as was made the preceding winter, and once turned over. The dung should neither be long nor quite rotten ; the best condition is, when it is in such a state, that the labourers say it will neither spit nor fork. When the dung is rather long, and ploughed in with the seed-earth, the seed should be only rolled in. It is the custom with some farmers, to turn in the dung very shallow at the last ploughing but one, harrowing well to mix it with the soil, and they think it will ferment by the time the seed-earth is given to the land. It seems, however, to be the better method, to turn in the dung by the last ploughing or seed-earth, because it is then turned down, not by a shallow furrow ; but covered as soon as possible from the sun, and deposited where the roots will be sure to find it, and where the immediate action of the sun and wind is excluded ; whereas, in mixing the manure with the soil by the harrow, much of it is pulled out and exposed on the surface. Rough dung is in general preferred before such as is rotten ; a better crop, however, has been obtained, by mixing dung with earth or other manure in the winter, and getting it rotten enough to lay at top, and harrow it in with the seed, than by ploughing in long dung. Rape-cake, in a pulverized state, is also recommended for Turnip manure : being reduced to powder by two mills, it is put into the drills. The quantity used to an acre, is a quarter of a ton, which has never exceeded 25s. in price. Others use malt-coombs, soot, soaper's ashes, lime, crag, &c. but none of these manures are very general, or so effectual as farm-yard dung.—The quantity of seed to be sown depends much on the soil ; upon a naturally good Turnip sand, a pint an acre, evenly delivered by a good hand or sowing engine, will be enough ; but in general two pints are allowed. No soil requires so much seed as chalky lands, when the chalk comes quite to the surface : upon such soil a quarter of a peck will seldom be too much for an acre, because the fly is sure to attack the plants more voraciously, and with greater certainty, on this soil than on any other. The sowing engine

though with care a good tool, yet is liable to have the holes stopped by two seeds sticking in them, so that if the sower is not very attentive, he may go some distance without a regular delivery. The common season for sowing Turnips, is any time from the beginning of June till the middle of August, or a little later, though it is not advisable to sow them much after, because if the autumn should not prove very mild, they will not have time to apple of a proper size before winter, nor will the roots of those which are sown after the end of July grow very large, unless the frost keeps off very long in autumn. But notwithstanding this is the general season in which the greatest part of the Turnips are sown in the country, yet about London they are sown successively from March till August, by those who propagate them to supply the markets with their roots; but there is a great hazard of losing those which are sown early in the year, if the season should prove dry, by the fly, which will devour whole fields of this plant while young, so that where a small quantity for the supply of a family is wanted, it will be absolutely necessary to water them in dry weather; and where a person sows those seeds in April or May, it should always be upon a moist soil, otherwise they seldom come to good, the heat of the weather being too great for them at that season upon a dry soil: but those which are intended for the general crop, are sown towards the end of June, when they commonly receive some refreshing showers to bring them forward, without which it is very common to have them all destroyed. The season for field-sowing extends from a week before Midsummer, to the middle or end of July: this variation is necessary for two reasons; first, because the land cannot be all manured to sow early; and secondly, because the late-sown will last much longer than the early ones, which are subject to the blight or mildew, and consequently are more likely to be rotted by hard frosts afterwards, for which reason all farmers should take care to have some late-sown. Sometimes a crop sown the first week in August, has proved the most profitable, this having escaped, whilst the rest has been killed by the frost. An active farmer, therefore, will, in cases where it is necessary, as soon as he has set up or shocked his wheat, plough up the intervals, and sow them immediately with Turnips, for the chance of a late crop, which will furnish spring-feed, although they should fail of appleing well. Where a farmer has many Turnips, it does not seem a bad plan to sow a fourth part at the end of June, or the beginning of July, to come up early; half in the middle of July, for the main crop, and the remainder at the end of the same month to come late: this, however, must depend upon his business, the weather, and other contingencies. At any rate, the main crop should not be sown too soon, nor allowed too much room, because large roots will not stand the frost near so well as smaller ones. What is ploughed for the last earth should always be sown the same day, else, unless rain fall, the ground will be too dry for the seed to vegetate: the seed must be harrowed in as soon as it is sown with a short-tined harrow, and the ground rolled with a wooden roller to break the clods, and make the surface even: the plants will come up in ten days or a fortnight after sowing; but this will vary very much with the weather: and there will be a difference of three days between the germinating of new and old seed.—When the plants have got four or five leaves, they should be hoed, to destroy the weeds, and to cut up the plants where they are too thick, leaving the remaining ones about six inches asunder each way, which will be room enough for the plants to stand for the first hoeing: and the sooner this is performed when the plants have four leaves, the better they will thrive;

but in the second hoeing, which must be performed about a month after the first, they should be cut up so that the remaining plants may stand fourteen or sixteen inches distance or more, especially if they are designed for feeding cattle, for where the plants are allowed a good distance, the roots will be proportionably large, provided the ground is good, so that what is lost in number, will be overgained by their bulk: but in places where they are sown for the use of the kitchen, they need not be left at a greater distance than a foot, because large roots are not so generally esteemed for the table. The time for the first hoeing of field Turnips is very uncertain, depending on the soil and the season, and varying from three to eight and nine weeks from the time of sowing: the size of the plants is the only guide, and the best rule is, to begin hoeing as soon as they are about the size of the palm of the hand, or spread upon the ground from three to four inches: if the hoe be put in too soon, the plants which are set out are liable to be buried, and their roots disturbed in setting out others which are near them; and if the Turnips be suffered to grow too large, it is difficult to set out the plants, and they are liable to be drawn up by weeds; if these be numerous or luxuriant, it will be necessary to begin hoeing somewhat earlier, in order to check them in time: some persons remove the ground with a light harrow once in a place, as soon as the plants are stout enough, to assist the hoeing; and if any of the fields after the hoeing begin to get too forward, which in a wet season is often the case, they give them a second harrowing the contrary way. Nothing but practice can teach the method of hoeing Turnips; to be performed well, it requires a quickness of eye and a dexterity of hand which does not fall to the lot of very many. The hoe is generally drawn round the plant with a long sweeping stroke; and when the plants are small, then only that stroke ought to be used; but when the plants are out of danger of being buried, a short straight stroke is more expeditious, and in some hands makes tolerably good work. The general effect of hoeing ought to be, that the whole ground should be stirred, all the weeds effectually cut up, and the plants set out singly at proper distances: the common practice is, to set out the plants at fourteen or fifteen, and sometimes at eighteen inches distance; this, however, is not always necessary, and is frequently injurious. The proper distance depends upon the soil, and the time of sowing; the richest soil will admit of the greatest distance, because the plants in that will be more luxuriant than in a soil of inferior quality; and early-sown Turnips will come to a greater size than such as are sown late, and therefore should be allowed more room to spread themselves: the best general rule in this case is, to give the plants room to keep themselves in a state of vigour and full growth, without leaving any space unoccupied by, or even thinly filled with leaves. Since Turnips, therefore, commonly run from four to eight inches in diameter, twelve inches may be taken as a proper medium distance, except in land of an extraordinary goodness.—The main purpose of the second hoeing is to loosen the mould, and to draw it in some measure to the roots of the plants; to reduce the weeds effectually; and to single such plants as have been left double by the first hoeing, as well as to remove such as have been missed, or having been buried in the loose mould in moist weather, have struck root again in improper places. With respect to the time of the second hoeing, it ought to be given before the leaves become too large to prevent the plants from being properly singled and set out, or the weeds from being effectually cleared away; but the longer they stand before the last hoeing, the more effectually will the weeds be overcome. If when the

Turnips are so closed as to exclude all hoeing, any weeds still shew themselves, women and children should be sent in to pull them by hand. The second hoeing is sometimes omitted, but seldom without great detriment to the crop and the land; and, strange to tell, there are yet some parts of the kingdom wherein, it is said, hoeing of Turnips is altogether omitted. Upon the whole, the object of the first hoeing should be, not so much that of setting out the plants at exact and wide distances, as of checking the weeds, and thinning the plants, to prevent their crowding each other; the regulation of distances should be left in a great measure to the second hoeing: in the first, by reason of many accidents young Turnip plants are liable to, it is a work of hazard and uncertainty; in the second, not only proper distances, but proper plants, may be chosen with a degree of safety and certainty. The Norfolk hoes are from nine to eleven inches wide. It is the interest of the hoer to work with a wide hoe, because he performs his work sooner, and has fewer plants to set out; his interest, therefore, is, in this case, in direct opposition to that of his employer. The width of the hoe ought to be in proportion to the medium distance between the plants, and that, it has already been observed, should be in proportion to their expected size: for twelve inches, a seven-inch hoe is sufficient. By sowing at different seasons, six men will hoe a hundred acres twice over; such as do not vary the season, must of course proportionably increase the number. The price in Norfolk, is 6s. an acre for the two hoeings, when let jointly, as they commonly are; if let separately, the first is from 3s. 6d. to 4s.; the second from 2s. to 2s. 6d. In other counties, 8s., 10s., and even 12s. an acre, are given for the two hoeings; but the Norfolk men are more expert in the business, and the soil of that county is more friable, and free from obstructions. In crops of drilled Turnips, the work of hoeing may certainly be done cheaper, namely, from four to five shillings the acre; and cheaper still with the horse-hoe, when hand-hoeing will be required only in the rows.—When Turnips are sown in drills, it will be the best way to hoe between every other row first, and some time after to hoe the alternate intervals, by which method the plants will receive more benefit from the often stirring the ground, than they would do if all the intervals were hoed at one time, and the plants will be in less danger of suffering from the earth being thrown up too high on some rows, while others may be left too bare of earth; but when the earth has been thrown up on one side of the drill, it may be turned down again when the next interval is hoed, and this alternate moving of the earth will prepare the ground very well for the succeeding crop, as well as greatly improve the Turnips; but as this plough cannot be well drawn nearer to the drills than two or three inches, the remaining ground should be forked to loosen the parts, and make way for the fibres of the roots to strike out into the intervals; otherwise, if the land be strong, it will become so hard in those places which are not stirred, as to stint the growth of the Turnips, and this may be prevented at a small expense; a good hand will perform a great deal of this work in a day; and whoever will make the trial, will find their account in practising it, especially on all strong land, where the Turnips are much more liable to suffer from the binding of the ground, than on a loose soil; but yet in all sorts of ground it will be of great service to practise this. When the ground is thus stirred in every part, one ploughing will be sufficient, after the Turnips are eaten off the ground, to prepare it for the sowing of Barley or any other crop; so that there will be an advantage in this when the Turnips are kept late on the ground, as will often be the case, especially when they are cultivated for the feeding of ewes, because it

is often the middle of April before the ground will be cleared; for late feed in the spring, before the grass comes up, is the most wanted, where numbers of sheep and ewes may be maintained, and one acre of Turnips will afford more feed than thirty acres of the best pasture at that season.—The chief consumption of field Turnips, is for feeding either neat cattle or sheep: the first is most common in Norfolk, and the second in most other counties. In feeding neat or black cattle, the most common practice is, to draw and cart off the whole crop; the time of drawing begins about Michaelmas, and continues until the plants are in blow. They are drawn by hand until the frost is in the ground, or has cut off the tops; they are then pulled by two-tined hooks, which in Norfolk they call crooms. When the roots are buried in a deep snow, it is removed by an implement called the snow-sledge; the head-lands and side-lands are first cleared, and then they begin on one side, and clear the ground progressively for the plough: some leave the small roots to increase in size, and to throw out tops for feed in the spring: but this can be done only on land that will bring Barley with one ploughing.—The most common method of giving Turnips to cattle, is by throwing them abroad on stubbles, grass-land, and fallows: the general practice is, to begin with the Wheat-stubbles, until they are broken up for fallow for Barley. The next throwing ground is frequently the Barley-stubbles, until they in their turn are broken up for Turnip-fallow. From about Christmas till the beginning of April, the Clover lays are thrown open; and after these are shut up, the Turnip-fallows sometimes become the throwing place. In throwing Turnips, the carts begin on one side of the land, and work regularly to the other, giving every part an equal share, and never throwing twice in the same place, until the whole is gone over: At the beginning of the season, whilst grass is still in plenty for the lean stock, the fattening cattle are kept constantly in the same piece, having a fresh supply of Turnips every day, or every two days at farthest: but when the Clover stubbles are cleared, and the store-beasts begin to want assistance from Turnips, the fattening cattle are followed by rearing cattle, lean bullocks, cows, or store-sheep, to pick up their leavings. In this case it is convenient to have three shifts or pieces of throwing ground, one for the head beasts, one for the followers, and the third empty, to throw in: two pieces or divisions are indispensably necessary. The Turnips should be thrown evenly and thinly, about a yard asunder, not in heaps or parcels; for whilst a bullock is breaking one Turnip, he should not have it in his power to tread or dung upon another. The bullocks, sometimes, when the distance is not too great, are driven into the straw-yard at night, otherwise they have a little clean straw given them under the hedge, merely to clean their mouths from the dirt of the Turnips; not one in ten of the highly-finished bullocks, that are annually sent to Smithfield market out of Norfolk, taste one handful of hay, or any other food beside Turnips and Barley-straw, except such as are finished with Ray-grass in the spring: and a few, that have a little hay and Turnips towards spring, when the Turnips are going off, before the Ray-grass lays are ready to receive them; which is an excellent practice, bullocks being otherwise liable to receive a check between Turnips and grass. It is evident that this method of throwing Turnips cannot be practised except on dry land, and not even on that in a wet season: in such cases, nothing but a sound old lay will answer the purpose; and, where it can be done, a farmer should contrive to have two such pieces in the neighbourhood of his Turnips.—Another method of fattening cattle is, to keep them loose in a straw-yard, giving them the Turnips in close bins, or small cow-cribs, with boards or bars

nearly close at the bottom; the Turnips are usually put in whole, being first tailed, that is, having their taproot cut off in the field, and also topped, unless the tops be fresh and palatable; these, if eatable, being given to store cattle. This method is somewhat more troublesome than that of throwing the Turnips abroad; which, if the soil be dry enough to bear stock, and so light as to be benefited by treading, is, upon the whole, the most eligible management. But in deep land, and in a wet or severe season, the yard, if it be kept dry and well littered, is the most comfortable place, especially if it be provided with open sheds for the cattle to take shelter under in inclement seasons. By this method the dung is lost abroad, which is highly serviceable to light land; but then a great quantity of manure is made in a yard well littered.—A third method of fattening beasts on Turnips is, to keep them tied up in hovels, or under open sheds, with troughs or mangers to receive the Turnips, which are frequently chopped into slices, or else quartered, which is not so eligible. The top, with the crown of the root, is thrown aside for the store-cattle, and the taproot with the bottom rind is suffered to drop on one side of the basket, so that the fattening cattle have only the prime part of the bulb. This accounts for the quick progress which shedding-bullocks sometimes make, especially in cold weather: but on account of the extraordinary attendance they require, not only in cutting the Turnips, but in littering and cleaning out the stalls, besides the check they are liable to receive in close weather, this practice is seldom followed by large farmers, unless to push forward a particular beast: much depending on care and management in this method, little farmers, who have leisure and inclination to tend their own sheds, may find their account in it. The cattle have a little Barley straw given them from time to time, to clean their mouths, and dry up the superfluous juice of the Turnips. If the Turnips could be boiled or baked at a moderate expense, a much smaller quantity would suffice to fatten the bullocks. In some places good hay is given with the Turnips; and in others, pollard or Barley meal.—The second great application of Turnips is, to feeding sheep. On the best Turnip land, that is sufficiently dry, there is no better preparation for Barley than feeding sheep with Turnips upon the land. Those however which are eaten early in the winter will not give Barley so good as those which are eaten later, provided they do not run to flower; for then they are supposed to exhaust the land, and injure the succeeding crop. Carting off from such land, besides the expense, is not advisable, the crop of Barley depending on the manure and treading of the sheep. When the Turnips are fed off the ground, the sheep should not be suffered to run over too much of it at one time; for if they are not confined by hurdles to as much as is sufficient for them one day, the sheep will spoil three times the quantity of Turnips they can eat, so that it is very bad husbandry to give them too much room; therefore the hurdles should be once or twice every day removed forward; and if the Turnips be drawn out of the ground before the sheep are turned into the new enclosure, there will be less waste made, for they will then eat up the whole roots: whereas if they are turned upon the Turnips growing, they will scoop the roots and leave the rinds, which being hollow, the urine of the sheep will lodge in them; so that when they are forked out of the ground, the sheep will not eat any of those roots which are thus tainted. When a flock of sheep are turned into a piece of standing Turnips, the first thing they do is to run over the whole, and then to eat such of the tops as they have not trampled down. Whilst they are doing this, they stand upon the roots, which being firm in the ground, and flat in the top, are not incon-

venient to stand upon; and if one of their feet happen to fall near the edge of the Turnip, it frequently barks and fouls the root. Whereas, if sheep be put upon drawn Turnips, their tops may be injured, but their roots cannot; for being round, and lying loose on the ground, they afford no foothold, but become stumbling-blocks to the sheep, which therefore carefully avoid them, and stand upon the ground. But the better to avoid waste, it is frequently the practice, instead of hurdling the sheep upon the crop, to keep them back upon the cleared ground, and to throw the Turnips upon it. But in this case the Turnips must either be thrown in part over the ground already fouled by the sheep, or must be confined to the space from which they are drawn, by which means the principal intention of drawing is frustrated. Some farmers therefore, who fat large quantities both of neat cattle and sheep, pursue the following method in the consumption of their crop. The head-lands and side-lands being cleared, the area is drawn, and carried in alternate stripes about ten paces wide. The first drawing is expended on the bullocks in one or other of the ways already described; whilst the remaining stripes are drawn, and scattered over the whole ground for the sheep. The principal intention of drawing, which is, to distribute the Turnips evenly and thinly, so that whilst one is eaten another may not be soiled, is thus obtained. It is a common error, that has generally prevailed among most persons, who are ill informed upon the subject, that the mutton fattened upon Turnips is rank and ill-tasted; whereas it is a known fact, that the best mutton this country affords is all fattened on Turnips; and that rank mutton, the fat of which is yellow, is what the low marshy lands of Lincolnshire, and other rank pastures, produce.—Turnips are sometimes used for feeding milch cows; but this is a bad practice when the milk is used for making butter, which acquires a disagreeable taste from this root; but it answers very well in suckling, as it keeps the cow in heart, and furnishes abundance of milk.—Field Turnips are sometimes sold, but it is not the general practice to raise Turnips for this purpose; nevertheless every year some are sold. Little farmers who want convenience or skill, and larger ones who want money to lay in a proper stock, or who from the comparative prices of stock and Turnips judge it more eligible to sell them to feed, sell their Turnips to those who have judgment, money, and spirit, to buy stocks. Sale Turnips are usually consumed on the premises. Sometimes the buyer and sometimes the seller draws the crop and tends the cattle, for which sometimes the one and sometimes the other finds straw. The medium price of a middling crop of Turnips, is about fifty shillings an acre; but the price is subject to great and sudden fluctuations.—Raising of seed, is the third purpose to which Turnips are applied. In order to sow good Turnip-seed, transplant some of the fairest roots in February, place them at least two feet asunder each way, observing to keep the ground clear from weeds, until the Turnips have spread so as to cover the ground, when they will prevent the weeds from growing; and when the seed-pods are formed, you should carefully guard them against birds, otherwise they will devour them, especially when they are nearly ripe. When the seed is ripe, it should be cut up, and spread to dry in the sun: after which it may be threshed out, and preserved for use. It is generally understood that no Turnip-seed is fit to be sown that has not been raised from transplanted roots; but in Norfolk it is thought that if the seed be gathered from untransplanted roots, the Turnips will become coarse-necked and foul-rooted, and the flesh of the root rigid and unpalatable; and that if they be gathered year after year from transplanted roots,

the necks will become too fine, and the fibres too few, the plants acquiring a weak delicate habit, and the produce, though sweet, being small : sweetens therefore, and not size, being the quality requisite for the table, it is a good rule for the gardener to raise his seed generally from transplanted roots. But it is the farmer's interest to avoid the two extremes of coarseness and delicacy, which can be accomplished only by sometimes transplanting his seed-plants, and sometimes letting them run up in the seed-bed: and it is found by experience, that transplanting two, three, or four years, and letting the plants run up in the third, fourth, or fifth, will keep the stock in the desired state. The time of transplanting is from Old Christmas to Old Candlemas. The cleanest plants are the best, without much respect to size : a piece of good ground near a habitation is most proper for the purpose, because the plants can there be most easily defended from the depredations of the birds. It is of great consequence to secure seed of a good sort and quality, which cannot always be obtained from dealers ; without care it will degenerate, and a mixed seed is too frequently sold : such persons therefore as are curious, should either raise it themselves, or have it raised by a neighbouring labourer, or at least procured from those on whom they can depend. The large green-topped Turnip is the most productive, the sweetest, and most juicy ; but the red or purple-topped is the hardiest. Admirably as the Turnip is calculated for cleaning land, and feeding cattle and sheep, it is to be lamented that it is so liable to accidents and failures as not to be absolutely depended upon for these purposes. It has the fly, and many other enemies of its insect tribe, to contend with, in the early stage of its growth ; second and third sowings, which are frequent, seldom produce much more than the good spring-feed for sheep ; alternate frosts and thaws rot the Turnips before the season of greatest necessity arrives, or if they are not absolutely rolled, beasts fatten but ill on frozen Turnips ; if, on the contrary, the winter be mild, the Turnips run to flower, and then the root has little substance in it. The Turnip crop is precarious, principally because the farmer is obliged to depart from the common course of nature in accommodating it to his wants. Instead of putting the seed into the ground in the spring months, when there would be as great a certainty of a crop as of any other vegetable, he is obliged to defer sowing till the hottest season of the year comes on, when, unless he is so fortunate as to have a few rainy days, or cloudy weather with frequent showers, he can have little hopes of success.—The first enemy of the Turnip is the *fly*, as it is commonly called ; or, as others name it, the *fea* ; or, as it is provincially termed, the *black dolphin*. It is in fact a small insect of the coleopterous or beetle tribe, and is named by naturalists *Chrysomela saltatoria*. In hot summers it abounds to an amazing degree, and may be heard in a field or garden among the leaves of Turnips, or any of the Cabbage kind, making a pattering like rain from its continual skipping. This mischievous insect is not more than from one-twelfth to one-tenth of an inch in length ; it attacks the plant as soon as it appears above ground, whilst in the seed-leaf ; but as soon as the rough leaves are put out strong, the plant is supposed to be safe from this enemy, which is calculated to destroy an entire crop once in five or six years, besides the partial damage which it does in most years. It has however a rival in mischief, the *Turnip bug*, which becomes a small fly, about one-twentieth of an inch long, and not larger than a grain of Turnip seed. It is the same with the *black bug*, *collier*, or *negro*, with which beans are frequently infested, in some places termed *smother fly*. The bugs, or

fly in a larva state, frequently cover the under sides of the seed-leaves, and are of different colours, yellow, green, and black. When the seedling plants are infested with them, they make no progress, nor any visible effort to get into rough leaf ; fifty of these vermin have been counted under one pair of seed-leaves, sucking the juices through their long probosces. The smallest of the flies, or *aphides*, are of a cream colour, the next green, the next to these reddish-green, and the largest black. The destruction, however, which is imputed to the fly, or (to speak more properly) to the Turnip-beetle, sometimes seems to originate in the season. When the soil is fully and permanently moistened by a steeping rain, the seed will vegetate, the plants will push into rough leaf, and rise without a check, though the beetle and their other insect enemies be in full force : but if the Turnips have only showers to depend upon in hot dry weather, the seed will vegetate, but by the time the seed-leaves are formed, the moisture is wholly drawn off by the intervening days of drought ; and the plants, deprived of nourishment, pass away, parched up as in an oven. The injury, however, which is done by the fly being confessedly great, many remedies have been proposed for it, although it is much to be feared that they are by no means effectual. Some good, it is said, may be done by running a light roller over the crop, with a bundle of Blackthorn fastened behind it. Branches of elder are recommended to be drawn over the Turnips in the same manner ; and the seed is directed to be soaked in the juice of the bruised leaves. But these are palliatives at best, and have been found to be utterly ineffectual. Some recommend the land to be fumigated, by burning heaps of quick, and other weeds, to windward, when it is ready for sowing, and after the seed is come up ; whilst others prescribe a steep for the seed, of train or other oil, in which it is to be immersed twenty-four hours or more : when the seed is drained from the oil, it is to be mixed with good earth finely sifted, and sown immediately ; when the plants begin to appear, the ground is to be sown with soot, from eight to sixteen bushels the acre. Soot is very generally recommended as a specific against the fly ; so also is tobacco dust, but this can be applied only in small crops, such as are grown in gardens. We are told to shake the seed in a bottle with flower of brimstone, and to sow them together ; or to steep it in water strongly impregnated with brimstone or horse-aloes. A much more likely way than any of these to secure a good plant of Turnips, is, after having made the land clean and fine, as soon as the weather will permit, to sow two, three, and even four pints of seed upon an acre, in suspicious seasons : thus having a sufficient quantity of plants for the fly and the crop. In case the fly does not take them, it may be said that the plants will be so thick that they cannot easily be hoed ; they may however be made fit for the hoe by harrowing them first ; and, at any rate, it is a less evil to have too much work for the hoe, than little or no crop. Another method of securing a crop, is sowing seed that will germinate at different times. This may be done by mixing new and old seed together, and by soaking half of each in water, or the drainings of a dunghill, for half an hour, and then spreading it on a floor until it is dry enough for sowing. Thus there will be four chances for a crop, as the seed thus mixed and prepared will come up at four different times. Or, sow immediately after the plough without harrowing, and then the seed, lying at different depths, will come up at several times, and consequently have several chances of escaping the fly or Turnip-beetle. It is very sensibly remarked by Mr. Miller, that whatever will add vigour to the young plants will prevent their being destroyed by the fly, for these never

attack them until they are stunted in their growth. Good tillage therefore, and having the land in heart, is of more consequence to prevent the ravages of the fly, than all the nostrums that have been published. The provident farmer will, as far as he can, watch for favourable opportunities to sow his seed; and he had better defer sowing, than do it when the weather is hot and dry. He will have his land in proper order; he will be at the pains of procuring good seed, new, if he can get it; and he will sow a sufficient quantity: but, above all, he will lay in a proper quantity of manure, to promote the growth of the young plants, and to push them forward as fast as possible. It is this purpose which is answered by dressings of ashes, soot, composts of lime and dung, &c. in sufficient quantities; either sown with the seed, or rather immediately before, well harrowed in, and completely incorporated with the soil. There is some doubt, however, respecting the expediency of dunging largely for Turnips. One says, the only available precaution against the fly, consists in ploughing the land till it is very fine, and filling it with muck; whilst others are of opinion that the flies are increased by the dung, which certainly is a nest for a great variety of insects. Folding may perhaps be better than the dunging, the treading of the sheep both destroying the insects, and rendering light land more firm. In seasons wherein apprehensions of the fly are entertained, it is recommended to plough for sowing, as soon as it is light in the morning, only so much land as can be sown and harrowed by six o'clock; and about six in the evening again to plough as much as can be sown and harrowed before dark. The seed being thus sown while there is some moisture in the newly-ploughed ground, will vegetate sooner, and come up more regularly, than it would do if the ground were dry. If the season should prove dry, the ground should be well looked over; and when the young plants begin to be attacked by the fly, the land should be strewed all over with vegetable ashes, and the night following it should be rolled. If rain come on in a day or two after, the Turnips will soon be out of danger, by the rain washing the salts of the ashes to their roots; if not, in a week's time a fresh dressing of ashes, with rolling, should again be applied. Where wood or peat ashes are not to be had in plenty, the farmer ought to raise a quantity for the purpose, from burning quick and other weeds, or turf, litter, furze, heath, fern, &c. Or if he has only a small quantity of ashes, he may have recourse to a compost of these with soaper's ashes, coal-ashes, quick lime, and soot, mixed well by burning them two or three times, and passing them through a sieve; it is scarcely necessary to add, that the ashes should be kept in a dry place. When large patches are irrecoverably gone, it is best to plough immediately, and sow again, harrowing in the seed. The early stone Turnip is recommended for this purpose, because it comes to maturity sooner than the common sort, and may be sown twenty days after the first sowing.—The *bug fly*, or *aphis*, is by no means so tremendous an enemy as the beetle: being extremely soft and tender, and therefore easily crushed, a light roller, especially if it were muffled in some soft elastic covering, so as to press in between the clods, might perhaps be effectual in destroying these insects without injuring the plants.—Another danger of the crops being destroyed is from the *caterpillars*, which very often attack them when they are grown so large as to have six or eight leaves on a plant: the surest method of destroying these insects, is to turn a large parcel of poultry into the field, which should be kept hungry, and turned in early in the morning; these fowls will soon devour the insects, and clear the Turnips. The

Turnips sown in drills are not so much exposed to this evil, for as the ground between the rows will be kept stirred, the plants will be kept growing, and will not be in danger of suffering from these insects; for the parent insects never deposit their eggs upon any plants which are in health, but as soon as they become stinty, they are immediately covered with their eggs; so that it is the disease which occasions the vermin, and not the vermin the disease, as is commonly imagined; therefore as the plants will always be in greater health when the ground is well stirred about them, there will be less danger of their suffering from these enemies when they are cultivated by the horse-hoe, than by the common way. These caterpillars are provincially called *black cankers*; they are not so universal as the fly or Turnip-beetle, but their ravages, though partial, are in some seasons very great, especially near the sea coast. Many remedies have been proposed against this destructive insect: as, drawing a rope over the ridges, two persons holding the ends; this will brush the caterpillars off, and perhaps may save a few acres, where it can be frequently repeated, and the insects are not very numerous. It is an improvement upon this expedient to fasten twigs upon the rope, for which purpose elder twigs have been preferred, but certainly without sufficient reason. Stiff crooked boughs will injure and tear the plants. Others draw a brush made of furze over the Turnips; the branches are fixed to a long pole or axle-tree, with a wheel at each end, of such a height that the furze will brush the plants without pulling them up by the roots. This mischief might be prevented, if the inhabitants of the sea-coast would burn the flies on their arrival, when they are spent with their flight, and frequently may be taken up by shovels-full. Another enemy to Turnips, and to the garden in general, as well as to Flax, Wheat, &c. is the naked snail, or *slug*. This, however, is a trifling evil in comparison with the others. Slugs abound most in wet seasons, when the fly is least prevalent, and chiefly on fresh ground and bad fallows. The only remedy prescribed, is night-rolling, when the dew is upon the ground. The wire or red worm, is also complained of as injurious to Turnips, as well as to the gardens in general, particularly by those who pursue the drill culture. The grub is perhaps in itself not fatal, did not the rooks, in order to come at it, pull up not only the plants which are attacked, but those also which are free from it, and thus clear them as they go.—There is a disease to which Turnips are subject, called the *anbury* or *hanberry*. It is a large excrescence, which forms itself below the bulb or apple, grows to the size of both the hands, and when brought to maturity becomes putrid, and smells very offensively: it is irregular in its form, with excrescences, like races of ginger, hanging to it. The tops of those Turnips which are much affected, turn yellow, and flag with the heat of the sun. It is a common notion that this disease is caused by the soil's being tired of Turnips; that is, by their being sown too often on the same land. Now this is erroneous, for the anbury appears on land, which has never borne Turnips before. It is more probable, that it is caused by some grub or insect, that diverts the course of the sap by wounding the vessels of the tap-root. In Norfolk, marl is esteemed a certain preventive of the anbury.—The last enemy to be mentioned, is severe frost, which usually destroys the sown Turnips, and much injures the late ones. The only method of counteracting this evil, is to preserve or store up a certain quantity of Turnips, in case of frost or a deep snow. This may be done by drawing them in dry weather, when they have attained their full growth; topping and tailing them; and carting the roots into an adjoining new-made dry

ditch, first covering them with straw, and then with hurdles or fagots, from the cattle; or still better, by stacking them in the field with layers of straw between, covered and thatched with straw; either on the ground, or, if the land will bear it, in beds or pits dug one or two feet deep, or more, three yards wide, and of what length you want them. If straw be scarce, old haulm or stubble will answer the purpose. Or else, to carry them home, and pile them in small stacks in a clean home pasture, or near the yard; or, to house them where there is room, always screening them with straw, and putting some between the layers to absorb the moisture. This practice not only preserves some Turnips from the rot, and furnishes cattle and sheep with feed, in time of the greatest distress; but prevents the crop from exhausting and impoverishing the land, and gives time for preparing it for the succeeding crop of Barley. After all, the provident farmer will not absolutely depend upon his Turnip crop, for feed late in the spring; but have in reserve some Cabbages, Coleworts, Rye, or Winter Tares, according to his convenience and the nature of his land; not only to guard against failures in his Turnip crop from frost, &c. but to have some provision for the couples, by the time the lambs begin to feed, which will put them on much faster than the best Turnips.—A square perch of Turnips, which is sixteen feet and a half, drilled in rows three feet apart, has been found to contain eighty-four roots, weighing seven hundred two quarters; which is sixty tons to a statute acre; eighty-four Turnips picked within fifteen yards of the above perch, weighed eighteen hundred three quarters seventeen pounds; which is one hundred and twenty-six tons nine hundred and twenty pounds to an acre.

S. Brassica Oleracea; *Common Cabbage*. Root caulescent, columnar, fleshy. The Cabbage, as it is found wild on the shores of Britain, has the stem-leaves very much waved, and variously indented, the colour sea-green, frequently with a mixture of purple; the lower leaves somewhat ovate and sessile, the uppermost almost linear; the flowers are large. Early in the spring, the Sea-Cabbage is preferable to the cultivated sorts; but when it is gathered on the coast, it must be boiled in two waters, to take away the saltiness. When old, it is said to occasion giddiness. The roots may also be eaten, but they are not so tender as those of the Turnip and Navew. The varieties of garden Cabbage, which all originate from this, may be reduced to three general divisions: the first comprehending those which grow in the natural way, without forming the leaves or stalks into a head. This division, besides the Sea Cabbage, or Wild Colewort, would comprehend the Green Colewort, the Borecoles, and Turnip-cabbage. Secondly, those which form the leaves into a head, as the White Cabbage, the Red, the Savoy, &c. Thirdly, those which form their stalks into a head, as the Cauliflower, and the different varieties of Broccoli. The first division might be subdivided into the Wild, with broad leaves, and an even stem; the Turnip-cabbage, with broad leaves and a protuberant stem; and the Borecoles, with fine cut leaves and an even stem. The second division contains the Cabbages commonly so called: as, the Red, the numerous varieties of the White, such as the Sugar-loaf, the early, the foreign musk, the small Russia, the large-sided, the flat-topped, the Yorkshire, Scotch, American, &c. &c. and those with wrinkled leaves, as the common Savoy, the green Savoy, &c. Of the Borecoles in the first, and the Broccoli in the third section, there is also a variation in colour; the purple, and the white. The common Colewort, or Dorsetshire Kale, is now almost lost near London, where the markets are usually supplied with Cabbage plants, which are more tender and delicate, instead of them. The common Colewort is

indeed better able to resist the cold in severe winters; but it is not good till it has been pinched by frost, and our winters being generally temperate, Cabbage plants are now constantly brought to market, which, if they be of the sugar-loaf kind, are the sweetest greens from December to April yet known. Indeed, where farmers sow Coleworts to feed their milch-cattle in the spring, in case of a scarcity of herbage, the common Colewort is to be preferred, because no frost will destroy it. The curled Colewort, or Borecoles, are more generally esteemed than the common one, being, like that, so hardy as never to be injured by cold, and at the same time much more tender and delicate; these, however, are always sweeter in severe winters than in mild seasons. Of the heading Cabbages, the red is chiefly cultivated for pickling; the common white, flat, long-sided, and Savoy, for winter use. The Musk Cabbage is almost lost, although for eating it is one of the best we have; but, being tenderer than many other sorts, it is not so profitable for market gardeners; such, however, as cultivate for their own tables, should make choice of this rather than any of the common Cabbages, for it is always looser, the leaves are more crisp and tender, and it has a most agreeable musky scent when cut. The early and sugar-loaf Cabbages are generally sown for summer use, and are commonly called Michaelmas Cabbages. The Russian Cabbage was formerly in much greater esteem than at present, it being now only to be found in particular gentlemen's gardens, and rarely brought to market. The other varieties are chiefly cultivated for feeding cattle; for which they are certainly well adapted on strong lands, but they are undoubtedly a very exhausting crop.—The Germans cut Cabbages in pieces, and, with some aromatic herbs and salt, press them close in a tub, where they soon ferment, and are then eaten under the name of *sour crout*. In this state they are much recommended against the sea-scurvy; indeed Cabbages in general are esteemed a salubrious aliment in the putrid scurvy: they are laxative, and produce flatulencies; but the laxative matter is extracted by long boiling. The white Cabbage is the most putrescible, and the red most emollient.—The Cauliflower was first brought to England from the island of Cyprus, since which it has been greatly improved. Purple and white Broccoli are only varieties of the Cauliflower.—The following are the methods of propagating and cultivating the different kinds of Cabbages. Colewort seeds should be sown in July, in an open spot of ground, and transplanted, as soon as the leaves are two or three inches broad, into rows a foot asunder, and six inches distant in the rows; the rows may be drawn alternately for Coleworts, and the remainder left to Cabbage. To continue them for spring drawing, they should be sown again at the beginning of August.—In the *field culture* of Coleworts, the best method is to sow the seeds, nine pounds to an acre, about the beginning of July, choosing a moist season, which will bring up the plants in about ten days or a fortnight: when they have got five or six leaves they should be hoed, as is practised for Turnips, cutting down all the weeds from among the plants, and thinning them where they are too thick; but they should be kept thicker than Turnips, because they are more in danger of being destroyed by the fly: this work should be performed in dry weather, that the weeds may be killed, for if it should prove moist soon after, the weeds will take root again, and render the work of little use. About six weeks after, the plants should have a second hoeing, which, if carefully performed in dry weather, will entirely destroy the weeds, and make the ground clean, so that they will require no further culture. In the spring, they may either be drawn

up and carried out to feed the cattle, or the cattle may be turned in to feed upon them as they stand; but the former method is to be preferred, because there will be little waste: whereas, when the cattle are turned in amongst the plants, they will tread down and destroy more than they eat, especially if they are not fenced off by hurdles. The perennial Colewort is also little cultivated in the gardens near London at present: this is very hardy, and may be cultivated in the same manner as the former sort; this will continue two years before it runs up to seed, and will afterwards produce many side-shoots, and in poor land will continue three or four years, but in rich soils it will not last so long. This may be used as the former sort, to feed cattle, for it is not so good for the table (unless in very severe frost) as the plants which are now cultivated for that purpose.—The early and sugar-loaf Cabbages, are commonly sown for summer use, and are called by the gardeners about London, Michaelmas Cabbages: the season for sowing these, is about the end of July, or beginning of August, in an open spot of ground; and when the plants have got eight leaves, you must prick them into beds at about three inches' distance every way, that they may grow strong, and short-shanked: and in the middle of October, you should plant them out for good; the distance that these require, is three feet from row to row, and two feet and a half asunder in the rows; the gardeners near London commonly plant these Cabbages upon the same spot of ground where their winter Spinach is sown, so that when the Spinach is cleared off in the spring, the ground will have a crop of Cabbages upon it; you must therefore clear off the Spinach just round each plant early in the spring, that with a hoe you may draw the earth up to the stem, and when all your Spinach is cleared off, which is commonly in the beginning of April, you must hoe down all the weeds, and draw up the earth again about your Cabbage plants. In May, if your plants were of the early kind, they will turn in their leaves for cabbaging, at which time the gardeners near London, in order to obtain them a little sooner, tie in their leaves close, with a slender ozier twig, to blanch their middle; by which means they have them at least a fortnight sooner than they could have if they were left united. Fewest of the early kind should be planted, for they will not supply the kitchen long, generally cabbaging apace when they begin, and soon grow hard and burst open; but the sugar-loaf kind is longer before it comes, and is as slow in its cabbaging, and being of a hollow kind, will continue good for a long time. It has been known, that a large quarter of ground, which was planted with this sort of Cabbage for market use, has afforded a supply for nearly three months together. It may be planted out in February, and will succeed as well if planted earlier, with this difference only, that the plants will be later before they cabbage. Some plants of the early sort should also be reserved in some well-sheltered spot, as a supply in case of failure; for in mild winters many of the plants run to seed, especially when sown too early, and in severe winters they are often destroyed.—The Russian Cabbage must be sown late in the spring, and managed as above directed; with this difference only, that it must be finally planted out sooner, must have an open clear spot of ground, and requires much less room, being a very small hard cabbage; it will be fit for use in July or August, but will not continue long before it breaks and runs up to seed: the way to have this sort good, is to procure fresh seeds every year from abroad, for it soon degenerates in England.—The common-white, red, flat, and long-sided Cabbages, are chiefly cultivated for winter use: the seeds of these sorts must be sown at the end of March, or beginning of April, in beds of good fresh earth; and in

May, when the young plants will have about eight leaves, they should be pricked out into shady borders, about three inches square, that they may acquire strength, and to prevent their growing long-shanked; about the beginning of June, you must transplant them out where they are altogether to remain, which, in the kitchen-gardens near London, is commonly between Cauliflowers or Artichokes, at about two feet and a half distance in the rows; but if they are planted for a full crop in a clear spot of ground, the distance from row to row should be three feet and a half, and in the rows two feet and a half asunder; if the season should prove dry when they are transplanted out, they must be watered every other evening, until they have taken fresh root; and afterwards, as the plants advance in height, the earth should be drawn about their stems with a hoe, which will keep the earth moist about their roots, and greatly strengthen the plants. Weeds, if suffered to grow among them, will draw them up tall, and often spoil them. Some of these Cabbages will be fit for use soon after Michaelmas, and will continue until the end of February, if they are not destroyed by bad weather; to prevent which, the gardeners near London pull up their Cabbages in November, and trench their ground up in ridges, laying their Cabbages as closely as possible against one side of their ridges, burying their stems in the ground: in this manner they let them remain till after Christmas, when they cut them for the market; and, although the outer part of the Cabbage be decayed, yet, if the Cabbages were large and hard when laid, the inside will remain sound.—The Savoy Cabbage is also cultivated for winter use, being best when pinched by frost: it must be sown about the middle of April, and treated as the common White Cabbage, except that it may be planted closer, two feet and a half square being sufficient. This sort should have an open situation, clear of trees and hedges; for in close places it is very subject to be eaten by caterpillars and other vermin, especially if the autumn prove dry. If early Savoys are desired, some seed must be sown sooner, as in March, February, or autumn. The autumn-raised plants will be very large, and in order for the table from the end of August, through September and October.—The Musk Cabbage may be cultivated in the same manner as the common Cabbage, and the plants set out at the same distance; it is in use from the beginning of October until Christmas, and is apt to suffer in very severe winters.—With respect to the *field culture* of Cabbages, the sorts most commonly cultivated for feeding cattle, are, the *Scotch*, the *drum-head*, and the *American*. The first, if it be the true flat-topped firm sort, is never affected by frost, a few of the outside leaves excepted. The true drum-head is said to be hardy, and the heaviest of any for the size; it may be planted closer than the large American: it is called the *tallow-loaf* in some places, and being too tender to bear very sharp frost, a mixed stock has been procured by planting this and the common Red Cabbage together, and when the seed-pods were formed, cutting down the red, and leaving the other for seed; this mongrel is of a deep-green colour, with purple veins, retains the size of the drum-head, and has acquired the hardness of the red Cabbage. The American comes to a great size, and lasts good very late in the spring; there are many varieties, as, the flat, Dutch, Yorkshire, &c. and the same variety is known under several names in different parts of the country. The Cabbage culture is best adapted to strong land, and comes peculiarly in aid to the farmer, who cannot to much purpose avail himself of Turnips. It succeeds admirably on a rich, moist, friable loam. The tillage for Cabbages differs very little from that which is given for Turnips; they are commonly

planted on stubbles, after Wheat, Barley, Oats, or Beans; the land is ploughed up at Michaelmas, lies till spring, is then ploughed again three or four times; is manured with from fifteen to twenty three loads of dung, or else with from twenty to thirty loads of compost, to an acre, before the last ploughing, which lays the land in three-foot ridges, towards the end of May or the beginning of June, in which state it must be left for rain, to enable the farmer to plant. Some persons spread the dung upon the stubble, and bury it with the first ploughing; because, if the weather should set in dry at the time of planting, the dung opens the soil too much, lets in the drought, and thus destroys, or at least stunts, the plants. The best method of raising, is to sow the seeds as early in the spring as the weather will permit, (the end of February, or beginning of March,) upon good land, well sheltered, digged, and dunged, on beds from four to five feet wide, for the conveniency of cleaning them, and destroying the fly. Plants may be thus obtained, of sufficient strength to plant out by the third or fourth week in May, at the latest; and these plants will be in perfection by the third week in October, and will continue to the end of March, or the middle of April. The best seed, sown upon a poor soil without dung, will produce many runaway plants; these are also frequently spoiled by being sown too thick. An ounce and half of seed on a bed fourteen yards long, and five feet wide, will, allowing for all accidents, produce two thousand good plants: half a pound of seed is fully sufficient to produce plants for an acre; or a pound of seed, sown on ten rods of land, may do for three acres, according to the goodness of the land, and the season: seven thousand plants are fully sufficient for an acre. Though spring plants are most commonly reputed the best for general use, not so much on account of their size as their duration; (because the slugs are apt to destroy much of the autumn sowing in winter; and because, by good management, as large and heavy a Cabbage may be produced from spring sowing;) yet some persons are attached to sowing in autumn, about the middle of August; and pricking the plants out into a warm place, where they may be sheltered from very severe frost; they may be thus planted out in May, whereas the spring-sown ones can hardly ever be planted out till near Midsummer, perhaps in a dry time, when they will be scorched up, and are scarcely ever so large: it is to be considered, however, that the great use of Cabbages is for feed late in the spring, when the early-sown will be run up to seed. Some persons prick out the young spring-sown plants from the seed-bed, which is certainly an advantage to them, but is attended with too much expense and trouble to those who cultivate this crop on a large scale. As to planting, that operation depends upon the weather, and may be performed as soon after the middle of May as that will admit; but it is vain to attempt it until there has been a ground-rain, and then it must be done as quickly as possible: the plants are commonly set in one row on each ridge, at the distance of two or three feet, or, according to some, of four; most persons plant them two feet and a half asunder in the rows: some are for small distances, as two feet, or eighteen inches; others are for larger, as three feet; the distance ought, however, to be regulated by the size of the Cabbage, and the strength of the soil: they should be planted wide enough to admit of being cleared with the plough, and yet so near as to afford a full crop. It must be a great advantage, on land that will admit of it, to plant them at equal distances every way, so that the plough may pass crosswise as well as longwise, between the rows, in cleaning them. In the common practice, the rows are kept clean by hand-hoeing; and at the same time, any clods that may have

rolled on the plants, in ploughing between the rows, are removed. About three weeks after planting, taking the opportunity of rain, replant whatever vacancies may have arisen from failures. Cabbages are applied to feeding milch cows, to fattening bullocks, sheep, and swine; we have not heard of their being given to horses: and yet it is probable, that either alone, or mixed with chaff, or cut-meal, they may be a valuable horse feed. They are very generally and successfully applied to feeding milch cows, in the great dairy farms of High Suffolk; where they have eight or ten acres of the great Scotch and American Cabbage, to forty cows; and in some parts they are of opinion, that one good acre of Cabbages will do for seven or eight cows, yielding as much food as three acres of Turnips, and making the cows give more and better butter. A more common proportion, however, is, four cows to an acre, without hay or straw, and six or seven with straw and some hay: one acre and one rood, producing forty-five tons of Cabbages, fed nine cows and a bull thirteen weeks and two days. The report concerning the effect of Cabbages upon milk, is different; some asserting that the butter is as bad as from Turnips; others, that they yield not only more milk, but better butter. Cabbages are also reputed excellent for weaning calves; Turnips being apt to give them the garget, which Cabbages never do. In fattening beasts, three quarters of an acre of a middling crop, will do for two beasts of fifty stone each, that have had the summer grass. A middling bullock will eat two hundred pounds of Cabbages in twenty-four hours, and therefore a score may be kept on an acre for nearly a month, if the crop be tolerably good. Fifteen fattening oxen, nine hundred weight each when fat, were kept from the fifth of November to the thirty-first of December, that is, eight weeks, on two acres of autumn-sown Cabbages, with the addition of four tons of hay: upon the whole, an acre of Cabbages is supposed to fatten one beast in four more than Turnips, and all in two-thirds of the time. Another circumstance of consequence to the grazier, is, that they are said to have a remarkable effect in laying on the fat on the grazier's points. With respect to sheep, one of twenty pounds a quarter, will eat fifteen pound of Cabbage in twenty-four hours; one acre, therefore, will nearly maintain two hundred sheep a month, if it be a good crop. Thirteen fat wethers, who had nothing else to eat, except what they picked up, in open weather, on a bare grass-field, consumed one load in a week, that is, in the proportion of an acre to twenty-six sheep, for one hundred and twenty days, or more than sixteen weeks. When the autumn-sown plants run up to seed in April, sheep will eat every morsel of them clean up, when they will not touch a Turnip. When the plants are suffered to run up, that part of the land should have a light dressing of pigeon dung, soot, or malt-dust, to make it amend for supporting the Cabbage-stalks so much longer. Hogs do very well on Cabbages, and prefer them to Turnips; for when they get into a field containing both, they constantly take to the former, and will scarcely touch the latter: by sowing early in the spring, or by sowing some in autumn, a succession of Cabbages may be obtained, from the third week in October, or a month after Michaelmas, to the end of March; or, if desired, even to the middle or end of April: they ought, however, in the general opinion, to be off by the middle of March, because they then shoot, and exhaust the land. How valuable, therefore, must this crop be, thus adapted as it is to feeding milch kine, bullocks, sheep, &c. and which is in perfection during the months of February, March, and part of April; when the anxiety of farmers, particularly of those who keep large flocks for a supply of food, is at the height! On moist soils, Turnips,

however valuable they may be, are so much affected by the vicissitudes of the season, as to be a very uncertain provision; for how often does it happen, that after a year's fallow, an ample and expensive manuring, great care to prevent the ravages of the fly, slug, caterpillar, &c. unremitting attention to the hoers, and altogether an expense of from three to five pounds an acre, one sharp frost succeeding a wet season, in the months of January or February, destroys all the farmer's hopes, and leaves his flocks or bullocks destitute of food when they want it most; or reduces him to the necessity of feeding them on hay, which perhaps is so dear as to devour all his profits. Now, Cabbages are by no means so liable to these accidents, for unless a long-continued drought succeed the planting out, they are in a manner a certain crop, neither frost nor snow will materially injure it; and, as a farther recommendation, it is more grateful to the consumers. The dung of the cattle fed upon Cabbages is better, and more in quantity, than when they are fed on Turnips. They are an excellent preparation for Barley and Oats, as well as Turnips; or if they be, as some think, in a small degree inferior in that respect, it ought to be considered, that the crop in itself is more valuable, being worth from four to seven pounds an acre.—The accidents to which Cabbages are liable, are, first, to be destroyed in the seed-bed by the beetle or fly, as well as Turnips: but in this situation, these insects are easily destroyed, by sowing wood-ashes, soot, &c. the moment they appear; and at the same time the plants are invigorated by the dressing. They are, secondly, attacked both in the seed-bed and by the caterpillar of the *papilio brassica*, or Cabbage-butterfly; this insect, though destructive to the plants in general, is of little consequence in field-culture, because it comes too late to injure the seed-bed; and if the plants prosper after they are set out, they become so strong and numerous as to set it at defiance. An easy method of arresting their progress, is to turn-up the leaves, wherever the white butterflies are observed to be busy about the plants, and rub off the eggs, which they deposit along the ribs of them, with the back of a knife, which operation is performed in a very short time, whereas this picking of the caterpillars, after they are hatched and dispersed, is very tedious. The slug, that common enemy to all crops, attacks the Cabbage, but is by no means so injurious to it as to the Turnip, because it stands up above his reach. From frost Cabbages sustain little or no damage, if they be of a hardy sort, a few of the outside leaves excepted. There is a disease to which Cabbages are subject, which is, the roots becoming swollen or knobbed, and the plant at the same time smaller. It is occasioned by grubs, which are the *larvæ* of flies, and is incident chiefly to such Cabbages as are sown or planted for several years together on the same land. It does not, therefore, affect the field-culture, unless the seed-bed should be continued on the same piece.—The two principal objections to the field-culture of Cabbages are, the impoverishment of the land, and the difficulty of carting them off. That it is an exhausting crop, is generally allowed, and that it is much more so than Turnips; a gentleman, however, who has given it repeated trials for twelve years, on a wet clayey loam, declares himself fully assured, that it does not impoverish the soil, but, on the contrary, meliorates and cleans the land to which it is adapted, better than Turnips. One acre of his Cabbages is often worth three, and sometimes four, acres of adjoining Turnips, on land five shillings an acre better than his. The average crop of Cabbage is twenty-six tons; of Barley after it, thirty-seven bushels; of Wheat, thirty bushels; of Oats, sixty bushels; of Clover, when mown, twice three tons from an acre: this course of crops is worth

remarking. The Cabbages being disposed of, by carrying the best to the cows and other cattle in the straw-yard, and folding ewes and lambs upon the remainder in March and April; the land is sown with Barley and Clover: the autumn following, the Clover is broken up, and set with Wheat; the year after, Oats are sown upon the Wheat Stubble; and at Michaelmas following, from twelve to fourteen loads of compost being ploughed in the May or June after, Cabbages are again planted. Another great advantage of Cabbages is: by their being planted on four-furrow work, the land lies drier, and works better for Barley or Oats, than Turnip-land; there is always mould to sow in spring, after feeding off with sheep, which is by no means the case in the same sort of land with Turnips; if the season be wet when they are feeding, and sets in dry in seed-time, it is not possible to get the seed in properly. Many are inclined to attribute the exhausting of land by Cabbages, to the practice of leaving the stalks in the ground, which throw out sprouts, and thus draw the land, when the effect of the crops ought entirely to have ceased; but if we should allow, (what, however, some dispute,) that Barley after Turnips is better, by eight bushels an acre, than after Cabbages; yet, if one acre of Cabbages be more valuable, as is commonly thought, than two acres of Turnips, there will be a gain upon the whole; it is found, however, that to ensure a good crop of Barley, the Cabbages should not be taken off too late. As the crop cannot be fed upon the land by heavy cattle, this occasions an expense to cart it off, which also damages the land, by cutting it up and poaching it in a dreadful manner. The Turnips, however, are most damaged, because they are on straches nearly flat; whereas the Cabbages being on three feet ridges, the poaching is chiefly in the furrows, and no part of the crop which is left for the sheep is injured; the carting also is done at half the expense, and the food is cleaner for the stock. If broad-arched ridges were used, all the carting being in the furrows alone, the productive part of the field would be secure from injury, in the case both of Cabbages and Turnips.—The manner of cultivating the Turnip-cabbage, and the Turnip-rooted Cabbage, is, to sow the seeds in April, on a bed of light fresh earth, and when the plants are an inch high, they should be transplanted into a shady border, at two inches distance every way, kept clean from weeds, and watered till they have taken root; if the season should prove extremely dry, they should be watered afterwards, every four or five days, to prevent the mildew. In the beginning of June, they should be transplanted where they are to remain, at two feet distance every way, and watered till they have taken root. As their stems advance, draw the earth up to them with a hoe, but not too high, so as to cover the globular part, which is eaten. To cultivate these plants in the field, sow a pound of seed early in March, for every three acres intended to be planted; prepare the land by three or four earths, the first given at Michaelmas; before the last earth, manure as for Turnips; finish the whole ready for planting by the first week in June. The first ground-rain after that, set all hands to planting, the rows two feet asunder, and the plants twelve inches apart in good land, and eighteen in poorer soils; plough the intervals three times, and keep the rows perfectly clear by hand-hoeing. When the plants are to be taken up, plough the rows without a coulter, and a round share with a blunt edge. Every farmer should cultivate so much of this root, as will ensure him provision for his cattle and sheep three or four weeks in the latter end of the spring, unless he be otherwise provided. The Swedish Turnip, or *roota бага*, is of the same nature with those, and equally hardy; the root is sweet and firm, being nearly twice as heavy as one of

our Turnips of the same size: when dressed for the table, it is preferred to ours; and is particularly grateful to all sorts of cattle; hares and pheasants will take it, and leave Cabbages and common Turnips untouched. The culture and application of it are the same as that of the latter.—The *Borecole*, or *Fringed Cabbage*: of this sort the varieties are; 1. Green-curled. 2. Red-curled. 3. Thick-leaved curled. 4. Finely-fringed. 5. Siberian or Scotch Kale. All these plants bear our severest winters; are a useful reserve for the table in such seasons, and then eat very sweet and tender, for before they are frost-bitten they are tough and bitter. They may be cultivated in the same manner as winter Cabbages, but they need not be planted above one foot asunder in the rows, and these need not be more than at two feet distance. The seeds of the Siberian Borecole may be sown in the beginning of July, and when the plants are strong enough, they should be set in rows eighteen inches asunder, and ten inches distant in the rows: this work must be done in a moist time; they will be fit for use after Christmas, and continue good till April. Green Borecole is a very useful green food for sheep, because it is not only hardy, but growing three feet high, it may at all times be got at by the animals in deep snows, which frequently cause them to suffer much for want of food: it may be cultivated exactly as above directed for the Turnip-cabbage.—*Cauliflower*. This kind of Cabbage is continued for several months together, but the most common season for the crop is in May, June, and July. Having procured a parcel of good seed of an early kind, you must sow it about the middle of August, upon an old Cucumber or Melon bed, sifting a little earth over the seeds, about a quarter of an inch thick; and, if the weather should prove extremely hot and dry, you should shade the bed with mats, to prevent them from drying too fast, which would endanger the spoiling of your seed; and give it gentle waterings, as you may see occasion. In about a week's time, your plants will appear above ground, when you must take off your coverings by degrees, but do not expose them too much to the open sun at first; in about a month's time after sowing, your plants will be fit to prick out; you should therefore put some fresh earth upon your old Cucumber or Melon beds; or where these are not to be had, some beds should be made with a little new dung, which should be trodden down close, to prevent the worms from getting through it; but it should not be hot dung, which would be hurtful to the plants at this season, especially if it prove very hot: into this bed you should prick your young plants, at about two inches square, observing to shade and water them at first planting; but do not water them too much after they are growing, nor suffer them to receive too much rain, if the season should prove wet, which would be apt to make them black-shanked, as the gardeners term it, which is no less than a fatal rottenness in their stems. In this bed they should continue till the end of October, when they must be removed into the places where they are to remain during the winter season, which, for the first sowing, is commonly under bell or hand glasses, to have early Cauliflowers, and these should be of an early kind: but, in order to have a succession during the season, you should also be provided with another more late kind, which should be sown four or five days after the other, and managed in the same way.—*Broccoli*. The seeds of the Broccoli, of which there are several kinds, viz. the Roman or purple, the Neapolitan or white, and the black Broccoli, with some others, of which the Roman is chiefly preferred, should be sown about the latter end of May or beginning of June, in a moist soil; and when the plants are grown to have eight leaves, transplant them into beds, as was directed for the

common Cabbage, and towards the middle of July they will be fit to plant out finally, which should be in some well-sheltered spot of ground, but not under the drip of trees: the distance these require, is about a foot and a half in the rows, and two feet row from row: the soil in which they should be planted, ought to be rather light than heavy, such as that of the kitchen-gardens near London; if the plants succeed well, as they generally do unless the winter be extremely severe, they will begin to show their small heads, which are somewhat like a Cauliflower, but of a purple colour, about the end of December, and will continue catable till the middle of April: In order to have Broccoli produce well, transplant it into the alleys of your Onion, Carrot, &c. beds, the beginning of July; preserving it from snails, and hilling it up, it will produce most noble heads in January and February, and will furnish the table until it is quite over. By sowing very early in the spring, the most forward will succeed the autumnal-sown crops, and keep up by that means a constant succession.

9. *Brassica Chinensis*; *Chinese Cabbage*. Leaves oval, almost quite entire, the floral ones stem-clasping, lanceolate; calices longer than the claws or the petals.—Native of China.

10. *Brassica Violacea*. Leaves lanceolate-ovate, smooth, undivided, toothed.—Native of China.

11. *Brassica Polymorpha*. Inferior. Leaves linear-lanceolate, pinnatifid-toothed, upper subulate, entire.—Annual; a native of Siberia.

*** *Eruca*. *Siliques with a sword-shaped Style*.

12. *Brassica Erucastrum*; *Wild Rocket*. Leaves runcinate; stem hispid; siliques smooth and even; root annual, fusiform.—Native of the southern countries of Europe, in sandy fields, by way-sides, and on walls; flowering from June till August.

13. *Brassica Eruca*; *Garden Rocket*. Leaves lyrate. stem hirsute; siliques smooth; root annual.—Native of Switzerland, Austria, and Piedmont. It was formerly much cultivated in the gardens as a salad herb, but at present is little known, having been long rejected on account of its strong ungrateful smell. It is esteemed as a strong diuretic.—When this is propagated for salads, the seeds should be sown in drills, in the same manner as is practised for other small salad herbs, but if it be not eaten young, it will be too strong for most palates. When sown in summer, the plants soon run up to seed, and are too rank: when cultivated for the seed, which is sometimes used in medicine, it should be sown in March, on an open spot of ground; and when the plants have put out four leaves, they should be hoed to three or four inches' distance, and have a second hoeing in five or six weeks afterwards. When the seeds are ripe, the plants should be drawn up. They require no other culture, but to thin them, and keep them clear from weeds.

14. *Brassica Vesicaria*. Leaves runcinate; siliques hispid, covered with a swelling calix; root annual, spindle-shaped.—Native of Spain and Aleppo.

15. *Brassica Muralis*; *Wall Rocket*. Leaves lanceolate, sinuate-serrate, smoothish; stem erect, smooth; root perennial.—It grows on old buildings and walls, in many parts of England; as, at Yarmouth, Chester, Taunton Castle, Litchfield Close, Bristol, Exeter, Berwick, and plentifully in and about London: it flowers during the greatest part of the summer.

16. *Brassica Richerii*. Root caulescent; leaves petiolate, subserrate, upper linear-lanceolate, entire; siliques four-cornered.—Native of the South of France, and the mountains of Piedmont.

Brathys; a genus of the class Polyandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-

leaved; leaflets lanceolate, acute, permanent. *Corolla*: petals five, lanceolate, twice as long as the calix. *Stamina*: filamenta many, more than twenty, capillary, the length of the calix; antheræ twin. *Pistil*: germen superior, ovate; styles five, patulous, filiform; stigmas capitate. *Pericarp*: capsule ovate, with five little swellings, one-celled. *Seeds*: very many, roundish. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: five. *Nectary*: none. *Capsule*: one-celled, many-seeded.—The only known species is,

1. *Brathys Juniperina*. This shrub is of a habit between Heath and Juniper, very branching and upright, the branches covered with leaves; which are opposite, much crowded, acerose, an inch long, acute, unarmed, evergreen; flowers terminating the branches, several together, sessile.—Found by Mutis in New Granada.

Bread-fruit Tree. See *Artocarpus*.

Bread-nut Tree. See *Brosimum*.

Breynia; a genus of the class Polygamia, order Dicoëia. —**GENERIC CHARACTER.** *Hermaphrodite flowers.* *Calix*: perianth one-leaved, turbinate, minute, six-parted; parts concave, blunt, closely converging, depressed flat at the end, so that it is pervious only by a small hole. *Corolla*: none. *Pistil*: filamenta none; antheræ five, linear, upright, fastened longitudinally to the style, approximating. *Pistil*: germen very small; style cylindric, the length of the calix; stigma blunt. *Pericarp*: berry dry, globular, three-celled, propped on the perianth, now become three times its former size, and spreading very much; the segments orbiculate, and nearly equal. *Seeds*: two, convex at the back, flat on the sides. *Male Flowers.* *Calix*: perianth one-leaved, five-parted; leaflets roundish, concave, almost equal. *Corolla*: none. Nectary five glands, subpedicelled, alternate with the stamens. *Stamina*: filamenta five, very short; antheræ roundish, the length of the calix. *Female Flowers.* *Calix* and *Corolla*: as in the male. *Pistil*: germen globose; style none; stigmas five, obcordate, resembling petals. *Pericarp*: capsule five-celled. *Seeds*: solitary, subtriquetrous. **ESSENTIAL CHARACTER.** *Calix*: one-leaved. *Corolla*: none. *Hermaphrodite.* *Calix*: six-parted; antheræ five, linear, fastened to the style; berry three-celled; seeds two. *Male.* *Calix*: five-parted; filamenta five; antheræ roundish. *Female.* Stigmas five, obcordate, petaloid, without any style. Capsule five-celled; seed solitary.—The only known species is,

1. *Breynia Disticha*.—Native of New Caledonia, and the isle of Tanna in the South Seas.

Briony. See *Bryonia*.

Britannica. See *Rumex*.

Briza; a genus of the class Triandria, order Dygnia. —**GENERIC CHARACTER.** *Calix*: glume many-flowered, bivalve, spreading, collecting the flowers into a heart-shaped distich spike; valves heart-shaped, concave, equal, obtuse. *Corolla*: bivalve; lower valve the size and figure of the calix, upper very small, flat, roundish, inclosing the body of the other; nectary two-leaved; leaflets linear, crenulate. *Stamina*: filamenta three, capillary; antheræ oblong. *Pistil*: germen roundish; styles two, capillary, recurved; stigmas plumose. *Pericarp*: none. *Corolla*: unchanged, contains the seed, gapes, and drops it. *Seed*: one, roundish, compressed, very small. **ESSENTIAL CHARACTER.** *Calix*: bivalve, many-flowered; spikelet distich, with heart-shaped obtuse valves, the lower of which is minute. If the seeds of this genus be sown in the autumn, or be suffered to scatter themselves, the plants will come up much stronger, and flower much earlier, than when they are sown in the spring.—The species are,

1. *Briza Minor*; *Small Quaking-grass*. Spikelets triangular; calix longer than the seven floscules.—This is annual. Native of Germany, Switzerland, the south of France, Italy, and Britain; flowers from June till August.

2. *Briza Virens*; *Green Quaking-grass*. Spikelets ovate; calix equal to the seven floscules. It is an annual; native of the Levant, Spain, and the county of Nice; flowering in July.

3. *Briza Media*; *Middle or Common Quaking-grass*, *Cowquakes*, *Shakers*, *Ladies' Hair*, *Bird's Eyes*. Spikelets ovate; calix shorter than the seven floscules.—This beautiful grass is very common in pastures, especially dry ones, in most parts of Europe, and is easily distinguished by the continual shaking of the spikelets, from which it derives most of its common English names. It flowers from May to July. Cattle eat it, both green and made into hay with other grasses, but it has no peculiar excellence that we are acquainted with, nor has it ever been cultivated separately; indeed it furnishes very little food, and generally occasions a poverty of soil.

4. *Briza Maxima*; *Greatest Quaking-grass*. Spikelets heart-shaped; floscules seventeen. Annual.—Native of the south of Europe.

5. *Briza Eragrostis*; *Branched Quaking-grass*, or *Love Grass*. Spikelets lanceolate; floscules twenty, more or less; root annual. This grass varies much, being commonly small and decumbent, but sometimes rising to the height of seven feet; at others of a middling size, with longer and more contracted spikelets.—Native of the south of Europe; it flowers in July and August.

6. *Briza Monspensulana*. Spike nodding, simple; spikelets alternate, peduncled, subsolitary, ovate; calix five-flowered.

Broccoli. See *Brassica*.

Brome Grass. See *Bromus*.

Bromelia; a genus of the class Hexandria, order Monogynia. —**GENERIC CHARACTER.** *Calix*: perianth three-cornered, small, superior, permanent; divisions three, ovate. *Corolla*: petals three, narrow, lanceolate, erect, longer than the calix; nectary fastened to each petal above the base, converging. *Stamina*: filamenta six, subulate, shorter than the corolla, inserted into the receptacle; antheræ erect, sagittate. *Pistil*: germen inferior; style simple, filiform, the length of the stamina; stigma obtuse, trifid. *Pericarp*: berry roundish, umbilicate, one or three celled. *Seeds*: numerous, incumbent, somewhat oblong, obtuse. **ESSENTIAL CHARACTER.** *Calix*: trifid, superior. *Petals*: three, and a nectareous scale at the base of each. *Berry*: three-celled.—The species are,

1. *Bromelia Ananas*; *Ananas*, or *Pine Apple*. Leaves ciliate-spinous, sharp-pointed; spike comose; root perennial, fibrous.—The fruit now so well known in Europe by the name of *Ananas*, or *Pine Apple*, and so much esteemed for the richness of its flavour, is produced from an herbaceous plant, which has leaves somewhat resembling those of the Aloe, and for the most part serrate on their edges, but much thinner, and not so succulent as those of the aloe. The fruit resembling in shape the cone of some species of the Pine-tree, derives its vulgar name of *Pine-apple* from that circumstance. It is difficult to determine of what country this plant is a native; but it is probably indigenous in Africa, where it grows plentifully in uncultivated places. There are many varieties of this fruit, and if the seeds were sown frequently in their native country, they might be as numerous as those of Apples or Pears in Europe. The *Queen Pine* is the most common variety in Europe, but the *Sugar-loaf* is much preferable to it, being larger and much better flavoured; the juice also is not so astringent as that of the former, so that it may be eaten in greater quantities with less danger

The *Sugar-loaf Pine* is easily distinguished from all the others, by its leaves having purple stripes on their inside the whole length: the fruit is of a paler colour when ripe, inclining to a straw-colour. This was brought from Brazil to Jamaica, where it is esteemed far beyond the others. The next in goodness to this, is what the inhabitants of the islands in America call the *Montserrat Pine*: the seeds have been imported from the island of St. Thomas, where this fruit is in greater perfection than in any of the British islands. The *King Pine* was raised from seed taken out of a rotten fruit which came from the West Indies, and produced large fruit. The *Smooth Pine* is preserved by some curious persons for the sake of variety, but the fruit is not worth any thing. The *Green Pine* is at present the most rare in Europe; this has been esteemed the best sort known, by some of the most curious persons in America, many of whom have thrown out all the others from their gardens to cultivate this only. The fruit, if suffered to ripen well, is of an olive colour; to have it green, it must be cut before it is ripe, when it is unfit to be eaten: plants of this sort may be procured from Barbadoes and Montserrat. The other varieties, most known among the growers of Pines, are the following; the *Black Antigua* or *Ripley*: *Granada Pine*, with marbled leaves, and very large fruit; *Bog warp Pine*, with broad green leaves; *Smooth, Long, Narrow-leaved Pine*; *Montserrat* and *Surinam Pine*: with silver-striped, and also with gold-striped, leaves: but it is unnecessary to go beyond naming such varieties, because they are not permanent; new ones may be produced every day; and, after all, the oval Whitish-fleshed or *Queen Pine*, and particularly the *Pyramidal Yellow-fleshed* or *Sugar-loaf Pine*, are confessedly superior in flavour to all the rest.—They are propagated by planting the crowns which grow on the fruit, or the suckers which are produced from the sides of the plants, or under the fruit, both of which have been found to be equally good; although some persons think the crown preferable to the suckers, supposing it will produce fruit sooner than them, which is certainly a mistake; for by constant experience, we find the suckers, if equally strong, will fruit as soon, and produce as large fruit, as the crowns. The suckers and crowns must be laid to dry, in a warm place, for four or five days or more, according to the moisture of the part which adhered to the old fruit; for if immediately planted they will rot, especially the crowns. The certain rule of judging when they are fit to plant, is by observing if the bottom be healed over and become hard, for if the suckers be drawn off carefully from the old plants, they will have a hard skin over the lower part, and need not lie so long as the crowns, or those whose bottoms are moist: but whenever a crown is taken from the fruit, or the suckers from old plants, they should be immediately deprived of their bottom leaves, so as to allow depth for their planting; so that they may be thoroughly dry and healed in every part. If they are taken off late in the autumn, or during the winter, or early in the spring, they should be laid in a dry place in the stove, for a fortnight or three weeks; but in the summer season they will be fit for planting in a few days. As to the earth in which these should be planted, if you have a rich good kitchen-garden mould, not too heavy, so as to detain the moisture too long, nor over light and sandy, it will be very proper for them without any mixture; but where this is wanting, you should procure some fresh earth from a good pasture, which should be mixed with about a third part of rotten cow-dung, or the dung of an old Melon or Cucumber bed which is well consumed. These should be mixed six or eight months at least before they are used, but if it be a year, it will be the better; and should be often turned, that their parts may be the better united, and the clods well

broken: this earth should not be sieved very fine, but only cleared of the great stones. Always avoid mixing any sand with the earth, unless it be extremely stiff, and then it will be necessary to have it mixed six months or a year before it be used, during which time it must be frequently turned, that the sand may be incorporated in the earth, so as to divide its parts; but you should not put more than a sixth part of sand, for too much is very injurious to these plants. In the summer season, when the weather is warm, the plants must be frequently watered, but not with large quantities at a time: care must be taken to see that the moisture be not detained in the pots, by the holes being stopped, for that will soon destroy the plants. In very warm weather they should be watered twice or three times a week; but in a cool season once a week will be often enough: during the summer season their leaves also should be washed gently once a week all over, which will remove the filth from them, and greatly promote the growth of the plants. Some persons shift these plants from pot to pot, but this is by no means to be practised by those who propose to have large well-flavoured fruit; for unless the pots be filled with the roots by the time the plants begin to show their fruit, they commonly produce small fruit, which generally have large crowns on them; therefore the plants will not require to be potted oftener than twice in a season: the first time should be about the end of April, when the suckers and crowns of the former year's fruit (which remained all the winter in those pots in which they were first planted) should be shifted into larger pots, according to the size of the plants, nothing being more injurious than over-potting them. The second time for shifting them is in the beginning of August, when those plants which are of a proper size for fruiting in the following spring, should be removed into two-penny pots, which are full large enough for any of these plants. At each of these shifting times, the bark-bed should be stirred up, and some new bark added, to raise the bed to the height it was at first made; and when the pots are again plunged into the bark-bed, the plants should be watered gently all over their leaves, to wash off the filth, and to settle the earth to the roots of the plants. If the bark-bed be well stirred, and a quantity of good fresh bark added to it at this latter shifting, it will be of great service to the plants, and they may remain in the same tan until the beginning of November, or sometimes later, according to the mildness of the season, and will require but little fire before that time. They will not require watering more than once a week during winter, and then it must be sparingly given, as it is much better to give them a little water often, than to run the risk of over-watering them at that season. You must observe never to shift those plants which show their fruit, into other pots; for if they be removed after the fruit appears, it will stop their growth, and retard its ripening, so that many times it will be October or November before the fruit is ripe; therefore you should be very careful to keep the plants in a vigorous growing state, from the first appearance of the fruit, because upon this its goodness and size depends; for the fruit is generally small and ill-tasted, if it receive a check after this. When the fruit is cut off from the plants which you desire to propagate, trim the leaves, and plunge the pots into a moderate hot-bed, observing to refresh them frequently with water, which will cause them to put out suckers in plenty; so that a person may soon be supplied with plants enough of any of the kinds, who will but observe to keep the plants in health. The plants are sometimes attacked by small white insects, which appear at first like a white mildew, but soon after have the appearance of lice, which attack both root and leaves at the

East End of the Building.

same time, and if not destroyed will soon spread over a whole stove, and entirely stop the growth of the plants. The best method of destroying them, is to wash the leaves, branches, and stems, of the plant attacked, frequently with water in which there has been a strong infusion of tobacco stalks; which has been found to kill the insects, without prejudicing the plants. Care must be taken to examine between the leaves, or the evil will be but partially removed.—Those plants which shew their fruit early in February, will ripen about June; some sorts are at least a month or five weeks longer in ripening their fruit than others, from the time of the appearance of the fruit; but the season in which the fruit is in the greatest perfection, is from the beginning of July to the end of September; though in March, April, and October, they are sometimes found in tolerable perfection. The method of judging when the fruit is ripe, is by the sibeil, and from observation; for, as the several sorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; nor should they remain so long as to become soft to the touch, before they are cut, for then they become flat and dead, as they do also when they are cut long before they are eaten: therefore the surest way to have this fruit in perfection is, to cut it on the same day that it is to be eaten, early in the morning, before the sun has heated it, observing to cut the stalk as long as possible, and lay the fruit in a cool but dry place, preserving the stalk and crown to it till it is eaten.

2. *Bromelia Pinguin*; *Pinguin* or *Broad-leaved Wild Ananas*. Leaves ciliate-spiny, mucronate; raceme terminal.—The fruits of this plant are separate, each nearly of the size of a Walnut; the pulp has an agreeable sweetness, but joined with such a sharpness, that if it be suffered to lie any time in the mouth, it will corrode the palate and gums, so as to make the blood issue from those tender parts. It resembles the Pine-apple, by its tuft of leaves growing above the fruits: but on a closer inspection, the difference is easily discerned, the fruits not being coadunute as in that, but produced separately in clusters: it is now very common in Jamaica, growing wild in some of the savannas, and on the rocky hills. It is commonly used there, and in the other islands of the West Indies; for fencing pasture lands, its leaves being formidable to cattle; the edges being very prickly, and the prickles arched backwards.—The leaves, stripped of their pulp, soaked in water, and beaten with a wooden mallet, yield a strong thread, which is twisted into ropes and whips, and by the Spaniards is manufactured into hammocks; it has also been worked into good linen cloth. A small quantity of the juice of the fruit in water, makes an admirable cooling draught in fevers; a tea-spoonful, corrected with sugar, destroys worms in children, cleanses and heals the thrush, and other ulcerations in the mouth and throat, and is extremely diuretic; it also makes a very fine vinegar.—Dampier says, the Pinguin-fruit is of two sorts, the *yellow* and the *red*. The yellow grows on a green stem, as big as a man's arm, above a foot high, the leaves are half a foot long, and an inch broad, the edges full of sharp prickles. The fruit grows at the head of the stalk, in two or three great clusters, sixteen or twenty in a cluster; it is as big as a pullet's egg, round and yellow, the rind is thick, and the inside full of small black seeds. It is sharp and pleasant. The red sort is the size and colour of a small dry Onion, in shape much like a nine-pin; it grows not on a stem, as the other, but one end on the ground, the other standing upright: sixty or seventy grow close together on the same cluster of roots. The leaves are a foot and a half or two feet long, prickly like the former. Both are wholesome, and grow plentifully in the Bay of Cam-

peachy.—This and the next species are propagated by seeds; for, though there are often suckers sent forth from the old plants, yet they come out from between the leaves, and are so long, slender, and ill-shapen, that if they be planted they seldom make regular plants. These seeds should be sown early in the spring, in small pots, filled with rich light earth, and plunged into a hot-bed of tanner's bark. When the plants are strong enough to transplant, they should be carefully taken up, and each planted into a separate pot, filled with light rich earth, and plunged into the hot-bed, again observing to refresh them frequently with water until they have taken new root, after which time they should have air and water in proportion to the warmth of the season. In this bed the plants may remain till Michaelmas, at which time they should be removed into the stove, and plunged into the bark-bed, where they should be treated in the same manner as the Ananas. They will not produce fruit in England until they are three or four years old; therefore should be shifted into larger pots, as they advance in growth, for if their roots are too much confined, they will make but little progress. They should also be placed at a considerable distance from each other, for their leaves will be three or four feet long, which turning downward, occupy a large space.—The *Bromelias*, properly so called, are propagated by seeds procured from their native country, for they do not produce any in England. These must be sown in small pots, filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanner's bark; the earth in these pots should be sprinkled over with water two or three times a week, according to the heat of the weather, but must not have too much moisture. If the seeds be good, the plants will appear in about five or six weeks, and in about a month after will be fit to transplant, when they should be carefully shaken out of the pots, and each placed in a separate small pot filled with the same earth as before; they must then be plunged again into a moderate hot-bed, observing frequently to sprinkle them over with water, but be cautious of giving them too much, lest it should rot the roots. During the summer season they should have a moderate share of air, in proportion to the heat of the weather; and in autumn, they must be removed into the bark-stove, and treated in the same manner as the Ananas or Pine-apple, with which management they will make good progress; but after the first winter, they may be placed upon stands in the dry-stove, though they will thrive much better if they be kept constantly in the tan-bed, and treated like the Ananas, and will flower in three or four years, whereas those in the dry-stove will not flower in twice that time. The other part of their culture is only to shift them into fresh earth when they require it; but they should by no means be put into large pots, for they will not thrive if they are over-potted; nor must they have much wet, especially in winter.

3. *Bromelia Karatas*; *Karatas*, or *Upright-leaved Wild Ananas*. Leaves erect; flowers stemless, sessile, aggregate. This is an elegant plant, generally found growing at the root of some shady tree, in hilly and woody places, in America, and the Caribbee islands. The fruits, when ripe, are far from unpleasant; but when unripe, they set the teeth on edge, and excoriate the mouth. The economy of this plant, in preserving its fruit to maturity, is wonderful; being so protected by the spines of the surrounding leaves, as to be secured from all injuries. It propagates itself by mucus produced among the leaves, which become procumbent after the fruit is ripened.—For its culture and propagation in England, see the preceding species.

4. *Bromelia Lingulata*; *Tongue-leaved Bromelia*. Leaves serrate-spiny, obtuse; spikes alternate; root perennial, fibrous,

stem four feet high; berries round, with a small point, in simple racemes, of a bright coral red.—Native of the West Indies.

5. *Bromelia nudicaulis*; *Naked-stalked Bromelia*. Radical leaves tooth-spiny; stem-leaves quite entire.—Native of the West Indies: for its culture and propagation, see the second species.

6. *Bromelia humilis*; *Dwarf Bromelia*. Almost stemless: flowers aggregate, sessile; axillas stoloniferous; flowers blue, about thirty in number. This plant readily propagates itself by runners, which proceed from the axilla of the lower leaves, and which produce a young plant from their extremity.

7. *Bromelia acanga*. Panicle diffused; leaves ciliate.—spiny, mucronate, recurved.—Native of Brazil: for its propagation and culture, see the second species.

8. *Bromelia bracteata*. Leaves serrate-spiny; bractes ovate-lanceolate; scape elongated; raceme compound; racemes subdivided; flowers sessile.—For its propagation and culture, see the second species.

9. *Bromelia paniculigera*. Leaves serrate-spiny; bractes lanceolate; raceme compound; racemes subdivided; flowers peduncled.—See the second species.

Bromus; a genus of the class Triandria, order Digynia.—

GENERIC CHARACTER. *Calix*: glume many-flowered, bivalve, spreading, collecting the floscules into a spike; valve ovate-oblong, acuminate, awnless, the lowest smallest. *Corolla*: bivalve; lower valve, larger, the size and form of the calix, concave, obtuse, bifid, putting out a straight awn below the top; upper valve lanceolate, small, awnless. *Nectary*, two-leaved; leaflets ovate, acute, gibbous at the base. *Stamina*: filaments three, capillary, shorter than the corolla; antheræ oblong. *Pistil*: germen turbinate; styles two, short, reflex, villose; stignias simple. *Pericarp*: corolla very straitly closed, adhering, not gaping. *Seed*: one, oblong, covered, convex on one side, furrowed on the other. **ESSENTIAL CHARACTER.** *Calix*: two-valved; spikelet oblong, columnar, distich; awn below the top.—For the culture and propagation of this genus, see *Grass*.—The species are,

1. *Bromus secalinus*; *Field Brome-grass*. Panicle expanding; spikelets ovate; awns straight; seeds distinct. It has an annual root, and is chiefly a native of barren pastures: it abounds among corn, particularly Rye. When ground among flour, it is said to render the Rye-bread bitter and unpleasant, and to have the same narcotic quality with *Lolium temulentum*, or annual Ray-grass, or Darnel. It has been a popular notion in England, that the several species of corn degenerates into grasses which bear some resemblance to them: and that they were only these grasses improved by cultivation.

2. *Bromus japonicus*; *Japan Brome-grass*. Panicle spreading, branching; spikelets oblong, smooth; awns divaricate; root annual.—Native of Japan.

3. *Bromus mollis*; *Soft Brome-grass*. Panicle rather erect; spikelets ovate, pubescent; awns straight; leaves very softly villose. In corn-fields the root is annual; in uncultivated places, biennial. There are many varieties of this grass, both in degrees of pubescence, from universal hoariness, to almost perfect smoothness; and in size, from three and even four feet in height, to that of a few inches, not to mention other concomitant and less striking circumstances.—It is a native of most parts of Europe, by way-sides, on banks in uncultivated parts, on walls, in corn-fields, particularly among Barley, in meadows and pastures, especially in a dry sandy soil, flowering in May and June. With us it forms a principal part of many mowing-grounds, and abounds in most of our best meadows. It springs early, and ripens its seeds

about the time of hay-making. The seed is large, each panicle containing as much as a common Oat, and although cattle are not fond of the leaves and green panicle, it perhaps contributes to render the hay more nutritive: it has, however, a bad property, for the panicle is so heavy, that it is very apt to be laid by rain; it is also so much earlier than many other grasses, that by the ordinary time of mowing, it is in a manner withered away, and what seeds have not fallen are lost in the making and carting; finally, the seeds are said to bring on a temporary giddiness in the human species and in quadrupeds, and even to be fatal to poultry; if this be in any degree true, it is an objection to the cultivation of this grass, which in other respects does not rank among the best kinds. It is recommended for subduing or consolidating shifting sands; but surely a perennial grass, with creeping roots, would answer this purpose much better.

4. *Bromus squarrosus*; *Open-awned Brome-grass*. Panicle nodding; spikelets ovate; awns divaricate. This is a robust annual grass, flowering in July.—Native of England, France, Germany, Switzerland, and Siberia; with us in corn-fields near Glastonbury, in Somersetshire, and at Maresfield, in Sussex.

5. *Bromus purgans*; *Purging Brome-grass*. Panicle nodding, curled; leaves naked on both sides; sheaths hairy; glumes villose.—Native place uncertain.

6. *Bromus inermis*; *Awnless Brome-grass*. Panicle erect; spicules subcolumnar, subulate, naked, almost awnless.—Native of Germany and Switzerland.

7. *Bromus bifidus*; *Bifid Brome-grass*. Panicle erect, branching; spicules ovate, subtriflorous; glumes bifid, setaceous; awn divaricate.—Native of Japan.

8. *Bromus asper*; *Rough Brome-grass*. Panicle branched, nodding, scabrous; spikelets linear, roundish, ten-flowered, hairy, awned; culm and leaves rough with hairs. It is the tallest of our English grasses, often exceeding six feet in height.—It grows in hedges and woods, in Britain, Germany, Switzerland, &c. and flowers with us from June till August: it appears to be too coarse a grass to be cultivated for cattle.

9. *Bromus ciliatus*; *Ciliate Brome-grass*. Panicle nodding; leaves on both sides, and sheaths somewhat hairy; glumes ciliate; flowers eight, awned under the tip; calices naked; glumes of the corolla lanceolate.—Native of Canada.

10. *Bromus sterilis*; *Barren Brome-grass*. Panicle spreading; spikelets oblong, distich; glumes subulate, awned; root annual.—Very common under hedges, flowering in May and June.

11. *Bromus arvensis*; *Corn Brome-grass*. Panicle nodding; spikelets ovate-oblong; root annual.—Found by way-sides, and on the borders of corn-fields, flowering in July.

12. *Bromus geniculatus*; *Kneed Brome-grass*. Panicle erect; floscules distant; peduncles angular; culm with a procumbent knee.—Native of Portugal, and Naples.

13. *Bromus tectorum*; *Wall Brome-grass*. Panicle nodding; spikelets linear; root annual, or at most biennial.—Native of most parts of Europe, on walls, buildings, and in dry pastures; but not of England: it flowers from May to July, and when approaching to a state of maturity, may be useful in dyeing, where it can be obtained in sufficient quantities.

14. *Bromus giganteus*; *Tall Brome-grass*. Panicle nodding; spikelets four-flowered; awns shorter; root perennial.—Native of most parts of Europe, in woods, and under moist hedges, flowering from July till September. It is a productive grass, and cattle are said to be fond of it, but there is not much probability of its being good grass for meadows and pastures.

15. *Bromus rubens*; *Red or Spanish Brome-grass*. Pa-

nicle fascieled, ovate; spikelets subsessile, villose, seven-flowered; awns erect; root annual.—Native of the neighbourhood of Madrid, on the borders of corn-fields, flowering in May.

16. *Bromus Scoparius*. Panicle fascieled; spikelets subsessile, smooth; awns spreading. The awns in the same plant are sometimes upright, sometimes spreading; the corollas are smooth, especially the outer glume; the colour is sometimes green, often blood-red, but more frequently paler.

17. *Bromus Rigens*; *Stiff Brome-grass*. Panicle spiked; spikelets subsessile, erect, pubescent, subquadriflorous; culms six or seven inches high, clothed with leaves, which are nerved, and slightly haired on the upper surface, the sheaths covering the whole culm.—Native of Portugal.

18. *Bromus Racemosus*; *Racemed Brome-grass*. Raceme entirely simple; peduncles one-flowered; spikelets six-flowered, even-awned.—It is found in calcareous pastures in the neighbourhood of Oxford, flowering in June and July.

19. *Bromus Triflorus*; *Three-flowered Brome-grass*. Panicle spreading; spikelets subtriflorous; stem five feet high.—Native of Germany, and of Denmark, in woods; flowering in June and July.

20. *Bromus Madritensis*; *Madrid Brome-grass*. Panicle thinner, expanding, erect; spicules linear; the intermediate ones in pairs; pedicles thicker upwards.—Native of Spain, Italy, and England, on old walls, about London, Oxford, and Severnstoake in Worestershire: very common in dry meadows; flowering in May.

21. *Bromus Ramosus*; *Branched Brome-grass*. Culm much branching; spicules sessile; leaves involute-subulate; root perennial.—Found in the Levant, and observed also in Dauphny.

22. *Bromus Pinnatus*; *Pinnated or Spiked Brome-grass*. Culm undivided; spikelets alternate, subsessile, columnar, subawned; root perennial; leaves flat; the flat side of the spikelets is turned to the culm; awns terminating. Whilst it flowers, the spikelets separate horizontally from the culm; before and after flowering, they are pressed to it. The Meadow Spiked Brome-grass, according to Mr. Hudson, is smooth, of a yellowish green, the lower leaves sometimes a little hairy, the awn shorter than the floscules.—Found in pastures, especially in a calcareous soil, in many parts of Europe.

23. *Bromus Crista*; *Crested Brome-grass*. Spikelets imbricate, in a double row, sessile, depressed.—Native of Siberia and Tartary.

24. *Bromus Distachyos*; *Two-spiked Brome-grass*. Spikes two, erect, alternate.—Native of the south of Europe, and the Levant: it is an annual plant.

25. *Bromus Stipoides*. Panicle somewhat erect: peduncles ensiform.—Native of Majorca.

Brooklime. See *Veronica*.

Broom. See *Genista*, *Spartium*, and *Aspalathus*.

Brosimum; a genus of the class Diœcia, order Monandria, —GENERIC CHARACTER. *Male*. *Calix*: ament common, globular, covered on all sides with imbricate, orbicular, peltate, membranaceous, deciduous scales; three larger surrounding the base of the ament; and others smaller, of an irregular shape, between each of which the stamens break out. *Corolla*: none. *Stamina*: filamenta solitary, very short, cylindrical; antheræ bilamellate; lamellas orbicular, peltate; lower gaping from the upper, dispersing a globular pollen. *Pistil*: germen at top included in a spongy ament, very small, ovate, abortive; style single, upright, bifid at the tip; stigmas reflex, simple. *Female on a different tree*. *Calix*: ament like the male. *Corolla*: none. *Pistil*: germen globular, (the scaly body of the ament itself;) style springing

from the middle of the germen at top, long, bifid; stigmas simple, sharp, a little reflex. *Pericarp*: berry pedicelled, corticose, spherical, one-celled. *Seeds*: solitary, with a two-lobed kernel, surrounded by a thin membrane, and bipartite. ESSENTIAL CHARACTER. *Male*. *Ament*: globular, covered all round with orbiculate peltate scales. *Corolla*: none. *Filamenta*: solitary, between the scales. *Female*. *Ament* as in the male. *Corolla*: none. *Style*: bifid. *Berry*: one-seeded.—The species are,

1. *Brosimum Alicastrum*. Leaves ovate-lanceolate, perennial; aments globular, pedicelled, solitary, axillary: fruit corticose.—This tree is frequent in the parishes of St. Elizabeth and St. James, in the island of Jamaica; and in both is computed to make up a third part of the woods. The timber is not despicable; but the leaves and younger branches are more useful, and a hearty fattening fodder for all sorts of cattle. The fruit, boiled with salt fish, pork, beef, or pickle, has been frequently the support of the negroes and poorer sort of white people, in times of scarcity, and proved a wholesome and not unpleasant food: when roasted, it eats something like our European Chestnut, and is called *bread-nut*. The leaves and younger shoots are full of gum, which renders them disagreeable to most cattle at first, but they soon grow very fond of them.

2. *Brosimum Spurium*: Leaves lanceolate, ovate, acuminate; aments pedicelled, ovate, axillary in pairs; fruits soft.—This is pretty common in St. Mary's parish, Jamaica, where it is called *milk-wood*. It rises to a considerable height in the woods, is reckoned among the timber-trees, and is sometimes used as such, though not generally valued.

Brossæa; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER.—*Calix*: perianth one-leafed, five-parted; divisions ending in erect points, the length of the corolla. *Corolla*: monopetalous, conic, truncate at the end, entire. *Stamina*: five. *Pistil*: germen pentacœcous; style subulate, shorter than the corolla; stigma simple. *Pericarp*: capsule roundish, divided with five furrows, five-celled, covered with a large, converging, fleshy, succulent calix, bursting at the sides. *Seeds*: very many, extremely minute. ESSENTIAL CHARACTER. *Calix*: fleshy. *Corolla*: truncate. *Capsule*: five-celled, many-seeded.—The only known species is,

1. *Brossæa Coccinea*. Branches alternate; leaves alternate, ovate, serrate, petiolate; flowers few, terminating the branches, alternate. An obscure plant, and the character doubtful.—Native of South America.

Browallia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, short, five-toothed, permanent; toothlets a little unequal. *Corolla*: monopetalous, funnel-form; tube cylindrical, twice as long as the calix; border flat, equal, five-cleft; divisions rounded, emarginate; the upper somewhat large, constituting the upper lip; the four others equal. *Stamina*: filamenta four, in the throat of the corolla; the two upper shortest; the lower broader, higher coloured, reflex, closing the throat of the corolla. Antheræ simple, bent in, converging; the inner ones twin, the outer opening at the top with a little hole, and closing the throat of the corolla. *Pistil*: germen ovate, retuse; style filiform, the length of the tube of the corolla; stigma thick, four lobed. *Pericarp*: capsule ovate, obtuse, one-celled, covered, bursting into four parts at the top; partition thin, parallel. *Seeds*: numerous, small; receptacle nearly columnar, compressed. ESSENTIAL CHARACTER. *Calix*: five-toothed. *Corolla*: border five-cleft, equal, spreading, with the navel closed. *Antheræ*: two larger. *Capsule*: one-celled.—These plants being

annual, their seeds must be sown every year upon a hot-bed in the spring: and the plants must be brought forward on another, to perfect seeds in England. Some of them may be transplanted, in June, into the borders of the flower-garden; where, if the season prove warm, they will flower, and perfect seeds; but lest these should fail, there should be two or three plants kept in the stove for that purpose.—The species are,

1. *Browallia Demissa*; *Spreading Browallia*. Peduncles one-flowered. This usually grows about two feet high, and spreads out into lateral branches.—Native of South America, flowering from July till September.

2. *Browallia Elata*; *Upright Browallia*. Peduncles one-flowered and many-flowered; flowers of a dark blue colour. This also rises about two feet in height.—It is a native of Peru, and flowers from July till September.

Brownea; a genus of the class Monadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, turbinate, unequally bifid, acute. *Corolla*: outer monopetalous, funnel-form; border five-cleft; divisions oblong, concave, obtuse, erect; inner five-petalled. Petals obovate, flat, obtuse, patulous, sitting on the tube of the outer corolla; claws long. *Stamina*: filamenta ten or eleven, subulate, alternately shorter, fastened to the tubes of the outer corolla, united into a cylinder, divided above; antheræ oblong, incumbent. *Pistil*: germen oblong, acute, sitting on a pedicle fastened to the wall of the outer corolla; styles subulate, erect, longer than the corolla; stigma obtuse. *Pericarp*: legume oblong, compressed, narrowed about the partition, two-celled; partition membranaceous. *Seed*: solitary, ovate, compressed, somewhat wrinkled, involved in fungose fibres. **ESSENTIAL CHARACTER.** *Calix*: unequally bifid. *Corolla*: double; outer five-cleft, inner five-petalled; legume two celled.—The species are,

1. *Brownea Coccinea*. Flowers disjoined, umbelled. This is a shrub, or small tree, growing to the height of about eighteen feet. The wood is covered by an ash-coloured bark: when in flower, it has a beautiful appearance. The leaves are oval, entire, smooth, opposite, with short foot-stalks; they grow two or three pairs on a spray. The flowers grow about ten together, and are pendulous. The calix is ferruginous, the corollas scarlet, and the stamina yellowish.—Grows on hills and woody places in America.

2. *Brownea Rosa*. Flowers aggregate in heads, sessile; stamina very long. This is also an American shrub, or small tree, with an ash-coloured bark, and opposite leaves, which are entire, and smooth on both sides. The flowers are borne in a kind of aggregate manner, so as to form heads or bunches of the size of one's fist; they are red, and make a very beautiful appearance. The stamina are extremely long.—It grows principally in hilly situations.

Brucea; so named in honour of the celebrated traveller into Abyssinia, James Bruce, Esq. who first brought the seeds into England, a genus of the class Diœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male. Calix*: perianth four-parted, flat, villose; parts lanceolate, acute, spreading. *Corolla*: petals four, lanceolate, acute, ciliate, spreading, scarcely larger than the calix; nectary, a body placed on the receptacle, flat, four-lobed; lobes obscurely emarginate, opposite to the petals. *Stamina*: filamenta four, upright, short, opposite to the calix, inserted into the receptacle between the lobes of the nectary; antheræ, roundish. *Female. Calix* and *Corolla* as in the male. Nectary, the inner margin of the receptacle thickened, four-lobed; lobes emarginate. *Stamina*: filamenta four, inserted in the receptacle on the outside of the divisions of the nectary, filiform, but thicker

towards the tip, sharpish, a little shorter than the petals; without any antheræ. *Pistil*: germina four, superior, ovate, compressed on the inner side; styles subulate, reflex, lying on the germina; stigmas acute. *Pericarps*: four, one-seeded. *Seeds*: solitary. **ESSENTIAL CHARACTER.** *Calix*: four-leafed. *Corolla*: four-petalled. *Female. Pericarps*: four, one-seeded.—The only known species is,

1. *Brucea Ferruginea*. Mr. Bruce thus imperfectly describes it: leaf pinnate; leaflets oblong, pointed, smooth, and without collateral ribs that are visible; the upper side of a deep green, the reverse very little lighter, opposite, with a single one at the end. The flowers come chiefly from the point of the stalk, on each side of a long branch. According to Mons. L'Heritier, who has described it more completely, it is a shrub of the middling size; stem upright, the bark ash-coloured, becoming yellowish; branches few, alternate, patulous, round, thick, with broad scars from the fallen leaves continuing long on them; shoots angular, with the petioles tomentose, rufous; leaves alternate, spreading, unequally pinnate, consisting of six pairs of opposite lobes, one foot in length; petiole round, thickened at the base, tomentose, rufous; leaflets on short petioles, oblong-ovate, entire, acuminate, veined, villose, somewhat fetid when rubbed; the two lower ones smaller, the upper one on a longer petiolule, three inches long, and one inch broad; the midrib raised on both sides, especially beneath; the veins concentrically retuse towards the edges; spikes of the male flowers solitary, axillary, upright at first, then spreading, finally nodding; peduncled, almost simple, or scarcely compounded of many-flowered very short spikelets, remote at bottom, but gradually approximating towards the top, tomentose, rufous, from six to eight inches in length; the flowers are crowded together, either sessile or on very short pedicels, of an herbaceous colour, tinged with red or russet. The male plant began to flower in the stove of the Paris botanic garden, when it was between two and three feet high, in May and June, 1780 or 1781. The female plant has flowered in the royal garden, at Kew, in April and May.—Native of Abyssinia, where it is known by the name of *Wooginoos*. The root is a specific in the dysentery. It is a plain simple bitter, without an aromatic or resinous taste, leaving in the throat and palate something of roughness resembling ipecacuanha.

Brunella. See *Prunella*.

Brunfelsia; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, bell-shaped, five-toothed, obtuse, very small, permanent. *Corolla*: one-petalled, funnel-form; tube very long, slightly curved inwards; border flat, five-cleft, blunt. *Stamina*: filamenta four, very short; antheræ oblong, upright; two a little higher than the others, prominent from the mouth of the tube. *Pistil*: germen roundish, small; style filiform, the length of the tube; stigma thickish. *Pericarp*: capsule berried on the outside, globular, one-celled, two valved. *Seeds*: very many, compressed, convex on one side, angular on the other, rugged with dots. *Receptacle*: fastened to the bottom of the capsule, chuffy; chaffs coadunate, subulate at the tip, separating the seeds. **ESSENTIAL CHARACTER.** *Calix*: five-toothed, narrow. *Corolla*: with a very long tube. *Capsule*: one-celled, many-seeded, with a very large fleshy receptacle.—The plants of this genus may be propagated from seeds, which should be sown early in the spring, in pots of light earth, and plunged into a hot-bed of tanner's bark, observing to water the earth as often as you find it necessary. When the plants are come up, they should be transplanted each into a separate small pot, filled with fresh light earth, and plunged into the hot-bed again, observ-

BUPLEURUM — Shrubby Hare's Ear.

ing to water and shade them until they have taken root ; after which they must have air admitted to them every day, in proportion to the warmth of the season. When the plants have risen too high to be continued in the frames, they should be removed to the bark-stove, where, during the summer months, they should have a large share of free air ; but in winter they must be kept very close ; with this management the plants will be very strong, and produce their flowers every season. They may also be increased by planting cuttings in the spring, before they begin to make new shoots, in pots filled with fresh light earth, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root ; after which, they must be managed as has been directed for other tender exotic plants from the same countries.—The species are,

1. *Brunfelsia Americana*. Leaves elliptic, acuminate, on longer petioles ; tube of the corolla erect ; border entire.—Fruit green, with a red receptacle. This is a tree, with a smooth and even trunk ; growing from ten to fifteen feet in height ; native of Jamaica, and most of the sugar islands in the West Indies, where they call it Trumpet-flower.

2. *Brunfelsia Undulata*. Leaves lanceolate-ovate, drawn to a point at both ends ; petioles very short ; tube of the corolla curved ; border waved.—Native also of Jamaica.

Brunia, a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth common, roundish, imbricate, many-flowered ; leaflets ovate-oblong. Proper five-leaved, inferior ; leaflets oblong, villose. *Corolla*: petals five ; claws slender ; borders roundish, spreading. *Stamina*: filamenta five, capillary, inserted into the claws of the petals ; antheræ ovate-oblong. *Pistil*: germen very small, superior ; style simple, cylindric ; stigma obtuse. *Pericarp* and *Seed*: not ascertained. *Receptacle*: common, hairy. **ESSENTIAL CHARACTER.** *Flowers*: aggregate. *Filamenta*: inserted into the claws of the petals. *Stigma*: bifid. *Seeds*: solitary, two-celled.—The species are,

1. *Brunia Lanuginosa* ; *Heath-leaved Brunia*. Leaves linear, spreading, callous at the end ; stem a foot high, shrubby. Flowers white, borne in heads.—Native of the Cape.

2. *Brunia Ciliata* ; *Ciliate-leaved Brunia*. Leaves ovate, acuminate, ciliate ; the germen is superior, and the style bifid.—Native of the Cape.

3. *Brunia Verticillata* ; *Whorled Brunia*. Leaves three-cornered ; branchlets in whorls, fastigate ; heads terminating, smooth, small, not globular.—Found at the Cape of Good Hope by Thunberg.

Bryonia ; a genus of the class Monœcia, order Syngenesia, (Pentandria, Smith.)—GENERIC CHARACTER. *Male Flowers.* *Calix*: perianth one-leaved, bell-shaped, five-toothed ; toothlets subulate. *Corolla*: five-parted, bell-shaped, fastened to the calix ; divisions ovate. *Stamina*: filamenta three, very short ; antheræ five, two connate on each of two filamenta, and a single one on the third. *Female Flowers.* *Calix*: perianth as in the males, superior, deciduous. *Corolla*: as in the males. *Pistil*: germen inferior ; style trifid, the length of the corolla, expanded ; stigmas emarginate, patulous. *Pericarp*: berry subglobular, smooth, and even. *Seeds*: a few, fastened to the coat, subovate. **ESSENTIAL CHARACTER.** *Calix*: five-toothed. *Corolla*: five-parted. *Male.* Filamenta three. *Female.* Style quadrifid. Berry subglobular, many-seeded.—The species are,

1. *Bryonia Alba* ; *Black-berried White Bryony*. Leaves palmate, callous-seabrous on both sides ; flowers monœcous ; berries black.—Native of Sweden, Denmark, Carniola, England, and other parts of Europe, in hedges. The root is said to be one of the best diuretics known in medicine: it is

an excellent remedy in the gravel, and all other obstructions of urine, and in disorders of the urinary passages in females. For propagation and culture, see the next species.

2. *Bryonia Dioica* ; *Red-berried White Bryony*. Leaves palmate, callous-seabrous on both sides ; flowers diœcous ; berries red. It is easily distinguished by its prodigious root ; its stems climbing by tendrils ; leaves resembling those of the vine in shape, not smooth however as they are, but harsh and rugged, and of a paler colour ; and by its bunches of small berries, which are red when ripe, and produced on a different plant from the male flowers. It is called in English, Bryony, White Bryony, White Wild Vine, Wild Hops, Wild Nep, and Tetter-berry ; in German, *zaurube, stickwurz* ; in Dutch, *witte bryone, wild wyngaard* ; in Swedish, *hundrosva* ; in Danish, *valsbrove, galdebær, hundebær* ; in French, *bryone, couleurée* ; in Italian, *brionia, vile bianca* ; in Spanish, *nueza alba*. It is common in the hedges of these countries, and flowers in May with us. Goats alone are said to eat this plant. The roots of Bryony grow to a vast size, and have been formerly, by impostors, brought into a human shape, carried about the country, and shown for Mandrakes to the common people. The method which these knaves practised, was, to open the earth round a young thriving Bryony plant, being careful not to disturb the lower fibres of the root ; to fix a mould, such as is used by those who make plaster figures, close to the root, fastening it with wire to keep it in its proper situation ; and then to fill in the earth about the root, leaving it to grow to the shape of the mould, which is effected in one summer: see *Atropa Mandragora*. Bryony is a famous hydragogue, and highly purgative, and acrid: a drachm of it in substance, or half an ounce infused in wine, is a full dose ; others give two drachms in dropsical cases, and have used half an ounce of the fresh root, or three drachms of it dry, in decoction, without purging: some it purges moderately, others violently, and it frequently becomes diuretic and diaphoretic. A cold infusion of water is used externally in sciatic pains: a cataplasm of it is a most powerful discutient: a decoction, made with one pound of the fresh root, is the best purge for horned cattle. The active virtues of this plant seem to give it a claim to more attention than is now bestowed upon it. Small doses of the juice, given with white wine, promote the menses, and hasten delivery ; and in larger doses, it is an excellent medicine in the jaundice, dropsy, and other complaints of a like nature. Made into syrup with honey, and a small quantity of vinegar, it is beneficial in asthmatic complaints: it likewise kills worms in the stomach and intestines, and is good in hysteric cases, but for this purpose it must be given in very small quantities, and the use of it continued for some time.—This, and the first species, or common European Bryony, may be cultivated in a garden for use, by sowing the berries in the spring, on a dry poor soil: in two years' time, the roots will grow to a large size, if the plants be not placed too close together. It may, however, be in general easily procured on dry banks and in hedges, in most parts of England.

3. *Bryonia Palmata* ; *Palmated Bryony*. Leaves palmate, smooth, and even, five-parted ; divisions lanceolate, repand-serrate.—Native of Ceylon. This, and the fourth, fifth, sixth, and seventh species, require the protection of the bark-stove, according to the climate they come from. They are also propagated by seeds sown upon a hot-bed: when they are fit to transplant, they should be put into pots filled with light fresh earth, and must have as much air as possible, and may be frequently refreshed with water in dry weather: several of them will endure the open air in the summer season, but in winter they must all be sheltered, and then they

should have very little water : they mostly flower in July, and in favourable summers will perfect their seeds.

4. *Bryonia Granadis* ; *Great-flowered Bryony*. Leaves cordate, angular, smoothish, glandular at the base underneath ; stem shrubby ; tendrils simple.—Native of India, and Cochin-china. See the preceding species.

5. *Bryonia Cordifolia* ; *Heart-leaved Bryony*. Leaves cordate, oblong, five-lobed, toothed, scabrous ; petioles two-toothed.—Native of Ceylon. See the third species.

6. *Bryonia Laciniosa* ; *Laciniated Bryony*. Leaves palmate ; divisions lanceolate, serrate ; petioles muricate.—Native of Ceylon. See the third species.

7. *Bryonia Africana* ; *African Bryony*. Leaves palmate, five-parted, smooth, and even on both sides ; divisions pinnatifid.—Native of the Cape. See the third species.

8. *Bryonia Cretica* ; *Cretan Bryony*. Leaves palmate, callous dotted on the upper surface ; root long, running deep, but not so large as the common sort, covered with brown bark.—Native of Crete or Candia, as its name imports. This, and the tenth, fifteenth, and sixteenth species, must be raised on a hot-bed early in the spring, and when the plants are about three inches high, they should be each transplanted into a small pot filled with fresh light earth, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root. When the plants are grown so large as to ramble about on the surface of the bed, and begin to entangle with other plants, they should be shifted into larger pots, or placed in the bark-stove, where their branches may be trained to the wall, or against an espalier, that they may have sun and air, which is absolutely necessary for their producing fruit. When they are full of fruit, they make a pretty variety in the stove among other exotic plants.

9. *Bryonia Scabra* ; *Rough or Globe-fruited Bryony*. Leaves cordate, angled, villose underneath, callous-scabrous on the upper surface ; tendrils simple ; berries globular ; seeds smooth.—Native of the Cape of Good Hope, and flowers in September and October.

10. *Bryonia Seabrella* ; *Roughish or Bristly Bryony*. Leaves cordate, angular, and lobed, callous-hispid ; tendrils simple ; berries globular ; seeds muricate ; corollas small, yellow.—Native of the East Indies. For its propagation, see the eighth species.

11. *Bryonia Japonica* ; *Japan Bryony*. Leaves cordate, undivided, and angular, toothed, unarmed, hispid. It creeps on walls.—Native of Japan. For its culture and propagation, see the eighth species.

12. *Bryonia Latebrosa* ; *Hairy Bryony*. Leaves subtrilobate, hairy, drawn to a point at the base. This is easily distinguished from the rest, by the leaves not being in the least cordate at the base, but subdecurrent along the petioles.—It is a native of the Canary Islands.

13. *Bryonia Verrucosa* ; *Warted Bryony*. Leaves cordate, angled ; the upper surface, and the veins underneath, callous-scabrous, the callosities remote ; tendrils simple ; berries globular.—It is a native of the Canary Islands.

14. *Bryonia Racemosa*. Leaves cordate, three-lobed, the upper ones ovate, and somewhat rugged ; flowers in racemes ; berries nodding, oval.—Native of Jamaica.

15. *Bryonia Variegata*. Leaves palmate, with lanceolate segments, spotted on the upper, but smooth on the under side ; fruit ovate, scattered.—For the propagation and culture of this plant, see the eighth species.

16. *Bryonia Bonariensis*. Leaves palmate, five-parted, hairy, with obtuse segments. Root and stems like those of the common Bryony ; the latter the thickness of a quill at bottom and angular, towards the top deeply streaked, dark green.

—Native of Buenos Ayres. For the propagation and culture, see the eighth species.

17. *Bryonia Hastata*. Leaves hastate, toothletted, smooth ; peduncles many-flowered ; stem herbaceous, slender, scandent, cirrhose ; flowers androgynous, white, axillary.—Native of China, about Canton.

18. *Bryonia Triloba*. Leaves three-lobed, five-nerved ; stipules roundish, concave ; peduncles one-flowered ; stem shrubby, grooved, climbing by trifid tendrils. Native of Cochin-china.

19. *Bryonia Cochlin-chinensis*. Leaves five-cornered, rough, berries three-celled, ten-cornered. It differs from the other Bryonies, but cannot be so well placed in any other genus.—Native of Cochin-china, in hedges.

Bryum ; a genus of Moss, distinguished by a capsule covered with a lid, and over that a smooth veil ; but these characters it has in common with the *Mnium* and *Hypnum*, two other genera much resembling this. The peculiar note of the *Bryum* is, that the thread, or little stem supporting the fructification, grows from a tubercle at the ends of the stem and branches. The character of this genus, as given by Hedwig and Schröber, is as follows :—*Capsule*: ovate, oblong. *Peristemum*: double, outer with sixteen broadish sharp teeth ; inner membranaceous, plaited and keeled, jagged ; jags broadish, capillary, alternate. *Males*: capitate or discoid, or gemmaceous, on the same or a different plant. Linneus has thirty-seven species ; Hudson has forty-five, besides many varieties ; Lightfoot has twenty-nine, described particularly, with many good observations ; Withering has sixty-five, besides many varieties, well distinguished ; Allioni has only twenty-eight species ; and Haller enumerates thirty-three. Many of the figures of these Mosses have been given by Curtis, Dillenius, Vaillant. in *Flora Danica* ; also by Dickson, Hedwig, &c.

Bubon ; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel universal, of about ten rays, the middle ones shorter ; partial of fifteen to twenty rays ; involucre universal, five-leaved ; leaflets lanceolate, acuminate, patulous, equal, much shorter than the umbel, permanent. Partial with rather more leaflets, of the same shape, the length of the umbellule ; perianth proper five-toothed, very small, permanent. *Corolla*: universal uniform, all the floscules fertile ; proper of five, lanceolate, inflex petals. *Stamina*: filamenta five, simple, the length of the corollule ; anthera simple. *Pistil*: germen ovate, inferior ; styles two, setaceous, permanent, hardly the length of the corollule, spreading and reflex ; stigmas obtuse. *Pericarp*: none ; fruit ovate, striated, villose, bipartite, crowned. *Seeds*: two, ovate, flat on one side, and convex on the other, striated villose. **ESSENTIAL CHARACTER.** Fruit ovate, striated villose.—These plants make a pretty variety in the green-house in winter, and when they are placed abroad in the summer, with other green-house plants, they have a good effect, especially when they are grown to a large size. They generally flower the third year from seeds, but their flowers are produced so late in summer, that the seeds have seldom time to form before the cold comes on in the autumn.—The species are,

1. *Bubon Macedonicum* ; *Macedonian Parsley*. Leaflets rhomb-ovate, gash-toothed ; teeth acuminate, umbels very numerous ; seeds rough with hairs.—Native of Greece and Barbary, and probably of the East Indies ; it flowers with us in July, or from June to August. In warm countries it is biennial, but in England the plants seldom flower till the third or fourth year from seed ; but whenever they flower, they always die. In some parts of the east, this plant is used

to scent clothes; the smell is very strong, and in general disagreeable to Europeans. The plant, but especially the seed, is esteemed to be diuretic, emmenagogue, and carminative; the seeds are an ingredient in Theriaca.—It is propagated by seeds, which should be sown on a bed of light sandy earth, either early in the autumn, or in April; and if the season prove warm and dry, the ground should be shaded in the heat of the day, and frequently refreshed with water, which is a sure method to bring up the plants: but where this is not practised, the seeds often fail, or remain long in the ground. When the plants come up, they will require no other care but to be kept clean from weeds, till the beginning of October, when they should be carefully taken up, and planted in a warm border of dry ground. A few of them should be put into pots, that they may be sheltered under a frame in winter; for in severe frosts, those which are exposed to the open air are frequently killed, though in moderate winters they will live abroad without covering.

2. *Bubon Galbanum*; *Lorage-leaved Bubon*. Leaflets ovate, wedge form, acute, finely serrated; umbels few: seeds smooth; stem shrubby, glaucous. It rises with an upright stalk to the height of eight or ten feet. It flowers in August, but has not produced seed in England. When any part of the plant is broken, there issues out a little thin milk of a cream colour, which has a strong scent of Galbanum. The drug called Galbanum is obtained from this, partly by spontaneous exudation from the stem, but more commonly by incision in the stalk a little above the root, from which it immediately flows, and soon becomes sufficiently concreted for gathering. This gum-resin, medically considered, may be said to hold a middle place between assafoetida and ammoniacum, but is far less disagreeable than the former. It has the credit of being highly useful in hysterical cases, and of promoting and correcting various secretions and uterine evacuations. Externally, it has been applied to expedite the suppuration of indolent tumors, and especially as a warm stimulating plaster.—It is a native of the Cape of Good Hope; and to propagate it, the seeds should be sown in pots, filled with light loamy earth, as soon as they arrive; if it happen towards autumn, they should be plunged into a bed of tanner's bark, where the heat is gone, and screened from frost in winter. In the spring the plants will come up, and by the middle of April be fit to remove, when they should be gently shaken out of the pots, taking care not to tear off their roots, and replanted each into a separate small pot, filled with the same earth as before; then plunge the pots into the tan again, and water them to settle the earth to the roots of the plants, and shade them from the sun in the day-time, until they have taken new root; after this they must be aired gradually to bear the open air; into which they should be removed in June, and placed with other exotic plants in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy as much of the sun and air as possible, but defended from frost. They should have but little water given them in winter, for much wet is very injurious to them: in summer, when they are exposed to the open air, they must be often watered in dry weather; but too much watering must be guarded against, as that will rot their roots.

3. *Bubon Gummiiferum*; *Gum-bearing Bubon*. Leaflets gashed, acuminate, the lower ones broader; seeds smooth; stem shrubby. It rises with a woody stalk about two feet high, with leaves at each joint, branching out like those of the preceding species, but the leaflets are narrow, and indented like those of Bastard Hemlock. The stalk is terminated by a large umbel of small white flowers.—It is a native of the

Cape of Good Hope, and must be propagated in the same manner as the preceding species; which see. In hot summers it will perfect its seeds, if it stand in a warm sheltered situation.

4. *Bubon Rigidus*; *Stiff-leaved Bubon*. Leaflets linear. This is a low perennial plant, having short stiff leaves, which are very narrow. Stem about a foot and a half high, cylindrical, striated, but little branched; flowers yellow, in loose umbels.—Native of Sicily.

5. *Bubon Lævigatum*; *Smooth Bubon*. Leaflets lanceolate, very obtusely and obscurely crenated; seeds smooth; stem shrubby.—Native of the Cape of Good Hope: it flowers from December to February.

Bubroma; a genus of the class Polyadelphia, order Dodecandria.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets ovate, concave, acute, spreading, deciduous, two a little larger than the rest. *Corolla*: petals five; claws large, narrow at the base, vaulted, helmet-concave, inflex at the tip, beaked, emarginate, converging, inserted into the nectary at the base; borders semibifid, with linear spreading segments; nectary, a bell-shaped pitcher, divided into five, equal, lanceolate-sharp, minute, upright segments, spreading a little at the tip. *Stamina*: filamenta five, filiform, upright, bent outwards at the tip, outwardly fastened to the nectary, alternate with its segments and a little shorter, trifid at the tip; the divisions very short; antheræ, on each filamenta three, two at the tip on each side, the third a little lower, each placed on one of the divisions of the filamenta; the cells margined. *Pistil*: germen superior, roundish, hispid; style filiform, almost the length of the stamina; stigma simple. *Pericarp*: capsule subglobular, woody, muricated all round with club-shaped tubercles, terminated by a five-rayed leafy star, punched with a tenfold row of little transverse dots, five-celled, valveless, not opening; partitions woody, fibrous; cells covered on the inside with a thin membrane. *Seed*: very many, angular, fixed in a double row to a central subglobular receptacle. ESSENTIAL CHARACTER. *Calix*: three-leaved. *Petals*: five, arched, semibifid. *Antheræ*: on each filament three. *Stigma*: simple. *Capsule*: muricate, ending in a five-rayed star, punched with holes, five-celled, valveless, not opening.—The only known species is,

1. *Bubroma Guazuma*; *Elm-leaved Bubroma*, or *Bastard Cedar*. This tree rises to the height of forty or fifty feet in the West Indies; having a trunk as large as a middling-sized man's body; covered with a dark-brown furrowed bark, sending out many branches towards the top, which spread out wide every way. According to Linneus, this tree sleeps with the leaves hanging quite down, whilst the petioles remain entirely stiff and straight. From its similitude to the Elm, the French call it *orme d'Amerique*, and *bois d'orme*. In Jamaica it is known by the name of *Bastard Cedar*, and is peculiar to the low lands there, forming a very agreeable shade for the cattle, and supplying them with food in dry seasons, when all the herbage is burned up, or exhausted. The seeds are very mucilaginous, but otherwise agreeable to the palate. The wood is light, and so easily wrought, that it is generally used by coach-makers in Jamaica in all the side-pieces. It is also frequently cut into staves for casks. A decoction of the inner bark is very glutinous, and very like that of the Elm; it is said to be excellent in the elephantiasis, a disorder to which the poor negroes are greatly subject. It flowers here in August and September.—To propagate this tree, sow the seed on a good hot-bed in the spring, and when the plants are fit to remove, plant them each in a separate small pot, and plunge them into a hot-bed of tanner's bark, observing to shade them from the sun till they have taken new root; they then should be

treated in the same way as the Coffee-tree, keeping them always in the tan-bed in the stove.

Buchnera; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth, one-leaved, obscurely five-toothed, scabrous, permanent. *Corolla*: monopetalous: tube very long, filiform, bowed; border flat, short, five-cleft, equal; the two upper divisions very short, reflex; the three lower cordate, nearly equal. *Stamina*: filamenta four, very short, in the throat of the corolla; the two upper ones prominent, outward, short; antheræ oblong, obtuse. *Pistil*: germen ovate-oblong; style filiform, the length of the tube; stigma obtuse. *Pericarp*: capsule acuminate, covered, two-celled, gaping at the top into two parts, partition contrary. *Seeds*: numerous, angular. *Receptacle*: fastened to the middle of the partition. ESSENTIAL CHARACTER. *Calix*: obscurely five-toothed. *Corolla*: border five-cleft, equal; lobes cordate. *Capsule*: two-celled.—The species are,

1. *Buchnera Americana*; *North American Buchnera*. Leaves toothed, lanceolate, three-nerved; stem scarcely branching; flowers in a spike.—This herb grows black in drying. It is hardy, and a native of Virginia and Canada.

2. *Buchnera Cernua*; *Drooping Buchnera*. Leaves wedged, five-toothed, smooth; flowers spiked; stem shrubby.—Native of the Cape of Good Hope, requiring the protection of the dry stove, conservatory, or glass-case.

3. *Buchnera Cuneifolia*; *Wedge-leaved Buchnera*. Leaves wedge-form, smooth, seven-toothed at the end.—Native of the Cape of Good Hope; to be propagated in the same way as the other Cape plants.

4. *Buchnera Cordifolia*; *Heart-leaved Buchnera*. Stem four-cornered; leaves opposite, cordate, three-nerved, serrate; racemes terminal, subspiked.—Native of the East Indies.

5. *Buchnera Grandiflora*; *Great-flowered Buchnera*. Scabrous; leaves opposite, sessile, oblong, entire; peduncles axillary, one-flowered, two-leaved; calix funnel-form. This is a very beautiful plant, with an upright, smooth, and very simple stem.—It was found in South America by Mutis.

6. *Buchnera Æthiopica*. Leaves three-toothed; flowers peduncled; stem shrubby; calix somewhat hispid. Corolla yellow.—Native of the Cape of Good Hope.

7. *Buchnera Capensis*. Leaves toothed, linear; calices pubescent. Native of the Cape of Good Hope.

8. *Buchnera Asiatica*; *Eastern Buchnera*. Leaves quite entire, linear; calices scabrous. The corolla has a bifid purple border; one of the segments almost upright, and trifid; the other, spreading and widely cordate.—Native of Ceylon and China.

9. *Buchnera Pinnatifida*; *Pinnatifid-leaved Buchnera*. Leaves pinnatifid, smooth.—Found at the Cape of Good Hope by Thunberg.

10. *Buchnera Viscosa*; *Clammy Buchnera*. Leaves linear-lanceolate, loosely toothed, somewhat glutinous; flowers peduncled; stem shrubby. The flowers are purple, with a yellow eye. It does not boast much beauty, but nevertheless occupies little room, and flowers during most of the summer.—Found at the Cape of Good Hope.

11. *Buchnera Elongata*. Leaves entire, opposite; calices somewhat hairy, longer than the fruit.—Native of South America and Jamaica. It must be kept in the bark-stove, if cultivated in England.

Bucida; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-form, obscurely five-toothed, superior, permanent. *Corolla*: none. *Stamina*: filamenta ten, capillary, inserted into the base of the calix, and longer than it; antheræ

cordate, erect. *Pistil*: germen inferior, ovate; style filiform the length of the stamina; stigma obtuse. *Pericarp*: berry dry, ovate, one celled, crowned with the calix. *Seed*: one, ovate. ESSENTIAL CHARACTER. *Calix*: five-toothed, superior. *Corolla*: none. *Berry*: one-seeded.—The only known species is,

1. *Bucida Buceras*; *Olive Bark Tree*. Brown observes, that this tree is remarkable for its slender crooked branches, and the tufted disposition of the leaves; that it grows to a considerable size, twenty to thirty feet in height, and one in diameter; is reckoned an excellent timber tree, and the bark is greatly esteemed by the tanners. It is a native of the West Indies, in low swampy clayey lands near the coast, flowering in spring: in Jamaica it is called *Black Olive*; in Antigua, *French Oak*; and in the French islands, *Grignon*.

Buckbean. See *Menyanthes*.

Buckler Mustard. See *Biscutella* and *Clypeola*.

Buckthorn. See *Rhamnus*.

Buckwheat. See *Polygonum*.

Budding. See *Inoculating*.

Buddlea; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, four-cleft, acute, erect, permanent. *Corolla*: monopetalous, bell-form, four cleft half way, erect, three times greater than the calix; divisions ovate, straight, acute. *Stamina*: filamenta four, very short, placed at the divisions of the corolla; antheræ very short, simple. *Pistil*: germen ovate, style simple, shorter by half than the corolla; stigma obtuse. *Pericarp*: capsule ovate, oblong, two-furrowed, two-celled. *Seeds*: numerous, extremely minute, adhering to a fungous receptacle. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Corolla*: four-cleft. *Stamina*: from the divisions. *Capsule*: two-furrowed, two-celled, many-seeded.—The species are,

1. *Buddlea Americana*; *Long-spiked Buddlea*. This is a shrub, about the height of a man, branched, and all over hoary; the leaves ovate, lanceolate, opposite, serrate; the flowers in long slender spikes, axillary and terminating.—Native of the West Indies. Brown informs us, that it is used in emollient baths and fomentations, and is thought to have all the properties of the Mullein.—It is propagated by seeds, which should be brought over in their capsules or pods; for those which are taken out before they are sent, seldom grow. They must be sown in small pots filled with light rich earth, and very lightly covered; for as these seeds are very small, if they are buried deep, they perish. The pots should be plunged into a moderate hot-bed, and every third or fourth day must be gently watered, being very careful not to wash the seeds out of the ground by too hastily watering them. If the seeds be fresh and good, the plants will come up in about six weeks, provided they are sown in the spring; and if they grow kindly, will be large enough to transplant in four months after; they then should be carefully separated, and each planted into a small pot filled with light rich earth, and plunged into the hot-bed again, observing to shade them from the sun until they have taken new root, as also to refresh them with water when they require it. After the plants have again struck root in these pots, there should be fresh air admitted to them every day, in proportion to the warmth of the season; they must also be frequently but moderately refreshed with water. If the plants thrive well, they will have filled these small pots with their roots by the middle of August, at which time it will be proper to shift them into pots one size larger, that they may have time to take good root again before the cold weather comes on. When these are potted, the tan should be turned over, to

renew the heat; and if it is wanted, some fresh tan must be added to the bed, to encourage the roots of the plants. In this bed they may remain, till autumn, when they must be removed into the stove, and plunged into the tan-bed, where they must constantly remain, for they are too tender to thrive in this country if they are not so treated. During the winter they must have but little water, and should be kept warm; but in summer they should have fresh air admitted to them constantly when the weather is warm, and frequently sprinkled all over with water: with this management the plants will flower the fourth year from seeds, and continue to do so every year after, and will make a good appearance in the stove.

2. *Buddlea Occidentalis*; *Spear-leaved Buddlea*. Leaves lanceolate. This sort rises much taller than the first, and divides into a great number of branches, covered with a russet hairy bark.—Grows naturally in gullies, or other low sheltered spots, in the West Indies, the branches, being too tender to resist the force of strong winds, are rarely seen in open situations. For its culture, see the first species.

3. *Buddlea Virgata*. Leaves linear, oblong, obtuse, entire; racemes terminal; branches wand-like, erect; and leaves hoary with a fine down. This has the habit of *Hysop*.—Native of the Cape of Good Hope.

4. *Buddlea Incompta*. Leaves fascicled, ovate, hoary; branches flexuose, rigid; racemes terminal.—Native of the Cape of Good Hope.

5. *Buddlea Globosa*; *Round-headed Buddlea*. Leaves lanceolate; heads solitary. A branched evergreen shrub, eight to ten feet high.—Native of Chili; flowering in May and June. This, and the sixth species, may be propagated by cuttings, on an old hot-bed, in July, covered with a bell or hand glass, and shaded from the sun; in a month they will have taken root, and may then be planted in pots, placed in the shade, till they have taken fresh root, when they should be removed to a sheltered situation till the winter; and then they must be preserved in the conservatory or dry stove. The fifth will flower well, and live through a mild winter in an open border, provided it be in a warm sheltered situation.

6. *Buddlea Salvifolia*; *Sage-leaved Buddlea*. Leaves lanceolate, ovate, cordate, wrinkled. A shrub, five or six feet high, with tomentose four-cornered branches.—Native of the Cape, flowering in August and September. See the fifth species.

7. *Buddlea Asiatica*. Leaves lanceolate-linear wrinkled smooth; spikes full; stem suffruticose, three feet high.—Native of Cochin-china.

8. *Buddlea Ternata*. Leaves ternate, acuminate; peduncles one-flowered; stem suffruticose, two feet high, upright, round, branched.—Native of Cochin-china.

Buffonia; a genus of the class Tetrandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved, erect, permanent; leaflets subulate, keeled, with membranaceous edges. *Corolla*: petals four, oval, emarginate, erect, equal, shorter than the calix. *Stamina*: filamenta four, equal, the length of the germen; antheræ twin. *Pistil*: germen ovate, compressed; styles two, the length of the stamina; stigmas simple. *Pericarp*: capsule oval, compressed, one-celled, two-valved. *Seeds*: two, oval, compressed, with a swelling, convex on one side. ESSEN. CHAR. *Calix*: four-leaved. *Corolla*: four-petalled. *Capsule*: one-celled, two-seeded.—The only species is,

1. *Buffonia Tenuifolia*; *Small Buffonia*, or *Bastard Chick-weed*. Root annual, long, slender, firmly fixed, but having few, almost naked, filiform fibres; stem half a foot to a foot in height, upright, round, commonly branched at the base; branches diffused, procumbent; there are also smaller

branches higher up, which are straight, contracted, subdivided; the swelling joints more frequent at bottom, and become very distant towards the top; the internodes are round, where there are no branches, but somewhat angular about the origin of the branches, which are ancipital at the base: they are smooth, and slightly streaked.—Ray first noticed this little plant in England: he also found it near Montpellier. It is found wild in France, Italy, and Spain, and was observed by Mr. Ray on the sea-coast of Lincolnshire, about Boston, and by Mr. Doody on Hounslow Heath. It flowers in May and June.

Bugle. See *Ajuga*.

Bugloss, *Buglossa*, and *Buglossum*. See *Anchusa*, *Asperugo*, *Borago*, *Lythospermum*, *Lycopsis*.

Bugloss, *Viper's*. See *Echium*.

Bulbocodium; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: hexapetalous, funnel-form; claws very long, linear; throat connecting the petals; border erect; petals lanceolate, concave. *Stamina*: filamenta six, subulate, inserted into the claws of the petals; antheræ incumbent. *Pistil*: germen ovate subulate, obtusely three-cornered, superior; style filiform, the length of the stamina; stigmas three, oblong, erect, channelled. *Pericarp*: capsule triangular, acuminate; angles obscure; three-celled. *Seeds*: numerous. ESSEN. CHAR. *Corolla*: funnel-form, hexapetalous, with narrow claws bearing the stamina. *Capsule*: inferior.—The only known species is,

1. *Bulbocodium Vernum*; *Spring-flowering Bulbocodium*. Leaves lanceolate. The bulb or hybernacle, commonly called the root, resembles that of the common *Colchicum* in shape, but is much smaller: it is covered with a dark brown skin. Some time in January, or not later than the middle of February, according to the season, the flower springs up, inclosed within three brownish green leaves, which, opening themselves almost as soon as they are out of the ground, show their buds for flowers within them very white oftentimes before they open far, and also purplish at first appearing. There is frequently only one flower, but never more than two flowers, on a root; they never rise above the leaves, nor the leaves much higher than they, whilst they last; they are smaller than the flowers of *Colchicum*, and are at first of a pale red or deep blue colour; but afterwards change to a bright purple, and continue long in beauty, if the weather be not severe. After the flowers are past, the leaves grow to the length of a man's longest finger, and in the middle of them rises up the seed-vessel, which is smaller, shorter, and harder than that of *Colchicum*, and contains many small round brown seeds.—It is a native of Spain, and also of mountainous situations in Russia. At present it is a rare plant among us, the bulbs not admitting of much increase, and being liable to damage from frost. It is propagated by offsets, like other bulbous-rooted flowers. The time to remove them, is soon after the leaves decay, but the roots may be kept out of the ground two months without prejudice at that season: they should not be removed oftener than every third year, for the roots do not multiply very fast; by suffering them, therefore, to remain, they will flower much stronger, and make a greater increase, than if they are often taken up. It should have a warm situation, and may be planted in a south border, in a fresh loamy soil but not dunged. It may also be propagated by seeds, which should be sown in pots filled with fresh loamy earth, in September; and the latter end of October the pots should be placed under a frame, to protect them from severe frost; in the spring the plants will appear, when they may be removed out of the frame, and placed where they may have the morning sun, but screened from the south. In very

dry weather, they should be refreshed now and then with a little water, while their leaves continue green; but when these decay, the pots should be removed to a shady situation, where they may remain till autumn, observing to keep them clean from weeds. In October, there should be a little fresh earth laid on the surface of the other, and the pots placed in shelter again till the following spring, when they must be treated in the same manner as in the former year until their leaves decay; then the roots should be carefully taken up, and transplanted into the borders of the flower-garden, treating them as the old roots, and in the spring following they will produce their flowers.

Bulrush. See *Scirpus*.

Bumalda; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted almost to the base; divisions ovate, obtuse, concave, a little shorter than the corolla. *Corolla*: five-petalled, petals linear-obovate, inserted into the germen. *Stamina*: filamenta five, inserted into the claws of the petals, filiform, erect, rough with hairs, almost the length of the corolla; antheræ inserted into the back, ovate, twin. *Pistil*: germen superior, conic, villose; styles two, erect, villose, the length of the filamenta; stigmas simple, headed, truncate. *Pericarp*: seems to be a two-celled capsule. *Seeds*: not ascertained. ESSENTIAL CHARACTER. *Corolla*: five-petalled. *Styles*: villose; capsule two-celled, two-beaked.—The only known species is,

1. *Bumalda Trifolia*. Stem shrubby; branches close, in all parts smooth, obscurely angular, jointed, purple; divisions opposite, filiform, much spreading, leafy; leaves opposite, petioled, ternate; leaves ovate, acuminate, finely serrate, pale underneath, on very short capillary petioles, spreading very much, or reflex; flowers terminating the branches in racemes, on capillary peduncles.—Native of Japan.

Bumelia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leafed; leaflets roundish-ovate, incumbent, concave. *Corolla*: one-petalled, five-cleft, or five-parted; tube very short, round; border five-parted; parts ovate, entire, spreading, concave, with two little scales at the base of each; nectary five-leafed; segments smaller than the corolla, at the base of the filamenta, surrounding the germen, acute. *Stamina*: filamenta five, inserted into the corolla, at the bottom of the tube, between the lower segments, the length of the tube; antheræ ovate, erect. *Pistil*: germen superior, ovate; style thick, erect, shorter than the stamina; stigma obtuse. *Pericarp*: drupe oval. *Seed*: kernel single, oblong, smooth, with a lateral scar. ESSENTIAL CHARACTER. *Corolla*: five-cleft, with a five-leafed nectary. *Drupe*: one-seeded.—The species are,

1. *Bumelia Nigra*; *Bastard Bully-tree*. Branches wand-like, spreading; leaves terminating, oblong-lanceolate, smooth, waved about the edge; branchlets flower-bearing; fruit small, smooth.—Native of Jamaica.

2. *Bumelia Pallida*; *Pale Bumelia*. Branches upright; leaves terminating, elliptic, obtuse; flowers crowded, lateral.—Native of Jamaica.

3. *Bumelia Retusa*; *Mountain Bastard Bully-tree*. Leaves opposite, wedge-ovate, obtuse, rigid; flowers crowded, axillary; fruit small, smooth.—Native of the West Indies.

4. *Bumelia Montana*; *Mountain Bumelia*. Leaves scattered, alternate, oblong, obtuse; flowers axillary, peduncled.—Native of Jamaica.

5. *Bumelia Salicifolia*; *Willow-leaved Bumelia*. Leaves lanceolate-ovate, acuminate; flowers crowded, axillary, and lateral. See *Achras Salicifolia*.

6. *Bumelia Rotundifolia*; *Round-leaved Bumelia*. Leaves suborbiculate, margined, veined, coriaceous, smooth on both sides.—Native of the West Indies.

7. *Bumelia Pentagona*; *Pentagon-fruited Bumelia*. Leaves lanceolate, acuminate, shining; flowers axillary; drupes five-cornered.—Native of the island of St. Vincent.

Bunias; a genus of the class Tetradymania, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leafed; leaflets ovate-oblong, spreading deciduous. *Corolla*: tetrapetalous, cruciform; petals obovate, twice as long as the calix; claws attenuated, erect. *Stamina*: filamenta six, the length of the calix; of which two opposite a little shorter. Antheræ erect, bifid at the base. *Pistil*: germen oblong; style none; stigma obtuse. *Pericarp*: silicle irregular, ovate-oblong, four-sided, the angles with an acumen or two, not bursting, deciduous. *Seeds*: few, one under each acumen of the silicle, roundish. ESSENTIAL CHARACTER. *Silicle*: deciduous, four-sided, muricated with unequal acuminate angles.—These plants are all propagated by seed, to be sown where they are designed to remain, either in April or in autumn. When the plants come up, they should be thinned to the distance of one foot from each other; and after that they will require no other care, but to keep them clean from weeds. They are all hardy enough to flower in the open air, but some of them will scarcely perfect their seeds unless they be sown in the autumn.—The species are,

1. *Bunias Cornuta*; *Horned Bunias*. Silicles divaricate, two-horned, spiny at the base. This is a very singular plant: it has a silicle transversely oval, finishing on each side in a horn, or very long and strong spine, so that the silicle resembles a pair of horns; in the middle of the silicle are four small spines, directed different ways.—Native of the Levant and Siberia.

2. *Bunias Spinosa*; *Thorny Bunias*. Raceme spinescent. This is an annual plant. Stems a foot high, upright, branching, subdivided, round, rushy, very smooth and even, green; leaves ovate-oblong, blunt, petioled.—Native of the Levant.

3. *Bunias Erucaeo*; *Prickly-podded Bunias*. Silicles four-cornered; angles two-crested. This is also an annual plant, sending out many branches, which spread, and incline towards the ground. The leaves are glaucous, and deeply divided into many segments, almost like those of Swine's cress. The flowers are produced singly from the axils of the leaves, towards the extremity of the branches, they are small, and of a pale yellowish colour.—Native of the south of France, Switzerland, Austria, and Italy.

4. *Bunias Orientalis*; *Oriental Bunias*. Silicles ovate, gibbose, warted; root perennial, with an annual stalk.—It grows naturally in the Levant, and flowers from May to July.

5. *Bunias Cochlearioides*; *Scurry-grass Bunias*. Silicles cordate-ovate, even, inflected. It is about two feet high; the root slender, and fibrose at the sides. The corolla is white and veiny.—Found in low meadows near the river Jaik.

6. *Bunias Cakile*; *Sea Rocket*. Silicles ovate, even, ancipital. It is a smooth, annual, glaucous plant, with a saltish taste; root slender, woody, running deep into the sand; stem woody, about a foot high, with widely divaricating branches; leaves oblong-wedge-shaped, deeply cut, thick and succulent; flowers in short spikes or clusters, pale red, or purple; pods short, but large and fleshy, two-celled, with one or two roundish seeds in each.—It is a native of the sea-coast, in many parts of Europe, and North America: with us, on the coast of Norfolk, Suffolk, Scotland, and Ireland, in deep sand, frequently near high-water mark: flowering in June and July.

7. *Bunias Myagroides*; *Myagrum-like Bunias*. Silicles two-jointed, ancipital, torulose above; leaves pinnate, with

reflected sinuses; root annual; stem straight, two feet high, even, irregularly branched; racemes terminal, long, straight; flowers subsessile; calix oblong, closed; petals quite entire, pale purple, antheræ yellow; style ensiform.—Native of Siberia.

8. *Bunias Ægyptiaca*; *Egyptian Bunias*. Silicles four-cornered, wart-muricate on every side; leaves runcinate; root annual; stem a foot high, hispid at bottom, smooth at the top; flowers pedicelled; calix yellowish.—Native of Egypt. Flowering in August.

9. *Bunias Balearica*: *Minorca Bunias*. Silicles hispid; leaves pinnate; leaflets slightly toothed; root annual; stem a foot high, very much branched, spreading, angular, even; corolla yellow; petals oblong, obtuse, the length of the calix.—Native of Majorca and Minorca.

Bunium; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal, manifold, with rays fewer than twenty; partial, very short, crowded; involucre universal, many-leaved, linear, short; partial setaceous, the length of the umbellule; perianth proper scarcely apparent. *Corolla*: universal uniform; floscules all fertile; proper of five, inflex cordate, equal petals. *Stamina*: filamenta five, shorter than the corolla, simple; antheræ simple. *Pistil*: germen oblong, inferior; styles two, reflex; stigmas obtuse. *Pericarp*: none; fruit ovate, bipartite. *Seeds*: two, ovate, convex on one side, flat on the other. ESSENTIAL CHARACTER. *Corolla*: uniform; umbel crowded; fruits ovate.—The only known species is,

1. *Bunium Bulbocastanum*; *Earth Nut*, or *Pig Nut*. Root perennial, tuberous, on the outside of a Chestnut colour, within white, solid, putting forth slender fibres from the sides and bottom, of an agreeable sweetish taste, lying deep in the ground; stem from one to two feet high, upright, round, stiffish, the thickness of a crow-quill, slightly striated, smooth throughout of a green colour and branched; radical leaves on long petioles; stem leaves sessile, all very finely divided, deep green, the folioles edged with prickly hairs, visible only by a glass; sheath short, grooved, smooth, the edge membranous and whitish; umbels several; universal rays from seven to twelve; partial about twelve; universal and partial involucre, often wanting; filamenta longer than the corolla, deciduous; styles white, nearly upright; seeds oblong-ovate, smooth, and somewhat aromatic. The root commonly grows four or five inches deep in the earth.—This plant has several names in English besides the two given above: as, *Kipper-nut*, *Hawk-nut*, *Jur-nut* or *Yer-nut*, *Earth chestnut*, and *Ground-nut*. In German, it is called *erdnuss*; in Dutch, *aardnoot*; in Swedish, *jordnot*; in Danish, *jordol-den*; in French, *suron*, *terre-noix*; in Italian, *castagna di terra*; in Spanish, *castano di tierra*; in Portuguese, *castanha de terra*. In England it grows on heaths, in pastures, woods, and among bushes, in a gravelly or sandy soil. Foreign authors, as Haller, Pollich, &c. say, that it grows among corn. It flowers in May and June. The roots are frequently dug up, and are eaten raw by the poorer sort of people. Swine are very fond of them, and will soon become fat by feeding upon them. When boiled, they are very pleasant and delicious, and are supposed to afford great nourishment. They are said to be thus prepared and eaten in Holland, in the Alps, and in some parts of England, in soup or broth. Roasted, they are little inferior to Chestnuts, and might be no disagreeable addition to our winter deserts. The knobbed root, and finely divided leaves, so distinguish this plant from all the poisonous species of the umbellate tribe, that it can hardly be mistaken, especially if the place of growth be attended to. *Oenanthe fistulosa*, indeed, when thrown out on ditch-banks, or cultivated in a garden, has roots so much resembling those

of *Bunium*, that it may deceive even good judges: but this is a water plant, and it ought to be remembered, that all aquatics of this tribe are of a suspicious character.

Buphthalmum; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common, various in the different species, imbricate. *Corolla*: compound radiated; corollules hermaphrodite, numerous, forming a flat disk; females more than ten in the ray; proper of the hermaphrodite funnel form, with a five-angled patulous border: of the female, ligulate, longer, spreading, three-toothed. *Stamina*: of the hermaphrodite, filamenta five, capillary, very short; antheræ tubular, cylindrical. *Pistil*: of the hermaphrodite; germen ovate, compressed; style filiform, the length of the stamina stigma thickish, either simple or bifid: of the female, germen, anticlinal; style filiform, of the same length as in the hermaphrodite; stigmas two, oblong. *Pericarp*: none; calix unchanged. *Seeds*: of the hermaphrodite solitary, oblong, crowned with a gashed manifold edge: of the females, solitary, compressed, with each edge cutting, crowned like the others. *Receptacle*: chaffy, convex. ESSENTIAL CHARACTER.—Stigma of the hermaphrodite, floscules undivided. *Seeds*: the sides, especially in the ray, edged. *Down*: an obscure edge. *Receptacle*: chaffy.—The species are,

† *Asterisci* of *Tournefort*.

1. *Buphthalmum Frutescens*; *Shrubby Ox-eye*. Leaves opposite, lanceolate; petioles two-toothed, stem shrubby. It rises with several woody stems from the root, and grows to the height of eight or ten feet, furnished with leaves very unequal in size, some of which are narrow and long, others are broad and obtuse; these are intermixed, sometimes coming out at the same joint, and often at the intermediate one; they are soft, hoary, and placed opposite. The foot-stalks of the larger leaves have, on their upper side, near their base, two sharp teeth standing upwards, and a little higher there are generally two or three more, growing on the edge of the leaves. The flowers are produced at the end of the branches, single; these are of a pale yellow colour, and have scaly calices.—It grows naturally in America; and is also a native of Jamaica, where it grows only near the sea-side, in a bushy tufted form, seldom rising above two or three feet in height.—Neither this, nor the second species, will perfect their seeds in this country; they are therefore propagated by cuttings. They should be planted in July, when the plants have been for some time exposed to the open air, whereby their shoots will be hardened, and better prepared to keep root than when they first come abroad. The cuttings should be planted in small pots filled with light loamy earth, and plunged into a very gentle warmth, observing to shade them from the sun in the heat of the day, and gently refresh them with water; but it must be given to them sparingly, for much wet will rot them. In about six weeks these will have taken root, when they must be gradually inured to bear the open air; and soon after they should be each planted in a separate small pot, filled with light loamy earth, and placed in the shade until they have taken fresh root; after which they may be removed to a sheltered situation, where they may remain until the middle of October, when they must be removed into the green-house. The first species being harder than the other, may be placed in a common green-house, but the other will thrive better in a warm glass-case, where it will receive more sun, and have a dryer air. During the winter, they should have but little moisture, and in very mild weather should have fresh air admitted to them. In the summer they must be placed abroad in a sheltered situation, and treated in the same manner as other exotic plants.

2. *Bupththalmum Arborescens*; *Tree Ox-eye*. Leaves opposite, lanceolate, tomentose on both sides, toothless, quite entire; stem shrubby. This seldom grows more than three feet high, sending out many succulent stalks from the root. The flowers are produced at the end of the branches upon footstalks two inches long, and are larger than those of the first species, and of a bright yellow colour. They appear in July, August, and September, but often continue till the end of October.—Native of the Bermudas. For its propagation and culture, see the first species.

3. *Bupththalmum Sericeum*; *Silky Ox-eye*. Leaves scattered, wedge-shaped, acute, quite entire, villose-silky; branches thick, woody, covered with scars left by the falling leaves; flowers terminating, large and yellow.—Found in Fuerteventura, one of the Canary Islands; flowering from May to July.

4. *Bupththalmum Spinosum*; *Prickly Ox-eye*. Calices acutely leafy; leaves alternate, lanceolate, stem-clasping, quite entire. This is an annual plant. The ray of the corolla is manifold, and very slender; it is of a bright yellow colour; the disk is of a gold colour. The flowers appear from June to August, and the seeds ripen in September.—It is a native of the south of France, Spain, and Italy, on the borders of fields, and on ditch-banks. The leaves were formerly used in medicine. In Arragon it is called *cevadilla*, from its quality of exciting sneezing.—The seeds of this, and of the fifth species, should be sown in the beginning of April, on open borders, where they are to remain, and will require no other care but to keep them clear of weeds, and thin them to the distance of a foot and a half, that their branches may have room to spread. If the seeds be sown in the autumn, or be permitted to scatter when ripe, the plants will come up soon after, and these will more certainly ripen than the spring plants.

5. *Bupththalmum Aquaticum*; *Sweet-scented Ox-eye*. Calices obtusely leafy, sessile, axillary; leaves alternate, oblong, obtuse; stem herbaceous. This is also an annual; seldom growing more than a foot high in gardens, and, where it is wild, not so high: it sends out many alternate spreading branches near the root; the leaves are hairy and sessile; the flowers, which are sessile in the forks of the stem, have an agreeable odour.—Native of the south of Europe. It flowers in July and August. For the mode of propagating it, see the fourth species.

6. *Bupththalmum Maritimum*; *Sea Ox-eye*. Calices obtusely leafy, peduncled; leaves alternate, spatulate; stem herbaceous. This is a low perennial plant, with a shrubby stalk, rarely rising a foot high, with many spreading branches; leaves hairy, narrow at their base, but broad and roundish at the extremity; flowers yellow. Native of Sicily, flowering from July to September.—This plant seldom produces seed in England, but is easily propagated by slips during the summer season; if the cuttings are planted in a bed of fresh loamy earth, and covered with a hand-glass, observing to shade them from the sun in the heat of the day, and frequently refreshed with water, they will take root in about six weeks, when they should be carefully taken up, and each planted with a separate small pot filled with fresh undunged earth, and placed in a shady situation till they have taken fresh root; after which they may be removed to a sheltered situation until the end of October, when they must be placed under a frame for the winter season; but as they only require protection from hard frost, they will thrive better when they have a great share of air in mild weather, than if confined in the greenhouse; therefore the best method is to place them in a common frame, where they may be fully exposed in mild weather, but screened from the frost.

7. *Bupththalmum Durum*. Leaves alternate, lanceolate, quite entire; stem undershrubby; flowers terminal, solitary.—Native of the Cape of Good Hope.

† *Asteroides* of Tournefort.

8. *Bupththalmum Salicifolium*; *Willow-leaved Ox-eye*. Leaves alternate, lanceolate, subserrate, villose, calices naked; stem herbaceous. The root is perennial; the stem upright, round, a foot or eighteen inches in height, with upright one-flowered branches. It is thought to be the yellow *Aster* of the Italians, the juice of which, when applied to the wounds which a dog had received from the bites of a viper, enabled him to bear them without injury.—Native of Italy, the south of France, Switzerland, Austria, and Carniola. It flowers from June to October.—This, as well as the ninth and eleventh species, may be propagated by parting the roots towards the end of October, when the stalks begin to decay. Those of the eleventh should be removed every other year, to prevent their spreading too far. It is hardy, and will thrive in any situation, but as the roots are apt to extend, it is not proper for the borders of small flower-gardens; but in large borders, on the sides of rural walks, or in spaces between shrubs, it will be ornamental during the season of flowering.

9. *Bupththalmum Grandiflorum*; *Great-flowered Ox-eye*. Leaves alternate, lanceolate, subdentate, smooth; calices naked; stem herbaceous. This is also perennial, with an annual stalk: it grows near two feet high, with slender branching stalks, and oblong smooth leaves ending in a point; the flowers are produced at the extremity of the branches, and are of a bright yellow colour. It flowers in June and July, and the seeds ripen in autumn.—It is a native of Italy, Austria, and the south of France. There are two or three varieties, differing in the breadth of their leaves, and the size of their flowers, but they are all produced from the same seeds. For its propagation and culture, see the eighth species.

10. *Bupththalmum Speciosissimum*. Leaves alternate, stem-clasping, ovate, naked, serrate, subciliate; stem one-flowered; root fusiform, resembling a tuberous one. It grows wild in the mountains about Brixen in the Tyrol, and is perennial. The leaves of this, and those of the ninth species, have a taste somewhat like those of Tea, and may be used instead of them.

11. *Bupththalmum Helianthoides*; *Sunflower-leaved Ox-eye*. Leaves opposite, ovate, serrate, triply-nerved; calices leafy; stem herbaceous. This is a perennial plant, a fathom in height; root branched, whitish, fragrant.—It is a native of North America, and is said to be found wild every where between the tropics. It flowers from July till October.

12. *Bupththalmum Oleraceum*. Calicines leaflets acute, connected laterally; leaves opposite, lanceolate, curved back; stem herbaceous, two feet high, upright, round, whitish, smooth, branched; leaves linear, lanceolate, unequally toothed, smooth, juicy, thick, ash-coloured; flower large, solitary; calix hemispherical, with sharp leaflets, connected by a lateral membrane; disk of the corolla flat, with yellow florets; ray wide, spreading, with many white trifid florets; receptacle flattish, with very small chaffs; crown of the seeds margined; the stigma in the hermaphrodite flowers is simple.—It is an odorous plant, cultivated as a potherb in the gardens of China and Cochinchina.

Bupleurum; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal, with fewer than ten rays; partial with scarcely ten rays, erect-expanding; involucre universal, many-leaved; partial five-leaved, larger; leaflets expanding, ovate, acute. *Perianth proper*: obscure. *Corolla*: universal uniform; floscules all

fertile; proper, of five involuted, entire, very short petals. *Stamina*: filamenta five, simple; antheræ roundish. *Pistil*: germen inferior; styles two, reflected, small; stigmas very small. *Pericarp*: none; fruit roundish, compressed, striated, splitting in two. *Seeds*: two, ovate-oblong, convex and striated on one side, flat on the other. **ESSENTIAL CHARACTER.** *Involucres* of the umbellule larger, five-leaved. *Petals*: involuted. *Fruit*: roundish, compressed, striated.—The *Bupleurums* in general are cultivated only in botanic gardens. The seeds should be sown in Autumn, wherever the plants are designed to remain, for they do not bear transplanting well. To keep them clean from weeds, is all the culture they require.—The species are,

* *Herbaceous.*

1. *Bupleurum Rotundifolium*; *Common Thorough-wax*. Universal involucres, none; leaves, or rather stem, perfoliate; root annual, small, and fibrous; stem a foot high, upright, round, and alternately branched; leaves smooth, bluish-green, alternate, ovate, quite entire. Our common or round-leaved Hare's-ear, is known in England by the name of *Thorough-wax*, from the singular circumstance of the stalk waxing or growing through the leaf; which alone may serve to distinguish this plant, it being the only one, (as Ray observes,) among our indigenous herbs, which has a simple leaf perforated by the stem. Every part of the plant is remarkably hard and rigid, and has a slightly aromatic smell. It had the reputation formerly of being a vulnerary herb; but this is a quality which no medicine can have, any otherwise than as a tonic, strengthening the constitution; nor can any external application be specifically healing or consolidating, or be useful in any other way, except as a defence from the air. Country people make use of the leaves externally, against wounds and bruises; and the seeds inwardly, to prevent the bad effect of inward hurts. Culpeper says, the decoction of the herb, or powder of the dried herb, taken inwardly, and the same or the leaves bruised, and applied outwardly, is singularly good for all ruptures and burstings, especially in children before they be too old.—Native of most parts of Europe, from Britain southward, as a weed among corn. With us it is not very common. It has, however, been found near Lewisham and Dartford, between Queenhithe and Stone in Kent, and Harefield in Middlesex. It appears in tolerable plenty in several fields in Cambridgeshire, and was observed near Faversham by Mr. Ray, nearly a century and a half ago. Since that time, it has been remarked on the lower road to Gogmagog-hills, by Linton, and near Klingston wood. Mr. Crow has found it near Marham in Norfolk; Mr. Woodward at Carby, between Stamford and Bourn in Lincolnshire. It is plentiful in many parts of Kent; and between Farningham and Ainsford, it grows in great quantity in the corn-fields. Dr. John Sibthorp marks it as growing about South Leigh and Middleton Stony in Oxfordshire. It grows near Epsom, Sutton, and Leatherhead, in Surry. It has been noticed in the neighbourhood of Leeds in Yorkshire, but always among Beans. A dry calcareous soil suits it best. Martyn says, he has never observed it except among wheat. It flowers in June and July.

2. *Bupleurum Stellatum*; *Starry Hare's Ear*. Involucels united; universal involucre three-leaved; root perennial; stem a foot or eighteen inches high.—Native of the alps of Switzerland, and Dauphiny. It flowers from May to July.

3. *Bupleurum Petrarum*; *Rock Hare's Ear*. Involucels united; universal involucre five-leaved; root perennial; root-leaves very numerous, long, narrow, and tender, like those of the most delicate grasses, spreading on the ground. It is a native of Switzerland, Monte Baldo, and the South of France; and flowers from May to July.

4. *Bupleurum Angulosum*; *Angular-leaved Hare's Ear*. Involucels five-leaved, orbiculate; universal involucre three-leaved, ovate; leaves stem-clasping; cordate, lanceolate.—This sort is large, being eighteen inches high, and is easily known by its horned involucres.—It is a native of Switzerland, and flowers from May to July.

5. *Bupleurum Longifolium*; *Long-leaved Hare's Ear*. Involucels five-leaved, ovate; universal involucre; with about five leaflets; leaves stem-clasping. This closely resembles the first species; but the root is perennial, and the root-leaves are permanent, and more lengthened out.—Native of Germany, Flanders, Switzerland, Dauphiny, and Savoy; flowering from May to July. The fresh-gathered leaves are a good application to green wounds, which they speedily heal without any other assistance; the method of using them is as follows: take three or four of the leaves, and, after closing the lips of the wound, lay them one over the other, and secure them with a linen bandage for the space of three or four days; at the end of which time, in most cases, the cure will be effected, and nothing but a scar will be found remaining. It is likewise supposed to possess considerable efficacy in serofulous complaints, but is not altogether to be depended on for the cure of a disorder which frequently sets the most powerful medicines at defiance. This herb has always been included among the vulnerary plants.

6. *Bupleurum Falcatum*; *Twisted-stalk Hare's Ear*. Involucels five-leaved, acute; universal involucre, with about five leaflets; leaves lanceolate; stem flexuose; root perennial; flowers small, deep yellow.—Native of Germany, Switzerland, Austria, the south of France, and Italy. It flowers in our gardens from May to September.

7. *Bupleurum Odontites*; *Narrow-leaved Hare's Ear*. Involucels five-leaved, acute; universal involucre three-leaved, the central floscules higher; branches divaricated, root annual.—Native of the south of France, Switzerland, Carniola, Spain, and Italy. It flowers from June till August.

8. *Bupleurum Semicompositum*; *Dwarf Hare's Ear*. Umbels compound and simple. Stem scarcely a span high; branches divaricate; leaves lanceolate. The petals are purplish.—Native of Spain, Montpellier, Villa Franca. Annual; flowering in July and August.

9. *Bupleurum Ranunculoides*. Involucels five-leaved, lanceolate, longer; universal involucre three-leaved; stem-leaves lanceolate. This is commonly a very small plant; not more than a few inches in height; in some situations it is scarcely more than one inch high; in others, it rises to a foot. The root is perennial; the stem simple; the leaves grass-like and stiff.—Native of the south of France, Switzerland, and the Pyrenees.

10. *Bupleurum Rigidum*; *Stiff-leaved Hare's Ear*. Stem dichotomous, almost naked; involucres very small, acute; root perennial.—It grows naturally about Montpellier, and Frankfort-on-the-Maine.

11. *Bupleurum Gerardi*. Stem erect, panicled; leaves lanceolate, linear; involucres and involucels five-leaved; root annual, simple, naked.—Native of Provence and Austria.

12. *Bupleurum Tenuissimum*; *Least Hare's Ear*. Umbels simple, alternate, five-leaved, with about three flowers. This is an annual plant, with the stem a foot high, and much branching; the branches alternate, long, and many-flowered.—Native of Germany, Austria, Switzerland, France, Italy, and England, near Huntingdon, Ellesley, Cambridge, Lynn, Holkham, Malden, Hastings, Pett, in the isle of Thanet, and probably in many more places, being a plant of little appearance or colour, and in a manner lost in the grass among which it grows; it flowers in July and August.

13. *Bupleurum Junceum*; *Linear-leaved Hare's Ear*. Stem erect, panicled; leaves linear; involucre three-leaved; involucres five-leaved; root annual; stem two to six feet high, rushy, of an even surface, with alternate upright branches: the seeds are almost of the size and colour of Parsley.—It is a native of France, Italy, Switzerland, and Germany; it flowers in July and August, and was cultivated in the botanic garden at Chelsea.

14. *Bupleurum Pyrenaicum*. Partial involucre roundish, emarginate, united; universal three-leaved, cut at the base; leaves lanceolate, cordate, embracing the stem.—Native of the Pyrenees.

15. *Bupleurum Nudum*. Stem branched, leafless; root-leaves decomposed, plain, gashed; involucre, universal and partial, lanceolate-oblong; root perennial.—Native of the Cape.

** *Shrubby*.

16. *Bupleurum Fruticosum*; *Common Shrubby Hare's Ear*, or *Shrubby Ethiopian Hartwort*. Leaves obovate, quite entire. It is an evergreen shrub, rising to the height of five or six feet, and dividing into many branches, so as to form a large regular bush; the stem is covered with a purplish bark; the branches are well furnished with oblong, smooth, shining, stiff leaves, of a sea-green colour, placed alternately, four inches long, and one broad in the middle: at the ends of these the flowers are produced in umbels; they are yellow at first, but fade away to a brown; they appear in July or August, but seldom perfect seeds in England.—It is a native of the south of France, Spain, Italy, and the Levant. This is commonly known among gardeners by the name of *Shrubby Ethiopian Hartwort*, and is now propagated in the nursery gardens for sale: being hardy, it will thrive in the open air, and may be intermixed with other evergreen shrubs of the same growth in the front of taller trees, where their stems are designed to be excluded from sight. It is propagated by cuttings, which should be planted in pots filled with fresh loamy earth, and in winter sheltered under a hot-bed frame; in the spring the cuttings will put out roots, but they will not be fit to transplant till the autumn following; so the pots should be placed in a shady situation in summer, and in dry weather they must be refreshed with water the young plants may be placed in a nursery bed at two feet distance, for a year or two, to get strength, and then transplanted where they are to remain.

17. *Bupleurum Frutescens*; *Grass-leaved Shrubby Hare's Ear*. Leaves linear; involucre universal and partial. The leaves of this are sharp and rather fleshy.—It is a native of Spain, and flowers in August and September. This may be cultivated in the same manner as the preceding species, but it is not so hardy.

18. *Bupleurum Difforme*; *Various-leaved Hare's Ear*. Vernal leaves decomposed, flat, gashed; summer ones filiform, angular, trifid. This rises with a shrubby stalk to the height of five or six feet, sending out some side-branches, which in the spring have on their lower parts leaves composed of so many small flat leaflets, finely cut, like those of Coriander, and of a sea-green colour; these leaves soon fall off, and the upper part of the branches is closely covered with long rush-like leaves, having four angles, coming out in clusters from each joint.—It is a native of the Cape of Good Hope, and flowers from June till August. This is also propagated by cuttings, which readily take root, if they are planted in April, in pots filled with light earth, and plunged into a moderate hot-bed; when they have taken root, they should be inured to the open air by degrees, and after they have obtained strength, may be planted each into a separate pot filled with light loamy earth, placing them in the shade till

they have taken fresh root, when they may be placed with other exotic plants in a sheltered situation, where they may remain till the autumn, and then they must be removed into the green-house or dry-stove. If this plant be propagated by seeds, they should be sown in autumn, soon after they are ripe, in pots filled with light earth, which must be sheltered under a frame in winter, and in the spring removed to a very gentle hot-bed; the plants must be inured to the open air by degrees, and then treated in the same manner as those raised from cuttings.

19. *Bupleurum Spinosum*. Branches of the panicle, when old, naked and spinose; leaves linear; root perennial; stem low, shrubby, unequal, streaked, rigid, with very frequent joints; branches divaricate and bent back; root-leaves linear, lanceolate, three-nerved, acute; stem leaves very like them: those on the branches sharper and very short.—Native of Spain. This, as well as the eighteenth and nineteenth species, may be propagated by cuttings, and treated as the sixteenth; or by seeds, when they can be obtained. They will probably bear the open air in mild seasons, but are not yet sufficiently common to run that hazard.

20. *Bupleurum Nudum*; *Naked-stalked Hare's Ear*. Stem branched, leafless; root-leaves decomposed, flat, gashed; involucre and involucres lanceolate-oblong.—Native of the Cape of Good Hope.

21. *Bupleurum Coriaceum*; *Thick-leaved Shrubby Hare's Ear*. Frutescent: leaves lanceolate, coriaceous, oblique; stems upright, sparingly branched, round, dark-coloured, annulated with the scars left by the falling leaves, from three to four feet in height; branches alternate, upright, marked with lines, fistulose, green; leaves alternate, approximating, half stem-clasping, quite entire, cultrate about the edges, with a sharp reflex point, attenuate at the base, having one whitish nerve, glaucous, permanent, five inches long, and nearly an inch broad, when held up to the light, appearing very finely netted. It differs from the common shrubby sort, in the oblique situation of the leaves, and the peduncles being branched. The whole plant is very fragrant when rubbed.—Native of Gibraltar.

Burcardia; a genus of the class Pentandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, externally villose, acute, deciduous. *Corolla*: petals five, roundish, obtuse, spreading, almost the length of the calix. *Stamina*: filamenta five, capillary; antherae ovate. *Pistil*: germen three-cornered; styles five or six long; stigmas flat, broadish, fleshy, with five prominent streaks. *Pericarp*: capsule three-sided, one-celled, three-valved. *Receptacle*: linear, fastened longitudinally to the middle of each valve. *Seed*: seven or eight, subovate, adhering to each receptacle. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-petalled. *Capsule*: angular, one-celled, three-valved, seven or eight seeded.—The only known species is,

1. *Burcardia Villosa*. This is an annual plant, with a branched stem, two feet high, hirsute, with reddish-brown hairs; leaves alternate, subsessile, ovate-oblong, wrinkled, toothed, covered with hairs of the same colour with those on the stem; flowers at the end of the stem and branches, axillary, solitary, on long hairy peduncles; the whole plant, indeed, is covered with stiff hairs. It is found on the sandy coasts of Cayenne and Guiana.

Burdock. See *Arctium* and *Xanthium*.

Burmanna; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth long, oae-leaved, prismatic, coloured, with three longitudinal membranous angles; the mouth trifid, small. *Corolla*: petals

three, ovate, oblong, very small, placed in the mouth of the calix, extremely minute. *Stamina*: filamenta six, very short; antheræ in the mouth of the calix, very short, two always together, separated by a reflected point. *Pistil*: germen cylindric, shorter by half than the calix; style filiform, the length of the corolla; stigmas three, obtuse, concave. *Pericarp*: capsule covered by the calix, cylindric, three-cornered, three-celled, three-valved, gaping at the angles. *Seeds*: numerous, very small. **ESSENTIAL CHARACTER.** *Calix*: prismatic, coloured, trifid; angles membranous. *Petals*: three. *Capsule*: three-celled, straight. *Seeds*: minute.—These plants are very difficult to preserve in gardens; for, as they naturally grow in marshy places, which are covered with water great part of the year, they will not thrive when planted in dry ground, and, being too tender to live abroad in England, they must be planted in pots, plunged in troughs of water, so as to cover the surface of the mould about three inches.—The species are,

1. *Burmannia Disticha*. Spike double; root composed wholly of capillary fibres, and very small. The plant has the appearance or habit of an *Anthericum*; root-leaves six, eight, or nine, grass-like or ensiform, two inches long, quite entire; stem upright, straight, quite simple, a span or a span and a half in height, having six or seven very small, alternate, scale-like leaves, sheathing the base, an inch long, scarcely separating from the stem, but in a manner embracing it; two equal, simple, divaricating spikes, each composed of about nine flowers, terminate the stem. The flowers are sessile, in a single row, pointing upwards; they are blue, very elegant, and do not fall off.—Native of Ceylon, in open watery places; called in that country, *jawæl jawul*, or *dya-jawul*, that is, *water-jawul*.

2. *Burmannia Biflora*. Flowers two together; root strong and fibrous, with several oblong oval leaves arising from it, which are smooth and entire, four or five inches long; among these springs the flower-stem, six or eight inches high, terminated by blue flowers, growing two together in each sheath.—It grows naturally in watery places, in Virginia and Carolina. *Burnet*. See *Poterium*, *Sanguisorba*, and *Pimpinella*. *Bur-reed*. See *Sparganium*.

Bursera; a genus of the class Polygamia, order Dioecia.—**GENERIC CHARACTER.** *Hermaphrodite*. *Calix*: perianth one leaved, minute, three-parted; parts ovate, acute. *Corolla*: petals three, ovate, acute, spreading, entire, deciduous. *Stamina*: filamenta six, subulate, erect, fixed round the base of the germen; antheræ ovate, erect. *Pistil*: germen ovate; style short, thick, trifid at the tip; stigmas very short, simple. *Pericarp*: capsule fleshy, obovate, three-cornered, three-celled, three-valved. *Seeds*: berried, solitary, (commonly only one,) compressed. *Male in a separate tree*. *Calix*: perianth five-toothed, minute. *Corolla*: petals five, lanceolate, acuminate, reflex, shrivelling. *Stamina*: filamenta five, eight, ten, placed round a slightly convex surface, scarcely shorter than the petals, subulate; antheræ oblong, two-celled. *Pistil*: a rudiment; germen none; style trifid, caducous, or none. **ESSENTIAL CHARACTER.** *Hermaphrodite*. *Calix*: three-leaved. *Corolla*: three-petalled. *Capsule*: fleshy, three-valved, one-seeded. *Male*. *Calix*: five-toothed. *Corolla*: five-petalled. *Stamina*: ten.—The species are,

1. *Bursera Gummiifera*; *Jamaica Birch-tree*. This is a very lofty tree, with an upright, round, smooth trunk, covered with a livid shining bark, peeling off in round pieces, like the European Birch; branches terminating, smooth, horizontal; twigs ferruginous and villose; leaves pinnate; petioles round, villose; petiolules compressed, channelled, villose beneath;

flowers small and white; capsule red, resembling a drupe. On the male trees the flowers are more copious and crowded in the racemes, but are scarcely larger. According to Sir Hans Sloane, the roots run very superficially; the trunk is as thick as a hog'shead or pipe; there are four or eight pairs of leaflets, an inch and half long, and half as broad near the round base where broadest; the petals are five in number, thick, yellowish, and short; the berries three-sided, the size of a small pea, with a reddish-brown skin, very gummy, and smelling like turpentine, under which lies a white very hard triangular stone, containing a kernel. The tree having stood naked some time, has first its flowers come out, and its leaves begin to bud a little after.—This tree is common in all the sugar islands of the West Indies; the bark is very thick, and exudes a clear transparent resin, which soon hardens in the air, and looks like the mastic of the shops; but by incision, it yields a considerable quantity of a more fluid substance, which has much of the smell and appearance of turpentine, and may be used for the same purposes. The bark of the root is thought to be the *sima-rouba* of the shops, which is an effectual remedy in bloody fluxes; it is administered in decoctions, and one or two drachms is sufficient for a quart of water; for, if it be strong, it purges or vomits. In the French islands it is called *gommier blanc*; and an infusion of the buds and young leaves is recommended there in disorders of the breast: it flowers from May to July.

2. *Bursera Paniculata*. Racemes panicled, terminal; flowers purple, small, numerous, in panicled terminal racemes, about six inches long. It produces a resinous juice like the preceding.—Native of the isle of France.

3. *Bursera Obtusifolia*. Racemes panicled, subterminal; leaflets obtuse. This is a large tree, very resinous; flowers small, very numerous, whitish; fruit a drupaceous coriaceous berry, the size of a hazel-nut.—Native of the Isle of France.

Butcher's Broom. See *Ruscus Aculatus*.

Butomus; a genus of the class Enneandria, order Hexagynia. **GENERIC CHARACTER.** *Calix*: involucre simple, three-leaved, short. *Corolla*: petals six, roundish, concave, withering; three outer, alternate, smaller, more acute. *Stamina*: filamenta nine, subulate; antheræ bilamellate. *Pistil*: germen six, oblong, acuminate, ending in styles; stigmas simple. *Pericarp*: capsules six, oblong, gradually attenuated, erect, one-valved, gaping on the inside. *Seeds*: very many, oblong-cylindric, obtuse at both ends, fixed to the wall of the capsules. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: six. *Capsule*: six, many-seeded.—The only species hitherto discovered is,

1. *Butomus Umbellatus*; *Flowering Rush*, or *Water Gladiole*. Root perennial; leaves ensiform, long, triangular, smooth, quite entire, spongy, at bottom sheathing, at top flat and twisted; scape upright, round, smooth, from one to three or five and six feet high; corolla handsome, nearly an inch in breadth, commonly of a bright or pale flesh-colour.—It is found in and by the sides of watery ditches, moats, lakes, ponds, and brooks, in most parts of Europe, from Lapland to Italy. It flowers with us from July to September: the corolla varies in different shades of red or purple; mixed with white, and is sometimes entirely white. This is the only plant of the Enneandria class, which grows wild in Britain.—This plant may be propagated in boggy places; or by planting it in cisterns kept filled with water, and having about a foot thickness of earth in the bottom, in which the roots should be planted, or the seeds sown as soon as they are ripe; or on the sides of ponds, or slow-flowing streams; where it will have a good effect in diversifying the scene.

Butterbur. See *Tussilago*.

Butterwort. See *Pinguicula*.

Büttneria; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, deciduous; divisions ovate, acute, spreading very much. *Corolla*: petals five, oblong, short, converging; above, broadish, concave, ending in a long subulate bristle, incumbent on the nectary at the base, then erect, expanding longer than the calix, and in two other small, lateral, short reflex bristles. Nectary five-leaved, ventricose-campanulate, shorter than the calix; leaflets obovate, obtuse, flat, erect, semiconnate by the filamenta. *Stamina*: filamenta five, subulate, on the outside of the nectary, each springing from two adjoining leaflets of it; antheræ twin, distinct, bifid, roundish. *Pistil*: germen roundish, quinquangular; style subulate, short; stigma obtuse, obscurely quinquefid. *Pericarp*: capsule roundish, depressed, five-grained, five-valved, muricate. *Seeds*: solitary, ovate, compressed. ESSENTIAL CHARACTER. *Corolla*: five-petalled. *Filamenta*: at the top, connate with the petals. *Capsule*: five-grained, muricate.—The species are,

1. *Büttneria Scabra*. Leaves lanceolate; rib and petioles prickly. This is a perennial plant, shrubby at bottom, from three to five feet high, with alternate long angular branches, armed with short, reflex, cartilaginous prickles.—Found by Aublet between Cayenne and Couron, in June.

2. *Büttneria Carthaginensis*. Leaves ovate; rib and petioles prickly; stems perennial, rather woody, five-cornered; the furrows and angles obtuse, armed with crooked reflex prickles; the tender branches round, prickly, alternate; flowers without smell, small, white, very numerous.—Native of Carthage and St. Domingo, flowering in September and October.

3. *Büttneria Microphylla*. Branches flexuose, even; leaves ovate, obtuse, on short peduncles. A shrub, four or five feet high: prickles solitary, stipular, horizontal; flowers small, whitish-green, from three to five together.—Found in the island of St. Domingo.

Button-tree. See *Conocarpus*.

Button-weed. See *Spermacoce*.

Button-wood. See *Cephalanthus*.

Buzbaumia; a kind of Moss, of which there are only two species, both of which are to be found in the Dissertation of the younger Linneus on Mosses, p. 25 and 33.

Buxus; a genus of the class Monœcia, order Tetandria.—GENERIC CHARACTER. *Male flowers*, prominent from the buds of the plant. *Calix*: perianth three-leaved; leaflets roundish, obtuse, concave, spreading. *Corolla*: petals two, roundish, concave, very like the calix, but larger. *Stamina*: filamenta four, subulate, erect, expanding, rather larger than the calix; antheræ erect, twin. *Pistil*: rudiment of a germen without style or stigma. *Females*, in the same bud with males. *Calix*: perianth four-leaved; leaflets roundish, obtuse, concave, spreading. *Corolla*: petals three, roundish, concave, very like the calix, but larger. *Pistil*: germen superior, roundish, obtusely three-cornered, ending in three very short permanent styles; stigmas obtuse, hispid. *Pericarp*: capsule coriaceous, roundish, three-beaked, three-celled, bursting elastically into three points. *Seeds*: twin, oblong, rounded on one side, flat on the other. ESSENTIAL CHARACTER. *Male*. *Calix*: three-leaved; petals two; the rudiment of a germen. *Female*. *Calix*: four-leaved; petals three; styles three; capsule three-beaked, three-celled; seeds two.—The only known distinct species, of which there are several varieties, is,

1. *Buxus Sempervirens*; *Evergreen Box*.—Box is well known in its dwarf state, and is a shrub about three feet in

height; it becomes, however, when left to itself, a tree twelve or fifteen feet high, with a trunk equalling the human thigh in thickness, covered with a rugged greyish bark, that of the branches being yellowish. The wood is of a yellow colour, of an even close grain, very hard and ponderous, and is the only kind of European timber which will not swim in water. It is ranked with the Ebony for closeness of grain. The leaves are ovate or oval in the common sort, hard, smooth, glossy, evergreen, very dark green above, pale green underneath, something resembling those of Myrtle, but blunt, and commonly emarginate at the end; the edges are revolute, they are commonly set on very short petioles, and on the twigs they come out regularly in pairs, so close as almost to conceal them. Mr. Miller insists that the Common Box tree, the Narrow-leaved, and the Dwarf or Dutch-Box, are three certainly distinct species. The two sorts of Box-tree have been frequently raised from seeds, and constantly produced plants of the same kind as those the seeds were taken from; and the Dwarf Box will never rise to any considerable height with any culture, nor have I seen this sort flower, where the plants have been encouraged to grow many years in the greatest luxuriance. There are two or three varieties of the first, which are propagated in the gardens: one with yellow, and another with white-striped leaves; the other has the tops of the leaves only marked with yellow, which is called Tipped Box.—The Box-tree is a native of most parts of Europe, from Britain southwards. There are whole mountains covered with it, between Lyons and Geneva, and in Savoy, but not of any size. It is also very common in many parts of Burgundy, Dauphiny, and Provence. It abounds in many countries of Asia, as about Mount Caucasus, in Persia, China, Cochin-china, &c.; also in America. In England it was formerly much more common than it is at present. Gerarde says, "it groweth upon sundry waste and barren hills in England;" and Parkinson, "that it is found with us in many woods, and wood-grounds; that it is also planted in divers orchards, or house back sides, where it never groweth high, but serveth as a bush to dry linen on," &c. Many of these bushes, however, have grown up to trees of a reasonable size, about old mansions and farm-houses, but are now for the most part destroyed. "These trees rise naturally," says Evelyn, "in Kent, at Boxley, and in Surry, giving name to Box-hill. He that in winter should behold some of our highest hills in Surry clad with whole woods of them, for divers miles in circuit, as in those delicious groves of them belonging to the late Sir Adam Brown, of Bechworth-castle, might easily fancy himself transported into some new or enchanted country." The enchantment, alas! has been long broken. In 1759, Mr. Miller lamented that the trees on Box-hill had been then pretty much destroyed, though many of a considerable size still remained: but the destruction since that time has been much greater. It has been conjectured, that Box-hill was planted with these trees by the Earl of Arundel; but there is the most authentic proof that they were there before his time; and the ground on which they grow was not his property. Not only this hill near Darking in Surry, and Boxley in Kent, but Boxwell in Coteswood, Gloucestershire, was named from this tree. Mr. Woodward remarks it "as plentiful on the chalk hills near Dunstable. It is fond of open dry situations, and a calcareous soil. In temperate climates and seasons, it flowers in February and March.—The wood of the Box sells at a high price, by weight. Being very hard and smooth, and not apt to warp, it is well adapted to a variety of nicer works." "It is of special use," says Evelyn, "for the turner, engraver, carver, mathematical-instrument maker, comb and pipe or flute-maker; the roots are also employed

by the inlayer and cabinet-maker. Of Box are made wheels and shivers, pins, pegs for musical instruments, nut-crackers button-moulds, weaver's shuttles, hollar-sticks, bump-sticks and dressers for shoe-makers, rulers, rolling-pins, pestles, mall-balls, beetles, tops, tables, chess-men, screws, bobbins for bone-luce, spoons, knife-handles, nay, the stoutest axle-trees, and especially combs; which was the custom of the ancients, who also made of it musical instruments to be played upon by the mouth, according to Pliny and Martial. The Romans likewise clipped it into the shape of various animals, for which purpose it was second to the Yew with us in former times, but the Dwarf-box stood unrivalled for "bordering up a knot, and was esteemed a marvellous fine ornament to the flower-garden."—The branches were in request among our ancestors, for decking up houses; they are still seen among other evergreens in churches at Christmas, and in some countries they are borne by attendants at funerals. In our plantations, the Box still keeps its place deservedly among ornamental evergreens. It will flourish under the deepest shade, and thrive in any soil and exposure. Dr. Stokes affirms, that it is fit to cut down in about thirty years.—Box has been much celebrated as a medicine in the venereal disease, colics, intermittent fevers, &c. But our shrewd old Gerarde sensibly remarks, "that it is more fit for dagger-hafts, than to make medicines; though foolish empiries and women-leeches do minister it against the apoplexy and such diseases." He adds, "that the turners and cutlers call this wood dudgeon, because they make dudgeon-hafted daggers with it." Parkinson, in his first work, says, "it has no physical use among the most and best physicians, although some have reported it to stay fluxes, and to be as good as guaiacum for the French disease." Yet in his second work he sets it down as a medicine for the bite of a mad dog; as a cure for the bots in horses; and the leaves and saw-dust, boiled in lye, to change the hair to aborne (auburn) or abraham colour. According to Dr. Withering, "an empyreumatic oil, distilled from the shavings, is often used as a topical application for the piles, and seldom fails to procure ease; it will frequently relieve the tooth-ache, and has been given internally in epilepsies: the leaves powdered, destroy worms." Decoctions of the wood and bark are wholly disused, on account of their being very nauseous and disagreeable to the stomach. Meyrick observes, that Box-root is said to possess the same virtues with guaiacum wood, but in a much greater degree; consequently is a good medicine in a foul state of the blood and juices: A decoction of it is the best preparation; but the use of it must be continued for a long time, as it is one of those medicines which operate but slowly, though effectually. An oil distilled from the wood is frequently used to anoint the piles with, and seldom fails of giving ease; it likewise frequently relieves the tooth-ache, cleanses foul ulcers, and disposes them to heal, and is good to rub on such parts as are affected with old aches and pains. Hill assures us, "the wood of the Box-tree, and particularly the root, is an excellent medicine in all foulness of the blood; it has the same virtues with the guaiacum, but in a greater degree. It is to be given in a moderately strong decoction, and continued a long time. There have been instances of what were called leprosies cured entirely by this medicine. There is an oil made from it by distillation, which is good for the tooth-ache; it is to be dropped upon cotton, and put into the tooth." Pliny affirms, that no animal will touch the seed of Box. Gmelin states, that the branches are fatal to the camels that eat them. Not one of our animals will touch this tree. Corsican honey was supposed, by the ancients, to owe its infamy to the bees feeding on the Box.—The name of this tree varies little

from the Greek and Latin, in the European languages; being *bucks* or *bucksbaum* in German; *buxom*, in Swedish and Danish; *buis* or *bonis*, in French; *busso* or *bosso*, in Italian; *box*, in Spanish; *bucho* or *buxo*, in Portuguese: the Russians have adopted *samschit* from the Tartars; the Persians call it *schimschat*; in Turkey it is named *tschemtshir*; the Japanese call it *ko-tsuje*; the Chinese, *huyuh-duong*; the Cochinchinese, *hoam-tuon*.—*Propagation and Culture of the Common Box*. All the varieties of this tree may be propagated by cuttings, planted in autumn in a shady border, observing to keep them watered until they have taken root, when they may be transplanted into the nursery, until they are fit for the purpose intended. These cuttings may be planted as early as August, but the best time is during the fall of the autumnal rains. They should be a foot in length, and rather more than half should be planted in the ground, at the distance of four inches from each other. A slip of the last year's wood, stripped from an older branch, is an excellent set, and there is little fear of its growing. The cuttings or slips may stand three years, and then be transplanted into the nursery any time between August and April, choosing moist weather for the purpose, if this work be performed early or late. In the nursery, the rows may be two feet asunder, and the plants a foot from each other in the rows. The narrow-leaved Box-tree may be propagated by laying down the branches. This may be done between Michaelmas and March; and it is the natural way by which Box frequently propagates itself; for when it breaks down by its own weight, or by a fall of snow, soon after it comes into contact with the ground, it sends forth fibres. Box may be propagated by seeds sown soon after they are ripe, in a shady border, and duly watered in dry weather. This is the best method to raise large trees. The best soil for the seeds is a light loam or sand, and they should be sown half an inch deep. They will come up in the spring, though probably many will lie in the ground till a second season. They should stand two or three years in the seed-bed; and when they are strong enough to plant out, they may be removed into the nursery, and placed at the same distance as was prescribed for the cuttings. The best season for removing this tree is October, though it may be transplanted almost at any time, except in summer, if it be taken up with a good ball of earth. Dwarf-box is increased by parting the roots or planting the slips; but, as it makes so great an increase of itself, and so easily parts, it is hardly worth while to plant the slips that have no roots. It is so common, that it may be purchased from the nurseries at a cheap rate. The manner of planting it in edgings is understood by every working gardener.

Byssus; a genus of the Cryptogamia Algæ, and the last in the scale of vegetation in that class. According to Linneus there are fourteen species, but many more are certainly known. They appear in form of threads, or a kind of meal, on rotten wood, the bark of trees, rocks, damp banks, and walls, especially of damp cellars. Hudson and Withering enumerate nineteen British species, and Lightfoot fourteen. One sort is common on wine-casks; at first it is like flakes of snow, but turns yellow, and at last like a mouse's skin; in this state it has black grains at the base like gunpowder, rots the casks, and is excellent to staunch blood. The Green Paper Byssus is a farina concreting on the surface of the water, where it forms a wide thin film. Weis denies it to be a vegetable, but Withering believes it to be a Conferva.

Bystropogon; a genus of the class Didynamia, order Gymnospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, divided into five awl-shaped segments, closed by a beard at the opening. *Corolla*: monopetalous, ringent;

upper lip bifid, lower trifid, the outmost segment most produced. *Stamina*: filamenta four, didynamous, distant; antheræ incumbent. *Pistil*: germen superior, four-parted: style subulate; stigma bifid. *Pericarp*: none; calix closed with a beard, and cherishing the seeds. *Seeds*: four. **ESSENTIAL CHARACTER.** *Calix*: five-subulate, bearded at the opening. *Corolla*: upper lip bifid, lower trifid. *Stamina*: distant.—As to the culture and propagation of the plants of this genus, the three first sorts must be preserved in the bark-stove; and the four last, in the dry-stove or conservatory. They may all be propagated by cuttings during the summer months.—The species are,

1. *Bystropogon Pectinatum*; *Balm-leaved Bystropogon*. Panicles compact; flowers directed one way; leaves ovate.—Native of Jamaica, in all the low lands and dry savannas about Kingston and Spanish Town. It has also been found in Peru, by Dombey. It flowers in December and January.

2. *Bystropogon Sidæfolium*; *Sida-leaved Bystropogon*. Panicles very loose; peduncles in whorls, filiform; leaves cordate.—Native of Peru.

3. *Bystropogon Suaveolens*; *Sweet-scented Bystropogon*. Peduncles axillary, solitary; calices truncate, awned; leaves cordate. This is an annual plant, the whole of which has a very strong smell, like all the rest of this genus. On this account the Portuguese call it *erva cidreira*, or *citron herb*; and in Jamaica, where it is common about Kingston and Old Harbour, they call it *spikenard*, on account of its strong and pleasant smell. It is one of the most grateful cephalics and alexipharmics; and may be used in disorders of the

nerves and viscera, where such warm medicines are required.—It is a native of the continent of South America, as well as the islands of the West Indies.

4. *Bystropogon Plumosum*; *Woolly-flowered Bystropogon*. Panicles dichotomous; calices feathered; leaves ovate, subserrate, tomentose beneath.—It flowers in June and July, and is a native of the Canary Islands.

5. *Bystropogon Origanifolium*; *Marjoram-leaved Bystropogon*. Panicles dichotomous; calices feathered; leaves ovate, quite entire, very white beneath. This is very nearly allied to the foregoing, but the leaves are quite entire, and snow-white underneath.—Found in the Canary Islands.

6. *Bystropogon Canariense*; *Canary Bystropogon*. Peduncles dichotomous; flowers in heads; leaves ovate, crenate, very villose beneath; stem woody, three or four feet high, dividing into many branches; leaves on long peduncles, hairy, and ash-coloured on their under side. The flowers are produced from the side of the branches, on pretty long peduncles, each sustaining four roundish heads, dividing by pairs, and spreading from each other. They come out in June and July, but do not produce ripe seeds in England. The corolla is white; and the leaves, when bruised, emit an agreeable odour. The gardeners have given it the title of *Madame Maintenon*.—It flowers from June to August, and grows naturally in the Canary Islands.

7. *Bystropogon Punctatum*; *Cluster-flowered Bystropogon*. Panicles dichotomous; flowers in heads; leaves ovate, toothed, smooth, finely dotted.—Flowers from July till September, and is a native of Madeira.

C A B

CABBAGE. See *Brassica*.

Cabbage-tree. See *Aleraca Oleracea*, and *Cacalia Kleinia*.

Cacalia; a genus of the class Syngenesia, order Polygamia Æqualis.—**GENERIC CHARACTER.** *Calix*: common simple, oblong, at the base only subcalicled, cylindric; scales five to ten, equal, lanceolate-linear, forming a tube; a few very short, incumbent on the base. *Corolla*: compound tubular; corollules hermaphrodite, in number the same as the longer leaves of the calix, uniform; proper funnel-form gradually lessening to the tube; border four or five-cleft, erect. *Stamina*: filamenta five, capillary, very short; anthera cylindric, tubular. *Pistil*: germen oblong; style filiform, the length of the stamina; stigmas two, oblong, revolute. *Pericarp*: none; calix unchanged. *Seeds*: solitary, oblong, ovate-narrow. *Down*: capillary, very long. *Receptacle*: naked, flat, dotted. **ESSENTIAL CHARACTER.** *Calix*: cylindric, oblong, at the base only subcalicled. *Down*: capillary. *Receptacle*: naked.—The plants of this genus, which are natives of the Cape of Good Hope, should be propagated by cuttings during the summer months: these should be cut from the plants, and laid to dry a fortnight, that the wound may be healed over before they are planted. Most people plunge the pots, in which these are planted, in a moderate hot-bed, to forward their putting out roots; but if they are planted in June and July, they will root as well in the open air. Branches broken off by accident, which have fallen on the ground, have frequently put out roots without any care: these branches may be kept six months out of the ground, and will then take root if planted. They should have a light sandy earth, and in winter be placed in an airy glass-case, where they may enjoy the sun and air in mild weather, but must be protected from frost. During the winter season, the plants must have but little water; and in summer, when they

C A C

are placed in the open air, it should not be given them too often, nor in great quantity, but they must be treated like the *Ficoïdes*, and other succulent plants from the same country.—The species are,

**Shrubby.*

1. *Cacalia Papillaris*; *Rough-stalked Cacalia*. Stem shrubby, fortified with truncated petiolar spines. Perennial. Stem about three feet high, cylindric; leaves three or four inches long, nearly cylindric, with a longitudinal furrow, glaucous-green, scattered about the summits of the branches.—Native of the Cape of Good Hope. This, as well as the second species, requires a sandy poor soil, and to be kept very dry both summer and winter: hard rains often cause them to rot; but they require the open air in summer.

2. *Cacalia Anteuphorbium*; *Oval-leaved Cacalia*. Stem shrubby; leaves ovate-oblong, flat; petioles having a triple line at the base. This plant is generally known by the name of *Anteuphorbium*, being supposed to have qualities contrary to *Euphorbium*.—Native of the Cape: see the first species.

3. *Cacalia Cuneifolia*; *Wedge-leaved Cacalia*. Stem shrubby; leaves wedge-form, fleshy, flat above, but somewhat convex underneath.—Native of the Cape.

4. *Cacalia Kleinia*; *Oleander-leaved Cacalia*, or *Cabbage-tree*. Stem shrubby, compound; leaves lanceolate, flat; scars of the petioles obsolete. This rises with a thick fleshy stem, divided at certain distances, as it were into so many joints; each of these divisions swells much larger in the middle. The stalks divide into many irregular branches of the same form, which, towards their extremities, have long narrow leaves, of a glaucous colour, standing all round without order; as these fall off, they leave a scar at the place, which always remains on the branches. The flowers are produced in large clusters, at the extremities: they are of a

faint carnation-colour.—It grows naturally in the Canary Islands, and flowers in August, September, and the greater part of October, but does not produce seed in this country: it is called Cabbage-tree by the gardeners, from the resemblance which the stalks have to those of Cabbage; others have named it Carnation-tree, from the shape of the leaves and colour of the flowers. In some parts of England, fossils have been dug up, upon which Dr. Woodward supposed that he discovered impressions of this plant.—It requires a warm dry glass-case in winter, and very little water: in summer, it must be placed in the open air, in a warm sheltered situation. With this management, the plants will flower annually, and grow to the height of eight or ten feet.

5. *Cacalia Ficoides*; *Flat-leaved Cacalia*. Stem shrubby; leaves compressed, fleshy. This rises with strong round stalks to the height of seven or eight feet; they are woody at bottom, but soft and succulent upwards, sending out many irregular branches. These, for more than half their length, have thick taper succulent leaves, a little compressed on two sides, ending in points covered with a whitish meal; when broken, they emit a strong odour of turpentine, and are full of a viscid juice: at the extremities of the branches the flowers are produced in small umbels; they are white, and cut into five parts at top: the stigma is of a dark purple colour, and stands erect above the tube. The seeds do not ripen in England. In France, the leaves are sometimes pickled with the white meal preserved on them.—It flowers from June to November, and grows naturally at the Cape of Good Hope.

6. *Cacalia Repens*; *Glaucous-leaved Cacalia*. Stem shrubby; leaves depressed, fleshy; root creeping. This plant very much resembles the fifth species in stature; it is also covered with a glaucous meal; but the leaves have their upper surface concave, and are not compressed on the sides.—It flowers in June, and is a native of the Cape.

7. *Cacalia Suffruticosa*; *Flax-leaved Cacalia*. Stem undershrubby, branching; leaves linear, flat, scattered. This is an undershrub, a palm in height, variously branched, and filiform; leaves quite entire, by no means fleshy; down with hispid hairs.—Native of Brazil.

8. *Cacalia Laurifolia*; *Bay-leaved Cacalia*. Shrubby smooth: leaves petioled, ovate, triple-nerved, obtuse, quite entire, very smooth; thyse terminal; calix four-leaved, smooth. A very smooth shrub, resembling the *Laurustina*; border of the corolla larger than the tube, four-toothed.—Native of Mexico.

9. *Cacalia Cordifolia*; *Heart-leaved Cacalia*. Shrubby, hirsute: leaves petioled, cordate-ovate, nerved, acute, scabrous; calix four-leaved, four-flowered, pubescent. This and the preceding species agree so exactly in the flower, and are so remarkable in the four-fold division of the calix and the number of the floscules, that they might very well make a separate genus.—Observed by Mutis in South America.

10. *Cacalia Asclepiadea*; *Asclepias-like Cacalia*. Shrubby, tomentose: leaves petioled, ovate-lanceolate, quite entire, very smooth above, tomentose beneath, the edges rolled back; panicles terminal; stems round, hoary, with a soft nap, straight. This herb has the appearance of an *Asclepias*.—Found by Mutis in South America.

11. *Cacalia Appendiculata*; *Ear-leaved Cacalia*. Shrubby tomentose: leaves cordate, ovate, acute, angular, tomentose beneath; petioles with leafy appendices; stem angular, tomentose, hoary; flowers yellow.—Found by Francis Masson, in watery places of the island of Teneriffe.

12. *Cacalia Tomentosa*; *Woolly-leaved Cacalia*. Shrubby, tomentose: leaves lanceolate, toothed, tomentose beneath, sessile.—Found at the Cape by Thunberg.

**Herbaceous.

13. *Cacalia Porophyllum*; *Perforated Cacalia*. Stem herbaceous, undivided; leaves elliptic, subcrenate. The stem is from eight inches to a foot in height, round, slender. It flowers from June till October, is an annual plant, and a native of America. This, and the thirtieth species, (*Ruderalis*.) differ from the genus in their habit, and in having a subturbinate calix; but have no other generic distinctions separating them from the rest of the genus.

14. *Cacalia Sonchifolia*; *Southistle-leaved Cacalia*. Stem herbaceous; leaves lyrate, stem-clasping, toothed; root annual. Flowers few, the size of Groundsel. This plant is much used both in the medicine and economy of the Indians; as it is esteemed to be detergent, and the young leaves are eaten raw in salads. It flowers in July, and the seeds ripen in September.—Native of the East Indies, Ceylon, Amboyna, China, Cochin-china; and, according to Mr. Miller, seeds of it have been received from the Spanish West Indies.—This species is propagated by seeds, which, if sown in the autumn, soon after they are ripe, in a pot, and plunged into the tan-bed in a stove, will more certainly succeed than those sown in the spring; but where there is not such a convenience, the seeds should be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be planted on another hot-bed to bring them forward, shading them till they have taken new root, after which air should be daily admitted to them in proportion to the warmth of the season. When the plants have acquired strength, they should be planted in pots, and either plunged into a moderate hot-bed under a deep frame, or placed in a glass-case, where they will flower and perfect their seeds.

15. *Cacalia Incana*; *Hoary Cacalia*. Stem herbaceous, erect; leaves lanceolate, toothed.—Native of the East Indies.

16. *Cacalia Saracenicæ*; *Creeping-rooted Cacalia*. Stem herbaceous; leaves lanceolate, serrate, decurrent: the bractes are bristle-shaped. Native of the south of France: it flowers from August to October.

17. *Cacalia Hastata*; *Spear-leaved Cacalia*. Stem herbaceous; leaves three-lobed, acuminate, serrate; flowers nodding; root perennial. The stem is covered with a glaucous meal; and the flowers composed of about five white florets, without the bristle-shaped bractes, except at the subdivisions.—Observed by Gmelin and Pallas in Siberia.

18. *Cacalia Suaveolens*; *Sweet-scented Cacalia*. Stem herbaceous, upright; leaves hastate-sagittate, toothletted; petioles dilated at top. This has a perennial creeping root, sending out many stalks; it smells very sweet when dry.—Native of Virginia and Canada, flowering in August, and ripening its seeds in October. The roots of it which have been cast out of the Chelsea garden, having been carried by the tide to a great distance, have lodged on the banks of the river, and fastened themselves to the ground, where they have increased so much, that in a few years this plant may appear to be a native of this country.—Both this and the nineteenth species multiply greatly by their spreading roots, and also by the seeds, which are wafted to a great distance by the wind. The roots should be transplanted in autumn; it requires a moist soil and an open situation.

19. *Cacalia Atriplicifolia*; *Orach-leaved Cacalia*. Stem herbaceous; leaves subcordate, tooth-sinuate; calices five-flowered; root perennial, composed of many fleshy spreading tubers, sending out several strong stems in the spring, four or five feet high; flowers in a terminal loose corymb, small, oblong, of a pale reddish colour.—It flowers in August, and is a native of Virginia and Canada.

20. *Cacalia Alpina*; *Alpine Cacalia*. Leaves reniform,

cordate, acute, toothletted; root perennial; stem a foot and half high and more, leafy, and branching at intervals.—Haller, besides the two principal varieties of this species, the *smooth* and the *tomentose*, mentions that it is found with white florets, and with leaves deeply cut. Mr. Miller makes two species of it: the first, or rough sort, he calls *alpina*; the second, or smooth sort, *glabra*. Monsieur Villars has three species, besides varieties; but Allioni considers them all as one species: *smooth*, in subalpine moistish situations, among bushes; *hirsute*, or *very hairy*, in loftier, cold, rocky, alpine situations; *tomentose* or *cottony*, among stones in open situations on the higher Alps. He adds, that he has observed the tomentose variety to become hirsute, when cultivated in a garden.—Native of Switzerland, Mount Jura, Dauphiny, Piedmont, Austria, and Carniola. It is propagated by parting the roots, for it seldom produces good seeds in England; the best time to do this is in autumn: it requires a loamy soil and a shady situation.

21. *Cacalia Echinata*. Herbaceous: leaves reniform, cordate, angular-toothed, tomentose beneath; leaflets of the calix tubercled.—Observed by Masson in the island of Teneriffe, on precipices near the coast.

22. *Cacalia Albifrons*; *White-leaved Cacalia*. Herbaceous: leaves cordate, biserrate, acute, tomentose beneath; stipules oblong, rounded. This is a singular plant, and very distinct from the others, in having two leaves at the base of the petioles, resembling stipules; they are sessile, oblong, slightly toothletted, and tomentose beneath.—Native of Austria.

23. *Cacalia Bipinnata*; *Bipinnate-leaved Cacalia*. Herbaceous: leaves bipinnate, linear; stem upright, streaked even.—Native of the Cape of Good Hope.

24. *Cacalia Acaulis*; *Stemless Cacalia*. Stemless: leaves semicolumnar; scapes one-flowered.—Found by Thunberg at the Cape of Good Hope.

25. *Cacalia Radicans*; *Rooting Cacalia*. Herbaceous, creeping, rooting: leaves columnar ovate, fleshy.—Found by Thunberg at the Cape of Good Hope.

26. *Cacalia Articulata*; *Joint-stalked Cacalia*. Fleshy: stem decumbent, jointed, lower leaves hastate, upper lyrate. This is an elegant plant, smooth and glaucous, of an unpleasant balsamic flavour: it flowers in November, and was found by Masson at the Cape of Good Hope.

27. *Cacalia Lutea*; *Yellow Cacalia*. Stem herbaceous; leaves five-parted, acute, glaucous beneath; flowers terminal, on very long peduncles.—This species grows naturally at St. Helena; the roots spread and increase under the surface; the leaves arise immediately from the root, having very short foot-stalks. The flower-stalk arises between the leaves, immediately from the roots; this is naked, about eight inches high, terminated by six or eight yellow compound flowers, standing on long foot-stalks, almost in an umbel; the flowers are succeeded by oblong seeds, which rarely ripen in England.

28. *Cacalia Carnosa*; *Narrow-leaved Cacalia*. Stem shrubby; leaves roundish, fleshy, bent in; peduncles terminating, one-flowered, naked; it flowers in June.—Native of the Cape of Good Hope. It increases fast by the roots, which may be parted either in the beginning of September or the end of March, and should be planted in pots filled with light earth, and plunged into the tan-bed in the stove, where it should be constantly kept, being too tender to thrive elsewhere in this climate.

29. *Cacalia Scandens*; *Climbing Cacalia*. Stem herbaceous, climbing leaves sagittate, toothed; petioles simple.—It flowers in April, and is a native of the Cape of Good Hope.

30. *Cacalia Ruderalis*. Stem herbaceous, branched; leaves lanceolate, entire, glaucous. This is an annual plant, upright,

not more than three feet high, very smooth, panicled; flowers void of scent, with a green calix, and a corolla green and yellow mixed.—Native of St. Domingo and Martinico.

31. *Cacalia Procumbens*. Stem suffruticose, procumbent; leaves ovate, lanceolate, subserrate, fleshy; racemes elongated, interrupted; stems perennial, nine feet high, procumbent, round, equal, smooth, succulent, branched.—Native of China and Cochin-china, where it is used as a potherb.

32. *Cacalia Bulbosa*. Leaves radical, lyrate; stem almost naked; panicle few-flowered; root a roundish, knotted, perennial bulb.—Native of China and Cochin-china. This plant is emollient, refrigerant, and resolvent, used chiefly externally in resolving tumors; and in the erysipelas, as a cataplasm; the juice of the leaves in inflammations of the eyes, and as a gargarism in the inflammation of the fauces.

33. *Cacalia Pinnatifida*. Leaves pinnatifid; segments lanceolate, serrate; stem two feet high, upright, thick; flowers yellow, in a terminating panicle, few together.—Native of China, among rice near Canton.

Cachrys; a genus of the class Pentandria, order Digynia. —GENERIC CHARACTER. *Calix*: umbel universal, manifold; *partial* similar; involucre universal, many-leaved, linear-lanceolate; *partial* similar; perianth proper scarcely observable. *Corolla*: universal, uniform; floscules all uniform; proper of five, lanceolate, almost upright, equal flat-tish petals. *Stamina*: filamenta five, simple, the length of the corolla; antheræ simple. *Pistil*: germen turbinate, inferior; styles two, simple, the length of the corolla; stigma headed. *Pericarp*: fruit subovate, angular, obtuse, very large, suberos-cortical, splitting in two. *Seeds*: two, very large, very convex on one side, flat on the other, fungous, with solitary ovate-oblong kernel. ESSENTIAL CHARACTER. Fruit subovate, angular, suberos-cortical.—All the plants of this genus are propagated by seeds, which should be sown soon after they are ripe, for if they are kept out of the ground till the following spring, they often miscarry, and when they succeed, they never come up until the spring after; so that by sowing them in autumn, a whole year is saved, and the seeds seldom miscarry. The seeds should be sown on a shady border, where the plants are to remain, for as they have long tap-roots, they will not bear transplanting so well as many other kinds; the distance three feet apart, so that if each kind is sown in a drill, when the plants are come up they may be thinned, leaving two of the most promising plants of each kind to remain. These plants will begin to appear early in April, when they must be carefully cleared from weeds; and in dry weather, if they are gently watered while young, it will greatly promote their growth; after which time they will require no further care but to keep them clean from weeds, and every spring to dig the ground carefully between them. These plants decay to the ground every autumn, and come up again in the spring; they commonly flower in the beginning of June, and their seeds are ripe in September. Their roots sometimes run down three or four feet deep in the earth, provided the soil be light, and are often as large as Parsnips: they will continue many years, and if the soil be moist and rich, they will annually produce good seeds.—The species are,

1. *Cachrys Libanotis*; *Smooth-seeded Cachrys*. Leaves superdecompound; leaflets spreading, acuminate; seeds ovate, furrowed, unarmed. The whole plant has an aromatic sweet smell, and is esteemed carminative, astringent, and antiperi-
cetic.—Native of Sicily, the south of France, and Barbary.

2. *Cachrys Sicula*; *Hairy-seeded Cachrys*. Leaves superdecompound, with filiform leaflets: flowers yellow; seeds roundish, ovate, grooved, wrinkled. Native of Spain and Sicily.

3. *Cachrys Tenuifolia*; *Fine-leaved Cachrys*. Leaves superdecompound, smooth, with very numerous filiform leaflets; seeds oval. It flowers in May.—Native of the country about Montpellier.

4. *Cachrys Odontalgica*. Leaves superdecompound, rough with hairs; the end leaflets digitate-multifid, bluntish; seeds obovate, truncate, even. The root is very long, and being of a very sharp aromatic flavour, is used in the tooth-ache.—Found abundantly between the Volga and the Jaick.

5. *Cachrys Panacifolia*. Leaves pinnate and ternate, with oblong crenate leaflets; seeds hirsute. Stem three feet high, streaked, hoary, round, full.—Native of New Castile and Barbary.

Cactus; a genus of the class Icosandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth one-leaved, imbricate, hollow-tubular, with scaly leaflets scattered over it, superior, deciduous. *Corolla*: petals numerous, rather obtuse, broad; the outer ones shorter, the inner larger, converging. *Stamina*: filamenta numerous, subulate, inserted into the calix; antheræ oblong, erect. *Pistil*: germen inferior; style the length of the stamina, cylindrical; stigma headed, multifid. *Pericarp*: berry rather oblong, one-celled, umbilicate, roughened as the calix is. *Seeds*: numerous, roundish, small, nestling. ESSENTIAL CHARACTER. *Calix*: one-leaved, superior, imbricate. *Corolla*: manifold. *Berry*: one-celled, many-seeded.—This genus consists of succulent plants, permanent in duration, singular and various in structure; generally without leaves, and having the stem or branches jointed; for the most part armed with spines in bundles, with which, in many species, bristles are intermixed. These bundles of spines are placed on the top of the tubercles in the first species, or *Smaller Melon Thistle*, which is tubercled all over, and produces its flowers between the tubercles. In the second species, or *Great Melon Thistle*, the spines are ranged in a single row on the ridge of the ribs; these are of an ovate or globular form. From the third to the eleventh species, or the *Torch Thistles*, they are slender, rise up high, are jointed and branched; many of them are almost cylindrical, with from five to ten shallow ribs; some, however, are square or three-cornered. They are called in the West Indies, *Torch-wood*, because when they grow old they will burn, and the Indians use them as flambeaux. They are by no means perfectly known; and therefore remain to be well described by travellers.—The structure of the *Creeping Cereuses*, No. 12, 13, &c. is the same with these, except that the stems are weak, and cannot support themselves; they therefore seek support from trees, and throw out roots from the stem like Ivy. In the *Indian Figs*, No. 17, &c. the branches are jointed, and flatted like the sole of a shoe; the bundles of spines, or bristles, are scattered over the surface; and the flowers are produced from the edge of the extreme branches. In the *Phyllanthus*, No. 23, the branches are thinner, and may fairly be denominated *leaves*; they are indented along the edge, and the flowers come out singly from the indentures; it seldom has any spines. *Pereskia* has a round stalk with leafy branches; the leaves alternate, flat, and thick; the prickles are large and stiff, and come out in bundles on the stalk and branches, chiefly at the axils; the flowers are produced several together, from the axils also. In this and the *Indian-figs*, the flowers are pitcher-shaped; in the other species they are subcylindrical, and longer; in *Phyllanthus* very long. The fruit in some of the sorts is small, like currants, but in most it is larger, and shaped like a fig, whence the name of *Indian-fig*. These singular plants are all natives of the continent of South America, and the West Indian islands.—The species are,

VOL. I.—19.

* *Echinomelocacti* of a roundish form.

1. *Cactus Mammillaris*; *Smaller Melon Thistle*. Roundish, covered with ovate bearded tubercles. This differs from the second species, in being smaller and covered with tubercles, between which the flowers and fruit come out, round the middle of the plant; the flowers appear in July and August; the fruit is of a fine scarlet colour, and continuing fresh upon the plants through the winter, are very beautiful at that season. The chiding variety is but little larger than the other, growing nearly in the same form, but produces a great number of young plants from the sides, by which it is increased: it produces tufts of a soft white down upon the tubercles or knobs, and also between them, so that the whole plant appears as if covered with fine cotton.—This species produces quantities of fruit annually; and as the seeds grow very readily, it is now very common in those gardens where there are stoves to keep them, for if the fruit be permitted to drop upon the earth of the pots, and that is not disturbed, there will plenty of plants come up without any further trouble; and these seedling plants may be taken up as soon as they are of a proper size to remove, and planted six or seven of them into a small halfpenny-pot, where they may stand one year, by which time they will each be large enough for a separate pot, and afterwards they will make great progress, especially if they are plunged into a hot-bed of tanner's bark in summer, for although this sort is much more hardy than the large kind, and may be preserved in a moderate stove, yet the plants will not make near the progress of those which are kept in a greater degree of heat. This sort will continue many years with proper care, and the plant will grow to be a foot high or more; but when they are so tall, the lower part of them is not so sightly, their green being decayed, and the spines changed to a dark dirty colour, they appear as if dead, so that the upper part of these old plants only seem to have life, whereas the plants of the middling size appear healthy from top to bottom. In the spring, when the fruit shrivels and becomes dry, the seeds will be ripe, and may then be rubbed out, and sown upon the surface of the earth in small pots, which should be plunged into a hot-bed of tanner's bark, to bring up the plants. In the chiding variety, the young offsets may be taken off, and after laying them up to dry for two or three days, may be planted, and will succeed very well.

2. *Cactus Melocactus*; *Great Melon Thistle*, or *Turk's Cap*. Roundish, fourteen or fifteen angled; angles spirally twisted; spines erect. This appears like a large fleshy green melon, with deep ribs set all over with strong sharp thorns; when it is cut through the middle, the inside is found to be a soft, green, fleshy substance, very full of moisture; the flowers and fruit are produced in circles round the upper part of the cap. Some of these, brought to England, have been more than a yard in circumference, and two feet and a half high, including the cap: but in the West Indies there are plants nearly twice as large. There are several varieties of this species; indeed Mr. Miller has made four species of the great Melon Thistle, and thinks, if the islands in the West Indies were examined, many more sorts would be found. These strange plants commonly grow upon the steep sides of rocks in the hottest parts of America, where they seem to be thrust out of the apertures, having little or no earth to support them, their roots shooting down into the fissures of the rock to a considerable depth, so that it is troublesome to get the plants up. As they delight in such rocky places, they seldom live long when transplanted into a better soil. In times of great drought, the cattle repair to the barren rocks where these plants grow, rip them up with their horns,

3 K

tear off the outside skin, and greedily devour all the fleshy moist part. The fruit is frequently eaten by the inhabitants of the West Indies. It is about three quarters of an inch in length, of a taper form, drawing to a point at the bottom, but blunt at the top; the taste is an agreeable acid.—This species may be propagated by seeds; but as the plants which are raised from seeds in England will be some years in arriving to any considerable size, it will be much the best way to procure some plants from the West Indies; and if the plants arrive here in any of the summer months, so as that there may be time for them to get new roots before the cold comes on in autumn, the plants will more certainly succeed. When the plants come over, it will be proper to take them out of the earth as soon as possible, and lay them in the stove upon the shelves to dry, for a fortnight or three weeks; and when they are planted, they should be plunged into a good warm bed of tanner's bark, to promote their making new roots; in this bed they may remain till the beginning of October, when they must be removed into the stove, and treated in the manner directed for the first sort. The soil in which they should be planted, must be of a sandy nature, and mixed with some dry lime-rubbish. The plants require a very good stove to preserve them through the winter in England, nor should they be exposed to the open air in summer, for although they may continue fair to outward appearance, when they have been some time exposed abroad, yet they will imbibe moisture, which will cause them to rot soon after they are removed into the stove; and this is frequently the case of those plants which are brought from abroad, which have a fair healthy appearance many times at their first arrival, but soon after suddenly decay.

** *Cereuses erect, supporting themselves.*

3. *Cactus Pitajaya*. Erect, triangular. This is upright, and eight or ten feet high; when it grows higher, it wants support, but does not put out any roots from the stem; the flower is whitish and very handsome, but has hardly any smell; it is half a foot in diameter, and blows in the night. The fruit is of the form and size of a hen's egg, of a shining scarlet colour on the outside; the pulp is white, fleshy, sweet, eatable, full of small, black, shining seeds.—Native of Carthage, and the isle of Mango.—The *Cereuses*, or *Torch Thistles*, are all propagated by cuttings; so that if you intend to increase the number of them, you must cut off the stems of the upright sorts at what length you please; these should be laid in a dry place to heal the part cut, at least a fortnight or three weeks before they are planted; but if they lie a month it is much the better, and they will be in less danger of rotting, especially those sorts which are the most succulent. These cuttings should be planted in pots filled with the mixture of earth before directed, laying some stones in the bottom of the pots to drain off the moisture; then place the pots into a gentle hot-bed of tanner's bark, to facilitate their rooting, giving them once a week a gentle watering. The best season for this work is in June, or the beginning of July, that they may have time to root before winter. About the middle of August, give them air by degrees, but they should not be wholly exposed to the open air or sun; and at the end of September they must be removed into the stove or greenhouse, where they are to abide the winter, during which season you must be very careful not to let them have much water, and always observe to place the young plants, for the first winter, in a little warmer situation than the old plants, as being somewhat more tender. They should always have a dry situation in winter; for as they derive the greatest part of their nourishment from the surrounding air, so if this be too moist it will cause them to rot. They should not be

exposed abroad, not even in the midst of summer, unless they are under shelter, for the great rains which often occur at that season are very injurious to them; the upright sorts should be therefore placed so as to enjoy a free air in the summer, but at the same time screened from rains and great dews; it will therefore be the best method to set them in an open glass-stove, where the windows may be opened in fair weather, and shut in cold or wet. The creeping sorts must not be much exposed to the open air, even in the hottest season, especially if you design to have them flower, and in winter they should be kept very warm, and have no water given them. These plants being succulent, will bear to be a long time out of the ground, therefore whoever wishes to procure them from the West Indies, need only request their friends there to cut them off, and let them lie two or three days to dry, then put them up in a box with dry hay or straw, to keep them from wounding each other with their spines; and if they are two or three months on their passage, they will keep very well, provided no wet get to them.

4. *Cactus Heptagonus*; *Seven-angled Upright Torch Thistle*. Erect, oblong, seven-angled.—Native of the British islands in the West Indies. See the preceding species.

5. *Cactus Tetragonus*; *Four-angled Upright Torch Thistle*. Erect, quadrangular, long; angles compressed. The angles of this species are compressed, and far asunder. It is very subject to put out many shoots from the sides, which stop its upright growth, so that the plants rarely rise more than four or five feet high; it flowers in July.—See the third species.

6. *Cactus Hexagonus*; *Six-angled Upright Torch Thistle*. Erect, six-angled, long; angles distant.—The angles of this species are armed with sharp spines, coming out in clusters at certain distances, and spreading from a centre every way; the outer substance of the plant is soft, herbaceous, and full of juice, but in the middle there is a strong fibrous circle running the whole length, which secures the stems from being broken by winds. They will rise to the height of thirty or forty feet, if their tops are not injured, and they have room to grow; but whenever the stems are cut or injured, they put out shoots from the angles, immediately under the wounded part, and frequently one or two lower down; these, if they are not cut off, form distinct stems, and grow upright, but they are seldom so large as the principal stem, especially if more than one be left on a plant. The flowers come out from the angles on the sides of the stem; they have a thick, fleshy, scaly, round, channelled, hairy peduncle, supporting a swelling germen, upon the top of which sits the scaly prickly calix, closely surrounding the corolla, till a little time before it expands; the flower is then as large as that of a Hollyhock; the inner petals are white, and crenated at their extremity; the calix is green, with some purple stripes. It is not succeeded by fruit in this country, nor do the plants often produce flowers, but when they do, there are generally several.—Native of Surinam. See the third species.

7. *Cactus Pentagonus*; *Five-angled Upright Torch Thistle*. Erect, long, jointed, with about five angles. Sometimes, but rarely, the stem has six angles; it never puts out any roots, and though slender and weak, grows upright.

8. *Cactus Repandus*; *Slender Upright Torch Thistle*. Erect, long, eight-angled; angles compressed, waved; spines longer than the wool. The flowers are produced from the angles in the same manner as those of the sixth species, but they are smaller, and the calix is of a light green, without any mixture of colour. The fruit is about the size and shape of a bergamot pear, having many soft spines on the skin; the outside is a pale yellow, the inside very white, full of pulp, having a number of small black seeds lodged in it. This

sort frequently flowers in July, and in warm seasons will perfect its fruit, which has very little flavour in this country, but is frequently served up at table in the West India islands.—See the third species.

9. *Cactus Lunuginosus*; *Woolly Upright Torch Thistle*. Erect, long, with about nine angles; angles obsolete; spines shorter than the wool. This is very spiny; the spines, especially the younger ones, have a brownish wool upon them; the fruit is of the size and form of a hen's egg, red on the outside, and without spines.—A native of America. See the third species.

10. *Cactus Peruvianus*; *Peruvian Upright Torch Thistle*. Erect, long, with about ten bluntish angles.—The stem is a fathom or more in height, almost simple, two or three inches in diameter, blunt at the end, having ten deep angles, set with thorns, crowded eight or ten together, about an inch in length, spreading, the inner ones shorter, tomentose at the base. Berry blood-red within, eatable.—Native of dry situations on the coasts of Peru and Jamaica. See the third species.

11. *Cactus Royena*; *Royen's Upright or Nine-angled Torch Thistle*. Erect, jointed, nine-angled; joints subovate; spines equal in length to the wool.—See the third species.

*** *Cereuses creeping, with roots from the sides.*

12. *Cactus Grandiflorus*; *Great Night-flowering Creeping Cereus*. Creeping, with about five angles. This species, when arrived to a sufficient strength, will produce many exceedingly large, beautiful, sweet-scented flowers; like most of this kind, of very short duration, scarcely continuing six hours full blown; nor do the flowers ever open again when once closed. They begin to open between seven and eight o'clock in the evening, are fully blown by eleven, and by three or four in the morning they fade, and hang down quite decayed; but during their short continuance, there is scarcely any flower of greater beauty, or that makes a more magnificent appearance, for the calix of the flower, when open, is near a foot in diameter, the inside of which being of a splendid yellow colour, appears like the rays of a bright star; the outside is of a dark brown; the petals being of a pure white, add to the lustre; the vast number of recurved stamina surrounding the style in the centre of the flower, make a fine appearance: add to all this, the fine scent of the flower, which perfumes the air to a considerable distance. There is scarcely any plant which deserves a place in the hot-house so much as this, especially as it may be trained against the wall, where it will not take up any room. The usual season of its flowering is in July; and when the plants are large, many flowers will open the same night, and there will be a succession of them for several nights together. Sometimes six, eight, or ten flowers, open at the same time on one plant, making a most magnificent appearance by candle-light; but none of them are succeeded here by any appearance of fruit.—Native of Jamaica and Vera Cruz. See the third species.

13. *Cactus Flugelliformis*; *Pink-flowering Creeping Cereus*. Creeping, ten-angled. This produces a greater number of flowers than the preceding sort; they come out in May, and sometimes earlier when the season is warm; the petals are of a fine pink colour both within and without; they are not so numerous, and the tube of the flower is longer than that of the other: these flowers keep open three or four days, provided the weather, or the place where the plants stand, be not too warm; and during their continuance they make a fine appearance. This sort has very slender trailing branches, which require a support; they are not jointed, nor do they extend so far as those of the other sort, so that they may be easily trained to a little trellis of sticks,

and the plant may be conveyed into the house whilst in flower, to adorn any of the rooms. The flowers are so beautiful, and are produced in such great plenty, that this may be placed in the first class of exotic plants.—Native of Peru. See the third species.

14. *Cactus Parasiticus*; *Parasitical Creeping Cereus*.—This is probably the root of some species of *Epidendrum*.

15. *Cactus Pendulus*; *Slender Cereus*. Pendulous; branches in whorls, round, smooth, without prickles; stem roundish, green, woody, striated, as big as a goose-quill, divided into several slender, round, striated branches, and they into twigs, at distances of one, two, and three inches; at which divisions are set little twigs an inch and a half long, in whorls.—It grows chiefly on the largest trees in Jamaica, hanging commonly to the length of three or four feet.

16. *Cactus Triangularis*; *Triangular Cereus*, or *Strawberry Pear*. Creeping, triangular. This climbs up trees to a considerable height, supporting itself by throwing out roots; it also covers shady rocks. The fruit is the best flavoured of any of the sorts, being slightly acid, with a mixture of sweetness, and also pleasant and cooling. It has no leaves, but is somewhat irregular with scars. In Martinico, where the fruit is esteemed by the inhabitants, they call it *poirier de chardon*, or *thistle pear*. There is a variety of this species, (native of the island of St. Eustatia,) the fruit of which is much larger, of a shining scarlet-colour, and clothed with leaves which are almost entire; the pulp is white, sweetish, eatable, but has very little flavour; the seeds are black and glossy.—See the third species.

**** *Opuntias, compressed with proliferous joints.*

17. *Cactus Moniliformis*; *Neck-lace Indian Fig*. Proliferous jointed; joints globular, thorny, glomerate. This is a sessile plant, consisting of globular joints growing out of each other, armed with very sharp subulate spines. It is a very singular plant, and the least known of any in this genus.—Native of South America. All the *Opuntias*, except the following, or eighteenth species, are too tender to thrive in the open air in England; nor can many of them be preserved through the winter here, unless they have artificial heat, for when they are placed in a green-house they turn to a pale yellow colour, their branches shrink, and frequently rot on the first approach of warm weather in the spring. They may all of them be propagated by cutting off their branches at the joints, during any of the summer months; these should be laid in a warm dry place for a fortnight, that the wounded part may be healed over, otherwise they will rot with the moisture they imbibed at that part, as is the case with most other succulent plants. The soil in which these plants must be planted, should be composed after the following manner, viz. one-third of light fresh earth from a pasture, another third part sea-sand, and the remainder equal parts of rotten tan and lime-rubbish; these should be well mixed, and laid in a heap three or four months before it is used, observing to turn it over at least once a month, that the several parts may be well united; then you should pass it through a rough screen, in order to separate the largest stones and clods, but by no means sift it too fine, which is a very common fault; then you should reserve some of the smaller stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off; which is what must be observed for all succulent plants, for if the moisture be detained in the pots it will rot the roots and destroy the plants. When any branches of these plants, except those of the eighteenth sort, are planted, you should plunge the pots into a moderate hot-bed, which will greatly facilitate their taking root;

you should also refresh them now and then with a little water; but be very careful not to let them have too much, or be too often watered, especially before they are rooted. When the plants begin to shoot, you must give them a large share of air, by raising the glasses, otherwise the shoots will draw up so weak as not to be able to support themselves; and after they have taken strong root, you should inure them to the air by degrees, and then remove them into the stove, where they should remain, placing them near the glasses, which should always be opened in warm weather, so that they may have the advantage of a free air, and yet be protected from wet and cold. They often require water in summer: they thrive best when the heat is at the temperate point, as marked upon the botanical thermometers, for if they are kept too warm in winter, it causes their shoots to be very tender, weak, and unsightly. Those sorts which are inclinable to grow upright, should have their branches supported with stakes, otherwise their weight is so great it will break them down. These plants are by most people exposed to the open air in the summer season; but they thrive much better if they are continued in the stoves, provided the glasses be kept open, so that they may have free air; for when they are set abroad, the great rains which generally fall in summer, together with the unsettled temperature of the air in our climate, greatly diminish their beauty, by retarding their growth; and sometimes in wet summers they are so replete with moisture, as to rot the succeeding winter; nor will those tender plants which are set abroad produce their flowers and fruit in such plenty, as those which are constantly preserved in the house.

18. *Cactus Opuntia*; *Common Indian Fig*, or *Prickly Pear*. Proliferous-jointed, loose; joints ovate, setaceous. The joints or branches of the common *Opuntia*, or *Indian fig*, are ovate, compressed, and have very small leaves coming out in knots on their surface, as also on their upper edges, which fall off in a short time; and at the same knots there are three or four bristly spines, which do not appear unless they are closely viewed; but on being handled they enter the skin, are troublesome, and very difficult to get out again. The branches spread near the ground, and frequently trail upon it, putting out new roots, and thus extending to a considerable distance, but never rising in height; they are fleshy and herbaceous whilst young, but as they grow old become dryer, of a tough contexture, and have woody fibres. The flowers come out on the upper edges of the branches generally, though sometimes they are produced on their sides; the skin or cover of the fruit is set with small spines in clusters, and the inside is fleshy, of a purple or red colour: It flowers here in July and August; but, unless the season is very warm, the fruit will not ripen in England. This sort is now found growing wild on the sides of the roads about Naples, and other parts of Italy, in Sicily, Spain, Portugal, the Valais, the south of France, Minorca, &c.—For the propagation and culture, see the preceding species.

19. *Cactus Ficus Indica*; *Oblong Indian Fig*. Proliferous-jointed; joints ovate, oblong; spines setaceous. The flowers come out from the upper edges of the leaves, like those of the preceding species; but they are larger, and of brighter yellow colour: the fruit is also larger, and of a deeper purple colour; the outer skin is also armed with longer spines. This is the most common sort in Jamaica, and upon the fruit of this, the wild sort of cochineal insect feeds, which is called *Silvester*. Dr. Houstoun, who was writing a history of these insects, sent some of the plants from Jamaica with the insects alive upon them, and they lived three or four months after their arrival. If the fruit of this plant be eaten, it will dye the urine of a bloody colour.

This seems to be a native not only of South America, but also of the East Indies, Cochin-china, Japan, and Madeira.—See the seventeenth species.

20. *Cactus Tuna*; *Great Indian Fig*, or *Upright Prickly Pear*. Proliferous-jointed; joints ovate, oblong; spines subulate. This species has stronger branches than the foregoing sort, and they are armed with larger thorns, which are awl-shaped, whitish, and in clusters; the flowers are large, of a bright yellow colour; and the fruit is shaped like that of the foregoing species. Professor Martyn enumerates two varieties; the first of which grows taller, with larger and thicker branches, and of a deeper green, and are armed with strong black spines coming out in clusters, which are far asunder; the flowers are smaller, and of a purplish colour, as are also the stamina; the fruit is of the same form with that of the common sort, and does not ripen here. The second variety, called *Opuntia Maxima*, is the largest of all the sorts yet known; the joints are more than a foot long, and eight inches broad; they are very thick, of a deep green colour, and are armed with a few short spines; the older branches of this often become almost taper, and are very strong; it has not flowered, though many of the plants were more than ten feet high. It makes very strong fences; the prickles are so sharp that the cattle are afraid of coming near them; and it spreads very much, both by the joints and the seed. When the island of St. Christopher was to be divided between the English and the French, three rows of the *tuna* were planted by common consent between the boundaries. Dr. Smith, in his very ingenious paper upon the irritability of vegetables, informs us, that the long and slender stamina of the flower are very irritable; and that if a quill or feather be drawn through them, in the space of two or three seconds they begin to lie down gently on one side, and in a short time become recumbent at the bottom of the flower.—It is a native of South America and Jamaica. See the seventeenth species.

21. *Cactus Cochinillifer*; *Cochineal Indian Fig*. Proliferous-jointed; joints ovate-oblong, almost unarmed. This, which is supposed to be the plant upon which the cochineal insect feeds, has oblong, smooth, upright branches; rising to the height of eight or ten feet, having scarcely any spines on them, and the few which there are, so soft as not to be troublesome when handled. The flowers are small, and of a purple colour; they do not spread open, appear late in autumn with us, and the fruit drops off in winter without coming to perfection. The cochineal insect feeds on many succulent plants, but most commonly on the *Cactus* Genus. For this reason the Indians propagate large quantities of the most harmless species, to breed the insects upon; Dampier's account of which is as follows, "The plant on which the cochineal insect feeds is like the prickly pear, about five feet high, and as prickly, only the leaves are not quite so large, although the fruit is larger: on the top of the fruit there grows a red flower; this, when the fruit is ripe, falls down on the top of it, and covers it so that no rain or dew can wet the inside. A day or two after, the flowers being scorched up by the heat of the sun, the fruit opens wide, and the inside appears full of small red insects. The Indians, when they perceive the fruit open, spread a large linnen cloth, and then with sticks shake the plant, to disturb the insects, so that they take wing to be gone, but keep hovering over the plant, till by the heat they fall down dead on the cloth, where they let them remain two or three days to dry. The cochineal plants are called *toona* by the Spaniards. They are planted in the country about Guatimala, Cheapo, and Guaxaca, in the kingdom of Mexico." The difference in point of goodness, observable in the cochineal, is entirely owing to the

CACTUS GRANDIFLORUS — Night-flowering Creeping Cactus.

LIBRARY
OF THE
UNIVERSITY
OF
CALIFORNIA

plant it feeds upon. The prickly pear, so abundant in Jamaica, is covered with the insects, but not having their proper food, they are in general diminutive, and have very little red tincture in their bodies. These plants bear a succulent fruit at their extremities, filled with a delicate red-coloured juice. This is the natural food of the insect; the exuviae and animal salts of the insect are, from the minuteness of its parts, inseparable from the essential principles of the dye, and must diminish the brilliancy of the colour: and this has put some persons upon inspissating the juice of the fruit itself. The fruit, when ripe, is said to check fluxes by its mild restringency; it is also a powerful diuretic, and sometimes imparts a tinge to the urine.—See the seventeenth species.

22. *Cactus Curassavicus*; *Curassao*, or *Least Indian Fig*, or *Pinpillow*. Proliferous-jointed; joints cylindric, ventricose, compressed. This has thicker and more swelling joints than the other sorts, closely armed with slender white spines. The branches spread out on every side, and where they have no support fall to the ground, very often separating at the joints, and, as they lie upon the ground, putting out roots, and forming new plants. It very rarely produces flowers in England. In the West Indies it is called *Pinpillow*, from the appearance which the branches have to a pin-cushion stuck full of pins. It is said to grow naturally at Curassao.—See the seventeenth species.

23. *Cactus Phyllanthus*; *Spleenwort-leaved Indian Fig*. Proliferous, ensiform-compressed, serrate, repand. It has very thin branches, which are indented regularly on their edges like *Spleenwort*; they are of a light green, shaped like a broadsword, and without spines: the flowers come out from the side and at the end of the branches, and are of a pale yellow colour; the fruit rarely ripens in England.—Native of Brazil.—See the seventeenth species.

24. *Cactus Alatus*. Proliferous, ensiform, compressed, serrate, repand. The stem round, ash-coloured, flexible, whence issue several leaves, at first hairy, growing to a foot in length, an inch broad in the middle; and having round indentures on their edges, out of which proceed the flowers. The fruit small and compressed.—Native of Jamaica.

25. *Cactus Spinosissimus*; *Cluster-spined Indian Fig*. Stem upright, compressed; branches opposite, bifarious, compressed; spines bristle-shaped. The branches of this species have the joints much longer, narrower, and more compressed, than in any of the others; the spines are very long, slender, and of a yellowish-brown colour, coming out in clusters all over the surface of the branches, crossing each other, so as to render the plant dangerous to handle; for upon being touched, the spines quit the branches, adhere to the hand, and penetrate the skin, so as to be very troublesome: its growth is more upright and lofty than the other *Opuntias*; the trunk below the branches is so absolutely covered with spines as to be invisible, and to seem nothing but a congeries of these. Hence the gardeners whimsically call this plant *Robinson Crusoe's Coat*. Upon the whole, this species is very different from the rest, and has more of an air of neatness and elegance than any of these strange plants, notwithstanding its roughness.—Native of Jamaica.

26. *Cactus Pereskia*; *Barbadoes Gooseberry*. Stem arboreous, round; prickles double, recurved; leaves lanceolate, ovate. This has many slender branches, which trail on whatever plant grows near them; these, as also the stem, are beset with long whitish spines, or tufts; the leaves are roundish, very thick and succulent; and the fruit is about the size of a walnut, having tufts of small leaves on it, and within a whitish mucilaginous pulp. It grows in some parts of the

Spanish West Indies, whence it was brought to the English settlements in America, where it is called *Barbadoes gooseberry*. The Dutch have named it *blad-apple*. It may be propagated by cuttings planted during any of the summer months, in pots filled with fresh light earth, and plunged into a moderate hot-bed of tanner's bark, observing to shade them from the sun in the heat of the day, and to refresh them every third or fourth day with water; in about two months the cuttings will have made good roots, when they should be carefully taken out of the pots, and each planted into a separate pot filled with fresh earth, and then plunged into the hot-bed again, where they may remain during the summer season; but at Michaelmas, when the nights begin to be cold, they should be removed into the stove, and plunged into the bark-bed. During the winter season the plants must be kept warm, and watered twice a week, but not in large quantities. In summer they demand a greater share of air and more water, but they should remain constantly in the stove; for though they will bear the open air in summer in a warm situation, yet they will make no progress if they be placed abroad; nor do they thrive so well in the dry-stove, as when they are plunged in the tan; so that the best way is to set them next a trellis, at the back of the tan-bed, to which their branches may be fastened, to prevent their trailing on other plants.

27. *Cactus Portulacifolius*; *Purslain-leaved Indian Fig*. Stem round, arboreous, thorny; leaves wedge-form, retuse. The stem is leafless, but armed with bundles of bristle-shaped spines; fruit roundish, having no tufts of leaves on it; by which it is distinguished from the foregoing, which it much resembles.

Cadia; a genus of the class Decandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth one-leafed, five-cornered, five-cleft. *Corolla*: petals five, equal, obcordate. *Stamina*: filamenta ten, filiform, equal, the length of the petals or nearly so, protuberant at the base; antheræ oblong, rather sharp at the top, placed obliquely at the ends of the filamenta. *Pistil*: germen linear; style bowed; stigma acute. *Pericarp*: legume linear, compressed, bent at the end, membranous, many-seeded. *Seeds*: oblong, smooth. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: five, equal, obcordate. *Legume*: many-seeded.—The only known species is.

1. *Cadia Purpurea*; *Purple-flowered Cadia*. This is a shrub rising to the height of nearly three feet; the branches and petioles are pubescent. Forskal observes, that the flowers hang down; that the corolla has sometimes six or seven petals, and that in such cases there are more stamina, frequently twelve or fourteen; and that there is no gland to the antheræ. Native of Arabia; it has not flowered in England.

Cænopteris; a genus of the class Cryptogamia, order Filices.—GENERIC CHARACTER. *Fructifications*: in submarginal lateral lines, covered with a membrane, gaping on the outside.—The only species is,

1. *Cænopteris Rhizophylla*. Frond bipinnate, rooting at the tip; pinnules obovate, somewhat sickle-shaped, petioled; primordial leaves lobed.—Native of Dominica.

Casalpinia: a genus of the class Decandria, order Monogynia. GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted; tube short; segments oblong, deciduous, the lowest longer than the rest, slightly arched. *Corolla*: petals five, inserted into the throat of the calyx tube, unequal; lamina roundish. *Stamina*: filamenta ten, inserted into the throat of the calix, filiform, woolly at the base, declining; antheræ oblong, decumbent. *Pistil*: germen superior, linear-oblong, compressed, attenuated at the base;

style filiform, the length of the stamina blunt. *Pericarp*: legume oblong, compressed, one-celled. *Seeds*: few, sub-ovate, compressed flat. **ESSENTIAL CHARACTER.** *Calix*: five-parted, the lowest segment longer, and slightly arched. *Stamina*: woolly at the base. *Petals*: five. *Legume*: compressed.—The plants of this genus are propagated by seeds, which should be sown in small pots filled with light rich earth early in the spring, and plunged into a hot-bed of tanner's bark, observing to shade them from the sun, and to water the earth as often as it appears dry; if the nights should prove cold, the glasses must be covered with mats, to keep the bed in a moderate warmth: in about six weeks the plants will begin to appear, when they must be carefully cleared from weeds, and frequently refreshed with water: in warm weather the glasses should be raised in the middle of the day to admit fresh air. When the plants are about three inches high, they should be carefully taken out of the pots, and each transplanted into a separate small pot filled with fresh light earth, and plunged into the hot-bed again, observing to water them, and screen them from the heat of the sun, until they have taken new root; after which time the glasses should be raised every day in proportion to the warmth of the weather. In this hot-bed the plants are to remain till autumn, when they should be removed to the stove, and plunged into the bark-bed, where they may have room to grow; here they should remain; and being placed among tender exotics of the same climate, will afford an agreeable variety.—The species are,

1. *Cæsalpina Elata*. Unarmed: leaflets linear, blunt with a point; corymbs compound; calices coriaceous, tomentose; petals fringed; stamina very long. This is a tree, with bipinnate leaves: the flowers are large, yellow; filamenta very dark purple.—Native of India.

2. *Cæsalpina Pulcherrima*; *Barbadoes Flower Fence*. Prickly; leaflets oblong, oval, emarginate, they and the calices smooth; corymbs simple; petals fringed; stamina very long. It rises with a straight stalk ten or twelve feet high; it is covered with a smooth gray bark, and is sometimes as thick as the small of a man's leg; it divides into several spreading branches at the top, armed at each joint with two short strong crooked spines.—This beautiful plant is a native of both Indies; it is planted in hedges, to divide the lands in Barbadoes, where it has the name of *Flower-Fence*; it is also called *Spanish Carnations* in some of our islands in the West Indies. Dr. Houstoun has found varieties in the colour of the corolla, some having a red and others a yellow flower in the Spanish West Indies. All parts of this plant are thought to be very powerful emmenagogues, and are frequently used for that purpose among the negroes. The *Flower-Fence*, if care be taken to water and shift the plants as often as it is necessary, will grow three feet high the first season. When they are grown large, care must be taken, when they are shifted into larger pots, not to suffer the ball of earth to fall from the roots. They are very impatient of moisture in winter, and if damp seizes their top, it very often kills them, or at least occasions the loss of their heads. The beautiful flowers of this shrub appear in December here; but in the West Indies it flowers twice a year.

3. *Cæsalpina Sappan*; *Narrow-leaved Prickly Brasiletto*. Leaflets oblong-oval, unequal-sided, blunt; they and the calices smooth; stamina longer than the corolla. This tree is a native of mountains in the Circars.

4. *Cæsalpina Pyramida*. Unarmed: leaflets oval, quite entire, equilateral; petals with claws roundish, flat, equaling the stamina.—This tree is a native of the West Indies.

5. *Cæsalpina Crista*, Prickly; leaflets oval; racemes simple;

petals ovate, shorter than the smooth calix; stamina longer than the calix.—This tree is also a native of the West Indies.

6. *Cæsalpina Brasilinesis*. Unarmed: leaflets ovate oblong; midrib pubescent; calices tomentose; stamina shorter than the corolla.—Native of the West Indies.

7. *Cæsalpina Bijuga*. Leaves doubly pinnate, with two pairs of obcordate leaflets; they and the calices smooth; stamina equalling the corolla.—This tree is about 15 feet high; native of Jamaica and Curaçoa.

8. *Cæsalpina Coriaria*. Leaflets linear; racemes in form of spikes; calices smooth, equalling the corolla; stamina longer than the corolla; legumes curved inwards.—An elegant tree, growing in salt-marshes in Carthagen, &c.

Calabash. See *Cucurbita* and *Crescentia*.

Calamint. See *Melissa* and *Mentha*.

Calamus; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth six-leaved, permanent; the three outer leaflets shorter, broader; the three inner longer, narrower, acuminate. *Corolla*: none, except the calix be so called. *Stamina*: filamenta six, capillary longer than the calix; antheræ round. *Pistil*: germen roundish, superior; style trifid, columnar, spiral, filiform; stigmas simple. *Pericarp*: membranous, globular, covered with scales, imbricated backwards, and obtuse; it is one-celled, at first pulpy, but afterwards juiceless. *Seed*: one, globular, fleshy. **ESSENTIAL CHARACTER.** *Calix*: six-leaved. *Corolla*: none. *Berry*: dried, one-seeded, imbricate backwards.

1. *Calamus Rotang*, or *Rattan*.—All the sorts or varieties of the *Calamus Rotang*, or *Rattan*, have a stem which is perennial, quite simple or unbranched, long, round, unarmed or without prickles, solid, jointed, procurrent when unsupported, scandent when near trees, but without any tendrils. The *Rattan* seems to form the connecting link between the palms and the gramineous plants, having the flower of the former, but the habit of the latter. Loureiro has discriminated six species of *Calamus*, viz. 1. The *Stone Rattan*, with a stem as thick as the human arm, and a hundred feet long, used for large spears and halberts. 2. The *Cable Rattan*: stem more than five hundred feet long and about an inch thick, very tough, used for ships' cables, for ropes to draw great weights, and to tame and fasten wild elephants. 3. The *Walking Cane Rattan*, with very long, subulate, glossy internodes. It grows abundantly on both sides of the straits of Malacca, whence it is exported into China and Europe. 4. The *Genuine Rattan*: stem a hundred feet long, yellowish, brown, equal, very flexible, the thickness of a finger. In India the largest cables are made of the stem cut into thongs; besides all sorts of ropes for fastening the planks of the country vessels and the boarding of houses, in which no nails are used; and also for tying a variety of utensils, both domestic and rural. 5. The *Bitter Rattan*: stems sixty-feet long, the thickness of a finger. It is used for the same purposes as the genuine *Rattan*, but is harder and more durable. 6. The *Diacous Rattan*: stem the thickness of a goose-quill, twenty feet long, very regular and flexible. It is used for weaving, and fastening smaller and nicer utensils. All these are specifically different, for they grow wild in places very remote from each other, where they regularly preserve their peculiar habits and differences. Many others grow in Cochin-china, the straits of Malacca, and other places, which, on an accurate examination, may be found to be different both from these and each other. They grow abundantly in the East Indies, by the sides of rivers. Their extreme toughness and pliability render them very useful to the natives, for withs, and almost all the purposes to which we apply ropes. The

Rattan is imported into Europe, and used for a variety of minor purposes, such as bottoming chairs, for riding and walking canes, hoops for the petticoats of fools, &c. &c. The Zalaced or Salxch, another species, is cultivated for the fruit, which is about the size of a walnut, and covered with scales like those of a lizard; below the scales, are two or three yellow kernels, in flavour somewhat resembling a strawberry. This is supposed to produce the dragon's-blood.

Calceolaria; a genus of the class Diandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, four-parted, spreading, equal; divisions ovate, permanent. *Corolla*: monopetalous, bilabiate; lower lip resupine; upper very small, contracted, globular, bifid anteriorly, lower very large, slipper-form, inflated, gaping anteriorly. *Stamina*: filamenta two, very short, within the upper lip; antheræ incumbent, club-form, with the handle prominent through the chink. *Pistil*: germen roundish; style very short; stigma bluntish. *Pericarp*: capsule subconic, acuminate, two-furrowed, two-celled, two-valved. *Seeds*: numerous, ovate. **ESSENTIAL CHARACTER.** *Corolla*: ringent, inflated. *Capsule*: two-celled, two-valved. *Calix*: four-parted, equal.—The species are,

1. *Calceolaria Pinnata*; *Pinnated Slipperwort*. Leaves pinnate. Root annual; stem erect, two feet high, round, brachiate, brittle, with a very thick down, and from fifteen to twenty joints.—It flowers from July to October; and is a native of moist places in Peru. This species may easily be raised from seed, sown on a gentle hot-bed in the spring; the seedlings, when of a proper size, are to be transplanted into the borders of the flower-garden, where they will flower, ripen, and scatter their seeds; but it appears to most advantage in a tan-stove.

2. *Calceolaria Integrifolia*; *Whole-leaved Slipperwort*. Leaves lanceolate, wrinkled, serrate; flowers panicled, terminating.—It was observed in Chili by Feuillée.

3. *Calceolaria Perfoliata*; *Perfoliate Slipperwort*. Leaves perfoliate, sagittate, villose on both sides. This is a very singular and handsome plant, the whole of which is villose, except the corolla; stem round, from a foot to two feet high, leafy, terminated by a many-flowered leafy corymb; corolla yellow, large; antheræ two-lobed, large, the lobes bent down.—Found in New Granada, by Mutis.

4. *Calceolaria Nana*; *Dwarf Slipperwort*. Scapes one-flowered; leaves ovate, quite entire. Stemless; flowers large, specious, yellow, spotted with red.—Found by Comerson in the Straits of Magellan.

5. *Calceolaria Plantaginea*; *Plantain-leaved Slipperwort*. Scapes few-flowered; leaves rhomboid, serrate. Root perennial, fibrous; stem none; corolla yellow.—Found in the Straits of Magellan.

6. *Calceolaria Ovata*. Stem branching; leaves ovate, crenate. Root annual, fibrous; stem erect, round, hairy; leaves opposite, on short petioles, with white pellucid hairs, and underneath paler; corolla like that of the first species, small and yellow.—Found by Dombey in Peru.

7. *Calceolaria Fothergillii*; *Spatula-leaved Slipperwort*. Leaves spatulate, quite entire; peduncles scape-form, one-flowered. Stem scarcely an inch high, subdivided near the root: flowering from May to August.—Native of the Falkland Isles.

Calea; a genus of the class Syngenesia, order Polygamia Æqualis. **GENERIC CHARACTER.** *Calix*: common imbricate; scales oblong, somewhat loose. *Corolla*: compound, uniform; corollules hermaphrodite, very many, equal; proper funnel-form, with a five-cleft border. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular.

Pistil: germen somewhat oblong; style filiform, the length of the corollule; stigmas two, recurved, acute. *Pericarp*: none; calix unchanged. *Seeds*: solitary, oblong; down hairy, the length of the calix. *Receptacle*: chaffy; chaffs a little longer than the calix, eminent between the floscules. **ESSENTIAL CHARACTER.** *Calix*: imbricate. *Down*: hairy, or none. *Receptacle*: chaffy.—These plants may be propagated by seeds, sown upon a hot-bed in the beginning of April; when they come up, they should be tenderly treated whilst young; admitting, however, fresh air to them daily, in proportion to the warmth of the season, giving them water frequently, but sparingly. When they have strength enough to be removed, they must be each transplanted into a separate small pot, filled with light sandy earth, and plunged into a hot-bed, observing to shade them until they have taken new root, giving them air, and watering them frequently, but gently, as before. When the plants are grown strong, they must be removed into larger pots, and placed in the stove or glass-case, giving them plenty of fresh air in warm weather; with which management they will sometimes ripen their seeds in favourable seasons.—The species are,

1. *Calea Jamaicensis*. Flowers subtern, peduncled; leaves ovate-oblong, subserrate, petioled. Height six or seven feet or more; stems shrubby, narrow, round, obscurely tomentose; leaves hairy, rugged, three-nerved; flowers terminating, frequently three together, the pedicles of the same length with the flowers; calix coloured; the pappus or down is rugged, and as long as the flower.—Native of the woods and inland parts of the island of Jamaica.

2. *Calea Oppositifolia*. Corymbs heaped; peduncles very long; leaves lanceolate; stem herbaceous, two feet high, branched, upright, round, pubescent.—Native of hedges on the mountains of Jamaica.

3. *Calea Amellus*. Flowers subpanicled; calices short; seeds naked; leaves ovate-lanceolate, petioled. This species has woody branches, which spread over the neighbouring plants, and rise eight or ten feet high; the leaves are thick and opposite; there are many side-branches on which are smaller leaves, opposite like the others, and terminated by panicles of yellow flowers; seeds four-cornered, without down.—Native of Jamaica.

4. *Calea Lobata*. Corymbs heaped; leaves alternate, the upper ones ovate-lanceolate, the lower ones tooth-hastate, sinuate-serrate. This plant bears many naked yellow flowers, and generally rises to the height of four or five feet, according to Browne; who calls it *Halbert weed*, from the shape of the leaves: he affirms, that it is an excellent bitter, and much used in America, where a spirituous infusion of the tops is generally kept in most plantations, and is often administered as an active warm stomachic.—Native of Jamaica.

5. *Calea Scoparia*. Stem suffruticose; branches almost opposite, angular. This is a shrub or small tree; stem the height of a man or more, branched towards the top, even, streaked, wrinkled, with an ash-coloured bark.—It is a native of Jamaica, and there found only in the coldest parts of the mountains; it resembles our European Broom, and is therefore called *Mountain Broom-tree*; it is the only tree of the same appearance in that country. Flowers small, white.

6. *Calea Leptophylla*. Flowers terminating in threes and fives, heaped; leaves oblong, imbricate, quite entire, sessile; stem shrubby.—Native of New Zealand.

7. *Calea Pinifolia*. Peduncles terminating, heaped; leaves linear, acerose; stem shrubby.—Native of New Zealand.

Calendula; a genus of the class Syngenesia, order Polygamia Necessaria.—**GENERIC CHARACTER.** *Calix*: com-

mon simple, many-leaved, almost upright; segments linear-lanceolate, (fourteen to twenty,) nearly equal. *Corolla*: compound radiate; corollules hermaphrodite, very many in the disk; females the number of rays in the calix, very long in the ray: proper of the hermaphrodite tubular, semiquinquefid, the length of the calix; of the female, ligulate, very long, three-toothed, villose at the base, nerveless. *Stamina*: (hermaphrodite) filamenta five, capillary, very short; antheræ cylindric, tubular, the length of the corollule. *Pistil*: hermaphrodite; germen oblong; style filiform, scarcely the length of the stamina; stigma obtuse, bifid, straight. Females; germen oblong, trigona-cornered; style filiform, the length of the stamina; stigmas two, oblong, acuminate, reflex. *Pericarp*: none; calix converging, roundish, depressed. *Seeds*: hermaphrodite, central of the disk, none; of the circumference, seldom solitary, membranous, orbiculate, compressed; females solitary, larger, oblong, incurved, triangular, with membranous angles, marked on the outside longitudinally, with the figure of a vegetable. *Down*: none. *Receptacle*: naked, flat.—The flowers are commonly solitary, and terminating.—The species are,

1. *Calendula Arvensis*; *Field Marygold*. Seeds boatform, mucronated, bent in; the outmost erect, protended. Root annual; stalk slender, branching, spreading near the ground; leaves narrow, spear-shaped, hairy, half surrounding the stalk at their base; flowers produced at the extremity of the branches, upon long naked peduncles, they are very small, and of a pale yellow colour; the florets of the ray are very narrow, as are also the leaves of the calix.—It flowers most part of the summer, and is a native of Sweden, Germany, Switzerland, France, Carniola, Italy, and Spain. If the seeds of the Field Marigold be permitted to scatter; there will be a fresh supply of young plants, so that from May, when the flowers first appear, till the frost puts a stop to them, there will be a succession of plants in flower.

2. *Calendula Sancta*; *Palestine Marigold*. Seeds pitcherform, obovate, even; calices submucronated. This is very like the foregoing species, but the calix is mucronated on the outside. Mr. Miller informs us, that the leaves are much larger than those of the former sort, but yet not so large as those of the Garden Marigold; and that the flowers are of a middle size between the two others, and of a very pale yellow colour.

3. *Calendula Officinalis*; *Garden Marigold*. Seeds all boat-form, mucronated, bent in.—This differs from the Field Marigold not only in the seeds, but in having a loftier stem, more divaricated, pubescent, and pale green, as are also the leaves; these are longer and less sinuated, the lower and middle leaves ovate and blunt, the upper ones lanceolate.—Native of France, in the vineyards; of Italy in the corn-fields; of Silesia, in orchards, gardens, and fields; flowering most part of the summer. The golden splendour of this flower, says Bauhin, ennobled this plant before it was known to be of any use. It has however been cultivated time out of mind in kitchen gardens for the flowers, which were dried in order to be boiled in broth; from a fancy that they are comforters of the heart and spirits. Linneus accordingly says, that they may be used in a double dose, as a succedaneum to Saffron; but modern practice has little confidence in these supposed cordials. The common, or official Marigold, is a plant which is now much out of use in the materia medica, and has probably been commended beyond its merit as an aperient and detergent in visceral obstructions, jaundice, and menstrual suppressions. It has also been considered as useful in the scrofula of children, eaten in the manner of a salad. There is a certain acrimony in the

plant, insomuch that it has even been commended as an extirpator of warts. Formerly, the flowers were very much esteemed as preservatives against pestilential disorders, either chewed, or infused in vinegar; or the juice itself, drank to the quantity of some ounces. It has been highly recommended in the plague itself, by some writers, and is esteemed a powerful sudorific; the leaves are supposed to be more efficacious than the flowers. It has been asserted, that a Marigold flower, rubbed on the affected part, is an admirable remedy for the pain and swelling caused by the sting of a wasp or bee. According to Hill, an infusion of the fresh-gathered flower is good in fevers; it gently promotes perspiration, and throws out any thing which ought to appear on the skin. Meyrick says, a water distilled from them is good for inflamed and sore eyes: a decoction of the flowers, in posset drink, is much used among country people, as an expulsive in the small-pox and measles. The leaves of the plant, when chewed, at first communicate a viscid sweetness, which is followed by a sharp penetrating taste, very durable in the mouth, but not of the hot or aromatic kind, but rather of a saline nature. The expressed juice, which contains the greatest part of this pungent matter, has been given in doses of two or three ounces, in cases of costiveness, in which it is very efficacious; and it likewise promotes the other secretions of the body in general. Snuffed up the nose, it excites sneezing, and a discharge of mucus from the head. Linneus observes, that the flowers of this plant are open from nine in the morning till three in the afternoon. This regular expansion and closing of the flowers attracted early notice, and hence this plant acquired the names of *solsequia* and *solis sponsa*. There is an allusion to this property in the poems ascribed to Rowley:

“The Mary-budde that shootethe (shutteth) with the light.”

But more fully thus by Shakspeare,

“The Marigold, that goes to bed wⁱ th’ sun,
“And with him rises weeping.”

Of the garden Marigold, there are the following varieties:—
1. The single. 2. The common double-flowering. 3. The largest very double-flowering. 4. The double lemon-coloured. 5. The greater and smaller Childing Marigold, called by Gerarde, fruitful or much-bearing Marigold. There are other trifling varieties not worth observation.—This plant, in German, is called *gewohnlicken*, *ringelblume*, *goldblume*, *dotterblume*, *gilkenbutterblume*, *gemeine sonnenwendes*, *haussonnenwirbel*, *weckbroselchen*, *todtenblume*; in Dutch, *tanme goudbloem*; in Swedish, *ringblomma*; in Danish, *almindelige koebloem*, *solsikke*, *soelsik*; in English, *Common or Garden Marigold* or *Marygold*; by old authors, *Golds* or *Ruddes*. *Golds*, or *Gouldes*, is a name among the country people, not only for this but for *Chrysanthemum Segetum*, any sort of Hawkweed, and, in short, for most yellow flowers of the *Synghesia* class. The fondness of the British for tacking Christian names to animals and plants, is well known; the Virgin Mary, in particular, has sanctified many of the latter. The French term the garden Marigold *souci du jardin*; the Italians, *calendula ortense*, *fiorranvio*, *fiore d’ogni mese*, which latter name countenances the derivation of *Calendula* from the calends; the Spaniards and Portuguese also call it *calendula ortense*, and the latter sometimes term it *maravilha bastarda*; in Russian, its name is *nogotki*.—The seeds of the single garden Marigold will come up of themselves, if they are permitted to scatter: the varieties are supposed to have been originally obtained from the seeds of the single sort, but most of these differences continue, if the seeds be pro-

perly saved; but the two childing Marigolds, and the largest double, are subject to degenerate, where care is not taken in saving their seeds: the best way to preserve the varieties, is to pull up all those plants, whose flowers are less double, as soon as they appear, and to save the seeds from the largest and most double flowers; the childing sort should be sown by itself in a separate part of the garden, and the seeds sowed from the large centre flowers only, not from the smaller ones which come from the calix of the other, for the seeds of these are apt to change. The seeds may be sown in March or April where the plants are to remain, and will require no other culture but to keep them clean from weeds, and to thin the plants where they are too close, leaving them ten inches asunder, that their branches may have room to spread. These plants will begin to flower in June, and continue in flower until the frost kills them. The seeds ripen in August and September, which, if permitted to scatter, will furnish a supply of young plants in the spring; but as these will be a mixture of bad and good, the best method is to save the best seeds, and sow each of the varieties distinct, which is the sure way to have them in perfection.

4. *Calendula Pluvialis*; *Small Cape Marigold*. Leaves lanceolate, sinuate-toothletted; stem leafy; peduncles filiform. Root annual; lower leaves deeply indented on their edges, fleshy, and of a pale green colour; stems declining from six to eight inches long, leafy to within two inches of the top; stem-leaves much narrower and more indented than those of the root; upper part of the stem very slender, upon which stands one flower shaped like those of the common Marigold, having a purple bottom, with the ray of a violet colour on the outside, and of a pure white within: it opens when the sun shines, but shuts up in the evening, and remains so in cloudy weather; when the flower decays, it hangs down during the growth of the seeds, but when they are full ripe the peduncle is raised again, so that the heads of the seeds stand upright.—It is a native of the Cape of Good Hope, and flowers from June to August. The seeds of this and the two next sorts, should be sown in the spring, in the borders of the garden where the plants are designed to remain, for they do not bear transplanting well; therefore they may be treated in the same manner, and sown at the same time, with Candy-tuft, Venus Looking-glass, and other hardy annual plants, putting four or five seeds in each patch; if they all grow, there should not be more than two plants left in each patch; after this, they require no farther care but to keep them clean from weeds. If the seeds of these plants be permitted to scatter, the plants will come up the following spring without care, and these will flower earlier than those which are sown in the spring.

5. *Calendula Hybrida*; *Hybridous or Great Cape Marigold*. Leaves lanceolate, toothed; stem leafy; peduncles thickened at the top. Root annual; leaves much longer than in the foregoing, and broader at the end; those near the root are regularly indented, but the stem-leaves have only a few shallow indentures; flowers smaller, but of the same colour.—Native of the Cape. See the preceding species.

6. *Calendula Nudicaulis*; *Naked-stalked Cape Marigold*. Leaves lanceolate, sinuate-toothed; stem almost naked. This is also an annual plant, and has much the appearance of the fourth, but the leaves are more deeply indented on their edges. It flowers from June to August, and is a native of the Cape. See the fourth species.

7. *Calendula Graminifolia*; *Grass-leaved Marigold*. Leaves linear, almost entire; stems almost naked, one-flowered; seeds subcordate, orbiculate, even. This is a perennial plant,

which divides near the root into several tufted heads, closely covered with long grassy leaves coming out on every side without order; some of these have one or two indentures on their edges, but the most part are entire. From between the leaves arise naked peduncles, about nine inches long, sustaining one flower at the top, which is about the size of the common Marigold, having a purple bottom; the rays are also purple without, but of a pure white within; these expand when the sun shines, but always close in the evening and in cloudy weather. The general season of their beauty is in April and May, when they have the greatest number of flowers upon them; but there is commonly a succession of flowers late in the autumn, though not in so great plenty. The seeds are heart-shaped, like those of the foregoing.—They were brought from the Cape in 1698. Though this plant has been long in the English gardens, it has not been so often seen there as it deserves, there being few which continue so long in flower. It does not often produce good seeds in Europe, but is easily propagated by slips taken off from the heads, in the same manner as is practised for Thrift; they may be planted any time in summer, in pots filled with light fresh earth, which may be plunged into a very moderate hot-bed, to forward their putting out roots; or otherwise the pots may be sunk in the ground up to their rims, and covered with a melon-glass, which, in the middle of summer, will answer full as well, but in the spring or autumn the former method is to be preferred: when these are planted, the glasses must be shaded in the heat of the day, and the slips must be frequently refreshed with water, but it must not be given them too liberally, for much wet will rot them; after they have got strong roots, they should be each planted into small pots, filled with fresh light earth, and placed in a sheltered situation, where they may remain till autumn, and then should be placed in a dry airy glass-case, for the winter season, or under a common hot-bed frame; for these plants do not thrive in an artificial heat, they only require protection from frost and wet, and should enjoy the air at all times when the weather is mild.

8. *Calendula Fruticosa*; *Shrubby Marigold*. Leaves obovate, a little toothed; stem shrubby, decumbent. This has a slender shrubby stalk rising to the height of seven or eight feet, but requiring support; it sends out a great number of weak branches from the bottom to the top, hanging downwards; the leaves are on short footstalks; most of them are slightly indented towards the top, but some are entire; they are of a shining green colour on the upper surface, but paler underneath: the flowers come out at the ends of the branches on short naked peduncles.—Native of the Cape of Good Hope. It is easily propagated by cuttings, which may be planted any time in summer in a shady border, or otherwise shaded with mats in the heat of the day; in five or six weeks these will have taken root, when they should be carefully taken up, and each put into a separate pot filled with light sandy earth, but not dunged, and placed in the shade till they have taken fresh root; then they may be placed with other hardy exotic plants in a sheltered situation, where they may remain till the frost begins, when they must be removed into the green-house, placing them near the windows, that they may enjoy the free air, for they only require protection from frost. The earth in which they are planted should be light, but very poor; for in rich earth they grow too luxuriantly, and seldom flower.

9. *Calendula Stellata*; *Starry Marigold*. Five outer seeds boat-shaped, smooth; five alternate horned, patulous, muricate; the rest screw-shaped. Root annual; stem three feet high; leaves bright green.—Cultivated in Madrid,

where it flowers and perfects seeds from June to August.

Calf's Snout. See *Antirrhinum*.

Calla; a genus of the class Gynandria, order Polyandria.—GENERIC CHARACTER. *Calix*: spathe one-leaved, ovate-cordate, acuminate, coloured at top, very large, spreading, permanent; spadix finger-shaped, quite simple, erect, covered with fructifications. *Corolla*: none. *Stamina*: filamenta some, intermixed with the germina, the length of the pistils permanent, compressed, truncate; antheræ simple, truncate, sessile. *Pistil*: to each a roundish obtuse germen; style simple, very short; stigma acute. *Pericarp*: berries as many as there are pistils, four-cornered, globular, pulpy, one-celled. *Seeds*: many, (six to twelve,) oblong, cylindric, obtuse at both ends. ESSENTIAL CHARACTER. *Spathe*: flat. *Spadix*: covered with floscules. *Calix* and *Petals*: none. *Berries*: many seeded.—The species are,

1. *Calla Æthiopica*; *Æthiopian Calla*. Leaves sagittate, cordate; spathe crowded; spadix, male at top. This plant has thick fleshy tuberous roots, which are covered with a thin brown skin, and strike down many strong fleshy fibres into the ground; the leaves rise in clusters, having foot-stalks more than a foot long, which are green and succulent; the leaves are eight or nine inches in length, and of a shining green, ending in a sharp point, which turns backward; between the leaves comes out the scape, which is thick, smooth, of the same colour as the leaves, rises above them, and is terminated by a single flower, shaped like those of the Arum; the hood or spathe is twisted at the bottom, but spreads open at the top, and is of a pure white colour; in the centre of this is situated the spadix or club, which is of an herbaceous yellow colour, upon which the small herbaceous flowers are placed, so closely joined as that the stamina and pistils are very difficult to distinguish without the assistance of glasses, it is only about half the length of the spathe.—It grows naturally at the Cape, and has long been an inhabitant of the English gardens. It propagates very fast by offsets which should be taken off at the latter end of August, at which time the old leaves decay; but this plant is never destitute of leaves, for before the old ones decay there are young leaves produced, which advance in height all the winter; but at this season the roots are in their most inactive state: these roots have generally a great number of offsets about them, and the largest of them only should be chosen, which should each be planted in a separate pot, filled with kitchen-garden earth, and placed with other hardy exotic plants in the open air till autumn, when they must be removed into shelter for the winter, during which time they must not have too much wet, for that will rot the roots. This plant is so hardy as to live in the open air in mild winters without any cover, if it be planted in a warm border, and have a dry soil; but with a little shelter in hard frost, it may be preserved in the full ground. It flowers in May, and the seeds ripen in August; but as the roots increase so plentifully, few persons care to sow the seeds, because the young plants will not flower in less than three years.

2. *Calla Palustris*; *Marsh Calla*. Leaves cordate; spathe flat; spadix hermaphrodite all over. Leaves erect, acuminate, streaked, bright or yellowish green, smooth, four or five inches long, and three or four broad, alternately embracing the stem, with thick, smooth, succulent petioles five or six inches long; scape round, thick, succulent, smooth, bright green. The roots creep in the mud, so as sometimes to cover whole marshes; they have a hot biting taste, and yet bread is sometimes made of them. It flowers from June to August, and is a native of Lapland, Sweden, Denmark, Rus-

sia, Germany, and Holland. It is rarely admitted into gardens, and must be planted in an artificial bog, or at least in the mud of a pond, or in a pot or tub set in water.

3. *Calla Orientalis*; *Oriental Calla*. Leaves ovate. This has also a thick tuberous root, from which spring up several ovate leaves, standing on pretty long foot-stalks; the scape rises between the leaves, about six or eight inches high, supporting one white flower at the top.—Native of the mountains near Aleppo. The roots of this sort should be planted in pots filled with light earth, and in summer placed, with other exotic plants, in the open air; but in winter they should be put under a common hot-bed frame, to screen them from frost, which would be fatal to the roots.

4. *Calla Occulta*. Leaves cordate, ovate; spathe spiral; spadix male at top. Plant one foot high, perennial, with scarcely any stalks.—Native of Cochin-china, in moist places. *Callicarpa*: a genus of the class Tetrandria, in order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-form; mouth four-cleft, erect. *Corolla*: monopetalous, tubular; border four-cleft, obtuse, spreading. *Stamina*: filamenta four, filiform, twice the length of the corolla; antheræ ovate, incumbent. *Pistil*: germen roundish; style filiform, thicker at the top; stigma thickish, obtuse. *Pericarp*: berry globular, smooth. *Seeds*: four, oblong, shaped like a meniscus, compressed, callous. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Corolla*: four-cleft. *Berry*: four-seeded.—The species are,

1. *Callicarpa Americana*; *American Callicarpa*. Leaves serrate, tomentose beneath. A shrub, from three or four to six feet in height; branches rather compressed; the nerves of the upper surface of the leaves, and the whole under surface, tomentose; the flowers in axillary, dichotomous, tomentose panicles, scarcely the length of the leaves; with minute subulate bractes, opposite at each fork; corolla funnel-form, deep purple.—Native of Cochin-china as well as of North America, which shews the impropriety of the trivial name. It is the only plant of its genus which has been yet cultivated in England, and rises easily from seeds on a moderate hot-bed; it is best to sow the seeds in pots, and to plunge them into a tan-bed of a moderate warmth; when the plants come up, and have attained some strength, they should be gradually inured to the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn; during this time they must be kept clean from weeds, and gently refreshed with water in dry weather; but as these young plants are tender, they should be placed under a frame before the early frost comes on, for autumnal frosts will kill the tender part of their shoots, which often causes their stalks to decay most part of their length before the spring. During the winter season they should be screened from frost, but in mild weather they must enjoy the free air, otherwise their shoots will turn mouldy and decay. The following spring, just before the plants shoot, they should be carefully turned out of their pots, so as not to break their roots, and part of them may be planted in small pots filled with light earth, and the others in a nursery-bed in a warm situation, at about four or five inches asunder; those in the pots should be plunged into a moderate hot-bed, which will forward their taking root; but afterwards they must be hardened to bear the open air as before; these should be sheltered under a frame in winter for three or four years, till they have obtained strength; then they may be turned out of the pots, and planted in a warm situation, where they will live in the open air through common winters; but in severe frost they are in danger of being killed, if they be not sheltered; therefore the surface of the ground about the roots

should be covered with old tan to keep out the frost, and their tops protected with straw, pease haulm, or fern.

2. *Callicarpa Tomentosa*. Leaves quite entire, woolly. This is a singular tree, which has no parallel: a thick nap invests the branches, peduncles, and petioles, like woollen cloth; leaves ovate, the size of the hand, opposite, acuminate, coriaceous, wrinkled, naked, petioled; peduncles axillary, solitary, dichotomous, the length of the petioles, divaricated; corolla four-petalled; filamenta inserted into the receptacle; berry the size of a pepper-corn, black, terminated by the stigma, which is pale-coloured, within the calix, which is white with down, orbicular, scarcely toothed, or very obscurely four-toothed, spreading very wide: the berry is one-celled, and contains four bony seeds, convex on one side, on the other concave, with an obscurely elevated ridge. The Indians chew the bark of this tree when they have not the leaves of the betel.—Native of the East Indies.

3. *Callicarpa Japonica*. Leaves serrate, smooth; stem shrubby, erect, smooth; branches opposite, round; smooth, purple, divaricated; leaves opposite, on short petioles, oblong, acuminate, entire at the base and point, green above, pale beneath, nerved, two inches long; flowers above, axillary, panicled, very small.—Native of Japan.

4. *Callicarpa Ferruginea*. Leaves broad-lanceolate, serrate, somewhat rugged underneath; cymes terminating and axillary.—Native of Jamaica.

5. *Callicarpa Reticulata*. Leaves elliptic, lanceolate, subserrate, wrinkled, tomentose hoary underneath.—Native of Jamaica.

6. *Callicarpa Umbellata*. Leaves turbinate, ovate, smooth, alternate, umbels sessile. This is a middle-sized tree, with ascending branches; leaves quite entire, reflex at the edge; flowers herbaceous, small, in coloured umbels, almost at the ends of the branches; berry fleshy, roundish, small, containing four seeds.—Native of Cochin-china, in woods.

7. *Callicarpa Triloba*. Stem scandent; leaves three-lobed; peduncles dichotomous. A long branching shrub, climbing by bifid tendrils; leaves cordate, serrate, smooth, on long petioles; flowers axillary, pale; berry roundish, four-seeded.—Native both of China and Cochin-china.

Calligonum; a genus of the class Dodecandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, turbinate at the base, with a five-parted border; parts nearly equal, roundish, spreading, finally obscurely turned back, permanent, the two outer a little smaller than the rest. *Corolla*: none, unless the calix be taken for it. *Stamina*: filamenta about sixteen, diverging, capillary, at bottom thickened a little and pubescent, surrounding the germen like a nectary, with their slightly coalescent base, withering; antheræ roundish, two-celled, peltate. *Pistil*: germen superior, ovate, four-sided, acuminate; styles three or more, frequently four, filiform, spreading, subcoalescent as the base, or ending in an acumen of the germen, scarcely shorter than the filamenta; stigmas capitate. *Pericarp*: none, except the crust or shell of the nut. *Seed*: nut with a juiceless inseparable crust or rind, oblong, four-sided, four-winged, one-celled, valveless; the wings either membranaceous longitudinally, two-parted, toothed, curled, or bristly; the bristles branched, rigid, but soft; nucleus or kernel of the same form. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: none; filamenta about sixteen, slightly united at the base. *Germen*: superior, four-sided. *Nut*: one-celled, with a crust that has several wings, or many bristles.—The species are,

1. *Calligonum Polygonoides*. Fruit latticed; bristles branched, rigid. A shrub three or four feet in height, very bushy, and extending on every side; the trunk, crooked,

hard, brittle, the thickness of the arm, divided into crooked branches, subdivided into twigs, whence instead of leaves spring cylindric threads, composed of jointed pieces; the flowers are in the form of basins, cut into five parts to the middle, where they are pale green, the rest is white; from the bottom of the basin rises an angular pistil a line and half in length, surrounded with white filamenta, which have purple antheræ; each flower is supported by a very slender and short peduncle: the fruit is about half an inch long, and four lines thick, of a conical figure, deeply channelled longitudinally; the channels are sometimes straight, sometimes spiral; the angles are terminated by wings cut into very fine fringes; the pulpy part is white and angular. The flowers smell like those of the lime-tree; are long in withering, and continue at the base of the fruit.—Found in Armenia, at the foot of mount Ararat, by Tournefort.

2. *Calligonum Comosum*. Fruits latticed; bristles branched, soft.—Found in Egypt and Barbary.

3. *Calligonum Pallasia*. Fruits winged; wings membranaceous, curled. A shrub three or four feet high, with many alternate, round, reclining, flexuose, jointed, somewhat knotty, leafless branches; the shoots at each joint are numerous, (six to ten,) much crowded in bundles, rushy, some simple, others branched; few of these become branches, but most of them perish; they are subulate jointed, bright green, or somewhat glaucous; at each joint of the roots is a single leaf, fleshy, half an inch long, placed alternately; flowers lateral or axillary, usually three together at each joint, peduncled, white, with the disk of the calyxine segments greenish, fragrant. With us it flowers in August.—It was found by Pallas in the sandy deserts of Siberia, between the Volga and the Jaick, flowering in June.

Callisia; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets linear-lanceolate, keeled, erect, permanent. *Corolla*: petals three, lanceolate, acuminate, erect, spreading at the top, the length of the calix. *Stamina*: filamenta three, capillary, longer than the corolla, dilated at the top into a roundish lamina; antheræ double, globular, fixed to the inside of the lamina. *Pistil*: germen superior, oblong, compressed; style capillary, the length of the stamina; stigmas three, spreading, pencil-form. *Pericarp*: capsule ovate; compressed, acute, two-celled, two-valved, the valves contrary. *Seeds*: two, roundish. ESSENTIAL CHARACTER. *Calix*: three-leaved. *Petals*: three. *Antheræ*: double. *Capsule*: two-celled.—The only known species is,

1. *Callisia Repens*; *Creeping Callisia*. Herbaceous, tender, creeping from the joints, rather erect at top, a little branching at the base, smooth; leaves ovate, acuminate, subcordate at the base, quite entire, thickish, shining fat, sheathing, the edge purple, alternate; flowers small, tender, sessile, greenish, generally three together from each sheath of the lower leaves.—Native of the West Indies, in low moist shady places. In England it flowers in June and July.

Callitriche; a genus of the class Monandria, order Digynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals two, incurved, acuminate, channelled, opposite. *Stamina*: filamenta one, long, recurved; antheræ simple. *Pistil*: germen roundish; styles two, capillary, recurved; stigmas acute. *Pericarp*: capsule roundish, quadrangular, compressed, two-celled. *Seeds*: solitary, oblong. ESSENTIAL CHARACTER. *Calix*: none; petals two. *Capsule*: two-celled, four-seeded.—The species are,

1. *Callitriche Verna*; *Vernal Starwort*, or *Star-headed Water Chickweed*. Upper leaves oval; flowers androgynous. Stem long, round, branching, rooting; leaves in pairs, the upper ones radiating, and floating on the surface of the water;

flowers sessile in the axils; the upper ones male, the lower female; petals small, white, thick, flat, crescent-form; when magnified, they appear to be a collection of air-vessels, to enable the flower to float.—It is an annual plant, very common in ditches and standing waters, flowering from April to June. There is a variety of this species; but the difference is probably owing to its situation, in places where water has stood in the winter, or in ditches and marshes dried up.

2. *Callitriche Autumnalis*; *Autumnal Starwort*. All the leaves linear, bifid at the end; flowers hermaphrodite. This differs from the first species in having all the leaves linear, and cleft at the end; to which Withering adds, that the corolla is yellowish white; and Linneus, that it flowers in September. It is sometimes so thickly matted together on deep marshes, that a person may walk upon it without sinking.

Calodendrum; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, permanent, five-parted; parts ovate, acute, thickish, villose-muricate on the outside, with the edges slightly revolute. *Corolla*: petals five, lanceolate, blunt, spreading, channelled, keeled, waved villose, three times the length of the calix; nectaries five, shaped like the petals, inserted into the receptacle within them, linear-lanceolate, subulate at the tip, terminated by a gland, smooth, silvery-glandular, narrower than the corolla, but of the same length. *Stamina*: filamenta five, equal, the length of the corolla, four of which have antheræ, one being usually barren: antheræ ovate-cordate, grooved, inserted into the back. *Pistil*: germen pedicelled, capitate, muricate, superior; style inserted into one side of the germen, filiform, the length of the stamina; stigma simple, blunt. *Pericarp*: capsule peduncled, ovate, bluntly five-cornered, five-grooved, muricate, five-celled, five-valved. *Seeds*: in pairs, triangular, convex at the back, smooth. **ESSENTIAL CHARACTER.** *Calix*: spreading, five-petalled. *Nectary*: five-leaved. *Capsule*: five-celled.—The only species hitherto known is.

1. *Calodendrum Capense*. A tree, with branches opposite, or three together; leaves entire, evergreen; flowers in terminating panicles, on opposite one-flowered peduncles.—Native of the Cape of Good Hope.

Calophyllum; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved; leaflets ovate, concave, coloured, deciduous; the two outer ones shorter. *Corolla*: petals four, oblong, concave, spreading. *Stamina*: filamenta many, filiform, short; antheræ erect, oblong. *Pistil*: germen roundish; style filiform, the length of the stamina; stigma headed, obtuse. *Pericarp*: drupe globular. *Seed*: nut globular, subacuminate, very large. **ESSENTIAL CHARACTER.** *Calix*: four-leaved, coloured. *Corolla*: four-petalled. *Drupe*: globular.—The species are,

1. *Calophyllum Inophyllum*. Leaves oval; calix the size of the petals; flowers more racemed; leaves a span long, and a hand broad, marked with transverse distant streaks. The root exudes a whitish clear gum, without scent. Flowers eight-petalled, snow-white, sweet-smelling, growing in racemes; fruit the size of a walnut, under a fleshy bark, and a woody shell, having a very oily nut, which is bitter, and yields a yellow resinous juice. It is a tree of great size, ninety feet in height, and twelve in thickness; bark of the branches smooth, at first green, afterwards reddish; of the trunk thick, scaly, blackish and purple within, which, when wounded, exudes a yellowish viscid juice, frequently hardening to a gum; leaves like those of the Water-lily; fruits smooth, shining, green, when ripe reddish; the nut is at first sweet, but afterwards very bitter.—It is common in Malabar, in sandy soils, bearing fruit twice a year, in March and September, frequently to the age of three hundred years. An oil is ex-

pressed from the nuts to burn in lamps, to assuage pains, and to make ointments; the bark and gum is also used for medicinal purposes. The inhabitants of Java plant this tree about their houses, for the elegance of the shade, and the sweetness of the flowers.

2. *Calophyllum Calaba*. Leaves ovate, obtuse. This is also a lofty tree, putting out branches from very near the ground, so that it is well adapted for hedges and walks. The leaves are shining, coriaceous, firm, with parallel transverse streaks, on short petioles, opposite, four inches long; the flowers on axillary, simple, loose racemes, usually seven together, white, and smelling sweet; the fruit green, with a little pulp, and that hardish, involving a smooth yellowish ash-coloured nut, in which is a white solid kernel; it is not eaten, but the Caribbees express an oil from it for domestic uses. Brown informs us, that this tree is pretty good timber, but does not bear the weather well, although it is frequently used for staves and heading.

Caltha; a genus of the class Polyandria, order Polygynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals five, ovate, flat, spreading, deciduous, large. *Stamina*: filamenta numerous, filiform, shorter than the corolla; antheræ compressed, obtuse, erect. *Pistil*: germen superior, five to ten, oblong, compressed, erect; styles none; stigmas simple. *Pericarp*: capsules many, one-celled, two-keeled, gaping in the superior suture. *Seeds*: very many, (fifteen,) ovate, or ovate-oblong, smooth, affixed to the superior suture in a double row. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: five. *Nectary*: none. *Capsule*: several, many-seeded.—The only species discovered is,

1. *Caltha Palustris*; *Marsh Marigold*, (*Souci de Marois*.) Root perennial; stem several, almost upright, about a foot high, hollow, nearly round, smooth, branched, purple at bottom; radical leaves on long petioles, cordate-reniform, smooth, shining, and notched or crenated, sometimes scalloped, sometimes entire; stem-leaves nearly sessile, more pointed at top, and sharply crenated; stipules brown, membranous, and withering; branches dichotomous; peduncles one-flowered, upright, grooved; corolla of five petals, somewhat concave, large, without any gloss on the upper side; antheræ oblong, flat, bending inward, yellow; the inner row of filamenta with broad antheræ, the outer twice as long, club-shaped, with compressed antheræ; seeds beautiful, at the bottom of an olive, and at top of a reddish colour.—It is found in wet meadows, and by the sides of rivers, making a noble appearance in March and April, and sometimes so early as February. The flowers, gathered before they expand, are said to be a good substitute for capers. The juice of the petals, boiled with alum, stains paper yellow. Cows will not eat it, unless compelled by extreme hunger; it is a vulgar notion, therefore, and wholly unfounded, that the yellowness of butter in the spring is caused by this plant; where a high colour is not given by art, it is the effect of abundance of rich pasture. Boerhaave says, that when cows eat this plant, it occasions such an inflammation that they generally die. On May-day, the country people strew the flowers before their doors; the garlands are also ornamented with it on that day. The leaves seldom appear to be eaten; but the flowers are often destroyed by a species of chrysomela. This is the first flower that announces the spring in Lapland, where it begins to blow towards the end of May. Miller insists that the *greater* and *smaller* Marsh Marigolds never vary, either in their natural places of growth, or when cultivated in a garden. There is a variety with many double flowers, which is preserved in gardens for its beauty.—*Caltha* propagated by parting the roots in autumn; it should be planted in a moist soil and shady

situation, and may be allowed room where few other plants will thrive : during the season of flowering, it will afford an agreeable variety. The Marsh-marigold with double flowers does not appear so early in the spring as the single, but continues much longer in beauty: it flowers from May to the middle of June.

Calycanthus; a genus of the class Icosandria, order Polygynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, pitcher-shaped, squarrose; leaflets coloured, lanceolate, the superior ones gradually larger, resembling petals. *Corolla*: none, except the calycine folioles, representing petals. *Stamina*: filamenta numerous, subulate, inserted into the neck of the calix; antheræ oblong, furrowed, growing to the top of the filamenta. *Pistil*: germen a great many, ending in subulate compressed styles of the length of the stamina; stigmas glandulous. *Pericarp*: none; the calix being thickened, obovate, and berried. *Seeds*: very many, tailed. ESSENTIAL CHARACTER. *Calix*: one-leaved, pitcher-form, squarrose, with coloured leaflets. *Corolla*: calycine. *Styles*: very many, with a glandulous stigma. *Seeds*: very many, tailed, within a succulent calix.—The species are,

1. *Calycanthus Floridus*; *Carolina Allspice*. Inner petals longer than the outer. This shrub arrives at the height of eight or ten feet where it grows naturally, but it seldom rises more than four feet high in this country, dividing into many slender branches near the ground, covered with a brown aromatic bark, with two entire leaves placed opposite at every joint on short foot-stalks; the flowers grow single, on short peduncles at the extremity of the branches; they have two series of narrow thick petals, which spread open, and turn inward at the top, like those of the Starry Anemone, or the Virgin's Bower; these are of a dusky purple colour, and have a disagreeable scent; they appear in May. The bark of this shrub is brown, and has a very strong aromatic odour; and hence the inhabitants of Carolina call it *allspice*. There are two varieties of it; the Long-leaved Carolina allspice, and the Round-leaved Carolina Allspice.—It will thrive in the open air in England, if it be planted in a warm situation and dry soil: it is propagated by laying down the young branches, which will take root in one year, and may then be taken from the mother-plant, and set where they are designed to remain for they do not bear transplanting well after they are grown to any size. When the layers are transplanted, the surface of the ground should be covered with mulch, to prevent the drying winds from penetrating the ground to the roots; and if the season prove dry, they must be watered once a week, but should not have too much wet, for that will rot their tender fibres: the best time for laying down the branches is in autumn, but they should not be transplanted till the spring, twelve months after; for the spring is the safest time to remove these plants. After the branches are laid down, there should be some old tanner's bark laid upon the surface to keep out the frost, which should also be done every winter whilst the plants are young.

2. *Calycanthus Præcox*; *Japan Allspice*. Inner petals minute.—Native of Japan.

Calyptanthes; a genus of the class Icosandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, truncate, toothless, or very obscurely four-toothed, superior, permanent, covered with an orbicular, concave, deciduous lid. *Corolla*: none. *Stamina*: filamenta very many, capillary, inserted into the inside of the calix at the rim; antheræ roundish, twin, small. *Pistil*: germen roundish, fastened to the bottom of the calix, two-celled, with a few seeds fixed to the partition; style simple,

filiform, bent in the length of the stamina; stigma blunt. *Pericarp*: berry globular or oblong, crowned with the calix, one-celled. *Seed*: single, or few, slightly angular. ESSENTIAL CHARACTER. *Calix*: superior, truncate, covered with a veil-shaped deciduous lid. *Corolla*: none. *Berry*: one-celled, one to four seeded.—The species are,

Calyptanthes Chytraculia. Arboreous; peduncles terminating, paniced, trichotomous, tomentose; leaves ovate, attenuated at the tip. The leaves of this tree are smooth and opposite; the lid is fastened to the calix laterally, but afterwards turns back, and then the filamenta issue forth, which had been before twisted and concealed. It is reckoned an excellent timber tree, but it seldom exceeds fourteen or fifteen inches in diameter.—Native of Jamaica.

2. *Calyptanthes Zuzygium*. Arborescent; peduncles axillary, trichotomous, patulous; leaves ovate, blunt; branches dichotomous. This shrub seldom rises above ten or twelve feet in height; the whole is bushy, and bears black berries, crowned with the margin of the cup; these contain four smooth slightly angular seeds, one or two only usually arrive at maturity; the style is longer than the stamina, and the stigma is acute.—Native of Jamaica.

3. *Calyptanthes Rigida*. Arborescent; peduncles solitary, axillary, three-flowered, or thereabouts; leaves ovate acute, convex, veinless, rigid.—Native of Jamaica.

4. *Calyptanthes Jambolifera*. Leaves ovate, emarginate; corymb terminating. This is a tree above the middle size, with spreading branches, the smaller ones brachiata; berry black, esculent.—Native of the East Indies and China.

5. *Calyptanthes Odorata*. Leaves ovate, obliquely truncate at the base; corymbs terminating, distich. This is a small tree, about five feet high, with a very straight single stem, and brachiata branches; the young leaves are put into salads, and are not unpleasant. Berry white, dotted. Loureiro observed it in the gardens of Cochin-china.

6. *Calyptanthes Resinosa*. Leaves oblong; peduncles lateral. This is a middle sized tree, with spreading branches and a very tough resinous bark; leaves quite entire; flowers white, on many-flowered axillary peduncles; berry roundish, small, black, four-celled.—Native of Cochin-china; where the fishermen dye their nets in a strong decoction of the root, to prevent them from rotting.

Camax; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted; parts roundish. *Corolla*: one-petalled, wheel-shaped; tube very short; border five-parted; parts roundish, villose above. *Stamina*: filamenta five, inserted into the corolla between the segments, villose. *Pistil*: germen roundish, villose, superior; style capillary; stigmas three or four, sharp. *Pericarp*: berry ovate, villose, four-celled. *Seeds*: very many, nestling in a viscid pulp. ESSENTIAL CHARACTER. *Corolla*: wheel-shaped; filamenta inserted between the segments of the corolla. *Berry*: four-celled, many-seeded; all villose.—The only species known is,

1. *Camax Guianensis*. This is a shrub, growing to the height of twelve or fifteen feet, with a simple, knotty, cylindrical stem; leaves many, in whorls at the joints, declining unequally, pinnate, with six alternate leaflets, which are sessile, oval, acuminate, the largest of them ten inches long and three broad, and a little above each of them is a small spine issuing from the midrib; the flowers are sessile, in great numbers at the base of the leaves, and in the intervals between them. It is called *bois gaulete* by the Creoles, and *aroupouron* by the Coussaris, one of the nations of Guiana, where it is a native, and flowers in January. The inhabitants and negroes use the branches of this shrub for wattling their huts.

Cambogia; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets roundish, concave, deciduous. *Corolla*: petals four, roundish-oblong, concave, with oblong claws. *Stamina*: filamenta very many, short: antheræ roundish. *Pistil*: germen roundish, striated; style none; stigma four-cleft, obtuse, permanent. *Pericarp*: pome roundish, eight-angled, eight-celled. *Seeds*: solitary, reniform, oblong, slightly compressed. ESSENTIAL CHARACTER. *Corolla*: four-petalled. *Calix*: four-leaved. *Pome*: eight-celled. *Seeds*: solitary.—The only species known is,

1. *Cambogia Gutta*. This is a tall tree, with a trunk sometimes as thick as two men can compass, with spreading opposite branches. Flowers in whorls, sessile, saffron-coloured, the fruit is first green, then yellowish, and when ripe whitish.—Native of the East Indies, and of the woods in China and Cochinchina; very abundant in Siam and Cambodia, where incisions are made in the bark, and a great quantity of *gummi gutta*, or gamboge, is extracted, and exported into foreign countries. This concrete is a gum-resin, in part inflammable, compact, dry, yellow, inclining to orange colour, without smell, and almost without taste; producing, however, a slight sensation of acrimony in the throat. A greater quantity of it is dissolved in spirits of wine than in water, to which it imparts a lemon-colour: it is used medicinally in the East Indies, as a purgative, hydragogue, and emetic, particularly in dropsies and worm cases; it is said to lose the latter quality, when macerated in vinegar. The principal use, however, of gamboge, is in painting in miniature and water colours. The fruit is eaten at meals in the East Indies; and being much esteemed for provoking the appetite, is a frequent ingredient in their sauces.

Camellia; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth many-leaved, roundish, imbricate; the scales roundish, very blunt, the inner ones gradually larger, concave, deciduous. *Corolla*: petals five, obovate, coalescing at the base. *Stamina*: filamenta numerous, erect, coalescing below into a crown, larger than the style; above unconnected, shorter than the corolla; antheræ simple. *Pistil*: germen roundish; style subulate, length of the stamina; stigma acute, reflex. *Pericarp*: capsule turbinate, woody, marked with some furrows. *Seeds*: kernels equal in number to the streaks of the capsule, roundish, often filled with smaller seeds. ESSENTIAL CHARACTER. *Calix*: imbricate, many-leaved; the inner leaflets larger.—The species are,

1. *Camellia Japonica*; *Japan Rose*. Leaves acutely serrate, acuminate; bark ash-coloured; branches round and smooth; leaves alternate, ovate, shining on both sides, thick and stiff, paler green beneath, on short petioles; peduncles terminating, very short, commonly solitary, with the branches lengthened out beyond them. It is a vast and lofty tree, in high esteem with the Japanese, for the elegance of its large flowers, which exhibit a great variety of colours, but have no scent, and for its evergreen leaves: it is very common every where in their groves and gardens, flowering from October to April. It varies with single and double flowers, white, red, and purple. It is a native also of China, and occurs very frequently in Chinese paintings.—Having been hitherto scarce, and kept up to a high price, it has been generally treated as a stove plant, though it has been sometimes placed in the green-house. When it shall hereafter become more common among us, it may perhaps be treated in the same manner as the *Magnolia*: it is propagated by layers; it may also be propagated by cuttings, in the same manner as directed for *Gardenia*.

2. *Camellia Sasanqua*. Leaves obtusely serrate, emarginate. A tree of a middling size, differing from the first species, in having thinner and narrow leaves, obscurely serrate; flowers much smaller, with oblong emarginate petals, and a much smaller and more slender stem; the flowers are borne singly at the end of the branches; the calyx is five-leaved, sometimes six-leaved; the petals are five in number, sometimes six or seven, snow-white, deciduous. The leaves, dried in the shade, have a sweet smell; a decoction of them is used by the women to wash their hair with. The petals are mixed with tea, to give it a grateful odour. It yields, says Sir G. Staunton, a nut, from which is expressed an esculent oil, equal to the best from Florence; and on this account is cultivated in vast abundance, growing in a soil consisting of little more than fragments of stone.—Native of Japan; flowering in November.

3. *Camellia Drupifera*. Leaves ovate-oblong, slightly crenate; flowers two or three together, terminating; drupes four-celled.—This is a middle-sized tree, with spreading branches; leaves smooth, hard, small, alternate, petioled; flowers white, terminating, two or three peduncles together, one on each; petals eight, oblong, emarginate; style quadrifid, equal to the stamina; drupe roundish, with a grooved four-celled nut, and roundish kernels. The fruit is equal in size to the walnut, and not much unlike it; it is not however, esculent. It is both wild and cultivated in Cochinchina. The oil expressed from the nut is used by the natives to anoint their hair, and for various medical purposes; it has a pleasant odour, and does not easily become rancid.

Camel's Hay. See *Andropogon*.

Cameraria; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-cleft, acute, converging, very small. *Corolla*: monopetalous, funnel-form; tube cylindric, long, bellied out at the base and tip; border five-parted, flat; divisions lanceolate, oblique. *Stamina*: filamenta five, very small from the middle of the tube; antheræ converging. *Pistil*: germen two, with lateral appendages; style hardly any; stigmas obscure. *Pericarp*: follicles two, horizontally reflected, oblong, obtuse at both ends, and sending forth a lobe each way near the sides of the base, one-celled, one-valved. *Seeds*: numerous, ovate, inserted on the larger ovate membrane at the base, imbricate. ESSENTIAL CHARACTER. Contorted. *Follicles*: two, horizontal. *Seeds*: inserted into their proper membrane.—These plants are propagated by seeds, which must be procured from the places of their growth; they may also be increased by cuttings, planted in a hot-bed during the summer months. They must have a bark-stove, for they are very tender; but in warm weather they must have plenty of air.—The species are,

1. *Cameraria Latifolia*; *Bastard Manganeel*. Leaves ovate, acute at both ends, transverse, striated. This is a tall elegant tree, about thirty feet in height, the whole abounding with an acrid milky juice. Leaves somewhat resembling those of *Myrtle*.—Native of Cuba, Jamaica, and St. Domingo: the flowers, which are white, appear in August, but never produce any seed in England.

2. *Cameraria Angustifolia*. Leaves linear; stem irregularly branching, shrubby; leaves opposite, quite entire, the middle nerve decurrent; flower and fruit much smaller than in the foregoing species, as is the whole plant. It grows about eight feet high: the flowers are produced scatteringly at the ends of the branches: like the other species, it abounds with an acrid milky juice.—It grows naturally in Jamaica.

Cammoek. See *Ononis*.

Camomile. See *Anthemis*.

Campanula; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, acute, erect, expanding, superior. *Corolla*: monopetalous, bell-form, impervious at the base, half five-cleft, marescent; divisions broad, acute, spreading; nectary in the bottom of the corolla, composed of five valves, acute, converging, covering the receptacle. *Stamina*: filamenta five, capillary, very short, inserted on the tips of the valves of the nectary; antheræ longer than the filamenta, compressed. *Pistil*: germen angular, inferior; style filiform, longer than the stamina; stigma three-parted, oblong, thickish; divisions revolute. *Pericarp*: capsule roundish, angular, three or five celled, emitting the seeds at so many lateral openings. *Seeds*: numerous, small; receptacle, columnar, adnate. ESSENTIAL CHARACTER. *Corolla*: bell-form, the bottom closed with stamiferous valves. *Stigma*: three-cleft. *Capsule*: inferior, gaping, with lateral pores.—The directions for propagating and cultivating, which will be found subjoined to various species of this genus, may serve for all the other hardy annuals, biennials, and perennials, of which it consists. Those species which come from the Cape of Good Hope, must be kept in the dry-stove, and otherwise treated like the plants from that country; they may in general be increased from cuttings.—The species are,

* *Leaves more glossy and narrow.*

1. *Campanula Cenisia*; *Ciliate Bell-flower*. Stems one-flowered; leaves ovate, smooth, quite entire, subciliate. Root perennial, creeping, often a foot long, dividing into several branches at top; corolla blue, divided to the middle into five segments, which are frequently bent back, twice as long as the calix; capsule three-celled.—Native of the higher rocks of the Alps, about the Glaciers; on the highest pike of Mont Cenis, called Ronche; by the head of the river Durance, and on other neighbouring eminences; also in Dauphiny; it flowers in June and July.

2. *Campanula Uniflora*. Stem one-flowered; calix equaling the corolla. Root fibrous, annual; stem absolutely simple, the length of a finger, obliquely erect, round, entire; stem-leaves six or seven, alternate, the lowest vertically ovate, the middle ones lanceolate, the uppermost linear, the last of these is immediately under the flower. A single flower terminates the stem; it is nodding, bell-shaped, contracted towards the base, and blue; fruit turbinate, ovate, or pear-shaped, very large in proportion to the plant, slightly inclined, opening with three holes near where the capsule unites with the crowning calix.—Native of the mountains of Lapland, where it is very rare, and flowers in the beginning of July.

3. *Campanula Pulla*; *Russet Bell-flower*. Stemlets one-flowered; stem-leaves ovate, crenate; calices drooping. Root filiform, creeping; stems a short span in length, erect, flexuose, filiform, sometimes having a branch or two bearing a single flower; root and stem-leaves ovate, obtuse, with a few distant notches, naked and petioled; peduncle terminating; flower drooping, the same size as in the next sort, with a smooth calix. There is a variety which has several flowers at the top of the stalk; the corolla is of a very deep blue.—Native of the mountains of Austria, Carniola, and Arragon.

4. *Campanula Rotundifolia*; *Round-leaved Bell-flower*. Radical leaves kidney-form; stem-leaves linear. Root perennial, creeping, sweetish; stems several, a foot or more in height, varying from two inches to a yard, rather upright, but weak and crooked, round, smooth; solid, milky, and branched; radical-leaves heart or kidney-form, petioled, toothed (frequently quite entire;) stem-leaves near the base, lanceolate and toothed, near the summit linear and entire;

flower-branches spreading, simple or subdivided, almost naked; flowers nodding a little; corolla blue, sometimes white; calix permanent, segments linear, smooth, grooved, considerably expanded when out of blossom; nectary at the bottom of the corolla, formed of five pointed valves, closing and covering the receptacle, fringed, white; capsule three-celled. The radical leaves, whence this plant has its name, are usually hid in the herbage, and therefore seldom observed; they also dry away and drop off, when it is advancing to maturity.—It grows plentifully on heaths and other waste grounds, in dry hilly situations, flowering from June to September. A green pigment is obtained from the flowers; the juice stains blue, but with the addition of alum, green. The stalks and branches, when broken, give out a milky juice, which has a disagreeable smell. There are two varieties of this species, but not worth noticing.

5. *Campanula Patula*; *Spreading or Field Bell-flower*. Leaves stiff, the radical ones lanceolate-oval; panicle spreading. Root-leaves many together, spreading, small, roundish or oval, soon turning yellowish; those on the stems lanceolate, straight, and even. The herb, though bitter, being frequently eaten down by cattle, side-branches spring up, and flower till the winter frost destroys the root; corolla of an elegant form, tapering at the base, but spreading in the rim.—Native of Sweden, Denmark, Germany, Switzerland, Carniola, Piedmont; in corn fields, woods, hedges, and by roadsides; flowering in July and August: in England it is not common. Lyttleton, Browne, and Merrett, found it at Adferton near Wigmore in Herefordshire; Dillenius, in a wood called Elberry Hill, about a mile from Worcester, and near Bishop's Castle in Shropshire; Dr. Pulteney, by Buddon wood near Loughborough, and between Litchfield and Meriden; Mr. Nash, near Malvern; Mr. Woodward, near the bath at Litchfield, and on the road to Coleshill; Dr. Smith, in the park of the late Lord Ligonier, at Colsham in Surry. It may be propagated by seeds sown in autumn.

6. *Campanula Rapunculus*; *Rampion*. Leaves waved, the radical ones lanceolate-oval; panicle contracted. The whole plant is full of a milky juice; root biennial, spindle-shaped, sometimes branching; stem upright, angular, two feet high, hairy towards the base, smooth above; branches alternate, short, upright; leaves towards the base of the stem hairy, above, or on both sides, blunt; the upper ones smooth and becoming gradually more pointed, obscurely notched; an awl-shaped bracte at the base of each peduncle; segments of the calix awl-shaped or setaceous, twice as long as the germen, with a small tooth on each side of the base; flowers upright; corolla bluish purple, sometimes very pale purplish, or whitish; each segment marked with three lines; nectary fringed.—It grows wild in France, Flanders, Switzerland, Germany, Carniola, Piedmont, by hedges and road-sides, and woods, in fallow-fields and dry pastures; flowering in June, July, and August. In England it has been found growing near Croydon and Esher in Surry; old Buckenham Castle in Norfolk; and about Hindlip and Enville in Worcestershire. The fleshy roots are eatable, and are much cultivated in France for salads; some years past it was cultivated in the English gardens for the same purpose, but it is now generally neglected. Haller says, that it is in great request among the Swiss, in the spring; and that it increases milk; the roots are eaten, not only raw in salads, but boiled like asparagus: they were boiled tender and eaten cold with vinegar and pepper, in the time of Parkinson.—This plant is propagated by seeds, which should be sown in a shady border the latter end of May, and when the plants are about an inch high, the ground should be hoed, as is practised for

Onions, to cut up the weeds, and thin the plants to the distance of three or four inches ; and when the weeds come up again they must be hoed over to destroy them ; this, if well performed in dry weather, will make the ground clean for a considerable time, so that if thrice repeated it will keep the plants clean till winter, which is the season for eating the roots, when they may be taken up for use as they are wanted. These will continue good till April, at which time they will send out their stalks, when they will become hard and unfit for use, as do also those roots which have flowered ; the young roots only are fit for the table : when the seeds are sown too early, the plants frequently run up to flower the same year, and the roots are spoiled.

7. *Campanula Persicifolia* ; *Peach-leaved Bell-flower*. Radical leaves obovate ; stem-leaves lanceolate-linear, subserrate, sessile, remote. Root like that of Navew, and eatable ; stem very straight, eighteen inches high and more, (in gardens two feet and a half) unbranched, angular, smooth, as is the whole plant (except the germen and capsule ;) flowers in a thin spike, one or two together, on very long peduncles, which have two stipules at the base ; corolla large, broad, bell-form, deep blue, the segments short, and moderately acuminate.—This is a perennial plant, native of most parts of the continent of Europe, from Sweden to Spain, but not of Britain. The varieties are, the single blue, and white ; and double flowers of both colours : the latter have not been more than fifty years in England, but have been propagated in such plenty, as to have almost banished those with single flowers from the gardens.—This species, as well as all the other hardy perennial sorts, which are very numerous in this genus, are easily propagated by parting their roots in autumn, at which time every head that is slipped off will grow ; they will thrive in any soil and situation, and are proper furniture for the common borders of the flower-garden and shrubbery.

8. *Campanula Pyramidalis* ; *Pyramidal Bell-flower*. Leaves smooth and even, serrate, cordate ; stem-leaves lanceolate ; stems rushy, simple ; umbels sessile, lateral.—Scopoli thus describes this plant in its wild state : the root and stem are milky ; the latter is four feet high, paniced, with short branches from top to bottom ; all the leaves are ovate, petioled, and shortly toothed ; the teeth paler, and terminated by a gland ; the corolla spreading, five-cleft beyond the middle ; the calycine teeth even, whilst the corolla is closed, spreading out horizontally, and twice as long as the germen, which is three-cornered.—It is found about Idria, in Struk ; and, according to Allioni, in Savoy. It is thus described by Mr. Miller, as it appears in gardens. It has thick tuberous roots which are milky ; these send out three or four strong, smooth, upright stalks, which are nearly four feet high, and are garnished with smooth oblong leaves, whose edges are a little indented : the lower leaves are much broader than those on the stalks. The flowers are produced from the side of the stalks, and are regularly set on for more than half their length, forming a sort of pyramid ; these are large, open, and shaped like a bell ; the most common colour of the flower is a light blue ; but there have been some with white flowers, which make a variety when intermixed with the blue, but the latter is most esteemed. This plant is cultivated to adorn halls, and to place before the chimnies in summer, when it is in flower, for which purpose there is no plant more proper ; for when the roots are strong they will send out four or five stalks, which will rise as many feet high, and are garnished with flowers great part of their length ; these upright stalks send out some short side-branches, which are also adorned with flowers, so that by spreading the upright stalks to a flat frame composed of

slender laths, as is usually practised, the whole plant is formed into the shape of a fan, and will spread nearly to the width of a common fire-place. When the flowers begin to open, the pots are removed into the rooms, where being shaded from the sun, and kept from the rain, the flowers will continue long in beauty ; and if the pots are every night removed into a more airy situation, but not exposed to heavy rains, the flowers will be fairer, and continue much longer in beauty.—Those plants which are trained for adorning halls and chimneys, are seldom fit for the purpose the following season ; a supply of young plants therefore should be annually raised : the common method of doing this, is by dividing the roots ; and the best time for doing it is in September, that the offsets may have time to get strong roots before winter. This method of propagating by the offsets is the quickest, therefore generally practised, but the plants which are raised from seeds are always stronger ; the stalks will rise higher, and produce a greater number of flowers ; and is therefore recommended to the practice of the curious. In order to obtain good seeds, there should be some strong plants, placed in a warm situation, near a pale or wall, in autumn ; and if the following winter should prove severe, they should be covered with either hand-glasses or mats, to prevent their being injured by the frost ; and in the summer, when the flowers are fully open, if the season should prove very wet, the flowers must be screened from great rains, otherwise there will be no good seed produced : the not observing this had led many to conclude that the plants do not bear seed in England, which is a great mistake, though it has certainly been found that the plants which have been raised by offsets, seldom produce seeds ; and this is the case with many other plants which are propagated by slips or cuttings, which in a few years become barren. When the seeds are obtained, they must be sown in autumn, in pots or boxes filled with light undunged earth, and placed in the open air till the frost or hard rains come on, when they should be placed under a hot-bed frame, where they may be sheltered from both ; but in mild weather, the glasses should be drawn off every day, that they may enjoy the free air ; with this management the plants will come up early in the spring, and then they must be removed out of the frame, placing them first in a warm situation ; but when the season becomes warm, they should be removed where they may have the morning sun only : during the following summer, they must be kept clean from weeds, and in very dry weather now and then refreshed with water, which must be given with great caution, for the roots are very subject to rot with too much moisture. In September, the leaves of the plants will begin to decay, at which time they should be transplanted ; therefore there must be one or two beds prepared, in proportion to the number of plants. These beds must be in a warm situation, and the earth light, sandy, and without any mixture of dung, which last is an enemy to this plant. If the situation of the place be low, or the soil moist, the beds must be raised five or six inches above the surface of the ground, and the natural soil removed a foot and a half deep, putting lime-rubbish, eight or nine inches thick, in the bottom of the trench, to drain off the moisture. When the beds are prepared, the plants must be taken out of the pots or cases very carefully, so as not to break or bruise their roots, for they are very tender, and on being broken, the milky juice will flow out plentifully, which will greatly weaken them. These should be planted at four inches distance each way, with the head or crown of the root half an inch below the surface ; if there happen a gentle shower of rain soon after they are planted, it will be of great service to them ; but as the season

sometimes proves very dry at this time of the year, in that case it will be proper to give them a gentle watering three or four days after they are planted; and to cover the beds with mats every day, to prevent the sun from drying the earth; but these must be taken off in the evening, that the dew may fall on the ground. Towards the end of October the bed should be covered over with some old tanner's bark to keep out the frost, and where there is not a conveniency of covering them with frames, they should be arched over with hoops, that in severe frosts they may be covered with mats; for these plants when young are often destroyed in winter, where this care is wanting. In the spring the covering must be removed, and the plants kept clean from weeds during the following summer; and if the season should prove very dry, they must now and then be refreshed with water. The following autumn, the surface of the ground should be stirred between the plants, and some fresh earth spread over the beds, and in winter covered as before. In these beds the plants may remain two years, during which time they must be treated in the manner before directed, by which time the roots will be strong enough to flower: in September they should be carefully taken up, and some of the most promising planted in pots; the others may be planted into warm borders, or in a fresh bed, at a greater distance than before, to allow them room to grow. Those plants which are potted, should be sheltered in winter; and those in the full ground, should have some old tanner's bark laid round them, to prevent the frost injuring the roots.

9. *Campanula Americana*; *American Bell-flower*. Leaves cordate, and lanceolate serrate; petioles of the lower ciliate; flowers axillary, sessile; corollas five-parted, flat; styles longer than the corolla. Root annual; stem and germina smooth; leaves acuminate; flowers three or more from each axil or bracte.—Native of Pennsylvania; flowers in July.

10. *Campanula Lilifolia*; *Lily-leaved Bell-flower*. Leaves lanceolate; stem-leaves sharply serrate; flowers panicled nodding: It is singular in this plant, that the stem, before it produces the panicle, puts out leaves in a kind of rose, which, when the panicle comes forth, are dispersed about the stem. It is perennial, and varies much in the colour and size of the flower, quantity of branches, hardness and softness, smoothness and roughness, of the leaves.—It flowers most part of the summer; and was found from the Jaick eastward to the very confines of China, where the roots, both boiled and raw, are eaten by the inhabitants.

11. *Campanula Rhomboidea*; *Germander-leaved Bell-flower*. Leaves rhomboid, serrate; spike one-ranked; calices toothed. Root creeping, perennial; stem erect, smooth, from six, eight, or ten, to eighteen inches in height, unbranched; leaves few, tender, smooth, ending in a point; the upper ones smaller; corollas blue, sometimes white, short, and swelling; calix capillary.—Native of the mountains of Switzerland, Dauphiny, Carniola, and Italy, on mount Cenis. It flowers in July.

12. *Campanula Unidentata*; *One-toothed Bell-flower*. Erect, smooth; leaves lanceolate, acute, one-toothed on each side; panicle divaricated, leafy; stems extremely simple.—Native of the Cape.

13. *Campanula Capillacea*; *Five-leaved Bell-flower*. Herbaceous erect; leaves filiform, smooth; panicle terminal; flowers alternate.—Native of the Cape.

14. *Campanula Linearis*; *Linear-leaved Bell-flower*. Herbaceous, erect; leaves linear, entire, smooth; flowers drooping; capsules hispid.—Native of the Cape.

15. *Campanula Lobelioides*; *Lobelia-like Bell-flower*. Small stems round, stiff, smooth; leaves linear-lanceolate,

toothletted; corollas nearly funnel-form, trifold, and quadrifid.—This species, as its name signifies, has the air of a *Lobelia*, the same tenderness, divided in the same manner, and even the same inflorescence. Perianth three or five-leaved; leaflets ovate, obtuse, permanent; corollas very small, purplish white, twice as long as the calix, funnel-form; tube round, gradually widened; segments erect. It varies with the calix and corolla, three and five-parted, and even with three and five stamina; the capsule also is two-celled. It flowers in July and August.—Native of Madeira.

16. *Campanula Carpatia*; *Carpathian or Heart-leaved Bell-flower*. Leaves smooth, cordate, serrate, petioled; branches filiform, one-flowered. This pours out a milky juice when wounded; the root is whitish, and perennial; stems herbaceous, annual, weak, hardly branching, bearing one or very few flowers. In gardens it becomes branching and many-flowered: the root-leaves are kidney-form, roundish; the peduncle elongated and smooth; the corolla blue. It flowers the whole summer, and was first observed on the Carpathian Alps. It is yet scarce in our gardens, but deserves to be more generally known and cultivated, its flowers being large and showy in proportion to the plant; and, like many other alpine plants, being well suited to decorate rock-work, or such borders of the flower-garden as are not adapted to large plants. It is a perennial plant; and may be propagated by parting the root.

17. *Campanula Grandiflora*; *Great-flowered Bell-flower*. Leaves tern; oblong; serrate; stem one-flowered; flower spreading. The whole plant is very smooth; root perennial, white, fusiform, the thickness of a finger, and branched; stems few, erect, or ascending, simple, round, a foot high, leafy all over, annual, terminated with one handsome flower, but without scent, nodding a little; with sometimes one or two flowers more from the upper axillas; corolla two inches or more in diameter, very deep blue, with numerous blue veins, elegantly pear-shape, before expanding, and at first green; no holes in the capsule: it flowers in June and the beginning of July, and ripens its seeds in August.—Native of Siberia.

18. *Campanula Aurea*, *Golden Bell-flower*. Capsules five-celled; leaves elliptic, serrate, smooth; flowers subpanicled, five-parted; stem shrubby, fleshy. It flowers in August and September.—Grows in Madeira.

19. *Campanula Tenella*. Stems diffused, filiform; leaves ovate, sometimes one-toothed, reflex; flowers solitary, terminal. Stem determinately branched and hard; branches simple, and covered with leaflets; calix glossy, acute; corolla five-parted. The leaves are seldom without a lateral tooth.—Found at the Cape.

20. *Campanula Purosa*; *Porous-stalked Bell-flower*. Leaves lanceolate, glossy; stem erect, porous, with dots upwards. This is a plant difficult to be distinguished; unless by the pores, scarcely distinguishable by the naked eye, which penetrate into the stem, not downward but upwards; stem round, a foot high, erect; branches numerous, erect, short; the upper leaves linear, even, quite entire; racemes terminal, erect; flowers small, rather erect; calix shorter by half than the corolla, even, with lanceolate segments.—Native of the Cape.

21. *Campanula Undulata*. Leaves lanceolate, tooth-waved; flowers subsolitary, peduncled. Stem a foot and a half high, erect, filiform, glossy, somewhat branched at top; leaves sessile, reflected at the edge, subdecurent, repand, somewhat glossy; peduncles terminal, long, leafless; flowers the size of the fourth species; calix glossy, with short acuminate teeth.—Native of the Cape.

** *Leaves rugged, broader.*

22. *Campanula Latifolia*; *Broad-leaved Bell-flower*, or *Giant Throatwort*. Leaves ovate, lanceolate; stem very simple, columnar; flowers solitary, peduncled; fruit drooping. Stem three feet high and more, angular, smooth, not branching; leaves sharply serrate, on short petioles, hirsute; flowers axillary, one or two together, on peduncles shorter than the leaf; corolla very large, blue, the segments triangular, divided by a line: the fruit compels the peduncle to bend down beneath its weight. The whole plant abounds with milky liquor; it varies with purple, and with white flowers.—It grows naturally in the northern parts of England, in Flintshire, Scotland, Denmark, Sweden, Switzerland, Piedmont, &c. flowering in July and August. It is perennial, and easily propagated by seeds, which it furnishes in great plenty; if these be suffered to scatter, the plants will come up abundantly the following spring, when they may be removed into the nursery till autumn, at which time they should be transplanted whither they are intended to remain. As this sort delights in shade, the plants may be placed under trees, or in shady borders, where few better things will thrive, and they will there afford an agreeable variety when in flower.

23. *Campanula Rapunculoides*; *Rampion-like Bell-flower*. Leaves cordate-lanceolate; stem branching; flowers one-ranked, scattered; calices reflex. The throat of the corolla is not very hairy; the root creeps prodigiously, and is said to be esculent.—Native of France, Germany, Austria, Switzerland, and Piedmont. Ray noticed it about Geneva, towards Gex, and on Mont Saleve. It is perennial, affects a dry soil, and flowers in July and August.

24. *Campanula Bononiensis*; *Bologna* or *Panicled Bell-flower*. Leaves ovate-lanceolate, rugged beneath, sessile; stem panicled. It grows to the height of three feet and more, with many ascending conjugate branches; leaves stem-clasping, almost cordate, villose, with a white nap beneath, but not rough, moderately serrate; the same under the flowers, which come out on almost naked branches, and at the top of the stem, the lower ones on erect short peduncles, three together, the upper ones sessile, in the axillas solitary or two together, at the top of the stem very numerous but small, forming a spike; they are of a violet colour.—Native of Bologna, Monte Baldo, Austria, Switzerland, and Piedmont: it is perennial.

25. *Campanula Graminifolia*; *Grass-leaved Bell-flower*. Leaves linear-subulate; head terminal. Stems extremely simple, scarcely longer than the leaves; leaves very narrow, like grass; flowers facicled into a head with ovate bractes, subulate at top; stigma bifid.—Native of Italy, in the mountains of Abruzzo near Salmone, and Monte Vergine.

26. *Campanula Cineria*. Erect, tomentose; leaves subulate, entire, erect, approximating; flowers solitary, terminal.—Native of the Cape.

27. *Campanula Hispidula*. Hispid; flowers erect; calices the length of the corolla. Stem branching, a hand high, and hispid, more branching at top; leaves alternate, linear, acuminate, ciliate, especially the midrib; calices subsessile, terminal, linear, with the keel ciliate; corolla funnel-form; stigma trifid, annual.—Found at the Cape.

28. *Campanula Trachelium*; *Great Bell-flower*, *Great Nettle-leaved Throatwort*, or *Canterbury Bells*. Stem angular; leaves petioled; calices ciliate; peduncles trifid. Root perennial; stems from two to three feet in height, upright, stiff, hairy, angular, the angles membranaceous, putting out a few short side branches; corolla pale or deep blue, purple or white, spreading very much, hairy within, the segments triangular, divided by a hairy line; when the corolla is double,

there are no stamina or nectary. The number of flowers varies from one or two to three, four, and even five; they are large, and nodding. The whole plant contains a juice of a dirty yellow colour.—Native of most parts of Europe, and of Japan, in woods and hedges; flowering in July and August. The double sorts of great Canterbury Bells are propagated by parting their roots in autumn, which should be annually performed, otherwise the flowers are apt to degenerate to single; the soil should not be too light or rich in which they are planted, for in either of these they will degenerate; but in a strong fresh loam their flowers will be in the greatest perfection: these plants, being extremely hardy, may be planted in any situation; those, however, with single flowers, do not deserve a place in gardens.

29. *Campanula Glomerata*; *Small or Clustered Bell-flower*, or *Little Canterbury Bells*. Stem angular, simple; flowers sessile; head terminal. Root perennial; stem upright, angular, hairy, from six to eighteen inches in height, but varying from two and even three feet in strong soils, down to two inches in lofty dry situations; seldom or ever branched, unless when it is eaten down by cattle; corolla blue, purple, or white, five-cleft to the middle, (sometimes four-cleft,) usually villose on the outside, and sometimes on the inside, with white hairs.—Native of most parts of Europe, in hilly and dry pastures, particularly in a calcareous soil; flowering from June to September. This plant is no contemptible ornament for rock work or dry flower-borders; a moist or rich soil makes it too luxuriant, and renders the flowers pale and degenerate.

30. *Campanula Cervicaria*; *Wave-leaved Bell-flower*. Hispid; flowers sessile; head terminal; leaves lanceolate, linear, waved. Root biennial.—It is a wood plant, native of Sweden, Denmark, Germany, Switzerland, Piedmont, Siberia; flowering in July and August. The root is esculent. This, as well as the fifth and thirty-ninth species, and several others, may be propagated by seeds sown in autumn; for such as are sown in spring often fail, or at least lie a year in the ground; when the plants come up, they should be removed into beds, and kept clean from weeds.

31. *Campanula Thyrsoides*; *Long-spiked Bell-flower*. Hispid; raceme ovate oblong, terminal; stem entirely simple; leaves lanceolate linear. Root large, woody, biennial; from which rises a round tuft of rough broad ovate-lanceolate leaves; from the centre of these springs a stem eight or ten inches high, unbranched, covered with leaves and flowers, the leaves tongue-shaped, longer than the radical ones, equal to the whole stem; the flowers hirsute, white, or yellowish white, long and slender, collected into one very long, ovate cylindrical, close terminating spike, leafy at bottom, but naked at top; sometimes the corolla is cut into four or six parts, and then there is a proportional number of stamina, and two stigmas.—In Switzerland it is common in stony alpine meadows; on the lower mountains it is more rare. It was observed by Ray to grow plentifully on the highest tops of Jura. It is also a native of Germany, Hungary, Austria, Carniola, Savoy, and Dauphiny; and it flowers in July.

32. *Campanula Petraea*; *Great Stone Throatwort*. Stem angular, simple; flowers sessile, headed-glomerate; leaves tomentose beneath. The stem is upright, rough, hairy, from a foot to two feet in height, beset with flowers from the top to below the middle, in alternate distinct bunches, with a leaf between each; the lower leaves are petioled, the rest are sessile; they are all bluntish, serrate, rugged on the upper surface, white with nap on the under: the corolla is white, divided into five, (sometimes seven,) sharp spreading seg-

ments, twirling at the extremity.—It was first observed by Pona on Monte Baldo, flowering in August; and is also a native of Piedmont, Silesia, &c.

*** *Capsules covered with the reflected Sinuses of the Calix.*

33. *Campanula Dichotoma*; *Dichotomous Bell-flower*. Capsules five-celled, covered; stem dichotomous; flowers drooping. The leaves are oblong, rugged; and the flowers solitary, from the forks and ends of the branches.

34. *Campanula Medium*; *Coventry or Canterbury Bells*. Capsules five-celled, covered; stem undivided, erect, leafy; flowers erect. Root biennial. Leaves oblong, rough, hairy, serrate, coming out without order from the root, narrowing into a petiole: from the centre of these, the second season, arises a stiff, hairy, furrowed stalk, about two feet high, sending out several lateral branches, with long, narrow, hairy, serrate, sessile leaves, placed alternately: from the setting on of these leaves come out the peduncles, those on the lower part of the stem and branches four or five inches long, diminishing gradually in length upwards, and thus forming a sort of pyramid. The flowers are very large, and make a fine appearance; they are smooth, and the segments turn back at the end; they come out at the beginning of June, and, if the season be not very hot, will continue a month in beauty; the seeds ripen in September, and the plants decay soon after.

According to Hill, the fresh tops of this plant, with the buds of the flowers upon them, contain most virtue, but the dried leaves may be used. An infusion of them, sharpened with a few drops of spirit of vitriol, and sweetened with honey, is an excellent medicine for sore throats, used by way of a gargle. The plant, he says, is so famous for this virtue, that one of its common English names is *Throatwort*: if the medicine be swallowed, there is no harm in it; but in the use of every thing this way, it is best to spit the liquor out, together with the foulness which it may have washed from the affected parts.—It grows naturally in the woods of Germany, Austria, and Italy; and is cultivated in the English gardens for the beauty of its flowers, of which there are the following varieties; blue, purple, white, striped, and double, but the two last are not very common in England. It is propagated by seeds, sown in the spring, upon an open bed of common earth. When the plants are fit to remove, they are to be transplanted into other beds in the flower-nursery, six inches asunder, observing to water them frequently till they have taken new root, after which they will require no other culture but to keep them clean from weeds till the following autumn, when they may be transplanted into the borders of the flower-garden. As these plants perish the second year, young ones should be raised annually for a succession.

35. *Campanula Barbata*; *Bearded or One-leaved Bell-flower*. Capsules five-celled, covered; stem quite simple, with only one or two leaves; leaves lanceolate; corollas bearded. Root perennial, white, large, and woody, fusiform, or rather tuberous, two, three, or more inches in length; root-leaves many, somewhat rugged, from two to three inches long and upwards, narrowing into flat petioles: from these arises a simple upright round stem, from six to eighteen inches in length, with very few leaves on it; and towards the top from three to five, and sometimes ten or eleven, flowers, forming a kind of loose spike; they are large, solitary, nodding, alternate, and commonly directed one way.—Native of the mountains of Italy, Austria, Switzerland, Silesia, &c.: it flowers in June and July.

36. *Campanula Spicata*; *Spiked Bell-flower*. Hispid: spike loose; flowers alternate; leaves linear, quite entire. Root biennial, the thickness of a finger, two or three inches

long, fusiform; root-leaves linear, lanceolate, quite entire, rough, hairy; stem leaves like them, but shorter and narrower; stem a foot high, or more, with white stiff hairs, like all other parts of the plant, and alternate branches terminating in a very long loose spike, of many sessile, alternate, remote flowers; calix hoary, with white hairs; corolla sub-cylindric, blue, small in comparison of the plant. Allioni remarks, that it assumes a variety of appearances; in very dry open situations at the foot of the Alps, where it has very rough linear leaves, with a curled waving hedge, and flowers in a very long close continued spike. In the county of Nice it has elliptic leaves, not curled about the edge, which flowers in an uninterrupted spike. But it has more usually linear leaves and flowers, though in a spike, yet interrupted so as to form lateral heads. It is common both in the Upper and Lower Valais, about Chiavenna, and by the Lago Maggiore, and Como, in the vineyards; between Pignucrolles and La Perosa; and in the whole valley of Fenestrelles, very common in dry open rocky situations; in Alsace, between Sultz and Zenne; in Dauphiny, but not very common; and in Silesia: it flowers in July.

37. *Campanula Alpina*; *Alpine Bell-flower*. Stem simple; peduncles one-flowered, axillary, two-leaved. Root perennial, fusiform; stem absolutely simple, smooth, a span high, loaded the whole length with axillary solitary flowers; root-leaves oblong, lanceolate, blunt, growing wider towards the top, hirsute, entire; stem-leaves ligulate, smaller, sessile; peduncles upright, very long, with two bractes; valves of the nectary semiovate, blue, germen blue, three-cornered, semi-ovate, fastened by its base to the bottom of the calix; stigma trifid; capsule roundish, three-celled; seeds brownish, with a membranaceous edge.—It is found upon Schneeberg, Scheidegg, and also in Silesia; flowering in July.

38. *Campanula Mollis*; *Soft Bell-flower*. Capsules five-celled, covered, peduncled; stem prostrate; leaves suborbiculate. The stems are decumbent, with few branches, rather stiff, villose; leaves small, sessile, nearly entire, tomentose, pubescent.—Native of Syria, Sicily, and Spain.

39. *Campanula Saxatilis*; *Rock Bell-flower*. Capsules five-keeled, covered; flowers alternate, nodding; leaves ovate, crenate. The stalks rise a foot high; the flowers are large, blue, nodding, alternate; they open in July, and are succeeded by five-celled capsules, filled with small seeds.—It grows naturally in Crete, upon rocks, where the roots penetrate the fissures, and continue much longer than in gardens. For the culture and propagation of this sort, see the thirtieth species. A few of these plants may be set in pots, to be sheltered in winter.

40. *Campanula Sibirica*; *Siberian Bell-flower*. Capsules three-celled, covered; stem panicled. Root biennial; stem a foot high, angular, a little hispid, straight, undivided; panicle thin, loose; leaves linear, half stem-clasping; stem-leaves rugged; flowers oblong, small; peduncles generally three-flowered; calices hispid. There is a variety with a subdivided stem, and broader leaves.—Native of Siberia, Austria, and Piedmont: it flowers from July to September.

41. *Campanula Tridentata*; *Three-toothed Bell-flower*. Capsule five-celled, covered; stem one-flowered; radical leaves three-toothed. The stem is twice as long as the leaves, with some linear leaves on it; flowers upright, rather large, solitary.—Found by Tournefort in the Levant.

42. *Campanula Laciniata*. Capsules covered, peduncled; leaves serrate, the radical ones lyrate; stem-leaves lanceolate. Root biennial; stem two feet high, suffruticose, branched from the bottom; lower leaves eight inches long, and two and a half wide; those on the branches two or three inches

long and sessile, the uppermost only four or five lines in length, slightly crenated and pointed; flowers large, pale, blue; capsule five-celled, nine or ten lines in diameter.—Found by Tournefort in the island of Policandro.

43. *Campanula Stricta*. Capsules covered; leaves rough with hairs; stem-leaves lanceolate, serrate; stem quite simple; flowers sessile. The stem is eighteen inches high, rough with hairs; root-leaves cordate or ovate, somewhat oblong, serrate, rough with hairs on both sides, petioled; stem-leaves alternate, remote, sessile, obtuse, serrate, toothed, rough with hairs, narrow at the base; flowers axillary, solitary, erect; calices rough with hairs, covering the germen with their sinuses.—Native of Syria and Palestine.

44. *Campanula Canariensis*; *Canary Bell-flower*. This is now made a distinct genus. See *Canarina*.

45. *Campanula Fruticosa*; *Shrubby Cape Bell-flower*. Capsules columnar, five-celled; stem shrubby; leaves linear, subulate; peduncles very long.—It flowers in August; and is a native of the Cape.

46. *Campanula Speculum*; *Venus's Looking-glass*. Stem very much branched, diffused; leaves oblong, subcrenate; flowers solitary; capsules prismatic. This is an annual plant, which rises with slender stalks a foot high; the flowers are of a beautiful purple, inclining to a violet colour, (sometimes pale, purple, or white) and in the evening fold up into a pentagon figure, whence it is also called *viola pentagonia*; the calix is composed of five narrow leaves, which spread open, and turn back, and are much longer than the petals; these remain on the top of the prismatic seed-vessel, which is filled with small angular seeds.—Native of the most southern countries of Europe, among corn; flowering from May till September. It is commonly sown in patches in the borders of the flower-garden, among other hardy annuals, in the spring: but if it be sown in autumn, it will grow much taller, and flower a month earlier, that is, in May.

47. *Campanula Hybrida*; *Corn Bell-flower*: *Small Venus's Looking-glass*; or *Coddled Corn Violet*. Stem a little branching at the base, and stiff; leaves oblong, crenate; calices aggregate, longer than the corolla; capsules prismatic.—An annual plant, common in corn-fields, in England, France, and Switzerland; flowering in June and July.

48. *Campanula Limonifolia*. Branches expanding, undivided; radical leaves elliptic, even, quite entire; flowers sessile, in threes. The root-leaves are petioled, but not rigid; stem with very simple wand-like branches, and linear or subulate leaves; flowers remote, axillary, with bracts the length of the germen.—Native of the Levant.

49. *Campanula Pentagonia*. Stem subdivided, very branching; calycine leaflets linear, acuminate. This is a small plant, a hand or not more than six inches in height, with a simple white root; the stem is slender, weak, shrubby, with frequent branches; flowers at the ends of the stem and branches, twice as large as those of *Venus's Looking-glass*, and of a paler purple, the bottom or eye white, but less so than in that; a broad blue band surrounds the eye, and the edges are purple; the flowers are more concave and bell-shaped than in our common garden sort, and the segments are not so deeply cut; the leaflets of the calix are narrow, oblong, sharp, spreading, but not revolute, and sometimes have little bristles at the edges; the flowers, before they open, are folded up like the other sorts, and have five wings like the feathers of a shaft, and hence the name *Pentagonia*. The seeds are large, round, and shining. Mr. Ray informs us, that the first seeds of this plant were brought from Thrace. This and the fiftieth, and also the fifty-sixth species, must be treated like the forty-sixth species, which

see; if, however, the seeds be permitted to scatter, they will come up without care.

50. *Campanula Perfoliata*; *Perfoliate Bell-flower*. Stem simple; leaves cordate, toothed, stem-clasping; flowers sessile, aggregate. This is an annual plant, which in good ground will rise a foot and half high, but in poor ground, or where it grows wild among corn, scarcely rises to the height of six inches; the stalk is single, rarely putting out any branches, unless near the root, whence sometimes one or two short lateral branches are produced; the leaves are roundish and stem-clasping, sharply serrate at the edge, and from their base comes out a close tuft of flowers surrounded with a leaf as with the calix. Native of North America, and flowering in June. See the preceding species.

51. *Campanula Capensis*; *Cape Bell-flower*. Leaves lanceolate, toothed, hispid; peduncles very long; capsules strigose. Root annual; stem round.—Native of the Cape. It flowers in August and September; ripens its seeds in October, and then dies.

52. *Campanula Elatines*. Leaves cordate, toothed, pubescent, petioled; stems prostrate; peduncles capillary, many-flowered. Root perennial; stems many, procumbent, round, generally simple, from the fissures of the rocks; flowers purple, half five-cleft; the segments lanceolate, revolute. The whole plant is pubescent, with soft hairs, and is very milky.—It is found at the foot of the Alps, in the country of the Valdenses, or Vaudois, in rocky shady situations.

53. *Campanula Hederacea*; *Ivy-leaved Bell-flower*. Leaves cordate, five-lobed, petioled, smooth; stem lax. Root perennial, fibrous, slender, creeping; stems procumbent, filiform, trailing, matted together, and covering spots of a foot diameter: the whole herb pale, tender, delicate, and smooth, except a very few scattered hairs, occasionally found on some of the leaves, the lower of which are heart or kidney-form, and nearly entire; peduncles long, filiform, solitary, either terminating or axillary; segments of the calix pointed and entire; corolla pale blue, slender, oblong; filaments longer than the antheræ.—Native of England and Wales, Denmark, France, and Spain, in moist shady places: it flowers from May till August.

54. *Campanula Erinoides*. Stems diffused; leaves lanceolate, subserrate, decurrent, with a scabrous line; flowers peduncled, solitary. See *Lobelia Erinus*.

55. *Campanula Heterophylla*. Leaves subovate, smooth, quite entire; stems diffused. Root perennial, white, sweet, and full of milk; lower leaves like those of the Daisy, disposed in a ring, brownish green, shining, two inches and a half long, and half an inch wide; those on the stems fleshy, smooth, bright green, eight lines long; stems eight or nine inches long, a line in thickness, milky, and full of white pith: flowers axillary, seven or eight lines long, and four or five wide, pale blue; calix five lines in length, and three in width, pale green; fruit three-celled, filled with brownish red, polished, oval seeds, the third of a line in length. The whole plant is insipid.—Native of the Levant; found by Tournefort in the desert isle of Cheiro.

56. *Campanula Erinus*; *Forked Bell-flower*. Stem dichotomous; leaves sessile; the upper ones opposite, three-toothed. This is a low annual plant, seldom rising six inches high, but dividing into many branches; flowers small, pale blue; they are produced at the ends of the branches, and are shaped like those of *Venus's Looking-glass*, but their colours are less beautiful, and the leaflets of the calix are broader.—Native of Spain, Portugal, Italy, Sicily, and the south of France; it flowers in July and August. See the forty-ninth species.

**** *New species.*

57. *Campanula Sessiliflora*. Prostrate; leaves linear subulate, entire; flowers axillary, solitary, sessile.—Native of the Cape.

58. *Campanula Fasciculata*. Shrubby, erect; leaves ovate, with a tooth or two, recurved; flowers glomerate, terminal.—Native of the Cape.

59. *Campanula Paniculata*. Herbaceous; stem paniced; branches divaricate; leaves lanceolate, entire; flowers terminal, solitary.—Native of the Cape.

60. *Campanula Adpressa*. Herbaceous, erect; leaves lanceolate, toothed, recurved, ciliate at the base, appressed; panicle decomposed.—Native of the Cape.

61. *Campanulata Verticillata*; *Whorl-leaved Bell-flower*. Leaves and flowers verticilled. Root perennial; stems many, straight; leaves in fives or sixes, lanceolate, serrate; corollas small, pale blue; style double the length of the corolla.—Native of Siberia; flowering in June.

62. *Campanula Procumbens*. Stem dichotomous, diffused; leaves ovate, crenate, obtuse; flowers solitary, erect.—Found in moist places near the Cape.

63. *Campanulata Triphylla*. Leaves tern, linear; flowers by threes in a whorl. Root fusiform; stem herbaceous, erect. The whole smooth. Native of Japan: flowering in September.

64. *Campanula Tetraphylla*. Leaves by fours, oblong, serrate. Stem obscurely angular, jointed, smooth, simple at bottom, paniced at top, two feet high; corolla whitish; antheræ linear; style double the length of the corolla; stigma trifid.—Native of Japan.

65. *Campanula Glauca*. Leaves sessile, ovate, serrate, glaucous beneath; stem angular, paniced; peduncles one-flowered. Stem undershrubby, smooth, erect, two feet high; branches very angular, flexuose, erect, subfastigiata, smooth; corolla large, blue.—It flowers in July and August; and is cultivated in Japan.

66. *Campanula Marginata*. Leaves lanceolate, waved, serrate, margined; branches weak; flowers terminal, solitary. Stem thick at the base, rather woody, decumbent; branches very many, capillary, rather erect, with a very few subdivisions, striated, smooth, a short span in length. It grows by road-sides, flowering in May and June.—Native of Japan.

67. *Campanula Gracilis*. Leaves linear-lanceolate, obscurely serrate; stem dichotomous; flowers solitary, terminal.—Native of New Zealand, and New Caledonia.

68. *Campanula Bellardi*. Stem naked, one-flowered; leaves petioled, elliptic-lanceolate, toothed. This very elegant plant has a few leaves at the bottom rather erect, on petioles the length of the leaves, and grooved within; the leaves are drawn to a point at each end, have on each side two or three sharpish teeth, are of a deep green, roughish, rather firm, and not juicy; the little stem is erect, rather firm, round, smooth, half a finger high; flower erect; calix smooth, five-cleft beyond the middle; the segments lanceolate-linear, not reflected, nor expanded, nor appendiced; corolla blue.—Native of Piedmont: perennial.

69. *Campanula Vesula*. One-flowered; leaves smooth, oval, toothed; stem almost naked; calix smooth. Radical leaves very many, petioled, decurrent, acute, shortly toothed, or rather notched, nerved beneath, finely and thinly haired, so as to seem almost smooth; stem round, a short span in height; calix livid, five-cleft beyond the middle; segments lanceolate, not reflex; corolla spreading; perennial.—Native of Piedmont.

70. *Campanula Cespitosa*. Radical leaves kidney-form, gashed; stem-leaves toothed, upper ones quite entire. Many stems and shoots form a tuft. The flowers nod; corolla deep

blue, half an inch long, and four lines over; form oval, wider below than at the edge, with three lines on each segment. It grows in dry rocky mountains, flowering at the beginning of August: it is perennial.—Native of Switzerland, Dauphiny, Carniola, and Piedmont.

71. *Campanula Valdensis*. Hirsute; leaves lanceolate, sometimes toothletted; flower solitary, nodding. Root perennial. The root is small, and throws out one or two stems only three inches high, often bending to one side and arched; stem-leaves oval, oblong, linear; a single flower at the top is deep blue or almost black, more lengthened out than in the species that most resemble it.—Native of Piedmont and Dauphiny.

72. *Campanula Urticifolia*. Stem roundish, simple; upper leaves sessile; spiko one-ranked; peduncles one-flowered; calices smooth. Root perennial: plant entirely smooth; stem three feet high, simple, streaked, round; each axil produces a flower on a short peduncle; corolla and calix nearly equal.—Native of Italy, in woods.

73. *Campanula Alpestris*. Stem quite simple, one-flowered; leaves lanceolate, quite acute, hispid; corolla bearded; capsules three-celled, covered. Root perennial, creeping; stems only two or three inches high, having at top a single flower, which hangs down; root-leaves, which appear the first-year, small, blunt, and almost round, those which come afterwards are longer; the bottom stem-leaves are still longer, pointed, and a little waved on the edge; they are all roughish, and ciliate on the edge with small stiff hairs.—It grows on the very high Alps, and on Mount Cenis.

74. *Campanula Nitida*; *Smooth-leaved Bell-flower*. Leaves oblong, crenate, glossy, those on the stem lanceolate, almost entire; corollas campanulate-rotate. This has many stiff oblong leaves coming out from the root on every side, which form a sort of head like those of Houseleek, crenate, having a strong rib, running on their border longitudinally. There is a white and blue flower of this sort in the gardens, but in Holland they have it with a double flower.—It is a native of North America, and flowers in July. As it does not produce seeds in England, it is propagated by offsets only, which should be taken off in August, that they may get good root before cold weather comes in; they must be planted in small pots, filled with fresh, light, loamy earth, and placed in the shade until they have taken root; then they may be put along with other hardy exotic plants; and in autumn they must be removed into shelter, for in severe winters plants which are exposed are often destroyed, though in mild winters they will live in the open air.

75. *Campanula Prismaticarpus*; *Long-Capsuled Bell-flower*. Capsules linear, two-celled; leaves lanceolate, loosely serrate, very smooth; stem decumbent. The stems are a little shrubby at the base. It is an annual, and flowers in September.—Native of the Cape.

76. *Campanula Fragilis*. Stems procumbent; branches directed one way, many-flowered; root-leaves kidney-form, crenate; calices angular. This is a very beautiful plant, but extremely brittle, abounding in milk, commonly quite smooth, bright green, and lucid, but sometimes lanuginous; it has a handsome head of flowers; the root is perennial, and brown.—Native of the kingdom of Naples, especially on the coast of the bays of Salerno and Amalfi.

77. *Campanula Virgata*. Branches wand-like; leaves lanceolate, sharp at both ends, toothed, somewhat rugged; flowers in pairs, sessile; corollas deeply parted. Root biennial; stem upright, streaked, a foot or more in height, scarcely leafy, with spreading branches; leaves radical, petioled; flowers remote, commonly two together, blue, with a bracte under them, the length of the germen; segments of

the calix acute; those of the corolla lanceolate, cut almost to the base.—Native of Mount Libanus.

78. *Campanula Repens*. Stem subdivided, creeping; leaves oblong, fleshy; flowers solitary. The stem is herbaceous, and very much branched; the leaves oblong, ovate, quite entire, small, hairy opposite; the flowers white, sessile, axillary, solitary.—Native of Cochin-china.

Campechy Wood. See *Hematoxylum*.

Camphire, or *Camphor Wood*. See *Laurus*.

Camphorosma; a genus of the class Tetrandia order Monogynia.—GENERIC CHARACTER. *Calix*: perianth pitcher-shaped, half four-cleft, compressed, permanent; segments acute, the opposite ones largish, recurved. *Corolla*: none. *Stamina*: filamenta four, filiform, equal; antheræ oval. *Pistil*: germen ovate, compressed; style filiform, half two-cleft, longer than the calix; stigmas acute. *Pericarp*: capsule one-celled, gaping above, covered by the calix. *Seed*: single, oval, compressed, shining. ESSENTIAL CHARACTER. *Calix*: pitcher-form; two of the teeth opposite, and the alternate ones very small. *Corolla*: none. *Capsule*: one-seeded.—These plants are preserved in gardens merely for the sake of variety; they are propagated by seeds, which succeed best when sown in the autumn. The European sorts require only to be thinned, and kept clean from weeds; and if they are permitted to scatter their seeds, there will be a supply of young plants in the spring.—The species are,

1. *Camphorosma Monspelica*; *Hairy Camphorosma*. Leaves hirsute. Annual; with trailing branches, a foot or more in length; leaves linear, hairy, close to the branches; flowers from the joints, very small.—Native of the south of France, Spain, and the county of Nice. The whole plant smells of camphor; it abounds in a volatile oily salt, and is warm and stimulating: an infusion of it is of service in the asthma; the dose from half an ounce to an ounce and a half.

2. *Camphorosma Acuta*; *Sharp-leaved Camphorosma*. Leaves subulate, rigid, smooth. Root perennial, slender, fusiform, fibrous; stems many, woody, decumbent, round, hairy, roughish, from a finger's length to a foot in height; branches alternate. It flowers in July and August.—Native of very dry sandy fields in the Palatinate, Italy, and Tartary.

3. *Camphorosma Glabra*; *Smooth Camphorosma*. Leaves subtriquetrous, smooth, unarmed. This is a perennial plant, with trailing branches. The flowers are not more visible than those of the first sort.

4. *Camphorosma Pteranthus*. Very branching; peduncles ensiform, dilated; bractes crested. Root annual, fibrous.—Native of Arabia, Egypt, and Barbary. It is singular in its manner of flowering, and in its fruit, which resembles a stag's horns.

5. *Camphorosma Palacea*. Shrubby; branches spike-form, chaffy, hairy. A shrub scarcely a foot high, determinately branched.—Found at the Cape.

Campion. See *Agrostemma*, *Cucubalus*, and *Lychnis*.

Canarina; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth superior; leaflets six, lanceolate, recurved, permanent. *Corolla*: monopetalous, bell-form, six-cleft, nerved; nectary of six valves, equal, distant, covering the receptacle. *Stamina*: filamenta six, subulate, spreading outwards, originating from the valves; antheræ pendulous from the tip. *Pistil*: germen inferior, six-cornered; style conical, short; stigma longer than the stamina, clavated, six-cleft. *Pericarp*: capsule six-angled, obtuse, six-celled. *Seeds*: numerous, small. ESSENTIAL CHARACTER. *Calix*: six-leaved. *Corolla*: six-cleft, bell form; stigmas six. *Capsule*: inferior, six-celled many seeded.—The species are,

1. *Canarina Campanula*; *Canary Bell-flower*. Stem erect; leaves hastate, in threes, or opposite. Root perennial, tuberos, fusiform; stem three feet high, erect, solitary, round, even with swelling joints; branches by threes from each joint; leaves on the stem in threes; flowers from the forks of the upper branches, solitary, peduncled, drooping; corolla larger than the leaves, resembling that of a Crown Imperial, rufous, brighter within, with a yellow eye; each segment with three purple nerves; style club-form, longer than the stamina. It flowers from January till March.—It is propagated by parting the roots, which must be done with caution, for if they be broken or wounded, the milky juice will flow out plentifully, so that if they be planted before the wounds are skinned over, it occasions their rotting; therefore whenever any of them are broken, they should be laid in the green-house a few days to heal. The root must not be too often parted, for that weakens the plants, and prevents them from flowering well; the best time for doing it is in July, soon after the stalks are decayed; the earth should not be rich, for that will cause the plant to be luxuriant in branches, but poor in flowers; the soil in which they succeed best, is a light sandy loam, with a fourth part of screened lime rubbish; the pots should at first be placed in the shade, and, unless the season be very dry, they should not be watered: about the middle of August the roots will begin to put out fibres, when, if the pots be placed under a hot-bed frame, and, as the nights grow cool, be covered with the glasses, (opening them every day,) it will greatly forward their flowering, and increase their strength: when the stalks appear, the plants must now and then be refreshed with water, but it must not be given too often, nor in great quantity; by the middle of September the plants will be grown so tall, that they must be removed into a dry airy glass case, where they may enjoy the free air in fine weather, and yet be screened from cold.

2. *Canarina Zanguebar*. Stem scandent; leaves hastate alternate. Flowers solitary, lateral; corolla pale-coloured.—Native of Zanguebar, on the coast of Africa.

Canarium; a genus of the class Diœcia, order Pentandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth two-leaved, leaflets ovate, concave, permanent. *Corolla*: petals three, oblong, like the calix. *Stamina*: filamenta five, very short; antheræ oblong, of the length of the petals. *Female*. *Calix*: as in the male; leaflets reflex. *Corolla*: as in the male. *Pistil*: germen ovate; style scarcely any; stigma headed, three-cornered. *Pericarp*: drupe dry, ovate, acuminate; base surrounded by a crenate membrane. *Seed*: nut ovate, three-cornered, acute. ESSENTIAL CHARACTER. *Male*. *Calix*: two-leaved. *Corolla*: three-petalled. *Female*. *Calix*: two-leaved. *Corolla*: three-petalled. *Stigma*: sessile. *Drupe*: with a three-cornered nut.—The only species known is,

1. *Canarium Commune*. Leaves alternate, pinnated with an odd foliole; panicles with divaricate rigid branches; flowers sessile. The fruit is covered with a thin olive-coloured skin, and having within it very little pulp, full of capillary fibres.—This tree is a native of the Molucca isles, Banda, and New Guinea. The nuts are eaten both raw and dressed by the inhabitants; an oil is expressed from them, which is used at the table when fresh, and for lamps when stale; bread is also made of them, and cakes, biscuits, &c. for the table: eaten fresh, they are apt to bring on diarrhoeas and dysenteries, and to occasion oppression of the breast.

Canary Grass. See *Phalaris*.

Candleberry Tree. See *Myrica*.

Candy Tuft. See *Iberis*.

Cane. See *Arundo*.

Canella; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, three-lobed; lobes roundish, concave. *Corolla*: petals five, oblong, sessile, longer than the calix; two a little narrower than the rest; nectary pitcher-shaped, the length of the petals, anther-bearing. *Stamina*: filamenta none; antheræ twenty-one, linear, parallel, distinct, fastened on the outside to the nectary. *Pistil*: germen superior, within the nectary, ovate; style cylindric, the length of the nectary; stigmas two, blunt, convex, wrinkled. *Pericarp*: berry oblong, three-celled. *Seeds*: roundish, kidney-shaped, in pairs cordate. ESSENTIAL CHARACTER. *Calix*: three-lobed. *Corolla*: five-petalled. *Antheræ*: twenty-one, fastened to a pitcher-shaped nectary. *Berry*: three-celled. *Seeds*: two to four.—The only species known is.

1. *Canella Alba*; *Laurel-leaved Canella*. This is a tree, the stem of which rises from ten to fifty feet in height, very straight and upright, and branched only at the top. It is common in most of the West India islands, and is frequently found near the coast; then seldom exceeding twelve or fifteen feet; in the inland woods it attains a more considerable height. The whole tree is very aromatic, and when in blossom perfumes the whole neighbourhood; the flowers dried and softened again in warm water, have a fragrant odour, nearly approaching to that of musk; the leaves have a strong smell of laurel. The berries, after having been some time green turn blue, and become at last of a black colour and glossy, with a faint aromatic taste and smell: when ripe, the white-bellied and bald-pate pigeons feed greedily upon them, and thence acquire their peculiar flavour. The bark of this plant, and the fruit of capsicum, were formerly common ingredients in the food and drink of the Caribs; and at present it makes a necessary ingredient in the meager pot of the negroes. The bark is brought to Europe in long quills, which are about three quarters of an inch in diameter, somewhat thicker than cinnamon, and both externally and internally of a whitish or light brown colour, with a yellowish hue, and commonly intermixed with thicker pieces, which are probably obtained from the trunk of the tree. In taste it is moderately warm, aromatic, and bitterish; its smell is agreeable, and resembles that of cloves: its virtues are extracted most perfectly by proof spirit. The use of *canella alba* now supersedes that of the old bark of Winter, on the authority of both the London and Edinburgh pharmacopœias. It has been supposed to possess considerable virtues, and is said to be useful in scorbutic and many other complaints. It is now, however, considered merely in the light of an aromatic, and, like many other spices, is employed for the purpose of correcting disagreeable drugs.—This tree is too tender to live in England out of a stove: the plants require to be plunged in the tan-bed, and in winter should be sparingly watered; in summer they should have it in greater plenty, and they should also have a good share of air admitted to them when the weather is warm; with this management they may be preserved very well; but as they are difficult to propagate either by layers or cuttings, the surest method is to procure fresh seeds from the West Indies.

Canna; a genus of the class Monandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets lanceolate, erect, small, coloured, permanent. *Corolla*: monopetalous, six-parted; divisions lanceolate, conjoined at the base, the three outer ones erect, larger than the calix; the three inner ones larger than the outer, two erect, one reflected, and thus constituting the upper lip; nectary petal-like, two parted, of the length and figure of the petals; the upper divisions ascending, the inferior revolute, imitating the upper lip of a corolla. *Stamina*: filamenta none; an-

theræ linear, growing to the upper margin of the division which bears the nectary. *Pistil*: germen roundish, rugged, inferior; style single, ensiform, growing to the anther-bearing nectary, lanceolate, of the length and figure of a petal; stigma linear, growing to the margin of the style. *Pericarp*: capsule roundish, rugged, crowned, three-grooved, three-celled, three-valved. *Seeds*: few, globular. ESSENTIAL CHARACTER. *Corolla*: six-parted, erect; lip two-parted, revolute. *Style*: lanceolate, growing to the corolla. *Calix*: three-leaved.—Every species of this genus is propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted into separate small pots filled with rich kitchen-garden earth, and plunged into a moderate hot-bed of tanners' bark, observing to shade them until they have taken root; after which they should have a large share of free air admitted to them every day in warm weather, and be frequently refreshed with water. As these plants will grow very fast, they must be shifted into larger pots filled with the same sort of earth, and part of them plunged into the hot-bed again; and the others may be placed abroad in June, with other exotic plants, in a warm situation. Those which are placed in the hot-bed, will be strong enough to flower well in the stove the following winter; but those in the open air will not flower before the following summer: the latter may remain abroad till the beginning of October, but must then be removed into the stove, and treated in the same manner as the old plants until May, when a gentle hot-bed should be made, covered a foot thick with rich earth, and the plants turned out of the pots, planting them with their balls of earth upon the hot-bed, covering each with a bell-glass, which may be raised on one side every day to admit the air to the plants; and as they advance, they must be gradually inured to bear the open air. With this management the plants will grow much taller and stronger than those which are kept in pots, and from these good seeds may be expected in autumn. These plants will continue many years; but as young plants always flower better than the old roots, it is not worth while continuing them after they have borne good seeds.—The species are,

1. *Canna Indica*; *Indian Shot*. Leaves ovate, acuminate at both ends, nerved. This plant has a thick fleshy tuberous root, which divides into many irregular knobs, spreading wide near the surface of the ground, sending out many large ovate leaves without any order; these, at their first appearance, are twisted like a horn, but afterwards expand, and are near five feet long, and five inches broad in the middle, lessening gradually to both ends, and terminating in points; the stalks are herbaceous, rising four feet high, encompassed by the broad leafy footstalks of the leaves; the flowers are produced at the upper part of the stalk in loose spikes; the petal is of a pale red colour. There are several varieties, not worth enumerating; the stalks are sometimes of a pale red, and sometimes of a beautiful scarlet colour, succeeded by a prickly pericarp, with several black seeds, which will kill small birds. The juice of the root is said to be a counter-poison, and to be good, mixed with the bruised leaves and Water Lily, as a cataplasm for hard tumors and indurations of the spleen. Gerarde informs us, that in his time it was in the garden at Padua, and that he had planted it in his garden divers times, but it never came to a flowering; and that it must be set or sown in a pot with fine earth, or a bed made of horse-dung, in the same manner as cucumbers and musk melons are. Parkinson says, that in some kindly years this beautiful plant has borne its brave flowers, but never any ripe

seed; and that it will not abide the extremities of our winters, unless it meet with a stove or hot-house, such as are used in Germany, for neither house nor cellar will preserve it. Clusius saw it flowering by house-sides in Spain and Portugal: and says that the inhabitants there use the seeds for making their rosaries.—It is found wild within the tropics on all continents.

2. *Canna Angustifolia*; *Narrow-leaved Indian Reed*. Leaves lanceolate, petioled, nerved. This can hardly be distinguished from the first species, but is nevertheless lower and narrower.—It is found within the tropics of America, in shady and boggy places.

3. *Canna Glauca*. Leaves lanceolate, petiolate, nerveless. The roots of this are much larger than the former sorts, and strike down strong fleshy fibres deep in the ground; the stalks rise seven or eight feet high; the leaves are nearly two feet long, narrow, smooth, and of a sea-green colour; the flowers are produced in short thick spikes at the extremity, are large, and of a pale yellow colour; the segments of the petal are broad, but their shape like those of the other sorts.—Native of New Spain. The young plants of this species, when raised from seeds, are more certain of flowering than the old ones, for their roots send out many offsets, which when they have room soon spread to a considerable distance, but seldom produce flowers. It is, therefore, the best way to raise a succession of plants from seeds, and to throw out the old ones after they have perfected their seeds.

4. *Canna Flaccida*. Leaves narrow, lanceolate, smooth and even on both sides; inner limb of the corolla five-cleft; segments flaccid, obovate, the outmost largest. Four feet high or more, very much resembling the preceding in the herb, with which it is often confounded in our stoves.—Native of South America.

5. *Canna Juncea*. Leaves linear, nerved. The leaves resemble those of grass, with five raised nerves, sheathing at the base, near the root covered with capillary fibres, a span or a foot in length; scape with several lanceolate sheaths and few flowers; corolla small, of a dusky rufous colour; pericarp muricated.—It was discovered by Bladh in China.

Cannabis; a genus of the class Diœcia, order Pentandria. —GENERIC CHARACTER. *Males*. *Calix*: perianth five-parted; leaflets oblong, acuminate, obtuse, concave. *Corolla*: none. *Stamina*: filamenta five, capillary very short; antheræ oblong, four-cornered. *Female*. *Calix*: perianth one-leafed, oblong, acuminate, gaping longitudinally on one side, permanent. *Corolla*: none. *Pistil*: germen very small; styles two; subulate, long; stigmas acute. *Pericarp*: very small; calix tightly closed. *Seed*: nut globose, depressed, bivalve. ESSENTIAL CHARACTER. *Male*. *Calix*: five-parted. *Corolla*: none. *Female*. *Calix*: one-leafed, entire, gaping on one side. *Corolla*: none. *Styles*: two. *Nut*: bivalve within the closed calix.—The only known species of this important genus is,

1. *Cannabis Sativa*. Stem generally six feet, sometimes considerably more, branched, hairy, as are also the leaves, which are digitate, slender, serrate; the folioles seven, the outer ones smallest. In the female, plant the flowers are solitary in the axillas: in the male, they are in thin pendulous spikes, at the ends of the stem and branches. Some female flowers are frequently found among the males, and some males among the females. It is not therefore any objection to the sexual system, that female plants of the Hemp have produced perfect seed, when there have been no male plants near them. Mr. Miller, however, contradicts this assertion, and declares, that for several years he tried the experiment by removing all the male plants; when, although the female

plants continued strong and flourishing, they did not, nevertheless, produce any good seeds. It is also worthy of remark, that all the old authors, ignorant of the true doctrine of the sexes, and blind followers of the ancients, have fallen into an egregious mistake upon this subject, for they invariably call the male plants female, and the female male.—It is extremely difficult to ascertain the original place of the native growth of Hemp, but the most probable conjecture is, that it is a native of the East. Its use and great importance are well known. Huckaback of an excellent quality for towels and table-cloths, and the low-priced hempen cloths which husbandmen, servants, and labouring manufacturers, generally wear, as well as the better sorts for farmers and tradesmen in the country, are made from it. The finer cloths also, which are seven-eighths wide, and from 2s. 6d. to 3s. 6d. per yard, are preferred by some gentlemen for their strength and warmth. One advantage they certainly possess over the Irish and other linens; which is, that their colour improves by wearing, while that of the others declines. English Hemp, properly manufactured, is unrivalled for its strength, and in that respect much superior to the Russian. Considerable quantities of cloth are nevertheless imported from that country for sheeting, merely on account of its strength, which is entirely owing to its being coarser than British linen of the same price; but our hempen cloth is in reality more durable from the superior quality of the thread, and at the same time lighter in washing. The Hemp raised in England is not of so dry and spongy a nature as the Russian, and therefore requires less tar in proportion, to manufacture it into cordage. But as tar is cheaper than hemp, the rope-makers prefer foreign hemp to ours, because they obtain a greater profit in working it: but cordage must certainly be stronger in proportion as there is more hemp and less tar in it, provided there be a sufficient quantity of tar to unite the fibres. An oil is extracted from the seeds of hemp, and the seeds themselves are reckoned to be a good food for poultry, being supposed to make them lay a greater number of eggs. Small birds in general are very fond of them, but they should be sparingly given to birds confined in cages, and always mixed with other seeds. It is recorded, upon unquestionable authority, that the black and yellow feathers of the bulfinch and goldfinch have been sometimes changed to a total blackness by feeding them with hemp-seed alone, or giving them too large a proportion of it when mixed with other food. Hemp is called *hanf* or *hampf* in German; in Dutch, *hennip* or *kennip*; in Danish, *hamp*; in Swedish *hanpa*; in French, *chanvre*; in Italian, *canapa*; in Spanish and Portuguese, *canamo*; in Russian, *konapli*, *konopel*, *kanaple*; in Polish, *kanop*; in Illyrian and Selavonian, *konoplija*; in Walachian, *kenepe*; in Hungarian, *kender*; in Tartarian, *kinder*; in Armenian, *kanop*; in Arabian, *sjaranck*; in Persian, *cannab*; in Chinese *ma-fuen*, *chu-tsoo*. There is no doubt that the Greeks took their name from the eastern *kanop* or *coanab*, and that the plant originally migrated into Europe from those countries, notwithstanding what Pliny and Dioscorides affirm of its growing wild in Europe.—Hemp is commonly sown upon a deep rich moist soil, such as is found in the tract called Holland in the county of Lincoln, and the fens of the isle of Ely, where it is cultivated to great advantage; as it might in other parts of England where there is the same kind of soil. It will not thrive on clay, nor yet on stiff cold land; but is found to succeed very well after Turnips on friable loams, and good sands, provided it be well manured. Spalding-moor in Lincolnshire is a barren sand, and yet with proper care and culture it produces as fine hemp as any in England,

and in large quantities. In the isle of Axholme, in the same county, the culture and management of it is the principal employment of the inhabitants; and in the county of Suffolk, in the district extending from Eye to Beccles, it is cultivated on a sandy loam with great success; for upon such soils the quality is much finer, and better adapted to the fabric of hempen-cloth, though the quantity falls short of that produced in black rich mould. As it destroys weeds by depriving them of their nourishment, it is generally reckoned to be a cleansing crop; but it is at the same time a great impoverisher of the land, and must not be repeated upon the same ground, unless it be annually manured, in which case it is said to have been continued for seventy successive years upon the same spot. The letting it stand for seed, is universally acknowledged to exhaust the land; but many suppose, that if previously cut, it is an excellent preparation for Wheat. The land in which it is to be sown, must have three earths given to it, with sufficient harrowing to make the soil perfectly fine, and laid flat, with as few furrows as possible; it must be well manured with twenty-five or thirty-three horse-loads of muck, or from sixteen to twenty loads of dung, to an acre, immediately after the Wheat-sowing is finished, or, according to others, a fortnight before seed-time, which is from the beginning, or rather middle, to the end of April. If it be sown earlier, the spring frosts will greatly endanger the plants. Sowing is sometimes deferred till the middle of May; but when the weather is fine, early sowing is to be preferred, because it improves the quality of the Hemp. Although three bushels of seed is commonly allowed to an acre, two are fully sufficient. In the choice of the seed, the heaviest and brightest-coloured should be preferred; and some of them should be cracked, to see if they have the germen perfect. When sown, the seed should be lightly and gently harrowed in; and the birds should be kept off till the plants appear. In the fen countries, the plants are hoed out in the same manner as is practised for Turnips, leaving them a foot or sixteen inches apart, and cutting down all the weeds: they give them a second hoeing about a month or six weeks after the first. If these hoeings be well performed, the crop will not require any further care, for the Hemp will soon cover the ground, and prevent all growth of weeds. The first season for pulling Hemp is usually about the middle of August, when they begin to pull the *fimble*, *femle*, or *thimble Hemp*, that is, the male plants; but it would be much better to defer this a fortnight or three weeks, if the Hemp be intended to seed, until these male plants have shed their dust, without which it is well known the seeds will not grow, nor will those persons concerned in the oil-mills give any thing for them. The second pulling is a little after Michaelmas, when the seeds are ripe; the female plants are then pulled, and called *seed Hemp*, or *karle Hemp*. It is bound up in bundles about a yard in circumference, which are laid in the sun a few days to dry, and then are stacked up or housed till the seed can be threshed out. An acre of Hemp on a rich soil will produce near three quarters of seed, which, together with the unwrought Hemp, is worth from six to eight pounds. If the Hemp be designed for making thread only, without any regard to the seed, the male and female plants are pulled together, thirteen or fourteen weeks after sowing. When the leaves turn yellow and the stalk white, it is known to be ripe: it bears a dry season better than a wet one, and the wetter the season the longer it stands. As soon as it is all pulled up, it is bound up in bundles small enough to be grasped with both hands, which bundles are tied at both ends, and are called *baits*. It is then conveyed to the water, to undergo the process of *water-retting* or *rotting*, for which operation clay

pits are preferred to running water, though they require cleansing once every seven or eight years. The usual produce of an acre, about three small waggon-loads, may be laid in one bed; but the same water is not fit for receiving Hemp more than three times in a season, although some persons employ the same water five times. The first water always produces the best colour in the least time: where there are not pits sufficient to hold the whole crop, it is customary to pull as they become ready, it being thought injurious to the Hemp to let it lie upon the land after it is pulled. In the pits, the bundles are placed in rows crossing each other, and are kept under water by blocks and logs of wood laid upon them. The Hemp generally soaks four days in warm weather, and rarely exceeds five or six, till the outside coat easily rubs off; when it is taken out of the pits, spread out singly upon grass, and turned, in dry weather twice, and in showery weather three times a week; which operation is called *grassing*, and generally occupies five or six weeks' time. Afterwards it is tied up in large bundles of eight or ten baits, and carted home to a barn or house, for *breaking* by a machine called a *brake*; which is either immediately done, or deferred till December or January, by laying up the bundles to dry for that purpose. Thus prepared, the Hemp is bound up in bundles, weighing a stone or fourteen pounds and a half each, and then taken to market. Whatever Hemp breaks off in the operation is called *shorts*, and is also bound up by itself, and is about half the value of the long Hemp. The offal is called *Hemp-sheaves*, which is sold for fuel at two-pence per stone. The custom of many is to *dew-ret* or *rot* their Hemp; which is done by spreading it upon meadow-land as soon as it is pulled, and turning it frequently; but it is a very bad method, for as the bark will not come off completely, it demands more violent means to be employed in bleaching the yarn, and consequently diminishes the strength, besides being much more liable to injury in rainy seasons. Hemp, when left for seed, is seldom water-retted, being generally stacked and covered during the winter, and spread upon grass in January or February; and if the season favour it, especially if it be covered with snow, it will acquire a good colour, and make a strong coarse cloth, but is after all greatly inferior to that which is pulled at a proper time, and water-retted. The Hemp now passes from the grower to the hatcheller, or heckler, who first bunches or beats it, either by hand, or more frequently by a mill; and then dresses or combs it, by drawing it through hatchels, or heckles, resembling wool-combers' tools, but differing from them in being fixed. It is dressed finer or coarser, to suit the designs of the purchasers: hence the whole is sometimes worked together for one sort, and sometimes it is divided into two or three sorts, called *long-strike*, *short-strike*, and *pull-tow*. The heckler either sells the latter to spinners and weavers, or puts it out to spin, and then disposes of the yarn to the weaver, who delivers it to the whitester, from whom he receives it back again bleached. The bleaching is a difficult operation; the art consisting in procuring the best colour, with the least diminution of strength. The yarn is laid in large tubs, covered with thick cloths, upon which ashes are placed, through which hot water is poured daily, turning the yarn frequently until the bark comes off, after which it is spread upon poles in the air. In general, hempen cloth is sold as it comes from the loom, and is bleached by the purchaser; some, however, is bleached ready for weaving, either by the weaver or a whitester, by boiling it in lees made from ashes, and frequently spreading it upon grass. Although in the process of manufacturing, Hemp passes through the hands of the breaker, heckler, spinner, whitester, weaver, and bleacher;

yet many of these operations are frequently carried on by the same person; some weavers bleach their own yarn and cloth, others their cloth only; some heckle their tow, and some put it out to spinning; others buy the tow, and put it out; and some carry on the whole of the trade themselves. When this trade is conducted by different persons, their interests often clash; by under-retting the Hemp, the grower increases the weight; by slightly beating it, the heckler increases the quantity of tow, but leaves it fuller of bark; by drawing out the thread beyond the staple, the spinner increases the quantity of yarn, but injures the quality; by forcing the bleaching, the white-ster increases his profit, but diminishes the strength of the yarn; and we generally find, that in manufacturing cloth, strength is sacrificed to fineness and colour. This is the practice in Suffolk: The expense of an acre of Hemp may be estimated at eight or nine pounds, and the average produce at forty-five stones, which produces £16. 17s. 6d. at 7s. 6d. per stone: some crops produce fifty-five stones, and even more, but are counterbalanced by others which fall as low as twenty-five; and the price also varies from 6s. to 9s. and 10s. per stone, according to the quality of the produce. The principal objections to the Hemp crops are, that their coming in the middle of harvest is embarrassing, and that the attention they require is very great during every stage of their progress, especially where they are only a secondary consideration: the cultivation of Hemp is nevertheless of great consequence to the country, particularly as it affords much employment for the industrious poor, and therefore certainly deserves every encouragement from the legislature.

Canterbury Bell. See *Campanula*.

Caper. See *Capparis*.

Caper Bean. See *Zygophyllum*.

Capparis; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, coriaceous; leaflets ovate, concave, gibbous. *Corolla*: petals four, obtuse, spreading, very large. *Stamina*: filamenta numerous, filiform, patulous; antheræ oblong, versatile, inclined. *Pistil*: germen pedicelled; style none; stigma obtuse, sessile. *Pericarp*: berry corticose, one-celled, pedicelled. *Seeds*: numerous, reniform, nestling. **ESSENTIAL CHARACTER.** *Calix*: four-leaved, coriaceous. *Petals*: four. *Stamina*: long. *Berry*: corticose, one-celled, pedicelled.—This genus consists of shrubs; the leaves are simple, frequently having in the berry-bearing sorts, two spines at the base, but in those which bear pods they are commonly naked or biglandular; the flowers are solitary, axillary, or in a kind of corymb, terminating. Every species, except the first, being a native of hot climates, requires the protection of a stove, to survive the rigour of an English winter: they are propagated by seeds, which must be procured from the countries where they naturally grow, since they do not produce them in England; the seed must be sown in small pots filled with light sandy earth, and plunged into a hot-bed of tanner's bark, which should be now and then moderately refreshed with water; they frequently remain in the ground a whole year without vegetating; and must be screened during the winter, and plunged, in the following spring, into a fresh hot-bed of tanner's bark, which, if the seeds were good, will soon compel the plants to appear. In warm weather they require little water, but much air; and when they are large enough to remove, must be each transplanted into a separate small pot, filled with the same earth, and replaced in the hot-bed again, observing to shade them until they have taken fresh root; after which, fresh air must be every day admitted to them, in proportion to the warmth

of the season. In the autumn they must be removed into the stove, and plunged into the bark-bed, where they should constantly remain, as they require the same treatment as other tender exotic plants from the same countries, with this difference only, that they require little water, especially in winter, for the roots of these plants are very subject to rot with wet. If the seeds be brought over in their capsules, they will keep much better than without them; but they should be secured from insects, by wrapping them in well-dried tobacco leaves, for without this precaution they will be destroyed before they arrive. The seeds are said to germinate immediately, and therefore cannot well be sent dry to Europe, which, together with the great difficulty of preserving the plants, account for the present scarcity of them in our stoves.—The species are,

1. *Capparis Spinosa*; *Prickly Caper Bush*. Peduncles one-flowered, solitary; stipules spiny; leaves annual; capsules oval. The common Caper-bush is a low shrub, generally growing out of the joints of old walls, the fissures of rocks, and among rubbish; the stems are woody, and covered with a white bark.—It grows wild in the southern countries of Europe, and in the Levant, on rocks, walls, and in dry places: Mr. Ray observed it on the walls of Rome, Sienna, and Florence, wild; and cultivated in the neighbourhood of Toulon. "It is surprising," says Dr. Smith, "that this beautiful shrub, which in the south of France is as common as the bramble is with us, and which even at Paris grows luxuriantly when trained against a wall in the open air, should be almost unknown in English gardens, where we can scarcely produce a flower, unless by stoving it with every possible precaution!" The flower-buds, which are produced in great plenty on the wild plant, are well known as a pickle; and in Italy, the unripe fruit is prepared in the same manner. The pickled Caper bud has the character of an antiscorbatic, and of removing hepatic and other visceral obstructions; but the part of the plant which has chiefly been recommended for medicinal purposes, is the bark of the root. Its taste is somewhat aromatic, bitterish, and acrid.—It thrives best in an horizontal position, so that when planted either in pots or the full ground, it seldom thrives, although it may be kept alive for some years. In the warmer parts of Europe, they are propagated by seeds, but the importers of orange-trees bring roots of this plant annually from Italy, some of which, when planted in walls, have lived a few years, but have not lasted long.

2. *Capparis Zeylanica*. Peduncles one-flowered, solitary; stipules spiny; leaves ovate, sharp at both ends; stem shrubby, six feet high, upright, but weak; branches divaricating; stamina thrice the length of the corolla.—Native of hedges in Ceylon and Cochin-china.

3. *Capparis Horrida*. Peduncles axillary, by two; stipules prickly; branches flexuose; leaves ovate-lanceolate, mucronate, smooth.—Found by Kœnig in Coromandel.

4. *Capparis Scpiaria*. Peduncles umbelled; stipules spiny; leaves annual, ovate, emarginate; branches round and woody; spines stipular, double-recurved, short, black.—Native of the East Indies.

5. *Capparis Frondosa*. Peduncles umbelled; leaves every where crowded; height above seven feet, extending as far as twenty; branches very few, and scarcely divided.—Native of thickets in South America.

6. *Capparis Ferruginea*. Peduncles umbelled; leaves permanent, lanceolate, tomentose beneath; flowers eight-stamined. This is a small tree or shrub, with striated rufous, or ferruginous coloured branches; corollas white; flowers in a sort of corymb, terminating, on bifid or trifid peduncles, and fragrant.—This plant is strongly impregnated with an

acid volatile salt, like the mustard tribe; and hence, in Jamaica, where it grows wild, it has obtained the name of the *Mustard Shrub*.

7. *Capparis Baduoca*. Peduncles one-flowered; leaves perennial; ovate-oblong, determinately crowded, naked; leaves smooth on both sides, obscurely netted.—It is a native of the East Indies, where it is cultivated for the beauty of the flowers, which appear in January.

8. *Capparis Cynophallophora*. Peduncles many-flowered, terminal; leaves oval, obtuse, perennial; glands axillary. This species varies considerably in its habit or general appearance, according to the soil in which it is found: in sunny hedges it is weak, thin, and, as it were, supported by the neighbouring vegetables; but in fields, and towards the shores, it is a kind of shrub, or little tree of twelve feet high, and of a pretty appearance; in the axilla of the leaves there is a roundish solitary gland, which is scarcely ever missing; the flowers are beautiful, very patulous, and extremely fragrant, of a white or greenish white; the stamina often four inches long.—Native of the West Indies.

9. *Capparis Pulcherrima*. Peduncles racemed; leaves oblong, obtuse; fruits berried. This is an upright shrub in open situations, only two or three feet high, but in woods rising to twelve feet; flowers beautiful, of a pale yellow colour, and having a very sweet scent; filamenta at first white, then bright purple: each raceme has only one or two berries, from two to four inches in diameter, variegated green and brown on the outside; the flesh or pulp when unripe, hard, and having little scent; but when ripe, soft, nauseous, and so fetid that no animal will touch it.—Native of Carthagera in New Spain, on the declivities of the mountains.

10. *Capparis Linearis*. Peduncles subracemed; leaves linear. This plant, which grows in great plenty on the woody hills of Carthagera, is an elegant upright branchy tree, about fifteen feet high; the flowers are white, inodorous, and about half an inch in diameter; the fruits are orange-coloured, with a redness intermixed, and about an inch in diameter.

11. *Capparis Breynia*. Peduncles racemed; leaves permanent, oblong; calices and peduncles tomentose; flowers eight-stamined. A small tree, with an upright smooth trunk, and flexuose branches, scarred with the fallen leaves; twigs angular and pubescent.—It is a native of dry coppices near the sea in Jamaica, and most of the other islands in the West Indies.

12. *Capparis Hastata*. Peduncles many-flowered; leaves hastate-lanceolate, glittering. This is an upright weak shrub, divided into a few very long branches, often six feet long; the common footstalks of the flowers are clustery, terminal, almost half a foot long, and support about eight flowers, which are somewhat odorous, purple, and nearly two inches in diameter.—Native of Carthagera, in woody places.

13. *Capparis Flexuosa*.—See the eighth species; from which it in nowise differs.

14. *Capparis Siliquosa*. Peduncles many-flowered, compressed; leaves permanent, lanceolate-oblong, acuminate, dotted beneath. The leaves of this species are extremely acuminate; the upper surface is glittering, and the lower powdered with ferruginous dust. Mr. Miller says, it rises with a shrubby stalk to the height of eight or ten feet, sending out many woody branches, covered with a reddish brown bark. It was sent to him from Tolu in America.

15. *Capparis Grandis*. Corymbs terminating; leaves ovate, acute, smooth; fruit globular. This is a large hoary tree; flowers whitish yellow.—Found by Koenig in Ceylon.

16. *Capparis Magna*. Stem arboreous, unarmed; leaves ternate, lanceolate; corymbs terminating. This is a mid-

dling-sized tree, with spreading unarmed branches; flowers large, white, in spreading corymbs.—Native of Cochinchina, on the banks of rivers.

17. *Capparis Falcata*. Stem arboreous, unarmed; leaves ternate, sickle-shaped; racemes loose, terminating. This is a large tree, with spreading unarmed branches; corolla white, resembling that of the foregoing sort; stamina eighteen.—Native of China, near Canton.

18. *Capparis Cantoniensis*. Peduncles racemed; stipules thorny; leaves ovate, acuminate, wrinkled; stem shrubby; upright, branched; flowers white, axillary, and terminating; filamenta long.—Native of China, near Canton.

19. *Capparis Torulosa*. Peduncles subbiflorous, round, terminating; leaves lanceolate-oval, dotted with white underneath; pods round, linear, torulose.—It grows into a shrubby tree, and is a native of Jamaica.

20. *Capparis Longifolia*. Leaves linear-lanceolate, dotted with meal underneath.—Native of Jamaica.

21. *Capparis Arborescens*. Leaves lanceolate, ovate, perennial; stem arborescent. It rises with a woody stem twelve or fourteen feet.—Native of Carthagera, in New Spain.

22. *Capparis Racemosa*. Leaves ovate, opposite, perennial; flowers racemed. It rises with a trunk about twenty feet high, sending out many long slender branches, which are covered with a brown bark, and garnished with leaves like those of the Bay-tree, but longer, and deeply ribbed on their under side, standing upon long pretty footstalks opposite; the flowers are produced upon long branching, terminating peduncles, each sustaining two or three flowers, which are large and white, and are succeeded by pods two or three inches long, the thickness of a man's little finger, which are filled with large kidney-shaped seeds; these pods have a thick fleshy cover.—Grows in Carthagera.

23. *Capparis Fruticosa*. Leaves lanceolate, acute, crowded, perennial; stem shrubby. This species rises with a shrubby stem to the height of twelve or fourteen feet, sending out many strong lateral branches, covered with a dark brown bark; the antheræ are of a purplish colour, but the stamina are white.—Sent from Tolu in America.

24. *Capparis Conferta*. Leaves lanceolate, alternate, on very long petioles; flowers crowded. It rises with a shrubby stalk to the height of ten or twelve feet, sending out slender horizontal branches, which are covered with a reddish bark.—Sent from Tolu in America.

25. *Capparis Triflora*. Leaves lanceolate, nerved, perennial; peduncles three-flowered. This has slender shrubby stalks, which rise seven or eight feet high, sending out many woody branches, with very long nerved spear-shaped leaves; the flowers come out at the ends of the branches, three standing upon each peduncle; they are small, white, and are succeeded by oval fruit.

Capparis; a genus of the class Didymamia, order Angiosperminia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, oblong; divisions linear, erect, distant, permanent, shorter than the corolla. *Corolla*: monopetalous, bell-form, five-cleft, nearly equal; divisions oblong, acute, the two upper ones more erect. *Stamina*: filamenta four, subulate, inserted into the base of the corolla, shorter by half than the corolla, the two lower ones rather shorter than the others; antheræ cordate. *Pistil*: germen conical; style filiform, longer than the stamina; stigma cordate, bivalve, equal. *Pericarp*: capsule oblong-conical, compressed at the tip, bilocular, bivalve, with a contrary partition, which is doubled by the bending in of the edge of the valves. *Seeds*: very many, roundish. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: bell-form, five-cleft, acute.

Capsule: bivalve, bilocular, many-seeded.—Those plants of this genus which are natives of the Cape of Good Hope, may be increased by cuttings, and are not so tender as the first species.—The species are,

1. *Capraria Biflora*; *Shrubby Goatweed*, or *Sweetweed*. Leaves alternate; flowers in pairs. This is a shrub, seldom exceeding four feet in height; branches long, somewhat woody, erect, roundish, sometimes slightly hirsute; flowers without scent; corolla white; seeds very small.—It is very common in Jamaica, and in all the Caribbees, and the neighbouring continent; and is one of the plants formerly taken for the Tea of the Chinese, and hence, in the French West India islands, called *thé du pays*. It is propagated by seeds, which must be sown upon a hot-bed in the spring of the year; and the plants must be brought forward by planting them upon a second hot-bed: about the middle or end of June, they may be transplanted either into pots of rich earth, or a warm border, and may then be exposed to the open air, where they will perfect their seeds in autumn.

2. *Capraria Durantifolia*. Leaves in threes, toothed; peduncles solitary; branches alternate; stem about a foot high, obtusely hexangular.—Native of sloughs in Jamaica, where mud has been worked up by carriages.

3. *Capraria Crustacea*. Creeping: leaves opposite, ovate, subtended, crenated.—It is a native of Amboyna and China.

4. *Capraria Lanceolata*; *Willow-leaved Capraria*. Leaves opposite, linear-lanceolate, quite entire; racemes terminating, compound: shrubby.—Found at the Cape of Good Hope.

5. *Capraria Undulata*; *Waved-leaved Capraria*. Shrubby: Leaves opposite, ovate-oblong, quite entire, waved; the upper subcordate, verticelled; racemes spike-form; flowers in an almost simple terminating raceme.—It flowers from March to July.—Found at the Cape of Good Hope.

6. *Capraria Lucida*; *Shining Capraria*. Smooth; leaves opposite, oblong, acute, finely serrulate, glossy; petioles winged; peduncles three-flowered; stems quadrangular; corolla silver-form; tube cylindric, pale purple, a little longer than the calix, gibbous on the outside at the base, above that a little bent, then erect, a little elongated on the outside, so that the border is entirely horizontal; segments ovate, obtuse, equal, reddish purple, with a dark purple spot near the throat, which is hairy. It flowers in April and May; is biennial.—Native of the Cape.

7. *Capraria Humilis*; *Dwarf Capraria*. Pubescent: leaves opposite, or in threes, ovate, serrate, petioled; peduncles axillary, shorter than the petiole.—Annual; and a native of the East Indies.

Capsicum; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, erect, permanent. *Corolla*: monopetalous, rotated; tube very short; border half five-cleft, spreading, plaited; divisions broad, acute. *Stamina*: filamenta five, subulate, very small; antheræ oblong, converging. *Pistil*: germen, superior, ovate; style filiform, longer than the stamina; stigma obtuse. *Pericarp*: berry without pulp, approaching to an ovate figure, bilocular, hollow, coloured; receptacles growing to the dissepiment, exsuccous. *Seeds*: very many, reniform, compressed. ESSENTIAL CHARACTER. *Corolla*: rotated. *Berry*: exsuccous.—Most of the plants of this genus are natives of both the Indies, but they have been principally imported from America into Europe. They abound in all the Caribbee islands, and are greatly used in sauces, especially by the negroes, whence the fruit is called Negro and Guinea pepper. The well-known preparation called Cayenne Pepper, made from the pods of the smaller sorts of *Capsicum*, when used in moderation, is by no means

unwholesome, especially to cold phlegmatic habits. In such temperaments, as well as in paralytic cases, it is used medicinally, in small quantities, as one of the highest stimulants. It has also been exhibited, in combination with aloeitic medicines and the deobstruent gums, in uterine disorders. A small quantity of the powder of *Capsicum* has sometimes given almost immediate relief in the tooth-ache, when arising from a caries or rotten tooth; it is to be applied to the part affected, by introducing it into the cavity of the carious tooth.—The species are,

1. *Capsicum Annuum*; *Annual Capsicum*, or *Guinea Pepper*. Stem herbaceous; peduncles solitary; fruit oblong. An annual plant, two feet high, upright, branched; branches short, ascending; leaves ovate-lanceolate, quite entire, smooth, dark green; flowers white, lateral, solitary. The fruit is a berry, varying much in size and shape, extremely smooth and shining on the outside, scarlet or yellow, inflated or yellow, two-celled, sometimes three-celled; the partitions at top commonly failing towards the axis; receptacle at the bottom of the berry solid, ovate, conical, intimately connected with the partitions, so that some of the seeds are sometimes fixed to the partitions themselves; seeds kidney-shaped or round, beaked, smooth, whitish or pale straw-coloured. Two seems to be the natural number of the cells; for berries which are three-celled become two-celled towards the top. Long informs us, that there are fifteen varieties cultivated in Jamaica: the common long-podded *Capsicum* has been long cultivated in our gardens; it varies, 1. with oblong fruit, growing erect; 2. with a divided fruit; 3. with oblong and short pods growing erect; 4. with a taper fruit a span long. The *Capsicum* with heart-shaped pods has also several varieties; 1. with round hanging pods; 2. with larger and rounder pods; 3. with the largest round pods; 4. with upright heart-shaped pods; 5. with upright round pods: these also have both red and yellow fruit. Bonnet-pepper has small wrinkled leaves; the fruit is also furrowed and wrinkled; generally growing upright, and of a beautiful scarlet-colour; some of them have their tops compressed like a bonnet, whence the name; others are bell-shaped. Cherry-pepper was sent from the Spanish West Indies; it does not grow so tall as the others, but spreads near the ground; the leaves come out in clusters, are of a shining green, and stand on long footstalks; the fruit is round, smooth, of a beautiful red, and the size of a common cherry. Olive-pepper came from Barbadoes: this is like the first in stalk and leaves, but the fruit is oval, and about the size of a French olive. These are all annual with us, their stalk decaying soon after they are ripe, whatever they may be in their native countries.—They are propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants have six leaves, they should be transplanted on another hot-bed, at four or five inches' distance, shading them in the day-time from the sun until they have taken root, after which they must have a large share of air admitted to them in warm weather, to prevent their drawing up weak. Toward the end of May the plants must be hardened by degrees to bear the open air; and in June they should be carefully taken up, preserving as much earth about their roots as possible, and planted into borders of rich earth, observing to water them well, as also to shade them, until they have taken root, after which time they will require no other management, but to keep them clean from weeds, and in very dry seasons to refresh them three or four times a week with water; they will flower at the end of June and in July, and ripen fruit in autumn. The above directions are for the culture of the common sorts of *Capsicum*, which are generally planted for ornament.—Bonnet-pepper, cherry-pepper,

and olive-pepper, being tender, the plants should be put into pots, and placed in an old hot-bed under a deep frame, where they may have room to grow; or if they are planted in the full ground, the plants should be each covered with a bell-glass, to screen them from cold; these glasses may be set off every day in warm weather, and placed over them in the evening again; and in unfavourable weather, the glasses should be raised on the side opposite to the wind, to admit fresh air. With these precautions the fruit will ripen in England, which seldom arrive at maturity without it; and never, except in very warm seasons. The beauty of these plants lies in their ripe fruit, which being of different forms and colours, intermixed with the green leaves and white flowers, which appear at the same time, make a pretty appearance at the latter part of the summer, when they are properly disposed in the borders of the flower-garden; or if planted in pots for the decoration of courts, and intermixed with other annual plants, which are in beauty at the same season, they will make a pleasing variety, especially if as many of the different-shaped fruits, of both red and yellow colours, as can be procured, are propagated.

2. *Capsicum Baccatum*; *Small-fruited Capsicum*, or *Bird-Pepper*. Stem shrubby, smooth, and even; peduncles in pairs. This differs but slightly from the fifth species; the stem is tenderer, more shrubby, and not roughish; the berries are very small, of an ovate form, and of the size of currants; the branches are divaricated, not spreading out at a right angle with the stem. According to Loureiro, the stem is three feet high, smooth, and upright, with longish, scattered, slender branches; leaves lanceolate, quite entire, smooth, scattered, small, petioled; berry roundish, very red, the size of a common cherry; the lower leaves opposite, the upper alternate. It is gathered when ripe, dried in the sun, pounded, and mixed with salt; it is then kept stopped in bottles, and is known by the name of *Cayenne-pepper*. A mixture of sliced cucumbers, eschalots, or onions, cut very small, a little lime juice and Madeira wine, with a few pods of this or bonnet-pepper, well mashed, and mixed with the liquor, seldom fails to excite the most languid appetite in the West Indies, and is therefore called *man-dram*. The pods, gathered fresh from the bush, are also liberally used in the West Indies, to assist digestion and correct flatulencies: both this and the common Guinea-pepper are given internally to horses and mules, to cure the dry gripes, occasioned by rank and sour grass: they are likewise externally applied in cataplasms. Miller enumerates four sorts with perennial shrubby stalks, and informs us, that they rise four or five feet high, and are not so hardy as the annual sort; hence, when they have been brought forward in the hot-bed, as was directed for the common sorts, they should be each planted in a pot filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance; and in warm weather, they should have a large share of air admitted to them, but must be covered with glasses every night in cold weather, and frequently watered. Thus managed, they will produce plenty of fruit in autumn, which ripen in winter; but they must be removed into the stove on the first approach of frost, and placed where they may have a temperate warmth, in which they will thrive better than in a greater heat; and the fruit will continue in beauty most part of the winter, making a pretty appearance in the stove during that season.

3. *Capsicum Sinense*; *Chinese Capsicum*. Stem shrubby; flowers and fruits pendulous; trunk perennial, woody, with an ash-coloured bark. The whole plant is smooth; fruit shining, ovate, obtuse, obscurely angular, yellow, very small;

seeds pale.—Native of China; cultivated in Martinico, and used there for culinary purposes.

4. *Capsicum Grossum*; *Heart-shaped Capsicum*, or *Bell-pepper*. Stem undershrubby; fruits thickened, various. This bears a great resemblance to the annual *Capsicum*, and indeed seems to be the connecting link between the herbaecous and shrubby sorts. The stem is perennial, a span in height, and somewhat branching; the fruit is very large in proportion to the plant, being almost as big as an apple, but differing in shape; it is solitary and erect, from an inch and half to two inches long, swelling and wrinkled, flattened and angular at top. Bell-pepper is the sort most proper for pickling, the skin being fleshy and tender, whereas in the others it is thin and tough; the fruit should be gathered before it arrives at the full size, whilst the rind is tender; it should be slit down on one side, to get out the seeds; after which it should be soaked two or three days in salt and water; when drained from this, it must be covered with boiling vinegar, and closely stopped down for two months, and then boiled in vinegar to make it green; it wants no addition of spice. If the ripe fruit of this, or any of the *Capsicums*, be thrown into the fire, it will raise strong and noisome vapours, which occasion vehement sneezing and coughing, and often vomiting. The powder taken up the nose will excite violent and dangerous fits of sneezing.—These plants, which are propagated for pickling, should be planted in a rich spot of ground, in a warm situation, about a foot and a half asunder, and shaded until they have taken root, and afterwards duly watered in dry weather, which will greatly promote their growth, and cause them to be more fruitful, as also enlarge the size of the fruit; thus there may be at least two crops for pickling obtained in the same year, provided the season does not prove too cold, but there should be one plant with large and forward pods chosen, to save seeds; and the first fruits on this should be suffered to remain, that they may have time to perfect their seeds before the frost comes on in autumn, for the early frost generally destroys these plants: when the fruit is fully ripe, it should be cut off, and hung up in a dry room till the spring, when the seeds are wanted.

5. *Capsicum Frutescens*; *Shrubby Capsicum*. Stem shrubby, roughish; peduncles solitary; stem three feet high, and rugged; branches diffused, frequently scandent; leaves lanceolate, quite entire, waved, small, smooth, petioled, alternate or scattered; flowers axillary, small, white, five or six cleft; fruit at first green, but when ripe golden or saffron-coloured, crooked, and shaped like a horn, an inch long, usually solitary.

Capura; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: monopetalous, tubular; tube cylindrical; border six-parted; divisions rounded, the exterior alternate ones narrower. *Stamina*: filamenta hardly any; antheræ six, oblong, within the tube; the alternate ones superior. *Pistil*: germen superior, triangularly roundish, truncate; style cylindrical, very short; stigma nearly globose. *Pericarp*: berry. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: six-cleft. *Stamina*: within the tube. *Germen*: superior. *Stigma*: globular. *Pericarp*: berry.—The species are,

1. *Capura Purpurata*. A tree with brachiate purplish branches; leaves opposite, subpetioled, ovate, quite entire, sharpish, deciduous; bunches of flowers axillary, shorter than the leaves, purple.—Native of the East Indies.

Caraway. See *Carus*.

Cardamine; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved;

leaflets ovate-oblong, obtuse, somewhat spreading, gibbous, small, deciduous. *Corolla*: four-petalled, cruciform; petals oblong-ovate, spreading much, ending in erect claws of twice the length of the calix. *Stamina*: filamenta six, subulate; of these the two opposite ones are twice the length of the calix, but the rest a little longer; antheræ small, cordate-oblong, erect. *Pistil*: germen slender, cylindric, length of the stamina; style none; stigma obtuse-headed, entire. *Pericarp*: silique long, cylindric, compressed, bivalve, the valves on opening, rolling spirally backwards. *Seeds*: very many, roundish. **ESSENTIAL CHARACTER.** *Silique*: opening elastically; the valves revolute. *Stamina*: entire. *Calix*: rather gaping.—Few of the plants of this genus are admitted into gardens; they are mostly low plants, growing in wet or alpine situations. The perennials may be propagated by parting their roots in the autumn, and require a strong soil with a shady situation. All the species may be propagated by seeds sown in the autumn, on a shady border, where they require no care but to be kept clean from weeds, and will flower early in the following season. As they are very prolific in seed, and their pods are provided with a particular mode of dispersing them, by means of the twisting of the valves in opening; they will propagate themselves abundantly when once introduced, but they will thrive best in the shade. All the species of Cardamine are mild antiscorbutics, as the taste sufficiently indicates, but they are not received in practice.—The species are,

* *Leaves simple.*

1. Cardamine Bellidifolia; *Daisy-leaved* or *Alpine Cress*. Leaves simple, ovate, quite entire; petioles long; root simple, white, very long. The plant has no smell, and flowers in July and August. On the highest Alps, at first it appears with a stem scarcely two inches high, yet with some-leaves on it.—It is frequent on the mountains of Lapland; on the Alps of Switzerland, Dauphiny, Austria, and Carniola; and upon the highest Alps between Savoy and Piedmont: there is some doubt whether it be a native of Great Britain. It is perennial, and flowers in April and May.

2. Cardamine Asarifolia; *Asarabacca-leaved Cress*. Leaves simple, subcordate; leaves round, a little sinuated; corolla white; siliques long, many, bursting at the least touch when ripe. This species has all the qualities of Scurvy-grass, and is substituted for it where it grows in abundance. It is found at Barga in Tuscany; in the Modenese: at the foot of Mount Cenis; in the Vandois Alps; above Tende, &c.

3. Cardamine Nudicaulis; *Naked-stemmed Cress*. Leaves simple, lanceolate, sinuate-toothed, smooth, firm, about three inches long; stems naked, about nine inches high.—Observed by Steller in Siberia.

4. Cardamine Petræa; *Rock Cress*, or *Alpine Ladies' Smock*. Leaves simple, oblong, toothed; roots perennial; stems from three to six inches high, reclining at the base, and increasing by offsets. Perennial; flowering in May and June.—Found upon lofty moist rocks in Wales, Scotland, Sweden, Denmark, and Silesia.

** *Leaves ternate.*

5. Cardamine Resedifolia; *Rocket-leaved Cress*. Lower leaves undivided, upper three-lobed and pinnate; root biennial.—Native of the south of France, the Swiss Alps, and the Pyrenees, Germany, Austria, Piedmont, on the highest rocks; flowering in July.

6. Cardamine Trifolia; *Three-leaved Cress*. Leaves ternate, obtuse; stem almost naked; root creeping. Stem branched, cicatrized with the fallen petioles; radical leaves often continuing to another year, ternate, on long reddish

semicylindric petioles; leaflets rounded above the middle, with repand or suberenated edges, the notches ending in a point; flowers white or reddish.—Native of Lapland, and Westrogothia, Switzerland, Carniola, and Austria.

7. Cardamine Africana; *African Cress*. Leaves ternate, acuminate; stem very branching; leaflets stiff, large, roundish, with sinuated edges, the terminating one very large; stems a span or more in height, round, somewhat hairy, and striated towards the top; flowers in spikes, purple; siliques long. Perennial; flowering in May, and a native of Africa.

*** *Leaves pinnate.*

8. Cardamine Chelidonia; *Celandine-leaved Cress*. Leaves pinnate; leaflets in fives, gashed; stem herbaceous, eight inches high, with many ascending branches; leaflets seven, lanceolate, smooth; flowers purplish white, in simple terminating spikes.—Native of Italy, Siberia, and China.

9. Cardamine Impatiens; *Impatient Ladies' Smock*. Leaves pinnate, gashed, stipuled; flowers without petals; root annual. Stems from six to twelve or eighteen inches high, angular, hollow, stiff, erect, somewhat flexuose, simple, or but little branched; radical leaves have five pairs or more, ovate; pinnas obtusely lobed; stem leaves very numerous, growing without order, shortest towards the bottom of the stem, pinnate; pinnas nine pairs or more, oval-lanceolate, or lanceolate, deeply and acutely lobed or indented, especially on the lower edge, smallest towards the stem, and gradually larger; odd leaflet usually three-lobed; flowers in erect spikes; siliques numerous, almost parallel to the stem, long, stiff, swelling out a little. It is called *impatient*, from the elasticity of the siliques, which, if touched when they are ripe, spring open, and cast out their seeds with violence to a considerable distance.—It is found upon the Swiss mountains, and in Sweden, Denmark, Germany, the south of France, Austria, Carniola, Piedmont, the Pyrenees: in England, it grows in Derbyshire, Yorkshire, Westmoreland, Worcestershire, and Somersetshire; flowering in May and June.

10. Cardamine Parviflora; *Little-flowered Ladies' Smock*. Leaves pinnate, without stipules; leaflets lanceolate, obtuse; flowers corolled.—An annual plant, and native of most parts of Europe.

11. Cardamine Græca; *Greek Cress*, or *Ladies' Smock*. Leaves pinnate; leaflets palmate, equal, petioled. Root annual; height less than a span; stems slender, jointed, branched; leaflets nine, small, ovate, semipalmate, obtuse, divided about the edge; flowers few, at the tops of the branches; calix erect; corolla white.—Native of Sicily, Corsica, and the Greek islands.

12. Cardamine Hirsuta; *Hairy Ladies' Smock*. Leaves pinnate; flowers four-stamined and six-stamined. Root annual, fibrous; stem a span high or more, solid, upright, flexuose, grooved or angular, purple near the base, and commonly very hairy, above nearly smooth, branched, sometimes very much so; radical leaves numerous, forming a circle, pinnate; leaflets petioled, round, angular, generally five-lobed, hirsute, roughish, with little prominent points, the lobes unequal, blunt or pointed; stem leaves narrower, and more deeply indented, with fewer lobes; calix with a few white hairs; corolla almost twice the length of the calix, small, white; petals entire, obtuse; silique about an inch in length, upright; seeds twelve, flattened, smooth, yellowish-brown. Early in the spring, when the weather is cold, it has only four stamina, but as the summer advances it has constantly six; in a wet and luxuriant soil, it loses its hairiness in a great degree; in exposed situations, it seldom exceeds six or eight inches high, and is generally much more hairy, and when it grows singly, also much more branched; the

leaflets vary much in shape. The young leaves are a good salad in the spring.—It is a native of most parts of Europe, in wet shady places, and flowers in April or May.

13. *Cardamine Pratensis*; *Common Ladies' Smock*, or *Cuckoo Flower*. Leaves pinnate; the radical leaflets roundish, those on the stem lanceolate. Root perennial; stem nine inches or a foot high, upright, at top a little branched, round, scarce perceptibly angular, smooth, stiffish, with a purple tinge at bottom; radical leaves on petioles from an inch to two inches in length, having three or four pairs of leaflets, frequently imperfect, after the stem is advanced; the pinnae roundish, running out into three unequal angles or teeth, the outermost largest, and having for the most part five angles; calix yellowish green; corolla large, purplish or white; lamina ovate, emarginate, deeply veined; claws yellowish; nectary of four glands, two surrounding the base of the short filamenta, and two on the outside of the base of the long filamenta. Most authors speak of the corolla as being purple; it is singular, therefore, that our poets should allude to the *silvery whiteness* of it, when it is generally more or less tinged with purple till it has been bleached by the sun.—It is very common in moist meadows, and by the sides of ditches and streams, flowering in April and May. From its early appearance, the name of *Cuckoo-flower* has been given to it, as well as to other spring plants. The young leaves of this species, as well as several others, are gathered in the spring, and put into salads, instead of cress, of which they have the flavour, and the antiscorbutic quality. Cows seldom touch it; but sheep will eat it, at least when they are first turned into a meadow or marsh. The medical virtues of the flowers, in hysteric and epileptic cases, was first mentioned by Ray and Dale, from Dr. Tancred Robinson; and since by Dr. Baker. The dose is from twenty to ninety grains twice a day, of the powder of the dried flowers. Withering asks, if they do not act like the *Erysimum Cheiranthoides* in the epilepsies of children, and cure the disease by destroying the worms in the stomach and intestines? He adds: I have accounts, upon good authority, of their success in young epileptics, but have never been fortunate enough to see them of much use in hysteric cases. From the disuse into which this medicine has fallen, it would seem to have disappointed the expectations of practitioners. Cases have, however, occurred to some very eminent physicians, in which epilepsies and obstinate head-aches, even in old people, after resisting every other remedy, have been cured by this medicine, given in the quantity above prescribed, twice or thrice daily. It usually operates by occasioning a degree of hemorrhage *per anum*, and sometimes from the other emunctories. It seems particularly serviceable in those kinds of epilepsies which are brought on by the recess or want of the menses; and has also been considered as useful in scorbutic cases, like many other plants of the same natural order. Meyrick prescribes the expressed juice of the leaves, which he says operates powerfully by urine, and is good in the jaundice, and all other complaints arising from obstructions of any of the viscera, and in scorbutic disorders. A wine glass, is a sufficient quantity to be taken at a time. He adds, the flowers, carefully dried, are very efficacious in nervous disorders, such as convulsions, the falling sickness, palsy, and hysteric fits. The dose is from a scruple to half a drachm, twice a day.—The double varieties of this species, which have white and purple flowers, deserve a place in the shady moist borders of the flower-garden, where they will thrive, and make a pretty appearance during their continuance in flower. They are propagated by parting their roots in autumn; at which time they should be annually transplanted.

14. *Cardamine Amara*; *Bitter Cress*, or *Ladies' Smock*. Leaves winged; root leaflets roundish; stem leaves angularly toothed; stem taking root at the base; root perennial, toothed; leaves nearly smooth; flowers large, white, or cream-coloured, antheræ violet-coloured. The young leaves are acrid and bitterish, but do not taste amiss in salads; they are pungent, bitter, and aromatic, in such a degree as to promise very considerable medicinal uses.—This plant is a native of Sweden, Switzerland, Germany, France, and Piedmont. It is found near London; at Chelsea, Battersea, Lewisham, Uxbridge, Harefield; Dorking in Surry; Braintree in Essex; Middleton in Warwickshire; Aston near Birmingham; above Worcester; and Great Comberton in Worcestershire; near Norwich; Bungay, Suffolk; and in Scotland.—It grows near rivulets, on the banks of rivers, in boggy places, and moist meadows; flowering in April and May. Perennial.

15. *Cardamine Virginica*; *Virginian Cress*. Leaves pinnate; leaflets lanceolate, one-toothed at the base; radical leaves in a circle, pinnate; leaflets numerous, almost imbricate, sublanceolate, with one short toothlet from the hinder side near the base; stem with few leaves, generally linear and entire.—Native of Virginia.

16. *Cardamine Thalictroides*. Leaves ternate, pinnate and simple; leaflets obliquely lobed, roundish; petals thrice the length of the calix. Stem striated, branching, procumbent, the extreme branches bearing flowers on a short umbel; leaves tender, juicy, not hirsute, pinnate; the radical ones have often two pinnae: biennial.—Native of Mont Cenis, St. Bernard, and the Grand Chartreuse.

17. *Cardamine Stolonifera*. Stem leaves oblong, sinuate-toothed; runners from the root and base of the stem. Stem six inches high, erect, branching, moderately hirsute; radical leaves on long petioles, obtuse, repand, with one pinnule beneath, a line in length; leaves of the runners small, petioled, sharpish with acuminate angles behind.—Native of Carniola, Austria, and the borders of Bohemia.

18. *Cardamine Scutata*. Leaves ternate, scutate, curled; stem almost naked. Root fibrous: fibres very close, capillary; scapes naked, a finger's length; root-leaves very many, petioled, ternate, erect, loose; lower stem-leaves often solitary, sometimes opposite, in pairs, ovate, subpetioled, very small; the terminating one round, curled, smooth, dotted.—Native of Japan.

Cardamom. See *Anomum*.

Cardinal Flower. See *Lobelia*.

Cardiospermum; a genus of the class Octandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets obtuse, concave, the alternative interior ones the size of the corolla, permanent. *Corolla*: petals four, obtuse, alternate with the larger leaflets of the calix; nectary four-petalled, coloured, inclosing the germen; leaflets obtuse, growing upon the petals, two upon the erect lip, callous at the tip, hooked at the side; the rest upon the closed lip, with equal sides. *Stamina*: filamenta eight, subulate, equal with the nectary; antheræ small. *Pistil*: germen three-sided; styles three, short; stigmas simple. *Pericarp*: capsule roundish, trilobate, inflated, trilocular, gaping at the tip. *Seed*: solitary, globular, marked at the base with a cordate scar. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Petals*: four. *Nectary*: four-leaved, unequal. *Capsule*: three, connate, inflated.—In both Indies, of which these plants are natives, they climb upon whatever shrubs are near them, and rise to the height of eight or ten feet; but in England they are seldom much above half so high; they send out many side branches, which spread to a considerable distance, and will fasten themselves to the neighbouring

plants by their small tendrils, if permitted. They are annuals, and die soon after they have perfected their seeds; and, being natives of hot countries, they will not thrive in England but in a stove. They are propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are two inches high, they should be each transplanted into a pot filled with light sandy earth, not too rich, then plunged into a very moderate hot-bed, where they must be carefully shaded until they have taken fresh root; after which a large share of fresh air must be admitted, to prevent them from being drawn up tall and weak; and when their roots have filled the pots, they should be carefully shaken out, preserving all the earth to their roots, and put into pots which are a little larger, filling them up with the same light earth, and placing them either under a deep frame, or behind the plants in the stove, where they may be screened from the sun till they are well settled in the pots; after which they may be removed into the glass-case, where they may have room to grow, escape the cold of the nights, and enjoy the air in warm weather. With this management they will flower in July, and ripen their seeds in autumn.

—The species are,

1. *Cardiospermum Halicacabum*; *Smooth-leaved Heart Pea*, or *Heart-seed*. Leaves smooth and even; stem herbaceous, twining, striated, unarmed, slender, long, branched; leaves broad-lanceolate, sinuate-gashed, smooth, biternate; flowers axillary, solitary, small, white, on long peduncles; calix five-leaved.—Native of both the East and West Indies, and the Society Isles in the South Seas. It flowers here in July.

2. *Cardiospermum Corindum*; *Woolly-leaved Heart Pea*, or *Parsley-leaved Heart-seed*. Leaves tomentose underneath. This rises, with a slender, channelled, climbing stalk, to the height of four or five feet, sending out many side-branches, with leaves upon very long footstalks, coming out opposite at the lower part of the stalk; but upward the leaves come out one side, and the peduncle at the opposite; the petioles are divided into three, each of which sustains small leaves, which are again divided into three parts, that are sharply cut on their edges, and end in sharp points. The peduncles are long, naked, and toward the top divided into three short ones, each sustaining a single flower; immediately under these divisions, come out tendrils or claspers, like those of the Vine, but smaller; these fasten themselves to whatever plants grow near them, and are thereby supported: the flowers are small, white, and composed of four small concave petals, two of which, standing opposite, are larger than the others; when these fall away, the germen becomes a large inflated bladder, having three lobes, in each of which is contained one, two, and sometimes three seeds, which are round, hard, and the size of small peas, each being marked with a black spot, in the shape of a heart.—It is a native of Brazil, and, according to Loureiro, of the suburbs of Canton in China. It flowers in July and August.

3. *Cardiospermum Grandiflorum*; *Great-flowered Heart-seed*. Leaves pubescent; capsules acuminate, very large, smooth and even.—Native of Jamaica.

Carduus; a genus of the class Syngenesia, order Polygamia Aequalis.—GENERIC CHARACTER. *Calix*: common ventricose, imbricate; scales very numerous, lanceolate, acuminate, spiny. *Corolla*: compound, tubular, uniform; corollules hermaphrodite, subequal, reflected; the proper one monopetalous, infundibuliform; tube very slender; border erect, ovate at the base, quinquefid; divisions linear, equal, one more deeply separated than the rest. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular, length of the corollule, five-toothed at the mouth. *Pis-*

til: germen ovate; style filiform, longer than the stamina; stigma simple, subulate, naked, emarginate. *Pericarp*: none; calix converging a little. *Seeds*: solitary, obovate, four-cornered, the two opposite corners obliterated; down sessile, very long. *Receptacle*: hairy, flat. ESSENTIAL CHARACTER. *Calix*: ovate, imbricate with spiny scales. *Receptacle*: hairy.—It is scarcely necessary to say any thing concerning the propagation of Thistles, as they are justly considered as weeds demanding eradication, not as plants fit for cultivation. A small number only of them is admitted in gardens, and merely because they are foreign plants. The greater part of the species are biennial, and must be raised from seeds. The perennial sorts are also easily increased in the same manner, and by the roots.—The species are,

1. *Carduus Leucographus*. Leaves decurrent, toothed, spiny; peduncles naked, very long, one-flowered; calices spiny, inclined. Root annual; stem three feet high, flowers upright; down simple.—Native of the county of Nice and Campania.

2. *Carduus Lanceolatus*; *Spear Thistle*. Leaves decurrent, pinnatifid, hispid; divisions divaricate; calices ovate, spiny, villose; stem hairy. Root biennial; stem upright, three or four feet high, angular, downy, frequently purple; corolla purple, sometimes white; down plumose, almost as long as the blossom. It is sometimes found the height of a man, with heads twice the size of the common; as also with smaller heads, in all respects a less plant.—It is called the Burthistle in Yorkshire, and is found on road-sides, hedges, and fallows, flowering in July. Although this plant, in common with most of the Thistles, is merely regarded as a noxious weed, yet, as Linneus judiciously remarks, it preserves annual plants, by protecting them with its spines, and giving them opportunity to seed in quiet. If a heap of clay, says Dr. Withering, be thrown up, nothing would grow upon it for several years, did not the seeds of this plant, wafted by the wind, fix and vegetate thereon; under the shelter of this, other vegetables appear, and the whole soon becomes fertile. The seeds are eaten by birds; and the flowers, like those of the artichoke, have the property of curdling milk. This is the most common species of its genus, and is a large succulent plant, well known upon all strong lands. Mr. Miller says, "I have seen the air perfectly filled with the down of this Thistle, for miles together, flying along in windy weather, till it was intercepted by a hedge, bank, or rising ground. The greatest part of it indeed is down without seed; and for this the husbandman is obliged to the goldfinch and other small birds, who nevertheless generally leave enough to stock his ground; and the misfortune is, that let a farmer be ever so neat in himself, if he happen to live near a slovenly neighbour, he will be stocked annually from the other's neglected banks, headlands and fallows. Nothing is easier than to destroy these Thistles; for they are biennial plants, and only require to be mowed down before they perfect their seeds. It is better to do this while the plant is yet tender, for as it advances to maturity the stalk grows very hard; but if the operation have been neglected till the seeds are forming, it will be a proper precaution to rake the plants into heaps, and burn them. The ashes may be afterwards spread; and as they contain a considerable quantity of salts, will be of some advantage to the soil, which they had previously impoverished."

3. *Carduus Arabicus*; *Arabian Thistle*. Leaves decurrent, pinnatifid, lanuginously villose; divisions divaricate; calices oblong, spinulose, sessile, aggregate. Root annual, fusiform, white; stem erect, about a foot high, scarcely branched, lanuginous, and hoary; corollules purplish; an-

there dark purple; pappus hairy, sessile, brown; seeds smooth.

4. *Carduus Nutans*; *Musk Thistle*. Leaves semi-decurrent, spiny; flowers drooping; scales of the calix spreading at top. Stems from two to three feet high, overspread, as are also the leaves, peduncles, and calices, with a cottony down; peduncles one-flowered; flower hanging down, smelling very sweet, particularly in the evening. This plant is well known to entomologists, on account of the moths which feed upon it. The dried flowers of this species, as well as the former, are sometimes used to curdle milk.—It flourishes in a calcareous soil, upon road sides, in a sandy or gravelly soil, and is common on most of the fallows about Cambridge: it is biennial, flowers in June, the earliest of the Thistles, and is easily known by its nodding bright purple heads, and musky scent; it does not however confine itself to borders, but takes possession of the arable lands in good soils, and does real injury to the farmer.

5. *Carduus Acanthoides*; *Prickliest Thistle*. Leaves decurrent, sinuate, spiny about the edge; calices peduncled, solitary, erect, villose; flowers small, pale purple, crowded on the top of the stem; the colour of the whole plant ash or gray; down simple, nearly as long as the corolla. Gerard calls it *Thistle upon Thistle*, and Parkinson, *the most prickly Thistle*.—It flowers from June until September, and is found in most parts of Europe, upon ditch-banks, road-sides, waste places, and borders of corn-fields. It is sometimes found with white flowers, and in different situations varies from two to five feet in height; is more or less hairy, and has its flowers more or less clustered.

6. *Carduus Crispus*; *Curled Thistle*. Leaves decurrent, sinuate, spiny about the edge; flowers aggregate, terminal; scales of the calix unarmed, subaristated, expanded.—It grows wild in the same soil and situations with the foregoing; flowers about the same time; and like that, is annual.

7. *Carduus Polyanthemus*. Leaves decurrent, sinuate, naked beneath; flowers peduncled, heaped, usually three or four at top, subsessile; peduncles curled, scarcely cob-webbed; corollas in the outside purple, in the disk red; antheræ violet; styles white; stigmas purple. Biennial.—Native of Rome.

8. *Carduus Palustris*; *Marsh Thistle*. Leaves decurrent, toothed, prickly at the edge; flowers in racemes, upright; peduncles unarmed. Root biennial; stem four, five, or six feet in height, in woods frequently ten or twelve, upright; branched, multangular, hirsute with numerous long white hairs, winged, prickly, variegated longitudinally with green and purple. It is called the Red Thistle in Yorkshire; and being never found except in wet places, it is not likely to be mistaken for any other Thistle; it has generally more purple about it than the other species; and formidable as its stems and leaves are from their numerous prickles, the heads of flowers and peduncles are perfectly harmless. The tender stalks of this plant, like most of the genus, are esculent when peeled and boiled, and are thus eaten, as Linneus informs us, by the inhabitants of Smoland.—It grows wild in most parts of Europe, in marshes, boggy woods, and moist heaths, commons, and meadows, flowering in July: it varies with a white flower, as most of the Thistles occasionally do.

9. *Carduus Pycnocephalus*; *Italian Thistle*. Leaves decurrent, pinnatifid-sinuate, pubescent, spiny; peduncles naked, tomentose; calices deciduous.—Native of the southern parts of Europe.

10. *Carduus Argentatus*. Leaves decurrent, runcinate, spiny; peduncles subtomentose, one-flowered; calices ovate mucronate, unarmed. Stem a foot high, flexuose, even,

alternately branched; corolla very small, purple, mixed with the down, scarcely gaping; antheræ blue; down ash-coloured. It is an annual plant.—Native of Egypt.

11. *Carduus Australis*. Leaves decurrent, runcinate, spiny; calices subsessile, terminal. Stem a foot high, round, striated, woolly, villose; corolla consisting of about eight purple floscules.—Native of southern Europe.

12. *Carduus Dissectus*; *Meadow Thistle*. Leaves decurrent, lanceolate; toothlets unarmed; calices spiny; flowers red. The leaves are wholly destitute of prickles.

13. *Carduus Cyanoides*; *Bluebottle-leaved Thistle*. Leaves decurrent, pinnatifid, linear, quite entire, unarmed, petioled, tomentose beneath.—The leaves have a white cotton underneath.—Grows wild in Tartary.

14. *Carduus Canus*; *Hairy Thistle*. Leaves decurrent, lanceolate, erose-toothed, ciliate-prickled, cobwebbed, subvillose on both sides. Roots fusiform, aggregate, fleshy, white like skerrets; stem four feet high, green, angular, cob-webbed; flowers solitary, purple; calices unarmed, with a white line on the outside of the scales.—Perennial; flowering in July; and a native of Austria and Tende.

15. *Carduus Pectinatus*. Leaves decurrent, lanceolate, pinnatifid-pectinate; peduncles very long; heads, when past flowering, drooping. Stem two feet high, erect, even, unarmed, as is the whole plant; leaves uninterrupted, decurrent, with a pale keel beneath, pinnatifid or very deeply toothed; flowers the size of Burdock, purple, with a long pistil; filamenta white, erect. Biennial: sent from Pennsylvania.

16. *Carduus Defloratus*; *Various-leaved Thistle*. Leaves decurrent, lanceolate, serrate, subspinose-ciliate, naked; peduncles very long, lanuginous, one-flowered. Stems many, angular, smooth, leafy, generally simple; peduncles leafless, somewhat woolly, very few; flower solitary, red. Perennial.—Native of Montpellier, Switzerland, Carniola, and Gorizia.

17. *Carduus Monspensulanus*; *Montpellier Thistle*. Leaves decurrent, lanceolate, subrepand, smooth, unequally ciliate; peduncles alternate; calices unarmed. Perennial.—Found about Montpellier, and in the county of Nice.

18. *Carduus Pannonicus*. Leaves semi-decurrent, naked, undivided, ciliate; flowers subsolitary. Unarmed; leaves smooth and even, with soft bristles; corolla pale purple.—Perennial: and a native of Austria.

19. *Carduus Tuberosus*; *Tuberous Thistle*. Leaves subdecurrent, petioled, subpinnatifid, spiny; stem unarmed; flowers solitary; corolla purple; down simple: perennial: flowering in July and August.—Native of Montpellier, Leipsic, Bohemia, the Palatinate, Austria, Geneva, Switzerland, and the county of Nice.

20. *Carduus Chius*. Leaves stem-clasping, the lower ones semidecurrent, semipinnatifid, ciliate-spinulose; stem unarmed; peduncles one-flowered. Stem the height of a man, branching from top to bottom, angular, villose, erect.—Native of Chios.

21. *Carduus Parviflorus*; *Small-flowered Thistle*. Leaves adnate at the base, lanceolate, naked, erose, ciliate-spinulose, unarmed. Stem erect; leaves repand-toothed, green on both sides; flowers terminal, peduncled, white, with very long styles. Perennial.—Native of the southern subalpine mountains.

22. *Carduus Linearis*. Leaves sessile, linear, ciliate-spiny, smooth; flowers terminal, solitary. Stem herbaceous, erect, round, striated, smooth, unarmed, a foot high and upwards; branches alternate, spreading, like the stem, a little tomentose at the end; flowers small; calices subtomentose at the base, smooth at the top.—Native of Japan.

23. *Carduus Casabonæ*; *Fish Thistle*. Leaves sessile,

lanceolate, quite entire, the edge with ternate spines. This is a biennial plant, which rises six feet high, with an upright stalk. The flowers come out in clusters from the top of the stalk; they are purple, and are succeeded by smooth, oval, black seeds.—Native of the south of Europe.

24. *Carduus Stellatus*; *Starry Thistle*. Leaves sessile, entire, lanceolate, unarmed, tomentose beneath; spines branched, axillary; flowers sessile, lateral. Stem a foot high, straight, round, cottony, it divides at top into several branches, each ending in a spiny head, under which are three leaves; floscules purple.—Annual; and a native of Sicily and the county of Nice. The seeds of this plant should be sown upon a bed of light earth in the spring, where the plants are to remain, for they do not bear transplanting unless performed when they are very young. The only care they require is, to keep them clear from weeds, and to thin them where they come too close together.

25. *Carduus Marianus*; *Milk Thistle* or *Ladies' Thistle*. Leaves stem-clasping, hastate-pinnatifid, spiny; calices leafless; spines channelled, doubly spined. The radical leaves spread on the ground, from one to two feet or more in length with white veins on the upper surface. The beautiful milky veins, forming an irregular net-work on the leaves, would form an obvious character to distinguish this species, if they were not sometimes found wholly green: in which case recourse must be had to the strong spines of the calix.—It is found upon banks, by road-sides, and in waste places; flowering from May and June till July and August. It is a biennial, and eaten when young as a salad, and is by some persons blanched, and dressed as a curious dish. The tender leaves stripped of their spines, are boiled and eaten as greens; the young stalks peeled, are excellent, after their bitterness is extracted by soaking them in water; and the scales of the calix are as good as those of Artichokes; the root is good to eat early in the spring. The seeds are large, and contain a portion of oil, whence they have sometimes been used in emulsions, to thin the blood, and to cure stiches and pleurisies, for which purpose they are still prescribed by the German physicians, in doses of from one to three drachms each. The Italian physicians give the expressed juice in agues. Granivorous small birds, particularly goldfinches, feed much upon the seeds of this and other Thistles. In Apulia this plant is grown in preference to grass, on account of its yielding a larger quantity of food for the cattle.—It makes a handsome appearance, and deserves a place in all large gardens.

26. *Carduus Syriacus*; *Syrian Thistle*. Leaves stem-clasping, angula-spiny; flowers solitary, subsessile, fortified with about five leaflets. Flowers white; in the Egyptian variety purple.—It is annual; and a native of Syria, Crete, and Spain.

27. *Carduus Eriophorus*; *Woolly-headed Thistle*. Leaves sessile, pinnatifid, in two rows; divisions alternate, erect; calices globular, villose. Stem four or five feet high, angular, striated, woolly without thorns, much branched; floscules purple, sometimes white; style much longer than the antheræ; down shorter than the corolla, fringed with long hairs. The receptacle is pulpy and esculent, like that of the artichoke.—It is biennial; flowering from July till September, and frequents dry pastures, road-sides, and waste places, in Great Britain, France, Switzerland, Germany, Austria, Carniola, Spain, and Portugal. It is the most showy of all the Thistles, and ought therefore to be introduced into large gardens, where it will not flower until the second year; but when once admitted, will sow and maintain itself without requiring any further care.

28. *Carduus Altissimus*; *Giant Thistle*. Leaves sessile,

pinnatifid, sinuate, serrate unarmed; stem very branching; calices villose, subserrate. Stature ten or twelve feet; corolla pale purple; down plumose.—Imported from Carolina.

29. *Carduus Virginianus*; *Virginian Thistle*. Leaves lanceolate, spinulose, tomentose, beneath; stem unarmed, leafy, one-flowered. Stem slender, a foot or eighteen inches high; corolla purple.—Imported from Virginia.

30. *Carduus Heterophyllus*. Leaves stem-clasping, lanceolate, ciliate, entire, and lacinate; stem with one or two flowers; calix unarmed. Root perennial, creeping; stem erect, quite simple, striated, tomentose, about eighteen inches high; leaves half-stem-clasping, serrate, the serratures spiny, the middle nerve white, alternate, the bottom ones petioled; flower one, purple, terminal; calix ovate; scales acute, somewhat spined.—Perennial: flowering in July, and abounding in moist meadows and marshy places.

31. *Carduus Helenioides*; *Melancholy Thistle*. Leaves stem-clasping, lanceolate, toothed; spinules unequal, ciliate; stem unarmed. The stem is above a foot high when wild, but generally double that height in gardens; where the leaves grow so much larger, that it seems a different plant; they are of a shining green on the upper side. The roots creep far under the surface. It has been cultivated in the gardens of some quacks, who pretended to cure madness with it; and from that circumstance in all probability obtained the name of Melancholy Thistle.—It is found in mountainous pastures in Yorkshire, Westmoreland, Cumberland, and Wales; at Mulbarton near Norwich; Acton in Gloucestershire; in a meadow near Highgate; on Hounslow Heath; near Croydon; and in Scotland. Perennial: flowering in July.

32. *Carduus Serratuloides*; *Saw-wort Thistle*. Leaves rather stem-clasping, lanceolate, entire; serratures spiny-setaceous; peduncles one-flowered. Stem solitary, from a foot and a half to three feet in height, simple, one-flowered, or divided into few elongated erect peduncles, striated, frequently flexuose, woolly as if covered with a cobweb, leafy to about half the height, the rest leafless and of a dusky purple; floscules purple; seeds pale shining; down plumose.—Native of Siberia, Switzerland, Austria, Carniola, Piedmont, and Montpellier.

33. *Carduus Tataricus*; *Tartarian Thistle*. Leaves stem-clasping, lanceolate; serratures spiny-setaceous; flowers three-leaved. Stem a foot and a half high, smooth, sometimes simple, sometimes branched, each bearing a yellowish-white flower. Perennial.—Native of Siberia.

34. *Carduus Ciliatus*; *Ciliate Thistle*. Leaves half stem-clasping, pinnatifid, lancinate, spiny-tomentose beneath; scales of the calix ciliate, reflex at the base. Corolla purple-red; seeds scarcely four-cornered, and of a pale purple.—Native of Siberia.

35. *Carduus Flavescens*. Leaves lanceolate, entire, unarmed, toothed, smooth; flowers leafless, weak-spiny. Stem eighteen inches high, upright, grooved, smooth, sparingly branched; corolla yellowish white; seeds turbinate, four-cornered; down plumose, very abundant.—Found in Spain by Loeßing, and in Silesia by Krocker.

36. *Carduus Rivularis*. Leaves at bottom pinnatifid into oblong divisions, at top entire and serrate, weak-spiny, sessile; stem unarmed; flowers in heads; root perennial. The stem is usually single, two or three feet high, erect, round, hollow, a little villose angular at bottom, striated at top, generally quite simple, but sometimes it puts forth short one-flowering branches from some, seldom from all the axils; corollules purple.—It is found in moist meadows, and begins to flower in the middle of May.

37. *Carduus Mollis*. Leaves pinnatifid, linear, tomentose

beneath; stem one-flowered, unarmed. Stem one, erect, a foot and a half or two feet high, round, a little angular, tomentose, sometimes tinged with red, the size of a pen or rather larger; radical leaves in a tuft; floscules deep purple, calix tomentose.—The whole plant smells strong of musk. It is found about Montpellier, in Germany, Austria, and Carniola; flowering in July and August.

38. *Carduus Acaulis*; *Dwarf Carline Thistle*. Stemless; calix smooth. Leaves lying close to the ground, with one purple flower in the midst of them; down long, plumose; root-leaves spreading in a circle on footstalks, pinnatifid; pinnae irregularly lobed and waved, angular, with sharp spines at the edge, green on both sides, hairy towards the base. Linneus justly observes, that this dwarf plant occupies a foot in diameter, not suffering any plant to grow beneath it; and that it is therefore injurious to pastures: it affects dry open situations, such as heaths and downs, particularly where the soil is calcareous.—It is a perennial, flowering in July; and is found in most parts of Europe. This Thistle is only to be destroyed by ploughing: it is common in the very dry light lands, beside being the great pest of the sheep downs.

39. *Carduus Inclians*; *Thistle upon Thistle*. Leaves decurrent, thorny at the edge; calices roundish, lax; scales of the calix subulate, straight, the innermost unarmed, coloured. Corolla purple. It is an annual plant, growing upon ditch-banks and road-sides, in hedges, among briars, in waste places, and on the borders of corn-fields, flowering in July.

40. *Carduus Pratensis*; *English Soft or Gentle Thistle*, *Single-headed*, or *Meadow Thistle*. Leaves sessile, half stem-clasping, lanceolate, somewhat toothed, fringed with small unequal thorns; stem mostly one-flowered. Root perennial, fibrous, creeping; flower terminal, purple; calix ovate, tomentose; the scales imbricate, ovate, acuminate, purplish; seed very short; down nearly as long as the corolla, plumose with long hairs.—Found in marshy places and swampy meadows.

41. *Carduus Carniolicus*. Lower leaves pinnatifid, on short petioles, upper ones stem-clasping; heads (three or four) terminal, heaped; stem two feet high, striated, simple, not winged, the thickness of the little finger; heads of flowers sessile, floscules pale yellow; antheræ ferruginous, putting out two little bristles behind; filamenta brown; down plumose.—Native of Carniola, Austria, and Piedmont.

42. *Carduus Carlinoides*; *Pyrenean Thistle*. Leaves decurrent, decursively pinnate; pinnules palmate-quadrifid, acute, woolly; stem corymbed, many-flowered; flowers glomerate. Root perennial; stem a-cubit high, sometimes panicle-branched, woolly; branches axillary, alternate, solitary, from half a palm to a foot in length; corollas purple.—This is a very handsome species, native of the Pyrenees, and of the mountains about Tende.

43. *Carduus Medius*. Leaves decurrent, pinnatifid, thorny about the edge; stem one-flowered; peduncles very long; scales of the calix unarmed, spreading, bristle-shaped; stem a cubit high, very simple, erect; leaves lanceolate, an inch wide, three inches long; flower nodding, purple or deep red. Biennial.—Found upon the Pyrenees, and on the mountains of Piedmont.

44. *Carduus Ochroleucus*. Leaves pinnate; pinnae ciliate; scales of the calix recurved. Height two feet; flowers yellowish-white; down plumose. Perennial.—Native of Switzerland.

45. *Carduus Pyrenaicus*. Leaves decurrent, oblong-lanceolate, ciliate at the edge, spiny and tomentose on both sides; flowers subsessile; stem three feet high or more, striated, green, smooth; top of the stem almost naked; corolla purple;

down plumose. Perennial.—Native of Provence, Austria, and Piedmont.

46. *Carduus Paniculatus*; *Panicled Thistle*. Leaves semi-decurrent, oblong-lanceolate, unequal, ciliate, smooth; the lower lyrate, waved; flowers panicled. This is a perennial plant, flowering in June and July.—Native of the south of Europe.

47. *Carduus Rigens*; *Upright Alpine Thistle*. Leaves oblong-lanceolate, smooth, thorny at the edge; pinnatifid; segments oblique, lobed; calices oblong, bracted. Calix oval, with close scales; corollules yellowish white. The whole plant has an ill smell. It is biennial or perennial, and is a large, thick, strong plant, but very low in proportion to the thickness of the stem, which is seldom more than a foot in height.—It flowers in July and August, and is a native of Switzerland and Dauphiny, in moist meadows exposed to the north.

48. *Carduus Diacantha*. Leaves sessile, lanceolate, tomentose underneath; spines in pairs, flowers corymbed; stem two feet high, straight, single, striated, tomentose; florets of a violet colour.—Native of Mount Libanus.

49. *Carduus Pinnatifidus*. Leaves pinnatifid, tomentose; nerves woolly; stem one-flowered. Root short, fibrous, annual; flowers terminating, solitary.—It flowers at the end of May and June, and is a native of Spain.

50. *Carduus Gnaphaloides*. Leaves sessile, in a sort of whorl, lanceolate, quite entire, tomentose beneath. Root perennial, woolly, adhering to the clefts of rocks, whence the plant hangs; flowers terminating, purple, an inch in length. It flowers early in the spring, and continues flowering through the summer to the autumn; the corolla smells sweet, the leaves are dry, and insipid to the taste. It is a native of the farther Calabria, where its leaves are only half the width, and much more tomentose: it grows very luxuriantly in gardens.

51. *Carduus Tenuiflorus*; *Slender-flowered Thistle*. Leaves decurrent, prickly about the edge; branches stiff; calices aggregate, sessile, oblong-conical; scales upright, spreading at top, and prickly at the end. Root annual; stem from two to three feet high, upright, branched at the base; branches few, long, upright, perfectly straight, roundish, slightly grooved, cottony, particularly towards the top, with broad spinous wings; flowers in clusters at the top of the branches, sessile, small, of a pale purple or flesh colour. It is very common in the neighbourhood of London, growing in the very suburbs, delighting in warm sheltered situations, and is frequently found under paling, walls, hedges, ditch-banks, and near the sea-side; flowering from June till August.

Carex; a genus of the class Monœcia, order Triandria.—**GENERIC CHARACTER.** *Male flowers*, disposed in a spike. *Calix*: ament oblong, imbricate, constant: scales one-flowered, lanceolate, acute, concave, permanent. *Corolla*: none. *Stamina*: filamenta three, bristle-shaped, erect, longer than the calix; antheræ erect, long, linear. *Female flowers* in the same plant. *Calix*: ament as in the male. *Corolla*: petals none; nectary inflated, ovate-oblong, bidentated at the tip, contracted upwards, gaping at the mouth, permanent. *Pistil*: germen three-sided, within the nectary; style very short; stigmas two or three, subulate, incurved, long, acuminate, pubescent. *Pericarp*: none; the nectary grown larger protects the seed. *Seed*: single, ovate-acute, three-sided, one angle being generally less than the others. **ESSENTIAL CHARACTER.** *Ament*: imbricate. *Calix*: one-leaved. *Corolla*: none. *Female Nectary*: inflated, three-toothed. *Stigmas*: three. *Seed*: three-sided, within the nectary.—These plants are very nearly allied to the Grasses, but are of a much harsher texture: the stem, which is fre-

quently three-cornered, is not hollow, but filled with a spongy substance; the difference in the fructification is very considerable, as will appear from a comparison of the generic character. Most of the species grow in wet swampy grounds, in bogs, fens, marshes, or by the sides of ditches and rivers, or in moist woods; some few, however, affect hilly pastures and heaths: they are perennial, and flower in May and June, or from April to July and August. Linneus has divided this genus into five sections, the two first comprising the species with androgynous spikes; and the three last, those which have the male or barren, and the female or fertile spikes distinct. The Carices or Sedges are classed rather among the noxious plants, than with such as are useful; because they yield a very coarse grass and fodder, to the exclusion of real grass, and other profitable plants, which they subdue by their strong creeping roots: but it should be considered that they grow chiefly on poor spongy land, on bogs, to which they give stability, or on the banks of streams, which they enable to resist the current; that they may be destroyed by draining and manuring; and hence, after all, are of considerable use: beside their common use for coarse fodder, they are employed for covering hovels and stacks, for lighting fires and heating ovens for tying the young hop-plant to the poles; the Italians use them to cover wine-flasks, for putting between the staves of casks to make them tight, and for chair bottoms. The Laplander combs and dresses some species of Sedge as we do flax, and in winter stuffs his shoes and gloves with it, as a defence against the extreme rigour of his climate. They cannot, upon the whole, be considered as useful plants, except in such situations as will not produce better fodder and herbage; or where they contribute to fill up marshes, and lay a foundation for their becoming hereafter dry land and useful meadows: wherever a meadow is capable of being drained, the Sedge may be destroyed, wet being necessary to the existence of those sorts which overrun pasture grounds. They are never cultivated, except in botanic gardens, for the determination of the species, and are then propagated by the roots; some few of them require a dry soil, and others a shady situation; but the greater part must be placed with water and bog plants, either by the side of ponds, or in pots or tubs filled with marsh or bog earth, and standing in water; and yet with all these advantages, some of them will scarcely flower in a garden.—The species are,

**With one simple Spike.*

1. *Carex Dioica*; *Small Sedge*. Spike simple, diœcous; margins of the capsules serrulate. Culm slender, upright, smooth, from four to six or even ten inches high, with three sharpish angles.—Found on boggy grounds, flowering in June.

2. *Carex Capitata*; *Round-headed Sedge*. Spike simple, androgynous, ovate; upper part male; capsules imbricate-expanding, with entire margins: very similar to the preceding species.

3. *Carex Pulcaris*; *Flea Sedge*, or *Flea Grass*. Spike simple, androgynous; upper part male; capsules divaricated, bent back, acuminate at both ends. Root not creeping, but fibrous.—Frequent in moorish and boggy places.

4. *Carex Squarrosa*. Spike simple, androgynous; lower part male; capsules imbricated, horizontal. Spike oblong, thick, consisting of horizontal imbricate capsules, with a linear tip as long as the capsule itself; the bottom of the spike is covered with dry barren chaffs. This is one of the largest species, and is a native of Canada.

5. *Carex Uncinata*. Spike simple, androgynous, linear; upper part male; awns of the females uncinated; males awnless. Fertile flowers constituting two-thirds of the spike, below the barren ones; small spicules sometimes hang down by the

side, probably barren.—It is the handsomest of the genus, and a native of New Zealand.

6. *Carex Cyperoides*. Head terminal, roundish; flowers very simple, subulated; involucre long. Culms a foot high three-cornered; head consisting of several glomerules in a small umbel; the outer glumes of each barren, the inner fertile; filamenta white; pistil longer than the nectary, with a bifid style.—Native of Siberia and Bohemia.

***Spikes androgynous.*

7. *Carex Baldensis*. Spikes tern, heaped, sessile, ovate, three-cornered, androgynous; involucre two-leaved.—Native of Monte Baldo.

8. *Carex Arenaria*; *Sand or Sea Sedge*. Spike leafy, oblong, sharpish; spikelets several, the terminating ones male; the lower ones female; culm incurved. Roots creeping horizontally about four inches under ground, in a moveable sand upon the sea-shores; as at Yarmouth, Lowestoff, and in Scotland, also in the interior of Germany: it rarely flowers in a garden.

9. *Carex Uliginosa*. Spike compound; spikelets androgynous; the lower ones more remote, furnished with a longer leaflet; culm round.—Found upon turf-moors in Sweden.

10. *Carex Leporina*. Spike compound; spikelets ovate, sessile, approximate, alternate, androgynous, naked.—Native of the highest Alps.

11. *Carex Vulpina*; *Great Sedge*. Spike superdecompound, contracted, branched, blunt; spikelets male at top; capsules diverging; angles of the culm very sharp; culm thick, firm.—It flowers in May, and is common on the banks of rivers and ditches, and in marshes.

12. *Carex Brizoides*; *Rough Sedge*. Spike compound, distich, naked; spikelets androgynous, oblong, contiguous; culm naked. Stem slender, three-cornered, eighteen inches high; leaves scarcely a line wide.

13. *Carex Muricata*; *Spiked Sedge*. Spike oblong, superdecompound; spikelets distinct; capsules diverging, with a cloven mouth; root fibrous; leaves longer than the culm.—Found in moist woods and meadows; flowering in May and June.

14. *Carex Loliacea*. Spikelets subovate, sessile, remote, androgynous; capsules ovate, roundish, awnless, divaricate. Root creeping; leaves grassy, tender, smooth and even; culm smooth and even, the upper part naked; spikelets four or eight, small, scattered at the top of the culm, whitish.—Native of Sweden and Saxony.

15. *Carex Remota*; *Remote Sedge*. Spikelets axillary, solitary, subsessile, remote; leaflets very long; capsule undivided at the tip. A very elegant plant, stems several, one to two feet high, slender, weak, three-cornered, above the lowest floral leaf rough, below smooth.—This is found in moist woods, and by the sides of ditches; flowering in May and June.

16. *Carex Elongata*. Spikelets oblong, sessile, remote, androgynous; capsules ovate, acute. Culms two feet high rough, three-cornered, almost naked; glumes brown, sharp.

17. *Carex Canescens*; *Gray Sedge*. Spikelets roundish, remote, sessile, obtuse, androgynous; capsules ovate, bluntish.—Native of Lapland, Upland, &c.

18. *Carex Paniculata*; *Panicled Sedge*. Spike superdecompound, panicled-branched, acute; branches alternate, somewhat remote; capsules spreading; culm three sided. Stems numerous, from one to three and sometimes four feet high, naked in the upper part, three-cornered, with the angles minutely toothed; the lax branchy disposition of the spike sufficiently discriminates this species from the rest.—It is a native of bogs and marshes, flowering in June, and is admirably well qualified for planting in loose boggy ground; its

immense tufts affording a firm support for the heaviest bodies.

19. *Carex Indica*; *Indian Sedge*. Spikes androgynous, cylindric, paniced, pinnate; a few of the lower floscules female; culms subtriangular, smooth and even, a foot and half in height, erect; fruit ovate, three-cornered, acute.—Native of the East Indies.

20. *Carex Brunnea*; *Brown Sedge*. Spikes androgynous, peduncled, linear; in the upper part male; leaves linear, attenuated toward the end, entire, smooth, erect, longer than the culm, which is three-cornered, smooth, and a foot in height; spikes erect, acute, brown, smooth, about twelve in number; glumes ovate, acute.—Observed in Japan by Thunberg.

*** *Male and Female Flowers on distinct Spikes; Females sessile.*

21. *Carex Flava*; *Yellow Sedge*. Sheaths short, nearly equalling the divaricate leaflet; male spike linear; females roundish; capsules rostrate-acuminate. Stems two inches to a foot high, numerous, declining; in the smaller plants leafy up to the spike, but in the larger usually naked upwards, triangular, not rough to the touch; leaves pale yellowish green.—Mr. Ray calls this species *Marsh Hedge-hog Grass*: it is common in boggy and wet meadows, marshes, and the boggy parts of barren heaths; flowering in May and June.

22. *Carex Pedata*. Female spikes, sessile, oblong, the lower axillary; leaves subfiliform. Leaves a foot long, very narrow, somewhat stiff, smooth and even at bottom; culm very solid, somewhat even, rounded on one side, longer than the leaves; spikes three, sessile; male terminal, oblong, ferruginous; females two, alternate, ovate-oblong, brown ferruginous; upper without any leaf under it; lower from the axilla the length of the culm; floscules less closely imbricate; capsules obscurely pubescent.—Native of Lapland.

23. *Carex Digitata*; *Digitated Sedge*. Spikes linear, erect; male shorter; bractes membranaceous, almost leafless, sheathing, halved; capsules distant. Leaves in a thick tuft; stems obscurely three-cornered, slender, not rough, from six to twelve inches high, entirely naked, except some reddish brown leafy sheaths at the base; male spike half an inch long, closely imbricate, from the same sheath with the uppermost female spike, and, being shorter, over-topped by it; scales numerous, yellowish brown, membranaceous, and shining at the ends, and so bluntly rounded as to seem truncate.—It flowers in May and June, and is native of many parts of Europe.

24. *Carex Montana*; *Mountain Sedge*. Female spikes sessile, subsolitary, ovate, approximating to the male; culm naked; capsules pubescent. Culms filiform, a short span high; leaves filiform, soft, of a yellowish green than the other species; stem leaves very short; male spike terminal, peduncled, subcylindric, brown; female when ripe becomes black; scales brown; seeds scarce perceptibly hairy, gibbous, divaricate.—It is found on mountainous pastures and heaths.

25. *Carex Tomentosa*. Female spikes subpeduncled; capsules subgloular, tomentose. Culm three-cornered; leaves narrow; bractes the length of the upper culm; capsules from fifteen to twenty in a spike, pear-shaped, villose.

26. *Carex Globularis*. Male spike oblong; female sessile, ovate; floral leaf shorter approximating. Leaves in a thick tuft, firm, short, not more than half a line broad; culm three inches high, almost naked, three-cornered.

27. *Carex Filiformis*. Sheaths short, nearly equalling the peduncles; male spikes commonly two; females ovate, remote; capsules downy. Leaves slender upright, ending in a very taper point, roughish on the edges and along the keel,

from one to three feet in length; culm upright, slender, almost equal to the leaves, the angles sharp and hispid.—It flowers in June, is a native of woods in several parts of Europe; and has been observed near Eaton in Shropshire, and at the south end of Ayr Links in Scotland.

28. *Carex Pilulifera*; *Round-headed Sedge*. Sheaths none; male spike sublinear; females rounded, sessile, crowded; culm weak. Leaves in a thick tuft, bright green; the longest scarcely half as long as the stem, which is three-cornered, slender, not rough, somewhat ascending at the base.—It is common in moist pastures and heaths; flowering in April and May.

29. *Carex Saxatilis*; *Rock Sedge*. Spikes three, ovate, sessile, alternate; male oblong, terminal. Male spike bay or pale ferruginous; female spikes two, black, and scaly; germina black, three-cornered; styles black, bifid, long; beneath the lowest spike is a setaceous leaf shorter than the spike.—Native of the mountains of Lapiand and Switzerland.

30. *Carex Tristachya*. Spikes monœcous, three, sessile, linear; male longer. One leaf or two leaves at most, alternate, linear, smooth, reflected, short; culm three-cornered, capillary, striated, smooth, erect, four inches high; spikes terminal; females lower than the male, and only half the length.

**** *Male and Female Spikes distinct; Females peduncled.*

31. *Carex Atrata*; *Black Sedge*. Spikes all androgynous, terminal, peduncled, when in flower erect, when in fruit pendulous; capsule ovate, sharpish; sheaths scarcely any. Stem three-cornered, smooth, with leaves from one inch and half to two inches from the root, naked upwards; the upper often longer than the stem. It is singular in this species, that it has for the most part only two stamina, and a few hermaphrodite flowers; its having no sheaths, or at least very minute ones, and black ovate spikes, are marks sufficient to distinguish it readily from all others with which it can come in any competition.—Native of most parts of Europe, on mountains; and found in Wales and Scotland; flowering from May till July.

32. *Carex Limosa*. Spikes ovate, pendulous when in fruit; male longer, more erect; root creeping. Styles three; root jointed, creeping. In a garden, where it will rarely flower, it frequently throws up barren leafy stalks, which will readily take root, if planted in pots plunged in water.—It is common in boggy ground, and flowers in June: found in Yorkshire, Lancashire, Westmoreland, &c.

33. *Carex Capillaris*; *Capillary Sedge*. Spikes pendulous; male erect; females oblong, distich; capsules naked, acuminate. Culm, when in flower, shorter than the leaf, scarcely a finger's breadth high, with a single leaf; from the end are produced four erect spikes, one of which is male; in a short time the culm becomes a span in height, filiform, erect, with one sheathing leaf in the middle of it, but shorter than the culm.—Native of the Highland mountains of Scotland.

34. *Carex Pallescens*; *Pale Sedge*. Sheaths very much abbreviated; female spikes subcylindric, when fruit-bearing pendulous; capsules oblong, blunt. Bractes permanent; capsules by no means acuminate; stems many, from one to two feet high, three-cornered, roughish, leafy below, naked upward, except that there is generally a kind of false floral leaf similar to the stem leaves, proceeding from a joint one or two inches below the spikes.—Native of woods, meadows, and moist pastures; flowering in May and June.

35. *Carex Panicea*; *Pink-leaved Sedge*. Spikes peduncled, erect, remote; females linear: capsules bluish, inflated, somewhat distant. Stems bluntly three-cornered, smooth, twelve to eighteen inches high; leaves smooth, sea-

green, shorter than the stem.—It is found in moist meadows, flowering in May and June.

36. *Carex Folliculata*. Spikes terminal, peduncled, male and female; capsules subulated, the length of the spike. Culm three-cornered, two feet high, clothed with very narrow leaves.—Found in Canada by Kalm.

37. *Carex Pseudo-Cyperus*; *Bastard Sedge*. Sheaths scarcely any; female spikes cylindrical, peduncled, pendulous; capsules awned and beaked, somewhat divaricate. Bractes almost setaceous.—Found flowering in June, upon the sides of ditches and moist woods.

38. *Carex Cæspitosa*; *Turfy Sedge*. Styles two; spikes subsessile, subcylindric, obtuse; leaves erect, softish. It is easily distinguished from the other species by its long narrow leaves, of a pleasant green, in fuller tufts than in any of the rest; by two female spikes, erect and blackish. Capsules yellowish, sessile, erect, obtuse, ovate, imbricate; culm naked, exactly three-cornered; under the lower spike a small leaf longer than the spike; that under the other is shorter. It fills up bogs by its large tufts or hassocks, and will speedily do this, as cattle will not eat it.—Grows in marshes and moist woods, flowering in May.

39. *Carex Distans*; *Distant-flowering Sedge*. Spikes very remote; bracte sheathing the peduncle; capsule angular, mucronate. Capsules acuminate; scales of the calix sharp; stems nine to eighteen inches high, sometimes two feet, or even a yard, leafy, very obscurely three-cornered.—It is found in marshes, especially salt-marshes, and usually flowers in May and June.

40. *Carex Japonica*. Spikes monœcous, peduncled, erect; females peduncled, ovate; male terminal, linear. Culm leafy, three-cornered, erect, weak, smooth, a span high.—Native of the island of Nippon, flowering in June.

***** *Spikes Male and Female, distinct; Males several.*

41. *Carex Acuta*; *Sharp Sedge*. Male spikes many; female subsessile; capsules bluntish. Style bifid, hispid, white, shrivelling; scales ovate, brown, with a longitudinal green line.—It is a very variable plant, an inch high, in dry meadows; but in watery situations often rises to the height of three feet.

42. *Carex Vesicaria*; *Bladder Sedge*. Male spikes linear; female spikes oblong, spreading; capsule inflated, oblong, acuminate-beaked, spreading. Stem three-cornered, leafy, finely serrate at the edges; leaves two lines broad, finely serrate, bright green.—It is found in bogs and marshes, and flowers in May.

43. *Carex Hirta*; *Hairy Sedge*. Hairy: all the spikes oblong; females remote, sheathed; capsules hairy. Leaves on the outside, and their sheaths white, villose; capsules villose, inflated, two-horned at the end; male spikes usually three; female very remote, erect, peduncled. It flowers in May and June, and grows in moist meadows, watery places, and marshes.

44. *Carex Pumila*; *Dwarf Sedge*. Male spikes two, terminal, sessile; females two, peduncled, oblong, erect. Culm very short, indeed scarcely any; leaves linear, attenuated, convolute, smooth.

45. *Carex Pauciflora*; *Few-flowering Sedge*. Spike simple, androgynous; female flowers two or three, remotish, spreading; one male flower, sometimes two in the upper part. Stem four inches high, obscurely three-cornered, smooth, striated, with two smooth grass-like leaves, the uppermost longest, but generally shorter than the stem.—Native of Scotland, and of the coast of Labrador, in a boggy soil.

46. *Carex Hamata*; *Hooked Sedge*. Spike simple, androgynous, linear; male at top; females awned; awns hooked at the tip and equal.—Native of Jamaica and New Zealand.

47. *Carex Rupestris*. Spike simple, androgynous, oblong, with male flowers in the upper part; female glumes awned. Culms scarcely four inches high, naked, three-cornered, twice as high as the leaves; spike an inch high; male glumes subovate, not awned; females broad, ovate, acute, bay-coloured, with a paler edge, and a broadish nerve ending in an awn.

48. *Carex Bellardi*. Spike one, androgynous, strigose; culm round; leaves capillary. From a brown fibrous root arises a tuft of many culms; leaves convoluted, striated, somewhat curved; culm near a span high, striated.

49. *Carex Curvula*. Spike one; glumes awned; culm and leaves hard, and a little curved.—This species forms little tufts, composed of hard round leaves, somewhat yellowish, resembling those of rushes, differing little from the culm, and about the same length, from three to six inches.—Native of the Alps, of Switzerland, Dauphiny, and Piedmont.

50. *Carex Fœtida*; *Stinking Sedge*. Spike conglomerate, brown, stinking. This plant is fœtid, both in a recent and in a dried state; culm naked, three-cornered, edges rough; spike one only, blackish, formed of very many small ones, irregularly conic, obtusely five-cornered, very broad.—Native of Switzerland, Dauphiny, and Piedmont.

51. *Carex Psyllophora*. Spike simple, androgynous; male at top; capsules reflex; seeds cylindric.—Native of Sweden, and Germany.

52. *Carex Leucoglochis*. Spike simple, androgynous, male at top; capsules reflex; seeds three-sided.—Native of Sweden and Germany.

53. *Carex Uncinata*. Spike simple, androgynous, linear, male at top; awns of the females hooked; males awnless.—This is the handsomest species of the genus; it is a native of New Zealand.

54. *Carex Cyperoides*. Head terminating, roundish; flowers quite simple, subulate; involucre, long.—Grows in various parts of Bohemia and Siberia.

55. *Carex Disticha*; *Soft Sedge*. Spike oblong, obtuse; spikelets very many; the lowest and end one females; the middle ones male; culm upright; style divided to the base.—It is found in marshes, flowering in June.

56. *Carex Divisa*. Spike ovate, subdecompound, with an upright leaflet; spikelets rather remote; capsules pressed close; root creeping. Leaves narrow, sometimes longer than the culm, which is from eighteen inches to two feet in height, and three-cornered.—It grows in salt marshes, where it flowers in May and June.

57. *Carex Incurva*. Spike conic; spikelets several, heaped, sessile; involucre none; culm incurved. Stems three or four inches high, obscurely three-cornered, smooth, and curved in the arc of a circle.—Native of Scotland, in deep loose sand; also of Denmark and Piedmont.

58. *Carex Divulsa*. Spike decompound, elongated, somewhat branched at the base; the lower spikelets remote, the upper ones contiguous; capsules somewhat erect. Leaves dark green, narrowish, sharp on the keel and along the edge, longer than the culm, which is from a foot to eighteen inches in height, weak, somewhat reclining, three-cornered, the corners acute and roughish.—Found in moist woods, flowering from May to July.

59. *Carex Tripartita*. Spike terminal, three-parted. Radical leaves shorter than the culm, a line or more in breadth; culm naked in the upper part, three-cornered, six inches high; neither that nor the leaves are rough.

60. *Carex Bipartita*. Spikes two, terminal, the upper compound; culm round, naked. Culms straight, twice as

Syrian Bindweed, or Scammony.

P. 551.

P. 553.

Trailing Bindweed, or Convolvulus Minor.

P. 557.

Jalap Bindweed.

high as the leaves, striated; leaves smooth, a little convoluted, striated, acute, and almost pungent.

61. *Carex Nigra*. Spikes androgynous, erect, sessile, tern, terminal, black; culm three-cornered, leafy. Leaves shorter than the culm, which is from a finger's breadth to a foot high, and striated; glumes ovate acute, black, with a whitish edge.

62. *Carex Bicolor*. Spikes androgynous, sessile, tern, terminal; capsules longer than the glumes; culm round, naked, scarcely more than a finger's breadth in height.

63. *Carex Stellulata*. Spikelets subtern, remote; capsules diverging, acute; mouth entire. Leaves pale green, narrow, rough at the edges and keel, especially towards the tip.—Grows in marshes, flowering in May and June.

64. *Carex Curta*. Spikelets six or more, ovate, remotish, naked; scales ovate, sharpish, shorter than the capsule. Leaves of a pale subglaucous colour, rough along the edges and keel, upright, narrow.—It inhabits marshes and watery places, but is not very common, and flowers in June.

65. *Carex Ovalis*. Spikelets about six, oval, approximating, alternate; scales lanceolate, equalling the capsule. Leaves dark green, roughish along the edges and keel, narrow, nearly equalling the stem, which is upright, a foot high, triangular, with the angles sharp and roughish.—It is found in marshes and moist meadows; flowering in June.

66. *Carex Teretiuseula*. Spike superdecoumpound, contracted, branched, sharpish; spikelets glomerate, male at top; capsules spreading; culm roundish. Leaves green, upright, stiffish, sheathing near half the culm, at the base convex without, channelled within, rough along the edges and keel, longer than the culm when in flower; the upper leaf longer than the rest.—Found in marshes near the city of Norwich.

67. *Carex Chordorhiza*. Spike compound; spikelets androgynous, approximating, male at top; capsules compressed; root creeping, filiform.—Native of Sweden.

68. *Carex Heleonastes*. Spike compound; spikelets androgynous, approximating, female at top; capsules imbricated, with the sides quite entire.—Native of Sweden.

69. *Carex Prostrata*. Bractes membranaceous, almost leafless, sheathing; female spikes remote, scarcely surpassing the sheath; the calix very large; stem, when old, prostrate. Leaves slender, three or four times as long as the culm, channelled, at the edges and keel, towards the tip rough.—Observed upon St. Vincent's rocks near Bristol. It flowers in the very beginning of April.

70. *Carex Conglobata*. Spikes sessile, approximating, few-flowered; capsules ovate, hirsute. Leaves in tufts, resembling those of pinks, repand, marked with a line, rough about the edge, a line in breadth and more; culm six inches high.

71. *Carex Mucronata*. Spikes sessile, approximating, very short; glumes lanceolate, mucronate. Leaves rush-like; culms a foot high, naked at the top.

72. *Carex Alba*. Spikes peduncled, white; sheaths long, obtuse; filamenta and styles long, white. Culm round, slender with three white leafy sheaths; styles long, trifid.

73. *Carex Fusca*. Female spikes three, erect; capsules ovate, shortly mucronate, petioled, sitting on the leaf. Culm sheathed, six inches high; capsules pale; leaves long, less than a line wide, nearly the length of the stem, and rough.

74. *Carex Trigonia*. Male spike peduncled; females sessile, remote, three-cornered. Culms leafy, a foot high and more, three-cornered, striated, smooth; leaves linear, striated, dark green, shorter than the culm.

75. *Carex Foliosa*. Female spikes sessile, the lowest peduncled; glumes very narrow. A very distinct species. Culm a foot high, three-cornered; capsules slender, with very long points.

76. *Carex Alpestris*. The lowest female spike radical; capsules three-cornered, elongated. Leaves in tufts, firm, keeled, with a nerve standing out, two lines broad, smooth except the end of the nerve; culms naked, from three to nine inches in height.

77. *Carex Obesa*. Female spikes sessile, tern; capsules ovate, three-cornered; leaves short, not above a line in breadth, rough. Culms four inches high, naked.

78. *Carex Ferruginea*. Male spike one, acuminate; female spikes two or three, slender, pedicelled; scales ferruginous; capsules bifid. Culm half a foot high, pale green; the leaves are long and hard, but flexible. It forms large tufts on high mountains exposed to the north.

79. *Carex Frigida*. Female spikes in threes and fours, distich; capsules long-pointed. Glumes sharply lanceolate, shining bay, with a green or yellowish nerve.

80. *Carex Extensa*. Sheaths very short, equalling the peduncle; the leaflet somewhat reflex; spikes crowded; females roundish; capsules ovate, acute; root-leaves narrowish, shorter than the culm, (except those which embrace the base of it, which often equal and even surpass it,) roughish along the edges and keel towards the top.—Found in open places, as in the marshy ground near Harwich, and on the west side of Braunton Burrows in the north of Devonshire. It is not very common; and flowers in June.

81. *Carex Fulva*. Lowest sheath about half the length of the peduncle, upper one nearly equal to it; female spikes two, oblong, acute; capsules acuminate-beaked; leaves upright, narrow, rough along the edges and keel, shorter than the culm, which is upright, slender, about a foot in height, three-sided, with the angles acute and rough.—Native of Newfoundland and America; and found at Eaton, near Shrewsbury. It flowers in June and July.

82. *Carex Rigida*; *Rigid-leaved Sedge*. Two-styled; sheaths none; spikes oblong, subsessile; leaves somewhat recurved, rigid; root thick, creeping very much.—Observed on the top of Snowden, and on the summits of the highest mountains in Scotland.

83. *Carex Striata*; *Stiff-leaved Sedge*. Two-styled; sheaths none; spikes subsessile, cylindric, acute; male one or two; leaves upright, stiff. The root creeps very much.—It grows in marshes, and flowers in April. Mr. Pitchford observed it near Norwich.

84. *Carex Præcox*; *Vernal Sedge*. Sheaths short, nearly equalling the peduncles; spikes approximating; males subclavate; females ovate; capsules roundish, pubescent; leaves dark green, slender, rough along the edges and keel, shorter than the culm, which is upright, from six to twelve inches high, three-sided, with the angles bluntish and smooth.—It is a very common plant, growing on most of our heaths, and in meadows; flowering in April and May.

85. *Carex Depauperata*. Sheaths more than half the length of the peduncles; female spikes remote, few-flowered; capsules ovate, inflated, acuminate-beaked. Stem upright, leafy, three-cornered, from a foot to eighteen inches high. It flowers in May and June, and was discovered by Dr. Goodenough in Charlton-wood; and by Mr. Dickson in dry woods, near Godalmin in Surrey.

86. *Carex Elata*. Male spikes two, females sessile; capsules ovate, with a very short undivided point. Leaves very long, two or three lines broad, the edges and nerve rough; culm three-cornered, three feet high.

87. *Carex Pendula*; *Pendulous Sedge*. Spikes cylindric, very long, pendulous; capsules ovate, acute, very much crowded; sheaths long, nearly equal to the peduncles. Leaves half an inch broad, thick, stiff, very dark green, somewhat

glaucous underneath.—It is not uncommon in woods and hedges ; flowering in May and June.

88. *Carex Strigosa* ; *Loose Sedge*. Spikes filiform, loose, recurved ; sheaths long, nearly equalling the peduncle ; capsules oblong, subtriquetrous, acute ; leaves broad.—It grows in woods and hedges ; as in Witham and Nokewoods, Oxfordshire ; flowering from April to June.

89. *Carex Sylvatica* ; *Wood Sedge*. Sheaths shorter than the peduncles ; spikes filiform, loosely pendulous ; capsules ovate, awned and beaked ; root creeping, and throwing out from the joints. Its pendent spikes, the elliptic bend of its stem, and the pale yellow green of its leaves, render it one of the most elegant ornaments of our woods.—It flowers in May and June.

90. *Carex Recurva* ; *Heath Sedge*. Spikes crowded, peduncled, cylindric, rather pendulous ; male terminal ; capsules imbricate, rather obtuse. Culms erect, three-cornered, with obsolete angles ; leaves and stem sea-green.—Found in meadows, woods, and heaths ; flowering in May and June.

91. *Carex Juncea*. Spikes very remote ; male longer than the females, which are subsessile ; capsules bifid, three-cornered, smooth ; seed three-cornered. Culm a foot high ; leaves scarcely two lines broad.

92. *Carex Leptostachys*. Spikes sexually distinct ; males single ; females peduncled, remote, pendulous, filiform ; capsules remote, entire at the end.—Native of Germany.

93. *Carex Chinensis*. Spikes erect ; male terminating ; females peduncled, four ; capsules acuminate.—This is a span high, and a native of China.

94. *Carex Riparia* ; *Common Sedge*. Spikes oblong, acute ; scales of the males lanceolate, those of the females acuminate and awned ; capsules lanceolate-ovate, with two teeth at the point. This is the largest and most common of all the Sedges ; its spikes, especially the lowermost of the female ones, frequently become branched ; the capsules are large, somewhat inflated, pointed and slightly bifid at the extremity.—It flowers in April and May ; and is common by the sides of ditches, lakes, and rivers. The glass-makers of Italy use the leaves to bind their wine-flasks ; the chair-makers to bottom their chairs ; and the coopers, in heading their casks, in the same manner as the stalks of the *Scirpus Lacustris* is used in England.

95. *Carex Paludosa* ; *Sharp Sedge*. Spikes oblong, bluntish ; scales of the males blunt, of the females lanceolate ; capsules ovate-lanceolate, somewhat toothed at the tip. This plant, which is so very common with us, does not appear to have been noticed by Linnæus.—It is found in marshes, and by the sides of ditches ; flowering in May and June.

96. *Carex Gracilis* ; *Slender-spiked Sedge*. Spikes filiform ; flowers two-styled ; mouth of the capsules very entire. The female flowers are always digynous.

97. *Carex Ampullacea* ; *Bottle Sedge*. Spikes filiform ; males more slender ; females round, upright ; capsules inflated, globose, awn-beaked, divaricate. Root creeping very much ; leaves glaucous, upright, narrow, longer than the culm, rough on a great part of the edges and keel.—It grows in fens, and flowers in May. Near London it is not common, but may be found in abundance at Virginia Water.

Carica ; a genus of the class Diœcia, order Decandria.—**GENERIC CHARACTER.** *Male.* *Calix* : scarce manifest ; it has, however, five very short sharp teeth. *Corolla* : mono-petalous, funnel-form ; tube slender, very long, gradually slender downwards ; border five-parted ; divisions lanceolate-linear, obtuse, obliquely and spirally revolute. *Stamina* : filamenta ten, in the top of the tube of the corolla ;

the five alternate ones inferior ; antheræ oblong, fixed to the filamenta on the inner side. *Hermaphrodite.* *Calix* : perianth very small, five-toothed, permanent ; teeth ovate, acute, spreading. *Corolla* : five-parted ; parts lanceolate, sharp, erect below the middle, but reflected and twisted above. *Stamina* : filamenta ten ; five alternate shorter subulate, all united by a membrane at the base ; antheræ ovate, erect, two-valved, fertile. *Germen* : ovate ; style none ; stigmas three or five, broad, flat, expanding, multifid ; segments very short, blunt. *Pericarp* : berry very large, angulated with three or five furrows, unilocular, fleshy. *Seeds* : numerous, ovate, green, very smooth, truncated, nestling in the middle of the berry. **ESSENTIAL CHARACTER.** *Male, Calix* : very small, five-toothed. *Corolla* : five-parted, funnel-form. *Filamenta* : in the tube of the corolla, alternately shorter. *Hermaphrodite.* *Calix* : five-toothed. *Corolla* : five-parted. *Stigmas* : five. *Berry* : one-celled, many-seeded.—These plants, being natives of hot countries, will not thrive in England, unless they are preserved in a warm stove ; where there are such conveniencies of proper height to contain the plants, they deserve a place as well as almost any of the plants which are cultivated for ornament : for when they are grown to a large size, their strong upright stems make a noble appearance, as they are garnished on every side near the top with large shining leaves, spreading out near three feet all round the stems ; the flowers of the male sort come out in clusters on every side ; and the fruit of the female growing round the stalks between the leaves, being so different from any thing of European production, may entitle them to the care of the curious. They are easily propagated by seeds, which are annually brought in plenty from the West Indies. These should be sown in a hot-bed early in the spring, that the plants may obtain strength before the autumn ; when they become nearly two inches high, they should be each transplanted into a separate small pot, filled with a light gentle loamy soil, and plunged into a hot-bed of tanner's bark, carefully shading them from the sun till they have taken root ; after which they must be treated in the same manner as other tender plants from the same country ; but as they have soft herbaceous stalks, and abound with a milky juice, they must not have too much water, for they are frequently killed with moisture : there should also be great care taken, when these plants are shifted from small pots into larger, to preserve the whole ball of earth to their roots, for they rarely survive their being left bare. As they grow, they will require larger pots, and when they are too tall to remain under frames, they must be placed in the tan-bed of the bark-stove, where they should constantly remain ; they must have but little water during the winter, and in the summer small quantities, but frequently repeated, should be given. In the West Indies these trees are easily propagated by layers as well as by seeds.—The species are,

1. *Carica Papaya* ; *Common Papaw Tree*. Lobes of the leaves sinuated. It rises with a thick, soft, herbaceous stem, to the height of eighteen or twenty feet, naked till within two or three feet of the top, and having marks of the fallen leaves great part of its length ; the leaves are on foot-stalks nearly two feet long, the lower ones nearly horizontal, the upper ones erect. The whole plant abounds with a milky acrid juice, which is esteemed good for the ringworm ; the stem of the plant, and also the footstalks of the leaves, are hollow in the middle. The male flowers stand in loose clusters, are of a pure white, and have an agreeable odour ; sometimes they are succeeded by small fruit, about the size and shape of a Catherine pear. The flowers of the female, or rather hermaphrodite Papaw, also come out between the leaves, toward

the upper part of the plant, upon very short peduncles, singly sitting close to the stem; they are large and bell-shaped, composed of six petals, which are commonly yellow, but those of the pyramidal sort are purple; when these fall away, the germen swells to a large fleshy fruit, the size of a small Melon, but of different forms; some are angular, and compressed at both ends, others are oval and globular, and some pyramidal; the fruit also abounds with the same acrid juice as the plants: this fruit, when ripe, is eaten like Melons, with pepper and sugar, by the inhabitants of the Carribbee Islands; but it is much inferior to our common Melon in flavour, even in its native country, and those which have ripened in England were detestable. The best use that can be made of this fruit is, to soak them in salt water till the milky juice is extracted, and then to pickle them for mangos; for which they have been esteemed a good substitute. Long informs us, that the flowers, buds, and tender footstalks of the hermaphrodite or female trees, are preserved as a sweetmeat, and the long mango Papaw, or fruit, as a pickle, which is little inferior to the East Indian mango: the rounder fruit is boiled when green, and eaten with any kind of flesh meat, being looked upon as perfectly wholesome; but when eaten raw, contains an acrid juice, which is very destructive to the intestines. The negroes suppose, that Papaw trees conduce to the purification of the air, and therefore plant them near their houses. The blossoms are extremely odiferous, and the trunks so succulent and so quick of growth, that they probably assist to drain off a large portion of superfluous moisture from the soil where they are planted.—Native of both Indies, America, and the Philippine Islands.

2. *Carica Posoposa*; *Dwarf Papaw Tree*. Lobes of the leaves entire. This was found growing in a garden at Lima, by father Feuillée, who remarks, that it was the only plant of its kind that he had seen in his travels. Brown says, that it is frequent in some parts of Jamaica, and that it seldom rises above four or five feet in height. It differs from the first species in having a branching stalk, the lobes or divisions of the leaves being entire, and the fruit shaped like a pear. Feuillée says, that the fruits were of different sizes: that which he designed was about eight inches long, and three and a half thick, yellow within and without, and of a sweet flavour; the flower of a rose-colour, and only divided into five parts.—Native of Surinam and Peru.

Carissa; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, five-parted, acute, permanent. *Corolla*: monopetalous, funnel-form; tube cylindrical, bellying at the mouth, longer than the border; border five-parted, flat; divisions oblong. *Stamina*: filamenta five, very short, in the top of the tube: antheræ oblong within the mouth. *Pistil*: germen roundish; style filiform, length of the stamina, stigma rather simple. *Pericarp*: berries two-celled, oblong, bilocular. *Seeds*: seven or eight, oval, compressed. ESSENTIAL CHARACTER. *Corolla*: contorted. *Berries*: two-celled, many-seeded.—The species are,

1. *Carissa Carandas*. Leaves elliptic, obtuse. A small tree, about six feet in height, with dichotomous branches; flowers like those of Jessamine; berry when ripe, black, and of a sweet acid flavour. The fruit is universally eaten by the natives, and is grateful even to the taste of an European.—Native of the East Indies.

2. *Carissa Spinaram*. Leaves ovate, acute. A tree with branches, first trichotomous then dichotomous, horizontal.—Native of the East Indies and Japan.

Carlina; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common

ventricose, radiated, imbricated; scales numerous, loose, acute, of which the interior ones are disposed in a circle, very long, expanding, glossy, coloured, radiating the compound flower. *Corolla*: compound uniform, tubular; corollets hermaphrodite, equal; the proper one monopetalous, funnel-form; tube slender; border five-cleft. *Stamina*: filamenta five, capillary very short; antheræ cylindric, tubular. *Pistil*: germen short; style filiform, length of the stamina; stigma oblong, bifid or entire. *Pericarp*: none. *Calix*: remaining unchanged. *Seeds*: solitary, somewhat rounded; down plumose, branched, sessile. *Receptacle*: flat; chaffs ternate, cleft. ESSENTIAL CHARACTER. *Calix*: radiated with long, coloured, marginal scales.—The plants of this genus may all be propagated by sowing their seeds in the spring, on a bed of fresh undunged earth, where they are to remain; for, as they send forth tap roots, they will not bear transplanting so well as most other plants. When they appear above ground, they should be carefully weeded, and, as they grow in size, thinned where they are too close, leaving them about ten inches or a foot asunder. The greatest part of them will flower in the second year; but unless the summer prove dry, they rarely produce good seeds in England, and most of them decay soon after they have flowered; and hence it is rather difficult to preserve a succession of them in this country.—The species are,

1. *Carlina Acaulis*; *Low Carlina Thistle*. Stem one-flowered, shorter than the flower. Root an inch thick, black, woody, having an acrid penetrating smell, and a bitter aromatic taste; flower usually one, but sometimes more, three inches in diameter when expanded, for it closes during the night and in rainy weather; rays white, shining; floscules greenish yellow, with purple toothlets.—Native of Switzerland, Germany, Carniola, Italy, and south of France. Perennial. The receptacle and upper part of the root are eaten when tender; but the root of the adult plant becomes acrimonious, and is recommended as an alexipharmic. It contains an acrid resinous principle, by which it stimulates the solids, dissolves the humours, and promotes perspiration. The dose of the dried root is from one to two drachms; when fresh, from two drachms to half an ounce; but it is more frequently given in decoction, than in substance.

2. *Carlina Lanata*; *Woolly Carlina Thistle*. Stem bifid; calices blood-red, terminal, the first axillary, sessile. When out of flower, it puts off the wool. The juice is blood-red: the true scales of the calix are all terminated by a very simple spine, but in the rest the spines are compound; ray purple on both sides. Annual; and a native of the south of France, and Italy.

3. *Carlina Corymbosa*; *Corymbed Carlina Thistle*. Stem many-flowered, subdivided; flowers sessile; ray of the calices yellow. Stem purplish at top, scarcely pubescent; the leaves even, next the flowers subpinnatifid: ray yellow, on the outside and at the base only purplish. Native of the south of France, and Italy.

4. *Carlina Vulgaris*; *Common Carlina Thistle*. Stem many-flowered, corymbed; flowers terminal; ray of the calices white or yellowish. Root long, fusiform, with a few stiff fibres; stem twelve to fifteen inches high, swelling just above the root, round, ribbed, purple, slightly downy, subumbellated at top; the chaffs of the receptacle are longer than the florets; the flowers expand in dry, and close in moist weather, which property they retain for a long time.—It indicates very barren soil, and is found in dry pastures all over Europe, and is biennial; flowering from June to September. It is serviceable in hysterical and other nervous complaints, and being of a diuretic nature, may be useful in the beginning of

dropsies. The powder of the dried root is said to kill worms, remove obstructions of the menses, and prove serviceable in defluxions on the lungs, or other parts of the body; but though it be not altogether destitute of virtues, more are evidently attributed to it than it really deserves.

5. *Carlina Racemosa*; *Racemed Carlina Thistle*. Flowers sessile, lateral, very few. The leaves have three nerves; the two side-ones run distinctly from the base to the middle, and then unite with the other; in each, small nerves run parallel across, from the principal to the side-nerves.—Native of a dry soil in Spain and Provence.

6. *Carlina Pyrenaica*; *Pyrenean Carlina Thistle*. Stem many-flowered; leaves decurrent, runcinated. Leaves tomentose on both sides; the pinnae hastate-toothed, with a yellowish spine at each apex.—Native of the Pyrenees towards Spain.

7. *Carlina Xeranthemoides*. Shrubby, branching, tomentose: leaves linear; subulate; serratures spinescent; panicle terminal; ray yellow. A handsome shrub; stem round, covered with wool pressed close; leaves scattered, not decurrent, terminating in a spine; upper surface green, smooth, lower white with wool.—Observed by Masson in Barancas about Chasna.

8. *Carlina Atractylodes*. Stem branching; calices with ciliate spines.—Native of the Cape of Good Hope.

9. *Carlina Acanthifolia*. Stemless: leaves sinuate, pinnatifid, tomentose; divisions half two-lobed, pungent; flower large, sessile, with white-coloured scales; bractes lanceolate having ternate diverging spines placed in a pinnate order, the middle one longer and stronger before the flower opens: these bractes represent a beautifully netted hemisphere, and when this is open they are reflected. This is the species, the receptacle of which is eaten, either as the artichoke, or preserved with honey and sugar.—Native of mountains of the Vaudois, and other high alps.

Carnation. See *Dianthus*.

Carob-tree. See *Ceratonia*.

Carolinea; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-form, truncate, quite entire, very short, deciduous. *Corolla*: petals five, ensiform, very long, somewhat erect. *Stamina*: monadelphous; filamenta very numerous, connate at the base, filiform, very long; antheræ oblongish, erect. *Pistil*: germen inferior, oblong, cylindric; style filiform, the length of the stamina; stigma simple. *Pericarp*: pome ovate, five-grooved, two-celled. *Seeds*: twin, one above the other, ovate, gibbous, flattish within. ESSENTIAL CHARACTER. Monogynous. *Calix*: simple, tubular, truncate. *Petals*: ensiform. *Pome*: five-grooved, two-celled.—The plants of this genus may be propagated by seeds or by cuttings, in a light loamy soil, plunged in the bark-stove, and watered moderately in summer, but sparingly in winter.—The species are,

1. *Carolinea Princeps*. Leaflets about five, ovate-lanceolate. It is a large thornless tree; leaves alternate, petioled, digitate; leaflets three or five, broad lanceolate, subpetioled, quite entire; stipules two, short, caducous; flowers solitary, axillary, sessile, very large and beautiful; petals yellow; filamenta red; antheræ purple. The fruit has the appearance of that of the Chocolate, (*Theobroma*) torulose and obovate, with seeds like almonds; the cotyledons plaited. The seeds are eatable, but are very flatulent when taken raw in any considerable quantity.—Native of Guiana, in salts by the banks of rivers.

2. *Carolinea Insignis*. Leaflets about seven, ovate-oblong.—Native of Tobago, and Vera Cruz.

Caroxylon; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved,

suborbiculate, rude, concave within, keeled on the outside, very thin at the edge, erect, shorter than the corolla. *Corolla*: one-petalled, five-parted; tube none; border segments obtuse, broad, roundish, concave, curled, membranous, expanding; yellowish or dusky purple; nectary scales five, inserted into the middle of the corolla, somewhat narrower and shorter, and connate with it at bottom; they are placed on the converging fruit; are ovate, sharpish, concave, membranous, yellowish with a greenish base. *Stamina*: filamenta five; inserted into the side of the germen, shorter than the corolla, white, capillary; antheræ very small. *Pistil*: germen superior, conic; smooth; style simple, shorter than the corolla, erect, white; stigmas two, revolute, whitish, seldom simple. *Pericarp*: none. *Seed*: one, depressed, round, green; spiral, clothed with a very thin membrane, covered with the permanent filamenta and nectary. ESSENTIAL CHARACTER. *Corolla*: five-petalled. *Nectary*: five-leaved, converging, inserted into the corolla. *Seed*: clothed.—The only known species is,

1. *Caroxylon Salsola*. Root perennial; stem arborescent, erect, very branching, naked; branches scattered, stiff, flexuose, spreading, subdivided. The Africans make soap with the ashes of this plant and mutton suet.

Carpesium; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common imbricate; the exterior leaflets larger, spreading, reflex; the interior ones equal, close, shorter. *Corolla*: compound equal; corollets hermaphrodite in the disk, female in the circumference; the proper one in the hermaphrodites funnel-form, border quinquefid, spreading; in the females tubular, quinquefid, converging. *Stamina*: in the hermaphrodites five, short; antheræ cylindric. *Pistil*: in the hermaphrodites, germen oblong; style simple; stigma bifid: in the females very similar to the hermaphrodites. *Pericarp*: none. *Calix*: unchanged. *Seeds*: in the hermaphrodites obovate, naked; in the females very similar to the hermaphrodites. *Receptacle*: naked. ESSENTIAL CHARACTER. *Calix*: imbricate; the outer scales reflex. *Down*: none; receptacle naked.—The species are,

1. *Carpesium Cerauum*; *Drooping Carpesium*. Flowers terminal. Root perennial; stem leafy, erect, from one to two feet high, round, striated, hirsute, branched at top. According to Miller, it is a biennial plant; flowering in July, and ripening the seeds in September.—Native of the south of France, Italy, Carniola, Austria, Switzerland, and Japan. The seeds must be sown upon a bed of light earth in the spring; and when the plants come up, if they be thinned and kept clean from weeds, they will require no other culture. The second year they will flower and produce seeds; soon after which the plants decay.

2. *Carpesium Abrotanoides*. Flowers lateral. Stems branching, hardish; leaves alternate, seeds oblong, naked, smooth, smeared with a kind of balsam.—Native of China and Japan. The seed should be sown on a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a single pot; and when the weather becomes warm, they may be exposed, but in autumn they must be housed.

Carpinus; a genus of the class Monœcia, order Polyandria.—GENERIC CHARACTER. *Male flowers*, disposed in a cylindric ament. *Calix*: ament common on all sides, loosely imbricate, consisting of scales, ovate, concave, acute, ciliate, uniflorous. *Corolla*: none. *Stamina*: filamenta generally ten, very small; antheræ didymous, compressed, villose at the tip, bivalve. Female flowers, disposed in a long ament upon the same plant. *Calix*: ament common, loosely imbricate, consisting of lanceolate scales, which are villose,

reflected at the tip, uniflorous. *Corolla*: caliciform, monophyllous six-cleft; two of the divisions larger than the rest. *Pistil*: germina two, very short, two styles on each, capillary, coloured, long; stigmas simple. *Pericarp*: none; ament becoming very large, concealing the seed at the base of each scale. *Seed*: nut ovate, angular. **ESSENTIAL CHARACTER.** *Calix*: one-leaved, with a ciliate scar. *Corolla*: none. *Male*. Stamina twenty. *Female*. Germina two, with two styles on each; nut ovate.—The species are,

1. *Carpinus Betulus*; *Horn-beam*, *Hard-beam*, *Horse-beech*, *Horn-beech*, *Wyeh-hasel*. Scales of the strobiles flat. Leaves ovate, acuminate, sharply serrate, strongly nerved, bright green, smooth, three inches or more in length, and nearly two in breadth, on round petioles which are slightly pubescent, half an inch in length, and having ovate red glandules at their base; they begin to open about the end of March, and are usually quite out by the middle of April: the flowers are in full blow towards the end of the same month. The Horn-beam is very common in many parts of England, but is rarely suffered to grow as a timber tree, being generally reduced to pollards by the country people; yet, where the young trees have been properly treated, they have grown to a large size. Mr. Miller says, "I have seen some of them in woods upon a cold stiff clay, which have been nearly twenty feet high, with large noble fine stems, perfectly straight and sound." The Eastern Hornbeam, which is a variety of this species, rarely rises above ten or twelve feet high.—As the common Hornbeam will thrive upon cold barren exposed hills, and in such situations where few other sorts will grow, the proprietors of such lands may cultivate it to great advantage: it will resist the violence of winds better than most other trees, and is by no means slow of growth. Those which are propagated for timber, should be raised from seeds upon the very spot where they are designed to be hewn down, and not brought from better soils and warmer situations, as is often the case: they should not be propagated by layers, according to the common method, when they are merely intended for hedges and underwood, which answers well enough for those purposes, but ought not to be preferred in raising timber trees. The seeds should be sown in autumn soon after they are ripe, for if they be kept out of the ground until the spring, the plants will not come up till the following year. When the plants appear, they must be kept clean from weeds, and treated as other forest trees: they will be fit to transplant in two years' time; for, like all timber trees, if they are at all transplanted, the sooner it is done the larger they will grow, and the more durable and firm will their wood become; and hence, as above stated, they ought if possible to be planted at first where they are always to remain. If these trees be not intermixed with others, they should be planted pretty close, especially on the outside of the plantations, that they may protect and draw each other up: and if they be kept clean from weeds three or four years, it will greatly promote their growth; after that they will have obtained sufficient strength to keep down the weeds themselves. For a wood of Hornbeam, Mr. Hanbury recommends to prepare the ground by a crop of Oats, Barley, or Turnips, to plough very deep when these are off, to harrow well, and just before planting to cross-plough and harrow as before. To plant from the seminary at two years old, in four-foot rows, at two feet distance in the rows. When they are too thick, to remove every other tree, and to thin them afterwards as often as their heads touch. Where hares and rabbits cannot be kept out, the plants must continue in the nursery, till their leading shoots are out of reach. As the trees advance in growth, they must be thinned with caution, cutting

away the most unpromising plants gradually, so as not to let in too much cold at once, especially on the borders of the plantations. The timber of this tree is very tough and flexible, and might be converted to many useful purposes, if it were suffered to grow to a proper size; but as this is not allowed, the principal uses it is applied to is for turnery ware, for which it is an excellent wood; for mill-cogs, heads of beetles, stocks, and handles of tools, and yokes: it is also excellent for fuel. As the leaves remain till the young buds in the spring thrust them off, so they afford much shelter for birds in winter; this also renders them very proper to plant round the borders of other plantations in exposed situations, to defend and promote the growth of more tender trees: it also preserves itself well from the bruttings of deer, so that the clumps of this tree are proper in parks both for beauty and shelter. There is a variety with striped leaves, which is propagated by budding on the common sort, but the colours are neither strong nor lively.

2. *Carpinus Ostrya*; *Hop Horn-beam*. Scales of the strobiles inflated. This in general habit resembles the first species, but is smaller.—Native of Italy and Germany.

3. *Carpinus Virginiana*; *Flowering Horn-beam*. Leaves lanceolate-acuminate; strobiles very long. About 30 feet high, and of quicker growth than the former.—Native of Virginia and Canada.

4. *Carpinus Duinensis*. Scales subcordate, doubly toothed; female ament ovate. This is about two fathoms high.—Native of Carniola.

Carpodetus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth turbinate, fastened to the germen, five-toothed; teeth subulate, deciduous. *Corolla*: petals five, ovate, small, inserted into the margin of the calix. *Stamina*: filamenta five, subulate, short, inserted into the margin of the calix; antheræ roundish. *Pistil*: germen inferior; style filiform, longer than the stamina; stigma flat-headed. *Pericarp*: berry dry, globular, surrounded with the margin of the calix, fastened to it like a ring, five-celled. *Seeds*: a few, slightly angular. **ESSENTIAL CHARACTER.** *Calix*: five-toothed, fastened to the germen. *Corolla*: five-petalled. *Stigma*: flat-headed. *Berry*: globular, five-celled.—The only species known is,

1. *Carpodetus Serratus*.—Native of New Zealand.

Carrot. See *Daucus*.

Carrot Candy. See *Athamanta*.

Carthamus; a genus of the class Syngenesia, order Polygamia Æqualis.—**GENERIC CHARACTER.** *Calix*: common ovate, imbricate; scales numerous, contracted below, increased at the tip by a foliaceous appendice, which is subovate, flat, spreading, obtuse. *Corolla*: compound uniform, tubular; corollets hermaphrodite, equal; the proper one monopetalous, funnel-form; border five-parted, erect, subequal. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: germen very short; style filiform, longer than the stamina; stigma simple; pericarp none. *Calix*: converging. *Seeds*: solitary. **RECEPTACLE**: flat, pilose, hairs longer than the seed. **ESSENTIAL CHARACTER.** *Calix*: ovate imbricate with scales, which at the end are subovate-foliaceous.—The species are,

1. *Carthamus Tinctorius*; *Official Bastard Saffron*, or *Safflower*. Leaves ovate, entire, serrate-aculeate. This is an annual plant, which rises with a stiff ligneous stalk, two feet and a half or three feet high, dividing upwards into many branches, with ovate pointed sessile leaves. The flowers grow single at the extremity of each branch; the heads are large, inclosed in a scaly calix, the lower part of the calix spreads open, but the scales above closely embrace

brace the florets, which stand out nearly an inch above the culix ; these are of a fine saffron colour : when the florets decay, the germina become oblong angular seeds, of a white colour, and having a pretty strong shell or cover to them. It flowers in July and August, and the seeds ripen in autumn; but, if the season prove cold and moist when the plant is in flower, it will produce no good seed, so that there are few seasons wherein the seeds of this plant come to perfection in England. It grows naturally in Egypt, and in some of the warm parts of Asia. Mr. Miller informs us, that he has frequently received the seeds from the British islands in America, but, whether they naturally grow there or not, he was never positively informed.—This plant was formerly cultivated in the fields in several parts of England for the dyer's use, and particularly in Gloucestershire, where the common people frequently gathered the florets and dried them, to give a colour to their puddings and cheesecakes; but by employing too great a quantity, they acquired a cathartic quality. If this plant were ever cultivated among us in large quantities, it is surprising how it came to be so totally neglected, that at present there are not the least traces of its cultivation to be met with in any part of England, insomuch that the commodity is scarcely known, except to those who deal in it. The quantity annually consumed in England is so great as to make it a considerable article of trade, so that it might be well worthy of public attention; for although the seeds seldom come to perfection in England, yet these might be procured from abroad, and the plants would constantly produce the flower, which is the only part used in dyeing. This plant is cultivated in great plenty in some parts of Germany, where the seeds constantly come to perfection; and a short account of their method of cultivation, by a curious gentleman of that country, is here inserted, for the benefit of those who may be induced to engage in cultivating it. The ground in which they purpose to sow, has always a double fallow given to it, first to destroy the weeds, and afterwards to make it fine: they make choice of their lightest land, and such as is clear from Couch-grass and other troublesome weeds. After the land has been fallowed a summer and winter, in which time they give it four ploughings, and harrow it between each, to break the clods and pulverize it: in the latter end of March, they give it the last ploughing, when they lay it in narrow furrows of about five feet or a little more, leaving a space of two feet between each; then they harrow these lands to make them level, and after it is finished they sow the seeds in the following manner: With a small plough, they draw four shallow furrows in each land, at near a foot and half distance, into which they scatter the seed thinly, then with a harrow, the teeth of which are little more than one inch long, they draw the earth into the drills to cover the seeds; after this they draw a roller over the ground, to smooth and settle it: when the plants are come up so as to be distinguished, they hoe the ground, to destroy the weeds; and at this operation, where the plants happen to be close, they cut up the least promising, leaving them all single, at the distance of three or four inches, which they always suppose will be sufficient room for their growth, till the second time of hoeing, which must be performed in about five weeks after the first, in which they are guided by the growth of the weeds; for as this work is performed with a Dutch hoe, so they never suffer the weeds to grow to any size before they cut them; in which they judge right, for when the weeds are small, one man will hoe as much ground in a day, as can be performed by three when they are permitted to grow large, and the weeds will also be more effectually destroyed: they give a third hoeing to the plants about five or six weeks after

the second, which generally makes the ground so clean, as to require no further clearing until the *Carthamus* is pulled up. When the plants begin to flower, and have thrust out their florets or thrum to a proper length, they go over the ground once a week, to gather it; and as it is from time to time gathered, it is dried in a kiln for use; there is usually a succession of flowers for six or seven weeks. After the crop is gathered, the stalks are pulled, and tied in bundles for fuel; and after they have been set up a few days to dry, they are carried off, and the ground is ploughed for wheat, which they say always succeeds well after this plant.—The following is the method pursued in cultivating the *Carthamus* in British gardens: The seeds are sown in April, upon a bed of light earth, in drills drawn at two feet and a half distance from each other; the seeds are thinly scattered, as the plants must not stand nearer to each other than a foot in the rows; but, as some of the seeds will fail, a sufficient quantity to admit of thinning when the ground is hoed, should be sown. If the seed be good, the plants will appear in less than a month; and in a fortnight or three weeks after they appear, it will be proper to hoe the ground to destroy the weeds, and at the same time thin the plants wherever they may be too close; but at this time they should not be separated to their full distance, lest some of them should afterwards fail; if removed six inches asunder, there will be room enough for the plants to grow till the next time of hoeing, when they must be thinned to the distance they are finally to remain: after this they should have a third hoeing, which, if carefully performed in dry weather, will destroy the weeds and make the ground clean, so that the plants will require no further care till they come to flower; when, if the Saffron is intended for use, the florets should be cut off from the flowers as they come to perfection; but this must be performed when they are perfectly dry, and afterwards they should be dried in a kiln, with a moderate fire, in the same manner as the true Saffron, which will prepare them for use. If the plants be intended to seed, the plants should not be gathered; for if the florets be cut off, it will render the seeds abortive, though they may swell and grow to their usual size, for when they are broken they will prove to be a shell without a kernel; this is frequently the case in wet cold seasons; and in very wet ones the germen will rot, and never come so forward as to form a shell. The good quality of the *Carthamus* consists chiefly in the colour, which should be a bright saffron, in which that cultivated in England often fails. Great care must be taken not to gather it till the dew is dried off, nor should it be pressed together till it has been dried on the kiln; for which, see the genus *Crocus*. Great quantities of this plant are annually imported from England for dyeing and painting, from the Levant, where, as well as in many parts of Europe, it is at present cultivated. The Spaniards retain this plant in their gardens, to colour their soups, olios, and other dishes, in the same manner as the Marigold in England. The Jews also are very partial to it, and mix it in most of their viands, and probably were the first importers of the seed into America, and taught the inhabitants the use of it, for it is now as commonly used by the English there as in any part of Europe. The plant itself may be admitted to have a place in the borders of large gardens, where it will add to the variety during the time of its continuance in flower, which is commonly two months or ten weeks.

2. *Carthamus Lanatus*; *Yellow Distaff Thistle*, or *Woolly Carthamus*. Stem hairy, woolly towards the top; lower leaves pinnatifid, upper stem-clasping, toothed. The florets are first golden, then saffron-coloured, with the edges of the

segments black, and five black lines running down the corolla.—It grows naturally in the south of France, Spain, and Italy, where the women use the stalks for distaffs, whence it derived the title of Distaff Thistle; some call it Bastard Wild Saffron. The leaves are rather bitter, and are sometimes prescribed as a medicine, and are supposed to have the same virtues as *Carduus Benedictus*. It flowers in June and July, and ripens seed in autumn.—If the seeds be sown in autumn, the plants will flower early the following summer, so that there will be a certainty of good seeds: they may be sown in any situation, and require no other culture but weeding and thinning when too close together. There is a variety of this species, which grows much taller; the heads also are larger, and the leaves are placed closer upon the stalks. It was found by Tournefort in the Levant.

3. *Carthamus Creticus*; *Cretan Carthamus*. Stem somewhat glossy; calices a little woolly; floscules about nine; lower leaves lyrate. This is an annual plant, growing nearly four feet high; it differs from the foregoing in having a smooth stalk: the leaves are very stiff, deeply indented, smooth, and armed with very strong spines; the heads of flowers are oval, and the florets white.—Discovered in Candia by Tournefort. Cultivated in the same manner as the preceding species; which see.

4. *Carthamus Tingitanus*; *Tangier Carthamus*. Radical leaves pinnate; stem-leaves pinnatifid; stem one-flowered. This species has a perennial root; the stalks rise about a foot and a half high, seldom putting out any branches; the stalk is terminated by one large scaly head of blue flowers.—It is a native of Barbary, and was brought from Tangier: it is increased by parting the roots, the best time for which is in the beginning of March; it should have a dry soil and a warm situation, otherwise it will be liable to be destroyed in severe winters.

5. *Carthamus Cœruleus*; *Blue-flowered Carthamus*, or *Bastard Saffron*. Leaves lanceolate, spiny, toothed; stem one or two flowered. This rises with a single stalk about two feet high, of a purplish colour, hairy, and channelled, closely beset with broad spear-shaped leaves, sharply serrate, and covered with a short hairy down; flowers blue; outer calix-scales broad, long, with a sharp spine on their edges; inner ones narrow, terminated with a sharp thorn: it flowers in June and July, and the seeds ripen in autumn. It grows naturally in Spain, France, and Italy, on arable land. It may be increased by parting the roots in autumn when the leaves decay: in a light soil it will survive the cold of our winters, and last many years; it may also be propagated by seed.

6. *Carthamus Mitissimus*; *Small Carthamus*. Leaves unarmed, those next the root toothed, on the stem pinnate. Root-leaves, some lanceolate, dilated at the end, and very smooth, from the middle to the end toothed, the teeth turned upwards, sharp, ending in a small thorn, others pinnatifid; flower bright blue.—Found about Paris and Montpellier.

7. *Carthamus Carduncellus*; *Mountain Carthamus*. Stem-leaves linear, pinnate, the length of the plant; root perennial; stem, in gardens, about six inches high, channelled and hairy; each stalk is terminated by one large head of blue flowers.—Native of the south of France, Spain, and Italy. The root is eaten in Africa. It is difficult to propagate this species in England, the roots not putting out offsets, and the seeds ripening only in warm dry seasons; it requires a dry soil and warm situation.

8. *Carthamus Arborescens*; *Tree Carthamus*. Leaves ensiform, sinuate-toothed. The whole plant is pubescent; stem firm, the height of a man, evergreen; leaves a foot long, pinnatifid-sinuate, toothed, mostly spinous at the end;

flowers terminal, sessile, yellow, sweet-smelling; down hairy.—Native of Andalusia. It is increased by the side-shoots slipped from the branches in the spring, and planted in pots filled with light sandy earth, which are to be plunged into a moderate hot-bed, observing to shade them till they have taken root; they then must be gradually hardened, and removed into the open air, and when they have acquired strength, some may be planted in a warm dry border, where they will endure the cold of our ordinary winters.

9. *Carthamus Salicifolius*; *Willow-leaved Carthamus*. Shrubby; petioles spiny; leaves lanceolate, entire, tomentose beneath, pungent at the end; branches one-flowered; florets white.—Native of Madeira.

10. *Carthamus Corymbosus*; *Corymbed Carthamus*. Flowers corymbed, numerous. Root perennial; stem single, white, smooth, and channelled, never putting out any side-branches; leaves long, narrow, pale green, closely armed on their edges with short stiff spines, which come out double; stems terminated by single, oval, scaly heads of white flowers, each scale ending with a purplish spike.—Native of Apulia, the Hellespont, Lemnos, and Thrace. It seldom perfects seeds in England, and is increased by parting the roots in the spring; and in a light soil and warm situation it will endure common winters in the open air, but in severe frost it is sometimes destroyed.

Carum; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal long; rays ten, frequently unequal; umbel partial, crowded; involucre universal, often monophyllous; partial none; perianth scarcely manifest. *Corolla*: universal uniform; florets of the disk abortive; proper unequal; petals five, unequal, obtuse, carinated, inflex-emarginate. *Stamina*: filamenta five, capillary, length of the corolla, caducous; antheræ roundish, very small. *Pistil*: germen inferior; styles two, very small; stigmas simple. *Pericarp*: none; fruit ovate-oblong, striated, bipartite. *Seeds*: two, convex on one side, ovate-oblong, striated, flat on the other side. ESSENTIAL CHARACTER. *Fruit*: ovate-oblong, striated. *Involucre*: one-leaved. *Petals*: keeled, inflex-emarginate.—The only known species is,

1. *Carum Carui*; *Common Caraway*. It is a biennial plant, has a taper root like a Parsnip, but much smaller, running deep into the ground, sending out many small fibres, and having a strong aromatic taste.—It grows naturally in rich meadows, in Lincolnshire, in Yorkshire near Hull, in Norfolk, near Cambridge, Bury, &c. and is cultivated in some counties, particularly in Essex: it flowers in May and June, and the seeds ripen in autumn. Parkinson says, the young roots are better eating than Parsnips: the tender leaves in the spring are boiled in soup. The seeds, it is well known, are much used in cakes, and incrustated with sugar for comfits; they are also distilled with spirituous liquors for their flavour: they were formerly recommended by Dioscorides for pale-faced girls; and it is said, that modern ladies have not despised his recommendation: they are a good remedy in tertian agues, and abound with an essential oil which is antispasmodic and carminative. Lewis says, that about one ounce in thirty of essential oil arises from the seeds in distillation: this oil is of a bright yellow colour, hotter, and more pungent to the taste, than what is obtained from most other warm seeds, and is given from one to five drops as a carminative, and is supposed to be of peculiar efficacy in promoting urine: the herb affords a similar oil, but sixteen pounds of it, stripped from the stalks, scarcely yield an ounce. The seeds are the part commonly employed in medicine; they are of an agreeable aromatic smell, and a

warm pungent taste: given in substance from a scruple to halfa drachm, they dispel wind from the stomach, and greatly strengthen that organ: the seeds bruised, and made into a poultice, will remove the marks occasioned by blows, falls, or bruises; and are good in hysteric fits. The best season for sowing the seeds of Caraway is in autumn, soon after they are ripe, when they will more certainly grow than those sown in the spring; and the plants which rise in the autumn generally flower the following season, so that a summer's growth is hereby saved: when the plants come up, the ground should be hoed to destroy the weeds, and where the plants are too close they must be thinned, in the same manner as is practised for Carrots, leaving them three or four inches apart: in the following spring they will require to be twice more hoed, which will keep the ground clean till the seeds are ripe, then the stalks must be pulled up and tied in bundles, setting them upright to dry, when the seeds may be threshed out for use. The method of culture in Essex, where it has long been cultivated, is, about the beginning of March to plough some old pasture land; (if it have been pasture for a century, the better, especially if the soil be a strong clayey loam) twelve pounds of Caraway seeds are mixed with ten of Coriander, and twelve pounds of Teasel seed; this is sufficient for one acre, and is sown directly after the plough, harrowing the land well: when the plants appear of sufficient strength to bear the hoe, which will not be till about ten weeks after sowing, it must not be omitted; and in the course of the summer the crop will require three hoeings, besides one at Michaelmas, each costing about eight shillings an acre. The Coriander being annual, will be fit to cut about the beginning of July, and is reaped at four shillings the acre; it is left in the field after cutting, and threshed by the day on a cloth, in the same manner as rape seed. About April following, the Caraway and Teasel will want a good hoeing, done deep and well, and another about the beginning of June, which hoeings are performed at the rate of seven shillings each per acre: the Caraway will be fit to cut the beginning of July, and must be threshed in the same manner as the Coriander. The Teasel will not be ready till the middle of September. Some of the plants of Caraway and Teasel do not perfect their seeds till the third or fourth year, though in general there is a crop the second year, yet enough is left for a crop the third year; and the seeds that are scattered from the crop the second year, often come to perfection in the fourth; and there are several instances of its being continued for seven years: the usual way, however, is to plough directly after the crop is gathered the third year, and to sow Wheat, of which commonly a very good crop is obtained, the land being in fine order from the rotting of the turf, and repeated hoeings. The produce of Caraway on the very rich old lays, in the hundreds or low lands of Essex, has often been twenty hundred-weight to an acre. There is always a demand for the seed in the London market, where it sometimes sells as low as twelve shillings the hundred-weight, and has been up to fifty shillings, but is mostly on an average at twenty-one shillings. The land can only be filled with plants; and the more one predominates, the less must reasonably be expected of the others. This compound crop is mostly sown on land so strong, as to require a little previous exhaustion to prepare it for corn. Caraway and Coriander are oftenest sown without Teasel, the latter being a troublesome and uncertain crop, and the produce of Caraway much greater without it.

Caryocar; a genus of the class Polyandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth quinquepartite, coloured; divisions obtuse, concave, deciduous.

Corolla: petals five, oval, concave, large. *Stamina*: filamenta numerous, filiform; antheræ oblong. *Pistil*: germen globose; styles four; stigmas obtuse. *Pericarp*: drupe fleshy, spherical, very large. *Seed*: nuts one to four, oval-triquetrons, reticulated with furrows, angulated with a suture on one side. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Styles*: usually four. *Drupe*: with four nuts, reticulated with furrows.—The only known species is,

1. *Caryocar Nuciferum*. A tall tree, with ternate leaves; calix and corolla purple; drupe the size of the human head; nuts esculent, having the taste of almonds.—Native of Berbice and Essequibo.

Caryophyllus; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth of the fruit superior, quadripartite, acute, small, permanent; perianth of the flower superior, tetraphyllous; leaflets roundish, concave, deciduous. *Corolla*: petals four, roundish, crenate; smaller than the calix of the flower. *Stamina*: filamenta numerous, capillary; antheræ simple. *Pistil*: germen inferior, oblong, large, terminating in the calix of the fruit; style simple, inserted into the quadrangular receptacle; stigma simple. *Pericarp*: oval, unilocular, terminated by the hardened converging calix of the fruit, umbilicate. *Seed*: single, oval, large. ESSENTIAL CHARACTER. *Calix*: four-leaved, duplicate. *Corolla*: four-petalled. *Berry*: one-seeded, inferior.—The only known species is,

1. *Caryophyllus Aromaticus*; *Clove Tree*. According to Mr. Miller, this tree rises to the height of a common Apple-tree, but the trunk generally divides at about four or five feet from the ground, into three or four large limbs, which grow erect, and are covered with a smooth thin bark, which adheres closely to the wood; these limbs divide into many small branches, which form a sort of conical figure: the leaves are like those of the Bay-tree, and are placed opposite on the branches. The flowers are produced in loose bunches at the end of the branches; are small, white, and have a great number of stamina, which are much longer than the petals; they are succeeded by oval berries, which are crowned with the calix, divided into four parts, and spreading flat on the top of the fruit; which, when beaten from the trees before it is half grown, is the Clove so commonly used all over Europe.—The Clove-tree is not confined to Banda and Amboyna, but is found in all the Moluccas, in many of the South Sea islands, New Guinea, and the neighbouring isles: it also grows wild in Cochinchina, where it has scarcely any smell or taste. There are no plants of this remarkable tree in either the English or Dutch gardens; indeed the Dutch have ever been particularly jealous lest other nations should share the spice-trade with them, and will not suffer them to grow wild any where if they can prevent it. Captain Rofy told Dampier, that he was sent to the uninhabited islands on purpose to cut them down, and that he actually destroyed seven or eight hundred trees at different times. But notwithstanding the unremitting caution and watchfulness of Dutch avarice, the French, at Cayenne and elsewhere, have had this valuable tree for some time in their possession. It has been received into the British botanic garden in the island of St. Vincent, and was sent thence to Barbadoes in 1794.—The Clove is esteemed one of the hottest and most acrid substances of the aromatic class; and is often used, not only internally but externally, as a stimulant; as, for example, in paralytic cases, wherein the oil of Cloves has been advantageously administered. It is often used in the tooth-ache, and frequently succeeds in suddenly subduing the pain. A tincture of Cloves in rectified spirits, and an essential oil extracted from them, are kept in the shops, but the latter is

not often unsophisticated. The culinary uses of Cloves are almost innumerable.

Caryota; a genus of the class Monœcia, order Polyandria. —GENERIC CHARACTER. *Male Flowers.* *Calix*: spathe universal, compound; spadix ramose. *Corolla*: tripartite; petals lanceolate, concave. *Stamina*: filamenta very numerous, almost longer than the corolla; antheræ linear. *Female Flowers*, in the same spadix with the males. *Calix*: common with the males. *Corolla*: tripartite; petals acuminate, very small. *Pistil*: germen roundish; style acuminate; stigma simple. *Pericarp*: berry roundish, unilocular. *Seeds*: two, large, oblong, roundish on one side, flat on the other. ESSENTIAL CHARACTER. *Male.* *Calix*: common. *Corolla*: tripartite. *Stamina*: very many. *Female.* *Calix*: ns in the male. *Corolla*: tripartite. *Pistil*: one. *Berry*: dispersmous. —The species are,

1. *Caryota Urens*; *Burning Caryota*. Fronds bipinnate; leaflets sessile; berry two-seeded. This palm becomes a lofty tree; the trunk is frequently so large as scarcely to be embraced by two men: it is covered with a sort of cinereous crust, which is quite smooth; leaves or fronds large, forming an ample head, twice winged; pinnules small with respect to the size of the leaf, wedge-shaped; spathe many-leaved, axillary within the lowest leaf; the corolla, which is sometimes bipartite, but commonly tripartite, is at first green, then red or purple, and finally yellow: the fruit is a succulent globular berry, a little flattened, terminated by a triangular twin stigma; at first it is hard and green, next yellow, then red, and, when quite ripe, dark red, (almost black) and shining: the rind is thin, and the pulp is soft and red, very sharp and acrid: within are two stones or seeds, (sometimes only one) hard, roundish or oblong, convex on one side, flat on the other, wrinkled; they are of a dark red or blackish colour on the outside. The Ceylonese know this tree by the name of *kettule*; it yields a sort of liquor, which they call *tellegie*, sweet and pleasing to the palate, wholesome, and not stronger than water: it is taken from the tree twice, and sometimes thrice a day, and the quantity obtained is three or four gallons; they boil this liquor, and thus make a kind of brown sugar, called *jaggory*, of it; but if they manage it skilfully, can make it as white as the second-best sugar. When the tree is come to maturity, there comes out a bud from the top, which if it be suffered to grow, will bear the fruit, but this is only fit to set for increase; this bud is cut and prepared, by putting salt, pepper, lemons, garlic, leaves, &c. upon it, which keep it from ripening: they then daily cut off a thin slice from the end, and the liquor drops into a vessel which they set to catch it. This tree bears a leaf like that of the Betel-nut tree, which is fastened to a skin as that is, only this skin is hard and stubborn like a piece of board; the skin is all full of strings as strong as wire, and is used for making ropes. While the tree grows, the leaves shed; but when it is come to its full growth, they remain many years before they fall. As the top bud withers, other buds come out lower and lower every year, till they come to the bottom of the boughs, and then, having done bearing, may stand seven or ten years, when it dies. The wood is not above three inches thick, very strong and hard, but apt to split; being very heavy, they make pestles of it to beat their rice with; the colour is black, but it looks as if it were composed of several pieces. The buds of this tree, like those of the Cocoa and Betel-nut tree, are excellently well tasted, resembling walnuts or almonds.

2. *Caryota Mitis*; *Mild Caryota*. Fronds bipinnate; petioles of the leaflets nodding; berries one-seeded. The trunk of this palm is fifteen feet high, two inches thick, very straight and regular; fronds four feet long, reclining on roundish un-

armed stipes. The berry is round, coriaceous, smooth, black, the size of a musket-bullet; containing one globular pale softish seed; pulp mild.—It is a most beautiful palm, and grows in the woods of Cochin-china.

Cassada, or *Cassava*. See *Jatropha*.

Cassia; a genus of the class Decandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth pentaphyllous, lax, concave, coloured, deciduous. *Corolla*: petals five, roundish, concave; the inferior ones more distant, more spreading, larger. *Stamina*: filamenta ten, declined; the three inferior ones longer, the three superior shorter: antheræ, the three inferior very large, arcuate, rostrate, gaping at the tip; the four lateral ones without the rostrum, gaping; the three superior ones very small, sterile. *Pistil*: germen subcolumnar, long, peduncled; style very short; stigma obtuse, ascending. *Pericarp*: legume oblong; partitions transverse. *Seeds*: many, roundish, affixed to the superior suture. ESSENTIAL CHARACTER. *Calix*: pentaphyllous. *Petals*: five. The three superior *Antheræ* sterile; the three inferior beaked. *Fruit*: a legume.—Many of these plants are preserved in curious gardens, though several of them have little beauty to recommend them. The handsomest are the eighth, fourteenth, thirty-first, thirty-ninth, fortieth, and forty-first species; these all make a good appearance in the stove when in flower, and, as they retain their leaves all the year, form an agreeable variety in winter. All the species contract their leaves every evening as the sun declines, and open them when he re-appears: the under surface of the leaflets is turned outward, the upper surfaces being clapped close together. Most plants whose under surface is thus turned outward, grow on dry sandy land, where the roots do not find a sufficient supply of moisture; the lower surface of the leaves being generally covered with a short soft down, detain and imbibe the nightly dews. Those which have the upper surface of the leaves turned outward, do not stand in need of this supply; and accordingly that surface being smooth, the moisture is cast off, and not imbibed. All the species of this genus are propagated by seeds, which, as they mostly come from very hot climates, must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, filled with light earth, and plunged into a moderate hot-bed, where they should be shaded until they have taken fresh root; after which they must have the air admitted to them every day, in proportion to the warmth of the season, and should be frequently watered. When the plants have filled the pots with their roots, they should be shifted into larger, and if they be too tall to remain in the hot-bed, they must be placed either in the stove, or in a glass-case, where they may be defended from cold, and have plenty of fresh air in warm weather: they will flower in July or August, and perfect their seeds in October, and may be preserved through the winter in a stove, where they will continue flowering a long time. In warm summers they may be placed in the open air, where they will flower very well about the end of June, but will not perfect their seeds, unless they are removed into the stove in autumn.—The species are,

1. *Cassia Diphylla*; *Two-leaved Cassia*. Leaves conjugate; stipules cordate-lanceolate. A shrub with a round stem. Annual.—Native of the West Indies.

2. *Cassia Bacillaris*. Leaflets two pairs, ovate, oblique, an obtuse gland between the lowest; racemes axillary, peduncled; silique round, long. A shrub of twelve feet in height, and very smooth.—Native of Surinam.

3. *Cassia Absus*; *Four-leaved Cassia*. Leaflets two pairs, obovate; glands two, subulate beneath the lowest.—A hairy

plant, with a slender striated stem. Annual.—Native of India, Ceylon, and Egypt.

4. *Cassia Viminea*; *Weakly Senna Shrub*, or *Twiggy Cassia*. Leaflets two pairs, ovate-oblong, acuminate, an oblong gland between the lowest; spines subpetioled, obsolete, three-toothed. Stem shrubby, climbing to the height of forty or fifty feet, striated, stiff; branches divaricate, loose, stiffish, round, striated, smooth; flowers large, on peduncles longer than themselves.—Native of Jamaica, in the woods of the higher mountains in the interior of that island; it is also called *atao* or *attoo*. Half a pint of the decoction of the root, taken three or four times daily, is prescribed as a cure for the dry belly-ache; ground into a paste, and plastered over the body, it cures the head-ache and fevers.

5. *Cassia Tagera*. Leaflets three pairs; gland petiolar; stipules ciliated, cordate, acuminate. A small procumbent shrub, with filiform branches.—Native of India.

6. *Cassia Tora*; *Oval-leaved Cassia*, or *Wild Senna*. Leaflets three pairs, obovate; the outer ones larger, a subulate gland between the lower. Stem erect, less woody, roughish, knotty from the scars of the leaves; flowers pale yellow.—Native of the East Indies, Japan, and Cochin-china. Annual; the leaves are substituted for Senna, in the natural place of its growth.

7. *Cassia Bicapsularis*; *Six-leaved Cassia*. Leaflets three pairs, obovate, smooth, the interior ones rounder and less, a globular gland interposed. A shrub, six or eight feet high, branched near the summit; with bright yellow flowers.—Native of South America.

8. *Cassia Emarginata*. Leaflets three or four pairs, obovate, almost entire; flowers in racemes, irregular; stem arborescent. Height from ten to twelve feet.—Native of Jamaica, where it is called the Senna tree. Its leaves are purgative, and are sometimes used instead of the true Senna.

9. *Cassia Obtusifolia*; *Round-leaved Cassia*. Leaflets three pairs, obovate, blunt.—Native of Jamaica.

10. *Cassia Falcata*; *Sickle-leaved Cassia*. Leaflets four pairs, ovate-lanceolate, back-sickled; a gland at the base of the petioles. Stem erect, roundish, obtusely grooved; branches scarcely pubescent. Perennial.—Native of America.

11. *Cassia Longisiliqua*; *Long-podded Cassia*. Leaflets four pairs, the outmost lanceolate, a subulate gland below the inmost, and between the outmost.—Native of America; and perennial.

12. *Cassia Occidentalis*; *Occidental Cassia*. Leaflets five pairs, ovate-lanceolate, scabrous about the edge, the outer ones larger; a gland at the base of the petioles. Stem a foot and a half high; flowers pale yellow without any spot.—It is very common about Kingston in Jamaica, and is there called *stinking weed*. The tops of it are commonly employed in all resolute baths; and it is accounted a very powerful ingredient on such occasions. According to Dr. Barham, the whole plant is cooling and cleansing, and the decoction of the root diuretic, and a powerful antidote against poison. An infusion of it in water with juice of Tansy, and a small quantity of garlic, is a good vermifuge.

13. *Cassia Planisiliqua*. Leaflets five pairs, ovate-lanceolate, smooth; a gland at the base of the petioles.—Native of South America.

14. *Cassia Fistula*; *Alexandrian Purging Cassia*, *Cassia Stick*, or *Pudding-pipe Tree*. Leaflets five pairs, ovate-acuminate, smooth; petioles without glands. This tree rises to the height of forty or fifty feet, with a large trunk, dividing into many branches; the flowers are produced in long spikes at the end of the branches, each standing upon a pretty long peduncle; they are of a deep yellow colour, and are suc-

ceeded by cylindrical pods, from one to two feet long, having a dark brown woody shell, with a longitudinal seam on one side, divided into many cells by transverse partitions, each containing one or two oval smooth compressed seeds, lodged in a sweetish black pulp; this pulp is an easy gentle laxative, opening the passages without irritating the intestines; but it grows rancid when it has been long out of the cells, and then acquires an acrimony that renders it precarious, and even dangerous.—Native of both Indies: the seeds may be procured from the druggists, who import the pods for use.

15. *Cassia Atomaria*. Leaflets five pairs, ovate, submottose; petioles round, without glands. Stem the height of a man, woody, ash-coloured, very branching.—Observed by Jacquin in America.

16. *Cassia Pilosa*. Leaflets four or five pairs, with very minute glands; stipules semicordate, acuminate; stem stiff, hairy, from one to two feet high.—Native of Jamaica; flowering toward the end of the year.

17. *Cassia Senna*; *Egyptian Cassia* or *Senna*. Leaflets four to six pairs, subovate; petioles without glands. The plant which produces the leaves commonly known in medicine by the name of Senna, is annual, and rises with an upright branching stalk about a foot high; the flowers are yellow, and produced in loose bunches at the top of the stalk; it grows naturally in Persia, Syria, and Arabia, whence the leaves are brought, dried and picked from the stalk, to Alexandria in Egypt, and being thence imported into Europe, acquires the additional title of Alexandria. Senna is one of the most general purgatives in the materia medica; for this purpose it is used in infusion, and is not unfrequently mixed with other substances, as manna, &c. it operates without violence, and is sufficiently efficacious, but is sometimes apt to excite tormina, and has the disadvantage of being nauseous to the taste. But to remedy this inconvenience, compositions of various kinds are prepared in the shops; thus, for example, six drachms of tamarinds, and two of crystals of tartar, are boiled in a pint and half of water till half a pint is exhaled, and the strained liquor poured boiling hot upon one, two, or three drachms of Senna; after maceration for four hours, the strained infusion is sweetened with an ounce of syrup of violets, and flavoured with half an ounce of simple cinnamon-water: or three drachms of Senna are infused in a quarter of a pint of boiling water for four hours, or till the liquor has grown cold, with the addition of a scruple of ginger; or with half a drachm of lesser cardamom seeds, husked, and three-fourths of a drachm of crystals of tartar, which last are previously boiled in the water till dissolved; or with two drachms of fresh lemon-peel, and the same quantity by measure of lemon-juice: the latter, which is the *infusum sennæ limoniatum*, is considered the most agreeable form in which the infusion of Senna can be contrived. Meyrick and Hill observe, that the dried leaves of this plant are imported by our druggists from the East, and that they are a moderately strong and safe purgative; they may be taken wherever cathartics are necessary, either in substance reduced to powder, or in a strong infusion; but it will be advisable to add a little of some warm aromatic to the dose, as they are otherwise apt to gripe during the operation.—It requires the same treatment as the other sorts; but being an annual plant, unless it is brought forward in the spring, it will not flower.

18. *Cassia Biflora*; *Two-flowered Cassia*. Leaflets six pairs, rather oblong, smooth; the lower ones smaller, a subulate gland between the lowest; pedicels two-flowered; flowers yellow; pods linear, compressed.—Native of the West Indies.

19. *Cassia Ruscifolia*. Leaflets six pairs, lanceolate, acute,

smooth, a gland above the base of the rib; flowers racemed.—This is an elegant shrub, the height of a man; gathered on the rocks of Madeira.

20. *Cassia Hirsuta*. Leaflets six pairs, broad-ovate, acuminate, woolly.—Native of America.

21. *Cassia Multiglandulosa*; *Glandulous Cassia*. Leaflets six pairs, villose beneath and about the edges, obtuse; a gland between each pair of leaflets.—Brought from Teneriffe to England, where it flowers most part of the summer.

22. *Cassia Tomentosa*. Leaflets six or eight pairs, linear, obliquely rounded at the base, rough with hairs on the upper surface; panicles axillary; legumes villose. This is a tree with round flexuose branches, covered with a thick soft white pile, which is yellow when they are dry; flowers pale yellow.—Found in South America by Mutis.

23. *Cassia Serpens*. Leaflets seven pairs; flowers pentandrous; stems filiform, prostrate, herbaceous.—This is an annual plant, native of Jamaica, where it is found in dry pastures, creeping among the grass.

24. *Cassia Ligustrina*; *Privet-leaved Cassia*. Leaflets seven pairs, lanceolate, the outmost smaller; a gland at the base of the petioles. Stem six or seven feet high or more, the thickness of the little finger, slightly angular, putting forth many deeply striated branches from top to bottom; flowers many, terminating, yellow: the leaves and flowers have somewhat of a fœtid smell.—Native of the isle of Providence, and other islands in the West Indies.

25. *Cassia Alata*; *Broad-leaved Cassia*. Leaflets eight pairs, oval-oblong, the lowest smaller; petioles without glands; stipules spreading. Stem subherbaceous, six feet high and more, branched, upright, furrowed, smooth, with simple striated branches; leaves alternate, a foot or a foot and half long; leaflets near two inches and a half long, one-inch broad, near together, quite smooth; flowers yellow, in terminal racemes. It lives but a few years, though it puts out the appearance of a shrub in its growth; and when cultivated, rises sometimes to the height of seven or eight feet, but seldom exceeds four in its native soil. Ants are very fond of the flowers: the juice of the leaves or buds is said to cure the ring-worm, whence it is called the *ring-worm bush*, in Jamaica. It flowers in the spring; and, according to Mr. Miller, has a strong fœtid odour.

26. *Cassia Marilandica*; *Maryland Cassia*. Leaflets eight pairs, ovate-oblong, equal; a gland at the base of the petioles. Root perennial; calix pale or greenish-yellow; flowers two or three together, from the axils of the upper leaves, and in loose spikes at the end of the stem, bright yellow.—Native of North America.

27. *Cassia Tenuissima*. Leaflets five pairs, oblong, a subulate gland between the lowest.—Native of the Havanna.

28. *Cassia Sophera*. Leaflets ten pairs, lanceolate; an oblong gland at the base; corolla very pale yellow with brown veins.—Native of the East Indies, China, and the island of Tongataboo in the South Seas.

29. *Cassia Bracteata*. Leaflets ten pairs, oblong, obtuse, without glands; racemes elongated; bractes ovate, swelling, imbricate; legume quadrangular, compressed. Corollas yellow.—Found at Surinam by Dalberg.

30. *Cassia Auriculata*; *Eared Cassia*. Leaflets twelve pairs, obtuse, mucronate; several subulate glands; stipules kidney-form, bearded.—Native of the East Indies.

31. *Cassia Javanica*; *Java Cassia*. Leaflets twelve pairs, oblong, obtuse, smooth; no gland. This rises to a great magnitude, with a large trunk, dividing into many branches. The flowers are in loose spikes of a carnation colour; and are succeeded by large cylindrical pods two feet long, divided

by transverse partitions into many cells, in which the seeds are lodged, surrounded with a black purging pulp; this is called *horse-cassia*, because it is generally given to horses, but is seldom used by the human species, on account of its gripping quality.—Native of the East Indies.

32. *Cassia Grandis*. Leaflets twenty pairs, somewhat silky, without glands. This is a stout tree, and the branches are covered with a purple silky down.—Native of Surinam.

33. *Cassia Chamæcrista*; *Dwarf Cassia*. Leaflets many pairs; a petiolar pedicelled gland; stipules ensiform. Stem herbaceous, a foot high or more, diffused, smooth, round, with hirsute branches; corolla small, yellow; legume compressed. Annual.—Native of dry pastures in the West Indies. Dr. Wright says, that two quarts of a decoction of this plant, taken daily, is an antidote to the poison of Night-shade.

34. *Cassia Glandulosa*. Leaflets many pairs, with many glands; stipules subulate. Stems suffruticose, with almost naked branches.—Native of the West Indies.

35. *Cassia Mimosoides*. Leaflets many pairs, linear; an obscure gland at the base of the petioles; stipules setaceous. Stem erect, two feet high.—Native of Ceylon.

36. *Cassia Flexuosa*. Leaflets many pairs; stipules half-cordate.—This is an annual plant, and native of Brazil.

37. *Cassia Nictitans*. Leaflets many pairs; flowers pentandrous; stem somewhat erect.—Annual; and a native of Virginia.

38. *Cassia Procumbens*. Leaflets many pairs, without glands; stem procumbent.—An annual plant; and a native of both Indies, Cochin-china, Africa, and Virginia.

39. *Cassia Fruticosa*. Leaflets two pairs, ovate-lanceolate, smooth; flowers terminal; pods long, round; stem shrubby. This grows upwards of twenty feet high, with several stems, covered with brown bark, and dividing into many branches at top; the flowers are produced in loose spikes at the extremity of the branches; they are large, of a gold colour, and succeeded by taper brown pods about nine inches long, having many transverse partitions, in which the seeds are lodged in a thin pulp.—Native of La Vera Cruz.

40. *Cassia Arborescens*. Leaflets two pairs, oblong-ovate, villose beneath; flowers corymbd; stem erect, arboreous. Trunk 25 to 30 feet high.—Native of La Vera Cruz.

41. *Cassia Villosa*. Leaflets three pairs, oblong-ovate, equal, villose; pods jointed; stem erect, arboreous. This rises with a woody stem to the height of fourteen or sixteen feet, sending out many lateral branches; flowers in loose bunches, pale straw-colour.—Native of Campeachy.

42. *Cassia Uniflora*. Leaflets three pairs, ovate-acuminate, villose; flowers solitary, axillary; pods erect.—Annual; and a native of Campeachy.

43. *Cassia Frutescens*. Leaflets five pairs, ovate, smooth, the outer ones longer; stems shrubby.—Native of Jamaica.

44. *Cassia Tetraphylla*. Leaflets two pairs, ovate; flowers solitary, axillary siliques hirsute; stems procumbent. Annual.—Native of La Vera Cruz.

45. *Cassia Minima*. Leaflets four pairs, oblong-ovate; stems procumbent; flowers axillary; peduncles two-flowered. Annual.—Native of Jamaica.

46. *Cassia Patula*; *Shining Cassia*. Leaflets five pairs, oblong, sharpish, smooth; a gland at the base of the petioles; branches even. It flowers in August and September.—Native of the West Indies.

47. *Cassia Stipulacea*; *Large-stipuled Cassia*. Leaflets about eight pairs, ovate-lanceolate; a gland between the lower; stipules ovate, very large.—Native of Chili.

48. *Cassia Frondosa*; *Smooth-leaved Cassia*. Leaflets nine

pairs, oval-oblong, smooth, bluntish; a cylindric gland between the lower; petiole without any gland at the base. It flowers in March and April.—Native of the West Indies.

49. *Cassia Sericea*. Leaflets about four pairs, ovate, hirsute; a subulate gland between the leaflets; peduncles four-flowered; legumes four-cornered.—Native of Jamaica.

50. *Cassia Lincata*. Leaflets five pairs, somewhat oblong, pubescent beneath, equal; an obsolete gland beneath the lowest; peduncles one-flowered.—Native of Jamaica.

51. *Cassia Virgata*. Leaflets ten pairs, ovate-lanceolate, villose; a petiolar pedicelled gland; peduncles one-flowered, longer than the leaves.—Native of Jamaica.

Cassia, *Poet's*. See *Osyris*.

Cassine; a genus of the class Pentandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth quinque-partite, inferior, very small, obtuse, permanent. *Corolla*: quinque-partite, spreading; divisions subovate, obtuse, larger than the calix. *Stamina*: filamenta five, subulate, spreading; antheræ simple. *Pistil*: germen superior, conic; style none; stigmas three, reflex, obtuse. *Pericarp*: berry roundish, trilocular, umbilicated with the stigmas. *Seeds*: solitary, subovate. ESSENTIAL CHARACTER. *Calix*: quinquepartite. *Petals*: five. *Berry*: trispermous.—The species are,

1. *Cassine Capensis*; *Cape Cassine*, or *Phillyrea*. Leaves petioled, ovate-oblong, retuse, crenate. It has a woody stalk, which seldom rises above five or six feet high in this country, with brown or purplish bark; flowers white, in axillary branched corymbs.—Native of the Cape. It is too tender to live abroad in England, but as it requires no artificial heat, may be preserved throughout the winter in a good green-house, where it deserves a place for the beauty of its leaves: it may be propagated by laying down those shoots which are near the root, but they are long in putting out roots; to facilitate this, the shoots should be twisted in the part which is laid; they should be laid in autumn, as they will then put out roots sufficient to remove in the following autumn. They may also be propagated by cuttings; but this is a tedious method, as they are seldom rooted enough to transplant in less than two years.

2. *Cassine Peragua*. Leaves petioled, serrate, elliptic, somewhat acute; branchless ancipital.—Native of Virginia and Carolina. It is propagated by laying down the branches, which afford shoots in plenty for that purpose from the root and lower part of the stem, so as to become very bushy and thick if they are not cut off; there are numbers of those shrubs which produce flowers in England every year, but none of them ripen their seeds; the leaves are frequently pinched by the frost in March, when they appear so soon: it loves a light soil, not too dry, and should have a warm situation; for in exposed places, the young shoots are frequently killed in the winter, whereby the shrubs are rendered unsightly; but where they are near the shelter of trees or walls, they are very rarely hurt.

3. *Cassine Barbara*. Leaves sessile, serrate-toothed, cordate, oblong; branchlets quadrangular.—Native of the Cape.

4. *Cassine Maurocenia*; *Great Hottentot Cherry*. Leaves sessile, quite entire, obovate, coriaceous.—Native of the Cape of Good Hope. For the propagation and culture of this plant, see the first species. It ripens its fruit in the winter; and having remarkably stiff and fine green leaves, makes a good appearance when fruit abounds.

Cassioberry Bush. See *Viburnum*.

Cassyta; a genus of the class Enncandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth triphyllous, very small, permanent; leaflets semi-ovate, acute, concave, erect. *Corolla*: petals three, roundish, acute, concave, permanent; nectary of three glands, oblong, truncate, coloured,

length of the germen, standing round it. *Stamina*: filamenta niae, erect, compressed; two globular glands seated on the sides of the base of the three interior filamenta; antheræ adjoined to the filamenta below the tip. *Pistil*: germen ovate, within the corolla and calix; style thickish, length of the stamina; stigma obscurely trifid, obtuse. *Pericarp*: receptacle growing out into a depressed globular drupe, crowned with the converging calix and corolla, perforated with a navel. *Seeds*: nut globular, acuminate with the converging stamina. ESSENTIAL CHARACTER. *Corolla*: calcine, sexpartite: nectary of three truncate glands, surrounding the receptacle; interior filamenta glanduliferous. *Drupe*: monospermous.—These may be propagated by cuttings, taken a week before planting, that they may have time to dry; then to be put into small pots of light sandy earth, and plunged into a moderate hot-bed.—The species are,

1. *Cassyta Filiformis*. Filiform, lax. Stems parasitical, twining, slender, succulent, branched, leafless, putting out numerous warts, resembling the feet of caterpillars, by which they adhere strongly to the stems and leaves of shrubs; flowers small, white, with a tinge of red; fruit about the size of a pea, white, shining, and sweet to the taste. This plant grows naturally in both Indies: Jacquin found it in the island of Tierra Bomba near Carthage; it also occurs in the Society and Friendly islands.

2. *Cassyta Conicula*. Branches woody, spinous.—Native of the mountains of the island of Celebes, among rotten trunks of trees; and of Java.

Castilleia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: one-leafed, tubular, longitudinally cloven in front beyond the middle, nerved, pubescent, coloured, somewhat swelling at the base, compressed at top; upper lip bifid, obtuse; lower none. *Corolla*: monopetalous, ringent; upper lip very long, curved inwards, emarginate, pubescent on the back; lower very short, trifid, with acute segments; nectary two glandular corpuscles, inserted into the throat of the corolla between the divisions of the upper lip. *Stamina*: filamenta four, inserted into the base of the corolla, the length of the upper lip, filiform, smooth, the lower pair a little shorter; antheræ twin, linear, oblique. *Pistil*: germen superior, oblong, compressed; style filiform, the length of the stamina; stigma simple, obtuse. *Pericarp*: capsule ovate, acuminate, compressed, even, two-celled, the partition contrary to the valves. *Seeds*: numerous, small. ESSENTIAL CHARACTER. *Calix*: tubular, compressed; upper lip bifid; lower none. *Corolla*: lower lip trifid, with two glands between the segments. *Capsule*: two-celled.—The species are,

1. *Castilleia Fissifolia*. Leaves pinnate, gashed at the tip; root branched, fibrous. Stem four or five feet high, rather herbaceous, erect, roundish, with few branches, pubescent.—Grows in New Granada.

2. *Castilleia Integrifolia*. Leaves linear-lanceolate, entire; stem herbaceous, round, upright, branched, leafy, slightly rough with hairs.—Grows in New Granada.

Casuarina; a genus of the class Monœcia, order Monandria.—GENERIC CHARACTER. *Males*, in a filiform ament, *Calix*: common ament loosely imbricate, consisting of small one-flowered one-leafed scales. *Corolla*: scales two-parted, ovate, minute. *Stamina*: filamenta capillary, longer than the calix; antheræ twin. *Females*, on the same plant. *Calix*: ament, ovate-cylindric; with ovate, acute, keeled, imbricate scales. *Corolla*: none. *Pistil*: germen minute; style filiform, longer than the calix, bifid; stigmas two. *Pericarp*: strobile of bivalve scales, gaping perpendicularly. *Seeds*: solitary conic, with a membranaceous edge. Es-

ESSENTIAL CHARACTER. *Male.* Calix: of the ament. *Corolla*: scalelets two-parted. *Female.* Calix: of the ament. *Corolla*: none. *Style*: bifid. *Strobile*:—The species are,

1. *Casuarina Equisetifolia*; *Horsetail Casuarina*. Monœcous: whorls of the stamina approximating. A very large, spreading, and lofty tree. The leaves, or rather branchlets, so called, hanging down in bunches from twelve to eighteen inches in length, like a long head of hair, or a horse's tail, all jointed from top to bottom, like the *Equiseta* or Horse's-tails, is a very remarkable character of this singular tree.—It is a native of the East Indies, and the South Sea islands; and flowers in October and November.

2. *Casuarina Nodiflora*. Monœcous: whorls of the stamina remote. A lofty tree; the branches and branchlets more deeply striated.—Native of the East Indies and New Caledonia.

3. *Casuarina Stricta*; *Upright Casuarina*. Diœcous: branchlets erect; scales of the strobiles unarmed, smoothish; male sheaths multifid, smooth.—Native of New South Wales.

4. *Casuarina Torulosa*; *Cork-barked Casuarina*. Diœcous: branchlets flaccid; scales of the strobiles villose, roughened with tubercles; male sheaths quadrifid.—Native of New South Wales

5. *Casuarina Africana*. Fronds filiform, swelling at the tip, and floriferous; strobiles roundish, axillary. This is a tree above the middle size, with few, long, diffused branches, and leaf-bearing reclining branchlets; the wood is very hard and heavy.—Native of the sandy east coast of Africa.

Catananche; a genus of the class Syngenesia, order Polygamia *Æqualis*.—**GENERIC CHARACTER.** *Calix*: common imbricate, turbinate; leaflets very many, loosely incumbent, acute, scariose; the squamule ovate-acuminate, concave, lax, glossy, permanent. *Corolla*: compound generally imbricate, uniform; corolla hermaphrodite, very many, the exterior ones longer; proper monopetalous, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: germen oblong; style filiform length of the stamina; stigma bifid, reflex. *Pericarp*: none. *Calix*: unchanged. *Seeds*: solitary, turbinate-ovate; down from a five-awned calicle. *Receptacle*: chaffy. **ESSENTIAL CHARACTER.** *Receptacle*: chaffy. *Calix*: imbricate. *Down*: awned from a five-bristled calicle.—The species are,

1. *Catananche Cœrulea*. The lower scales of the calix ovate. This sends out narrow hairy leaves, which are jagged on their edges like those of Buckthorn Plantain, lying flat on the ground, with their points turned upward: between the leaves come out the flower-stalks; these stalks rise nearly two feet high, dividing into many small branches upwards, with leaves like those below, but smaller; each of the peduncles is terminated with single heads of flowers, having a dry, silvery, scaly calix, in which are included three or four florets, whose petals are broad, flat, and indented at their ends; these are of a fine blue colour, having a dark spot at bottom in each of the stamina, and with their yellow summits standing a little above the petal, make a pretty appearance.—It is perennial; a native of the south of Europe; and flowers from July till October. It may be propagated by heads taken off the mother plant, either in spring or autumn; but those plants which are raised from seeds are much stronger than those which are raised from slips: they are commonly planted in pots filled with light sandy soil, in order to shelter them in the winter from severe frosts; but if they are planted in warm borders, near walls, pales, or hedges, in a moderately dry soil, they will endure abroad very well. It may also be propagated by seeds sown in March.

2. *Catananche Lutea*. The lower scales of the calix lanceolate. The flowers are yellow, and small; the leaves green, flexile, and three-nerved, smaller, smoother, and less jagged on their edges, than the first sort: the later flowers are sessile at the root, hardly unfolded, but more fertile.—Native of the island of Candia; it flowers in June and July. It is an annual plant, and therefore only propagated by seeds. Sow them early in March, in beds or borders of light earth; they will come up in a month or five weeks' time, and require no other care but to keep them clean from weeds, and thin them when they grow too close together.

3. *Catananche Græca*. Leaves gashed.—Native of the south of France, Spain, Italy, and Candia, from whence it derived the title of *Candia Lion's foot*.

Catchfly. See *Lychnis*.

Caterpillars. See *Scorpiurus*.

Catesbæa; a genus of the class Tetandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-toothed, superior, very small, acute, permanent. *Corolla*: monopetalous, funnel-form; tube extremely long, straight, gradually widening upwards; border semiquadrifid, broad, erect, flat. *Stamina*: filamenta four; growing within the neck of the tube; antheræ oblong, erect, almost longer than the corolla. *Pistil*: germen roundish, inferior; style filiform, length of the corolla; stigma simple. *Pericarp*: berry oval, crowned, unilocular. *Seeds*: many, angulate. **ESSENTIAL CHARACTER.** *Corolla*: monopetalous, funnel-form, extremely long, superior. *Stamina*: within the mouth. *Berry*: polyspermous.—The species are,

1. *Catesbæa Spinosa*; *Lily Thorn*. Tube of the corolla very long; berries oval. Discovered near Nassau Town in Providence, one of the Bahama islands. Mr. Catesby says, that the largest of the trees which he saw was about four inches thick, and twelve or fourteen in height; the bark smooth, of a greenish russet colour, and the wood seemingly tough and hard; the leaves like those of Box, but smaller, growing in clusters at intervals of about an inch; from every cluster two sharp pliant spines shooting out: the flowers are about six inches long, of an orange colour, in form of a Roman trumpet, except that they are divided at the verge into four deep segments, usually reflex; the fruit is the size of a pullet's egg; the pulp like that of a ripe apple, with an agreeable tartness, and a smooth yellow skin.—This shrub is propagated by seeds, which must be procured from the country where it naturally grows; if the entire fruit be brought over in sand, the seeds will be better preserved; and must be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark, and now and then moderately watered; if the seeds be good, the plant will appear in about six weeks after sowing, when, if the heat of the bed declines, the tan should be turned over to the bottom; and, if necessary, some fresh added to renew the heat, for these plants make but little progress the first year.—As these plants grow slowly, they will not require to be removed out of the seed-pots the first year: in the autumn the pots should be removed into the stove, and plunged into the tan-bed; they must be watered with great caution during the winter, and should be carefully taken up in spring, and separately planted in a small pot filled with light sandy earth, and plunged into a fresh hot-bed of tanner's bark, where they should be shaded until they have taken fresh root, and gently refreshed with water as they may require it: in warm weather a considerable share of fresh air should be admitted to them, but in autumn they must be removed into the stove, where they should constantly remain, and must be treated afterwards in the same manner as other tender exotic plants.

2. *Catesbæa Parviflora*. Tube of the corolla four-cornered, abbreviated; berries roundish.—Native of Jamaica. This as well as the first plant may be propagated by planting cuttings in small pots, filled with light earth, during the months of June and July; the pots should be plunged into a moderate hot-bed of tanner's bark, and the cuttings closely covered with small bell-glasses, to exclude the external air. If this be properly performed, the cuttings will put out roots in about two or three months, when they may be carefully separated, planting each into a small pot filled with light earth, and plunged into the hot-bed again, and must afterwards be treated as the seedling plants.

Cat's-Tail. See *Typha*.

Cat's-Grass. See *Phleum*.

Cat-Thyme. See *Teucrium*.

Caturus; a genus of the class Diœcia, order Triandria.—

GENERIC CHARACTER. *Male*. *Calix*: none. *Corolla*: monopetalous, tubular, semitrid; divisions ovate, concave, acute, permanent. *Stamina*: filamenta three, capillary, longer than the corolla; antheræ roundish. *Female*. *Calix*: perianth tripartite; leaflets ovate, flat, permanent. *Corolla*: none. *Pistil*: germen villose; styles three, long, pinnate-multifid; stigmas acute. *Pericarp*: capsulæ roundish, trilocular, trilocular. *Seed*: solitary, round.—The species are,

1. *Caturus Spiciflorus*. Spikes axillary, pendulous. This is a tree about twenty feet in height, with many branches diffused all round; the wood is white and close, with a thick, dusky, unctuous, inodorous bark, and a yellow pith within; flowers small, of an herbaceous colour.—Native of the East Indies; where a conserve of the flowers is used in the diarrhœa, and all disorders arising from a laxity of the vessels.

2. *Caturus Scandens*. Spikes axillary, upright; leaves oblong, subserrate; stem scandent. This is an unarmed shrub, with a long branching stem, climbing, but without tendrils. Flowers very small, white, in close short spikes, with small subulate bractes. The male flower has three petals, and three filamenta longer than the petals, both diverging elastically.—Native of the woods of Cochin-china.

Caucalis; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal unequal, with very few rays; umbel partial unequal, with more copious rays, of which the five exterior are longer. Involucre universal with leaflets of the number of the rays, undivided, lanceolate, membranaceous at the edge, ovate, short. Involucre partial, with consimilar leaflets, longer than the rays, often five; perianth proper five-toothed, protruded. *Corolla*: universal difform, radiate; disk florets abortive; proper one male, small; petals five, inflected-cordate, unequal, the exterior one very large, bifid. *Stamina*: in all the flowers; filamenta five, capillary; antheræ small. *Pistil*: germen of the ray oblong, rugged, inferior; styles two, subulate; stigmas two, spreading, obtuse. *Pericarp*: fruit ovate, oblong, with longitudinal streaks, hispid with little rigid bristles. *Seeds*: two, oblong, convex on one side, armed in the direction of the streaks with subulate points, flat on the other side. ESSENTIAL CHARACTER. *Corolla*: radiated in the disk, male. *Petals*: inflex emarginate. *Fruit*: hispid, with bristles. *Involucres*: entire.—These plants are all annual, or at most biennial, and are seldom cultivated except in botanic gardens. They will rise readily from seeds, where they are permitted to scatter; or if any person be desirous of raising them, the seeds should be sown in autumn, or soon after they are ripe. They will grow in any soil or situation.—The species are,

1. *Caucalis Grandiflora*; *Great-flowered Bastard Parsley*. Each involucre five-leaved; one leaflet double the size of the

rest. Stem very smooth and even, nearly two feet in height, and branched; leaves twice or thrice winged, finely cut, pale green, slightly villose; umbels two inches or more in diameter, of from five to eight rays; flowers white.—Native of the south of Europe.

2. *Caucalis Daucoïdes*; *Carrot-leaved Bastard Parsley*. Umbels trid, leafless; umbellules three-seeded, three-leaved. Stem a foot high, upright, angular-grooved, branched, and even, the joints white with bristles.—Native of the south of Europe.

3. *Caucalis Latifolia*; *Broad-leaved Bastard Parsley*. Involucres and involucrets membranaceous; universal umbel with about four rays; bristles of the seeds clustered and hispid; leaves pinnate, gashed, and hairy. This is the most beautiful of our native umbelliferous plants; stem from a foot to eighteen inches, or sometimes nearly two feet in height, branched, angular, set with short prickles pointing upwards. Corolla purplish; the outer petal large, the rest small.—Native of Germany, Switzerland, Italy, France, and England. It is one of our rare plants, and has been observed in Cambridgeshire and Hampshire, in corn-fields, flowering from June to August.

4. *Caucalis Mauritanico*; *Barbary Bastard Parsley*. Universal involucre one-leaved; partial involucrets three-leaved.—Native of Barbary.

5. *Caucalis Orientalis*; *Eastern Bastard Parsley*. Umbels spreading, partial; leaflets superdecompound, lacinated; small divisions linear. Stem herbaceous, round, straight, streaked, branching, three feet high.—Native of the Levant and China.

6. *Caucalis Leptophylla*; *Fine-leaved Bastard Parsley*. Universal involucre scarcely any; umbel bifid; involucrets five-leaved. Stem low, round, rugged backwards.—Native of the south of Europe, and of England, in corn-fields, and by way-sides; in Cambridgeshire, Lincolnshire, Norfolk, &c. flowering in June and July.

7. *Caucalis Arvensis*; *Corn Bastard Parsley*. Universal involucre scarcely any; seeds ovate; styles reflex; leaves decompound; outmost leaflet linear-lanceolate; stem branching very much. Common in England; and growing wild in Switzerland.

8. *Caucalis Anthriscus*; *Hedge Bastard Parsley*. Involucres many leaved; seeds ovate; styles reflex; leaves decompound; outmost leaflet linear, lanceolate. Stem from four to six feet high, upright, somewhat flexuose, round, purplish, rough, covered with minute white rigid bristles, pressed downwards to the stem, and scarcely visible. Dr. Withering says, that horses are fond of it.—It is common in hedges and bushes, flowering in July and August.

9. *Caucalis Nodosa*; *Knotted Bastard Parsley*. Umbels simple, sessile; leaves superdecompound. Stems two, three, or more, round, striated, rough, branched, commonly prostrate, from a span to a cubit in length.—Native of the south of Europe, and of England, on the borders of corn-fields, and on banks; flowering from May till August.

Cauliflower. See *Brassica*.

Ceanothus; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, turbinate; border five-parted, acute, close, converging, permanent. *Corolla*: petals five, equal, roundish, of an arched sacular shape, compressed, very obtuse, spreading, smaller than the calix, seated on claws the length of the petal, growing from the interstices of the calix. *Stamina*: filamenta five, subulate, erect, opposite to the petals, the length of the corolla; antheræ roundish. *Pistil*: germen superior, triangular; style cylindrical, semitrid, the length of the stigma; stigma obtuse. *Pericarp*: berry dry, three-grained or three-celled, obtuse, retuse, set with tubercles. *Seed*: soli-

CERES SILIQUASTRUM — Common Judas Tree.

CHELIDONIUM — Common or Great Celandine.

tary, ovate. **ESSENTIAL CHARACTER.** *Petals*: five, saccular, vaulted. *Berry*: dry, three-celled, three-seeded.—The species are,

1. *Ceanothus Americanus*; *American Ceanothus*, or *New Jersey Tea*. Leaves three-nerved. In England this shrub seldom rises more than three or four feet high, sending out branches on every side, from the ground upward; leaves alternate, deciduous, on short petioles: at the extremity of each shoot, the flowers are produced in close thick spikes, and are composed of five small petals of a clear white; they appear in July, and make a pretty appearance during their continuance; for as every shoot is terminated by one of these spikes, the whole shrub is covered over with flowers, the branches commonly growing very close to each other; and when the autumn proves mild, they often flower again in October.—Native of most parts of North America. The leaves dried, are used in America for the same purpose as tea. The Canadians use the root in venereal cases: it dies wool a fine strong Nankin cinnamon colour. These are best propagated by seeds, which should be sown in the autumn in small pots, and plunged into an old hot-bed, where they may remain during the winter. In the following summer, place them in the open air during mild weather, but screen them from the cold. The following spring they should be transplanted before they begin to shoot, in which state they may remain a year or two; when they may be finally removed to the places where they are designed to remain. They require a dry soil and sheltered situation.

2. *Ceanothus Asiaticus*; *Asiatic Ceanothus*. Leaves ovate, nerveless; branches alternate, flexuose, striated, smooth.—Native of Ceylon and Japan. It may be increased by layers or cuttings, and must have the protection of a bark-stove.

3. *Ceanothus Africanus*; *African Evergreen Ceanothus*. Leaves lanceolate, nerveless; stipules roundish. It rises to the height of ten or twelve feet, with a woody stem, covered with a rough dark-coloured bark, and sends out many weak branches, which hang downward; these while young are green, but afterwards change to a purplish colour: they are garnished with oblong pointed leaves of a lucid green, smooth and slightly serrate on their edges: the flowers are small, of an herbaceous colour, coming out from the side of the branches: they sometimes appear in July, but are not succeeded by seeds in this country, nor do the plants often produce flowers; so that they are merely preserved for the beauty of their shining evergreen leaves, which make a variety in the green-house during the winter season. They are generally propagated by cuttings, as that is the surest and most expeditious way: they should be planted in spring, in pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, observing to shade them in the heat of the day, and now and then to refresh them with water; in two months, or less, they will have taken root, when they must be gradually inured to the open air, placing them in a sheltered situation till they have obtained strength, when they may be separated, and each planted in a small pot filled with light earth, placing them in the shade until they have taken fresh root; then they may be removed, intermixed with other exotic plants, and treated in the same manner.

4. *Ceanothus Reclinatus*. Leaves ovate, entire, many-nerved; branches hanging down.—Native of Jamaica.

5. *Ceanothus Circumscissus*. Leaves obcordate, opposite, in two rows; prickles solitary, recurved, opposite to the leaves; branches simple, opposite, spreading very much, angular, even.—Native of the East Indies, Ceylon, and Mauritius.

6. *Ceanothus Capsularis*. Leaves ovate-cordate, acuminate. I.—23.

nate, serrate; capsules three-valved, gaping.—Native of Otaheite.

Cecropia; a genus of the class Diœcia, order Diandria.—**GENERIC CHARACTER.** *Male. Calix*: spathe ovate, bursting, caducous; aments very many, fasciculate, columnar, imbricate with scales; the scales (receptacles) copious turbinate, compressed-quadrangular, obtuse, with a double perforation. *Corolla*: none, unless the scales be called nectaries. *Stamina*: filamenta two, capillary, very short, from the perforations of the scales; antheræ oblong, quadrangular. *Female. Calix*: spathe; aments four, columnar, imbricate, with germina. *Corolla*: none. *Pistil*: germina many, imbricate, compressed-quadrangular, obtuse; styles solitary, very short; stigmas somewhat headed, lacerated. *Pericarp*: berry the form of the germen, one-celled, one-seeded. *Seed*: oblong, compressed. **ESSENTIAL CHARACTER.** *Male. Spathe*: caducous. *Ament*: imbricate with turbinate scales, compressed-quadrangular. *Corolla*: none. *Female* as in the *Male. Germina*: imbricate. *Style*: onc. *Stigma*: lacerated. *Berry*: one-seeded.—The only known species is,

1. *Cecropia Peltata*; *Trumpet-tree*, or *Snake-wood*. This tree seldom falls short of thirty-five or forty feet high, in the most perfect state: trunk a foot in diameter, hollow, stopped from space to space with membranous septa, which form slight annular marks on the surface; leaves in clusters at the ends of the branches, large, divided into nine or ten oblong lobes, on long petioles: the fruits rise four, five, or more, from the very top of a common peduncle, and shoot into so many oblong cylindrical berries, composed of a row of little acini, something like our raspberry, which they resemble in flavour when ripe, and are on that account agreeable to most European palates. The wood of this tree, when dry, is very apt to take fire by attrition. The native Indians have taken the hint, and always kindle their fires in the woods, by rubbing a piece of it against some harder wood. The bark is strong and fibrous, and is frequently used for all sorts of cordage. The trunk is very light, and for that reason much used for bark logs, and fishing floats. The smaller branches, when cleared of the septums, serve for wind-instruments. Both trunk and branches yield a great quantity of fixed salt, which is much used among the French to despumate and granulate their sugars. The fruit is much fed upon by pigeons and other birds; and thus the tree is spread and propagated.—Native of Jamaica, and other West India Islands, and also of South America. It may be propagated by seeds, procured from the places of natural growth. They should be brought over in sand; for if they be put up in moist papers, they will be apt to grow mouldy. It requires the same treatment as other tropical plants.

Cedrela; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth monophyllous, campanulate, very small, five-toothed, withering. *Corolla*: funnel-form, pentapetalous, the tube bellied below; petals linear-oblong, obtuse, erect, adjoined to the receptacle at one-third beneath. *Stamina*: filamenta five, subulate, seated on the receptacle, shorter than the corolla; antheræ oblong, bent outwards at the tip. *Pistil*: receptacle proper, five-cornered; germen globular; style cylindrical, length of the corolla; stigma headed, depressed. *Pericarp*: capsule superior, woody, roundish, five-celled, five-valved, the

valves deciduous. *Seeds*: numerous, fleshy, imbricate downwards, terminated by a membranaceous wing; receptacle woody, five-angled, free. **ESSENTIAL CHARACTER.** *Calix*: withering. *Corolla*: five-petalled, funnel-form, fastened by the base to the receptacle to one-third of its length. *Capsule*: woody, five-celled, five-valved. *Seeds*: imbricate downwards, with a membranaceous wing.—The only species known is,

1. *Cedrela Odorata*; *Barbadoes Bastard Cedar*. Flowers paniced. This tree rises with a straight stem, to the height of seventy or eighty feet: while young, the bark is smooth, and of an ash-colour, but becomes rougher and darker by age; leaves near three feet long, winged with 16 or 18 pairs of leaflets without an odd one; corollas whitish, flesh-coloured, liliaceous, resembling that of the hyacinth. The fruit is oval, about the size of a partridge's egg, smooth, of a very dark colour, and opens in five parts, having a five-cornered column standing in the middle, between the angles of which the winged seeds are closely placed, lapping over each other like the scales of fish. The trunk is covered with a rough bark, marked with longitudinal fissures, and, as well as the berries and leaves, has a smell like assafetida when fresh; the wood has, notwithstanding, a pleasant smell.—This tree is commonly known under the name of Cedar, in the British West India islands: the trunk is so large, that the natives hollow it out into canoes and peraguas, for which purpose it is extremely well adapted, the wood being so soft that it may be cut out with great facility, and so light that it will carry a great weight upon the water. There are canoes in the West Indies, which have been formed out of these trunks, forty feet long, and six broad: the wood is of a brown colour, and has a fragrant odour, whence the title of Cedar has been given to it: it is frequently cut into shingles for covering houses, and is found very durable; but as the worms are apt to eat this wood, it is not proper for building ships, though it is often used for that purpose, as well as for sheathing them: it is often used for wainscoting of rooms, and to make chests, because vermin do not so frequently breed in it, as in many other sorts of wood, owing to its very bitter taste, which is communicated to whatever is put into the chests, especially when the wood is fresh; for which reason it is never made into casks, because spirituous liquors will dissolve part of the resin, and thereby acquire a very bitter taste: it yields a fine essential oil, and a spirit not inferior to that which is drawn from Rosemary.—It is propagated by seeds, which may be easily procured from the West Indies: they must be sown upon a hot-bed in the spring, and the plants treated in the same manner as the Mahogany.

Cedrota; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, six-parted; parts ovate, obtuse, concave. *Corolla*: none. *Stamina*: filamenta eight, short; antheræ roundish. *Pistil*: germen superior, roundish, surrounded by a gland; style short; stigma obtuse. **ESSENTIAL CHARACTER.** *Calix*: six-parted. *Corolla*: none. *Germen*: superior, surrounded by a gland. *Style*: short.—The only known species is,

1. *Cedrota Guianensis*. A tree forty feet high, and two in diameter, with a thick, unequal, wrinkled bark, full of clefts; and a yellow, heavy, aromatic wood, which however becomes light when dry. Branches near the top of the trunk, numerous; leaves about seven inches long, and two broad; flowers very small, green, loosely racemed, on a long, weak, axillary peduncle.—It grows in the forests of Guiana, flowering in May: the inhabitants call it *bois de cedre*, and use it for making their *pirogues*; it is also fit for masts.

Celastrus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, half five-cleft, flat, small; divisions obtuse, unequal. *Corolla*: petals five, ovate, spreading, sessile, equal, reflected at the borders. *Stamina*: filamenta five, subulate, length of the corolla; antheræ very small. *Pistil*: germen very small, immersed in a large flat receptacle, which is marked with ten streaks; style subulate, shorter than the stamina; stigma obtuse, trifid. *Pericarp*: capsule coloured, ovate, obtusely triangular, gibbous, trilocular, trivalvular. *Seeds*: few, ovate, coloured, smooth, half involved in an unequal coloured *arillus*, with a four-cleft mouth. **ESSENTIAL CHARACTER.** *Corolla*: five-petalled, spreading. *Capsule*: triangular, trilocular. *Seed*: calyptated.—This genus consists of shrubs or small trees, with alternate leaves, and the flowers many together, on axillary subdichotomous peduncles.—The species are,

1. *Celastrus Bullatus*; *Virginian Staff Tree*. Unarmed: leaves ovate, quite entire. It rises to the height of eight or ten feet; but in England there are few of these shrubs much more than half that height. This shrub flowers in July, but rarely produces good seeds in England. The flowers come out at the ends of the branches, in loose spikes, and are white; the capsule is of a scarlet colour, set full of small protuberances, opening into three cells, each containing a hard oval seed, covered with a thin red pulp.—It grows naturally in Virginia, and many other parts of North America. It is propagated by layers, which will take root in one year; the young branches only are proper for this purpose, so that when there are not any of these near the ground, the main stalks should be drawn down and fastened with pegs to prevent their rising, and the young shoots from them should be laid: the best time for doing this is in autumn, when they begin to cast their leaves, and by that time twelvemonth they will be sufficiently rooted, and should be cut off from the old plant, and be replanted in the nursery for two or three years to get strength, after which they must be removed to the places where they are to remain: it grows naturally in moist places, and will not thrive in a dry soil, although it be very hardy, and bears the cold of our winters very well. It is also propagated by seeds brought from America, but as these rarely arrive in time to sow before the spring, the plants never come up the first year; therefore the seeds may be sown either in pots or in a bed of loamy earth, keeping them clean from weeds during the summer, and those in the pots in the shade till the autumn, when the pots should either be plunged into the ground in a warm situation, or placed under a common frame, to prevent the frost from penetrating through the side of the pots; and if the surface of those which are plunged into the ground, and also the beds where the seeds are sown, be lightly covered with some old tan from a decayed hot-bed, it will secure the seeds from being hurt by severe frosts. If the plants make a good progress the first summer, they may be transplanted into a nursery in autumn, otherwise they should remain in the seed-bed till the second year, when they may be treated in the same manner as the layers.

2. *Celastrus Scandens*; *Climbing Staff Tree*. Unarmed; stem twining. It sends out several woody stalks, which are flexible, and twist themselves round trees and shrubs, or round each other, to the height of twelve or fourteen feet or more, girding trees so closely as in a few years to destroy them. Leaves alternate, petioled, smooth; flowers small, whitish green. It flowers in the beginning of June, and the seeds ripen in autumn.—Native of North America and Japan. The seeds of this species generally ripen well in England, and

this may be propagated from these or by layers, as in the former; it delights in a strong loamy soil, rather moist than dry, and will grow in woods among other trees and shrubs; where, when the fruit is ripe, it makes a pretty appearance, and is remarkably hardy.

3. *Celastrus Myrtifolius*; *Myrtle-leaved Staff-Tree*. Unarmed; leaves ovate, finely serrate; flowers racemed; stem erect.—Native of North America.

4. *Celastrus Procumbens*; *Procumbent Staff Tree*. Unarmed, procumbent: leaves ovate, serrate; flowers axillary, subsolitary.—Native of the Cape of Good Hope. This, as well as all the Cape sorts, may be propagated by cuttings, which is more expeditious than raising them from seeds, which rarely come up the same year: the cuttings may be planted any part of the summer, but those which are planted early will have more time to acquire strength before the winter: let them be put into small pots filled with good kitchen-garden earth, four together; plunge them into a moderate hot-bed, shade them from the sun, and occasionally refresh them with water, expose them gradually to the open air when they have taken root, and then place them in a sheltered situation until they become strong. After which, plant each in a small pot; place them in the shade till they have taken root; and then treat them as other exotics.

5. *Celastrus Filiformis*; *Filiform-branched Staff Tree*. Unarmed: leaves lanceolate, entire; branches filiform; peduncles axillary, one-flowered.—Found at the Cape.

6. *Celastrus Acuminatus*; *Acuminate-leaved Staff Tree*. Unarmed: leaves ovate, acuminate, serrate; peduncles axillary, one-flowered; stem erect, lax.—Found at the Cape.

7. *Celastrus Microphyllus*. Unarmed: leaves ovate, obtuse, entire; cymes terminal, dichotomous.—Found at the Cape, as also the three former, by Thunberg.

8. *Celastrus Articulatus*. Unarmed: leaves rounded, acuminate, serrate; peduncles axillary, subtrifid; stem shrubby, erect.—Observed by Thunberg in Japan.

9. *Celastrus Dilatatus*. Leaves obovate, cusped, serrate at the tip, and smooth; stem unarmed.—Observed by Thunberg in Japan.

10. *Celastrus Striatus*. Unarmed: branchlets erect, striated; leaves ovate, acuminate, serrate; peduncles scattered, one-flowered.—Observed by Thunberg in Japan.

11. *Celastrus Alatus*; *Wing-branched Staff Tree*. Unarmed: branches winged; stem shrubby, a fathom in height; seeds arilled. This is a handsome shrub, singular for its winged branches; the Japanese frequently cultivate it in their gardens, and the young men hang bunches of the flowers before the doors of the houses where the young women reside, when they wish to signify their desire to pay their addresses to them.—Grows in Japan.

12. *Celastrus Buxifolius*; *Box-leaved Staff Tree*. Spines leafy; branches angular; leaves obtuse. It flowers in May and June, and is a native of the Cape.

13. *Celastrus Pyracanthus*; *Pyracantha-leaved Staff Tree*. Spines naked; branches round; leaves acute. A loose irregular shrub, three feet high; flowers from the sides of the branches in loose tufts; fruit large, about the size of a cherry, egg-shaped, with three obtuse angles, pendent.—It is a native of the Cape; whence the seeds were first brought to the gardens of Holland, and thence distributed among most of the curious gardens in Europe.

14. *Celastrus Lucidus*; *Shining Staff Tree*, or *Small Hot-tentot Cherry*. Leaves oval, shining, quite entire, margined. It is an upright shrub, with brown hard branches. It flowers in April and September, and is a native of the Cape.

15. *Celastrus Linearis*; *Linear-leaved Staff Tree*. Spines leafy; leaves linear, entire. Found by Thunberg at the Cape of Good Hope.

16. *Celastrus Integrifolius*; *Entire-leaved Staff Tree*. Spines leafy; leaves ovate, obtuse, quite entire; cymes lateral.—Found at the Cape.

17. *Celastrus Crenatus*; *Notch-leaved Staff Tree*. Unarmed: leaves ovate, crenulate; cymes axillary.—Native of the Marquesas Islands in the South Seas.

18. *Celastrus Corniculatus*. Leaves oval, quite entire, perennial; capsule three-horned.—Native of the Cape.

19. *Celastrus Cassinoides*; *Crenated Staff Tree*. Unarmed: leaves ovate, acute both ways, loosely toothed; perennial; flowers axillary.—It flowers in August and September; and is a native of the Canary Islands.

20. *Celastrus Phyllacanthus*. Thorns leafy; leaves lanceolate, serrate, perennial; flowers lateral, very small. A bushy shrub, two or three feet high; young branches reddish; leaves on short petioles. Found in Senegal.

21. *Celastrus Octogonus*; *Angular-leaved Staff Tree*. Unarmed: leaves elliptic, angular, almost nerveless. Perennial; capsules bivalve, one-seed; leaves glaucous.—Found in Pegu by Dombey, flowering in October.

22. *Celastrus Undulatus*; *Wave-leaved Staff Tree*. Unarmed: leaves nearly opposite, lanceolate, waved; capsules bivalve, many-seeded.—Found by Commerson in the island of Bourbon, where they call it *bois de joli cœur*; and use it as an antispasmodic.

Celeri, or *Celery*. See *Apium*.

Celosia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets lanceolate, dry, acute, permanent, stiffish, caliciform; nectary a margin surrounding the germen, very small, five-cleft. *Stamina*: filamenta five; subulate, conjoined at the base to the plaited nectary, length of the corolla; and antheræ versatile. *Pistil*: germen globular; style subulate, straight, length of the stamina; stigma simple. *Pericarp*: capsule globular, surrounded by the corolla, one-celled, circumcised. *Seeds*: few, roundish, emarginate. ESSENTIAL CHARACTER. *Calix*: three-leaved; leaflets similar to those of the five-petalled corolla. *Stamina*: conjoined at the base to the plaited nectary. *Capsule*: gaping horizontally.—The *Celosias* are all herbaceous plants, and annuals; the flowers are glomerate, in spikes or panicles, some of which are flattened, and shaped something like the comb of a cock, and hence they have been called *Cockscombs*.—The species are,

1. *Celosia Argentea*; *Silvery-spiked Celosia*. Leaves lanceolate; stipules subfalcated; peduncles angular; spikes scariose.—Native of the East Indies, China, Cochin-china, and Japan: it flowers from June to September.

2. *Celosia Margaritacea*. Leaves ovate; stipules falcated; peduncles angular; spikes scariose.—Native of America.

3. *Celosia Cristata*; *Crested Amaranth*, or *Cockscomb*. Leaves oblong-ovate; peduncles round, substriated; spikes oblong. This is a plant, well known by its common appellation of *Cockscomb*, which it especially received from the form of its crested head of flowers, resembling the comb of a cock. There are many varieties, differing in form, size, and colour, from the same seed: the principal colours of their heads are red, purple, yellow, and white; but some are variegated with two or three colours.—It is a native of Asia. Thunberg informs us, that the crests or heads of flowers are frequently a foot in length and breadth in Japan, where they are extremely beautiful, but that they degenerate in other countries.—*Propagation*. In order to have fine large Ama-

ranths, great care should be taken in the choice of seed, for if they be not carefully selected, the whole expense and trouble of raising them will be lost: they must be sown on a hot-bed which has been prepared a few days before, that the violent heat may abate, about the beginning of March; and if the bed be in good temper, in about a fortnight's time the plants will rise; but as they are tender when they first appear, they require great care for a few days, till they get strength; first in giving them a due proportion of air, to prevent their drawing up weak, and next to keep them from too great moisture, a small quantity of which will cause their tender stems to rot: in sowing the seeds, care must be taken not to put them too close, for when the plants come up in clusters, they frequently spoil each other for want of room to grow; in a fortnight or three weeks' time, they will be fit to remove, when you must prepare another hot-bed, covered with good light rich earth, about four inches thick; which should be made a few days, that it may have a proper temperature of heat; then raise up the young plants with your finger, so as not to break off the tender roots, and prick them into the new hot-bed about four inches' distance every way, giving them a gentle watering, to settle the earth to their roots; but in doing this be very cautious not to bear the young plants down to the ground by hasty watering. After the plants are thus replanted, they must be screened from the sun till they have taken fresh root; but as there generally is a great steam arising from the fermentation of the dung, which condenses against the glasses, and dropping upon the plants, very frequently destroys them; the glasses should be frequently turned in the day-time, whenever the weather will permit; but if the weather happen to prove bad, it will greatly assist the plants to wipe off all the moisture two or three times a day with a woollen cloth, to prevent its dropping upon the plants: when your plants are firmly rooted and begin to grow, you must observe to give them more or less air every day, let the weather be cold or hot, to prevent their drawing up too fast, which greatly weakens their stems: in about a month or five weeks these plants will have grown so as to meet; therefore another hot-bed, of a moderate temperature, should be prepared, and covered with the same rich earth, about six inches thick, in which they should be planted (observing to take them up with as much earth about their roots as possible) at seven or eight inches' distance every way, giving them some water to settle the earth about their roots, but taking care not to water them heavily, so as to bear them down: they must be kept shaded in the heat of the day, until they have again taken root, and should be gently refreshed with water in proportion to the heat of the weather, covering the glasses with mats every night, lest the cold chill your beds, and stop the growth of the plants. In the middle of May you must provide another hot-bed, which should be covered with a deep frame, that your plants may have room to grow: upon this hot-bed you must set as many threepenny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious steams; then with a trowel take up the plants, with as much earth as possible to the roots, and place each plant in the middle of one of the pots, filling the pot up with the earth before described, and settling it close to the root of the plant by the hand; then water them gently as before, and shade them in the heat of the day from the violence of the sun, by covering the glasses with mats; refresh them often with water, and give them a good quantity of air in the day-time: in about three weeks more these

plants will have grown to a considerable size and strength, so that you must now raise the glasses very much in the day-time; and when the air is soft and the sun is clouded, draw off the glasses, and expose them to the open air, and repeat it as often as the weather will permit, which will harden them by degrees, and prepare them to be removed abroad into the plants where they are to remain the whole season; but it is not advisable to set these plants out till some time in July, observing to do it when the air is perfectly soft, and, if possible, in a gentle shower of rain. Let them be at first set near the shelter of a hedge for two or three days, where they may be screened from the violence of the sun and strong winds, to which they must be inured by degrees: these plants perspire very freely when they have grown to a good stature, and must be refreshed every day with water, if the weather prove hot and dry, otherwise they will stunt, and never produce their plumes so fine as when they are taken care of.—The above is the proper management in order to have fine Amaranths, which, if rightly followed and the kinds be good, in a favourable season will produce wonderful large fine heads, and are the greatest ornament to a good garden for upwards of two months: by this method plants five or six feet high, with crests nearly a foot in breadth, have been raised; and if the kind be good, and there be no want of dung or conveniences, in a kindly season they will grow much larger. By the middle or end of September, the Amaranths will have perfected their seeds, so that you must make choice of the largest, most beautiful, and least branching plants, of each kind, for seed; which you should remove under shelter, especially if the weather prove wet or the nights frosty, that the seeds may be perfectly ripened. The seeds should not be taken from side-branches or the neck of the plume, but those only which are produced in the middle of the plant, which, though generally few in number, are the only ones that can be depended upon for producing good plants in the succeeding year.

4. *Celosia Paniculata*; *Panicled Celosia*. Leaves ovate-oblong; stem rising, panicled; spikes alternate, terminal, remote. Mr. Miller says, that the stems are nearly four feet in length, and that the slender spikes are of a pale yellow, shining with a gloss like silk; that it grows naturally in most of the sugar islands, and that Dr. Houston sent him the seeds from Jamaica.

5. *Celosia Coccinea*; *Scarlet Celosia*, or *Chinese Cockscomb*. Leaves ovate, stiff, earless; stem grooved; spikes manifold, crested. It has a furrowed stalk, four or five feet high, and terminated by several spikes of flowers variously formed, some being crested, others plumed like feathers, of a bright scarlet colour, and making a good appearance.—Native of China.

6. *Celosia Castrensis*; *Branched Celosia*, or *Cockscomb*. Leaves lanceolate-ovate, marked with lines, very much acuminate: stipules falcated; spikes crested.—Native of the East Indies; cultivated generally in China and Cochin-china.

7. *Celosia Trigynia*; *Oval-leaved Celosia*. Leaves ovate-oblong; raceme lax; pistil trifid. Stem upright, simple, slightly angular, striated, stiff, a foot and half high; corolla ovate, acute, scariose, permanent.—Native of Senegal.

8. *Celosia Lanata*; *Woolly Celosia*. Leaves lanceolate, tomentose, obtuse; spikes crowded; stamina woolly. This rises with a white woolly stalk from two to three feet high.—Native of the island of Ceylon.

9. *Celosia Gnaphaloides*. Shrubby, woolly: leaves opposite, ovate, white beneath; head globular, peduncled.—It was found on Monte Video in Brasil.

10. *Celosia Nodiflora*; *Knotted Celosia*. Leaves wedge-

form, somewhat acute; spikes globular, lateral.—There are two varieties; the one comes from Sumatra, and the other from Malabar. It flowers in July and August.

11. *Celosia Procumbens*; *Procumbent Celosia*. Stems decumbent; peduncles very long, leafless; spikes ovate, approximating; capsules compressed, crested, winged. Stems two feet high.—Native of St. Domingo.

12. *Celosia Monsoniæ*; *Downy Celosia*. Spikes compact, cylindric; branches brachiate; leaves subulate. Stems prostrate, branching.—Native of the East Indies.

13. *Celosia Polygonoides*. Leaves cordate; stem hispid; raceme spiked; loose; flowers three-styled. Stem almost upright, striated.—Sent by Kœnig from Tranquebar.

14. *Celosia Baccata*. Flowers three-styled; fruits berried; stem upright; flowers small, on very short peduncles.—Found in the East Indies,

Celsia; a genus of the class Didymia, order Angiosperma.—GENERIC CHARACTER. *Calix*: perianth five-parted; divisions lanceolate, obtuse, length of the corolla, permanent. *Corolla*: monopetalous, rotated; tube extremely short; border flat, half five-cleft, unequal; divisions roundish, of which the two superior ones are smaller, the inferior one larger. *Stamina*: filamenta four, capillary, inclined towards the smallest divisions of the corolla, of which the two longer ones are shorter than the corolla, and are outwardly woolly; antheræ roundish, small. *Pistil*: germen roundish; style filiform, length of the stamina; stigma obtuse. *Pericarp*: capsule roundish, compressed at the tip, acuminate, sitting on the calix, bilocular. *Seeds*: very many, small, angular; receptacles solitary, hemispherical. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: rotated. *Filamenta*: bearded. *Capsule*: two-celled.—The species are,

1. *Celsia Orientalis*; *Oriental Celsia*. Leaves bipinnate. It flowers in June, and the seeds ripen in September. Stem a foot and a half high, upright, herbaceous, cylindrical, simple or furnished with short branches; leafy from the top; leaves alternate, scattered, those from the root oblong, lying flat on the ground; flowers pale yellow, small, solitary, sessile, axillary. Annual.—Native of the Levant. If the seeds be sown on a warm dry border as soon as they are ripe, the plants will often come up and live through the winter, if the soil be poor; on rich ground they are apt to grow rank, and then they are generally destroyed by the early frosts, or will rot with much wet; but if the plants should not rise the same autumn, there will be little hazard of their not growing in the following spring. They only require to be weeded, and thinned when too close; for as they do not bear removing well, they should be sowed where they are intended to remain: sometimes when the season proves warm, the plants sown in the spring produce ripe seeds; but they cannot be depended upon.

2. *Celsia Arcturus*; *Scallop-leaved Celsia*. Radical leaves lyrate-pinnate; peduncles longer than the flowers; corolla yellow. Biennial.—Native of Crete. It requires the protection of a green-house.

3. *Celsia Cretica*; *Great-flowered Celsia*. Radical leaves lyrate; stem-leaves subcordate, embracing; flowers subsessile; corolla yellow, with two ferruginous spots at the upper part of the tube. Biennial.—Native of the East Indies, flowering in July. It also requires the protection of a green-house.

4. *Celsia Linearis*. Leaves tern, linear, toothletted. This is an elegant evergreen smooth shrub; the trunk is woody, but weak, the thickness of a quill, striated, pale brown, three feet high, putting out numerous spreading branches its whole length; the younger ones green, grooved, and very leafy; leaves growing three together, spreading much, the largest two inches long; corolla brilliant scarlet, with a blood-red

throat.—Found in Peru by Dombey. It may be propagated both by seeds and cuttings; and though it succeeds best in a moderate stove, will bear to be treated as a green-house plant.

Celtis; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite Flowers*, solitary, superior. *Calix*: perianth one-leaved, five-parted; divisions ovate, patulous, withering. *Corolla*: none. *Stamina*: filamenta five, very short, concealed at first by the antheræ, but growing longer after the shedding of the pollen; antheræ oblong, thickish, quadrangular, four-furrowed. *Pistil*: germen ovate, acuminate, length of the calix; styles two, spreading, variously inflected, subulate, pubescent on every side, very long; stigmas simple. *Pericarp*: drupe globular, one-celled. *Seed*: nut roundish. *Male Flowers*, on the same plant, inferior. *Calix*: perianth six-parted; the rest as in the hermaphrodites. *Corolla*: none. *Stamina*: six; the rest as in the hermaphrodites. ESSENTIAL CHARACTER. *Hermaphrodite. Calix*: five-parted. *Corolla*: none. *Stamina*: five. *Styles*: two. *Drupe*: one-seeded. *Male. Calix*: six-parted. *Corolla*: none. *Stamina*: six. These trees are all propagated by seeds, which should be sown soon after they are ripe, when they can be procured at that season; for such frequently come up in the following spring; whereas those which are sown in the spring, will not come up till a twelve-month after: therefore it is the best way to sow them in pots or tubs, that they may be easily removed; for those which are sown in the spring should be placed in a shady situation in summer, and constantly kept clean from weeds, but in autumn they should be placed in a warm situation, plunging the pots into the ground; and if they be covered over with a little tan from a decayed hot-bed, it will prevent the frost from penetrating the earth to injure the seeds; and if these pots be placed on a gentle hot-bed in the spring, it will greatly forward the vegetation of the seeds, whereby the plants will have more time to get strength before the winter: but when the plants appear above ground, they must have a large share of air admitted to them, otherwise they will draw up weak; and as soon as the weather is warm, they must be exposed to the open air, and in summer they must be constantly kept clean from weeds; if the season prove dry, they will require water two or three times a week. In autumn it will be proper to remove the pots, and place them under a hot-bed frame, to shelter them in winter from severe frost; or, where there is not that convenience, the pots should be plunged into the ground near a wall or hedge; and, as the plants when young are full of sap, and tender, the early frosts in autumn frequently kill the upper part of the shoots; therefore the plants should be either covered with mats, or have a little straw or pease-haulm laid over to protect them. In the following spring the plants should be taken out of the seed-pots, and planted in the full ground; this should be done about the middle or latter end of March, when the danger of the frost is over; therefore a bed or two should be prepared according to the number of plants raised, in a sheltered situation, and, if possible, in a gentle loamy soil. The ground must be well trenched, and cleared from the roots of bad weeds, and when levelled, should be marked out in lines at one foot distance; then the plants should be carefully turned out of the pots and separated, so as not to tear their roots, and planted in the lines at six inches asunder, pressing the earth down close to their roots. If the ground be very dry when they are planted, and there be no appearance of rain soon, it will be proper to water the beds to settle the ground to the roots of the plants; and after this, if the surface of the ground be covered with some old tan or rotten dung, it will keep it moist, and prevent the drying winds from penetrating to the

roots of the plants. The following summer the necessary care must be to keep them constantly clean from weeds ; but after the plants are pretty well established in the ground, they will not require any water, especially toward the latter end of summer, for that will occasion their late growth, whereby they will be in great danger of suffering by the autumnal frosts ; for the more any of these young trees are stopped in their growth by drought towards autumn, the firmer will their texture be, and the better able to bear the cold. The plants may remain in these nursery beds two years, by which time they will have acquired sufficient strength to be transplanted where they are designed to remain, because these plants extend their roots wide every way ; so that if they stand long in the nursery their roots will be cut in removing, which will be a great prejudice to their future growth.—The species are,

1. *Celtis Australis* ; *European Nettle Tree*. Leaves ovate-lanceolate. The European Nettle-tree, or Lote-tree, rises with an upright stem, to the height of forty or fifty feet, with many slender branches, and a smooth dark-coloured bark with some grey spots ; leaves alternate, nearly four inches long and two broad ; flowers axillary all along the branches, composed of a green calix without any corolla ; fruit the size of a small cherry, black.—It grows naturally in the south of Europe, where it is one of the largest trees : the wood is one of the hardest we are acquainted with. Evelyn says that it was anciently used for flutes and other musical instruments, and that hafts for knives and tools were made of the root. Whenever it arrives at any considerable size, its hardness, toughness, and flexibility, must fit it for important services : its fine regular spreading head, of a cheerful green colour, renders this tree extremely proper for clumps in parks, groves, single trees, or avenues. The branches are converted into hoops for casks ; the berries are eaten by birds, and also by children in the south of Europe.

2. *Celtis Occidentalis* ; *American Nettle Tree*. Leaves obliquely ovate, serrate-acuminate. This tree rises with a straight stem, which in young trees is smooth, and of a dark colour ; but as they advance it becomes rougher, and of a lighter green. The fruit when ripe is of a dark purple colour. It grows naturally in North America, and in a moist rich soil becomes a very large tree ; the wood of which being tough and pliable, is esteemed by coach-makers for their carriages.

3. *Celtis Orientalis* ; *Oriental Nettle Tree*. Leaves obliquely cordate, serrate, villose underneath. It rises with a stem about ten or twelve feet high, dividing into many branches, which spread horizontally on every side, and have a smooth greenish bark. The fruit is oval and yellow ; when fully ripe it turns to a darker colour : the wood is very white ; it yields gum like the Cherry-tree.—Native of the Levant, the East Indies, Japan, and the Society Isles.

4. *Celtis Americana*. Leaves oblong, ovate, obtuse, nerved, smooth above, golden beneath. This rises with a straight trunk nearly twenty feet high, covered with a grey bark, and dividing at the top into many branches ; the fruit is round and red.—It was first discovered by Father Plumier in the French West India islands. The seeds rarely come up the first year ; so that they may be sown in pots, and plunged into the tan-bed in the stove, where they should remain till the plants come up. They must be constantly kept in the bark-stove, and treated in the same manner as other tender exotics.

5. *Celtis Micrantha* ; *Jamaica Nettle Tree*. Leaves obliquely cordate, ovate-lanceolate, serrulate, somewhat rugged on the upper surface. This shrubby tree seldom rises above ten or twelve feet, and throws out a great number of loose branches. It flowers in August and September.—Native of Jamaica.

6. *Celtis Aculeata*. Leaves cordate-ovate, blunt at the

tip, almost entire, very smooth ; branches prickly. This inelegant little tree has very long, pliant, scarcely divided, and reclining branches ; drupe roundish or ovate, crowned with the withering style, yellow, double the size of a pea, containing a sweet pulp, which is eaten by the inhabitants of the Caribbee islands ; of which, and also of the neighbouring continent, this tree is a native.

7. *Celtis Lima*. Leaves ovate-lanceolate, acuminate, obliquely cordate, serrate, very rugged above. Height fifteen feet ; trunk straight, with a smooth, reddish, or light brown bark.—Native of the West Indies.

Cenchrus ; a genus of the class Polygamia, order Monœcia. —GENERIC CHARACTER. *Calix* : involucre many, lacinate, echnate, gathered into a head, each sessile, including three calices, biflorous ; perianth a bivalve glume, lanceolate, concave, acuminate, biflorous, shorter than the corolla. *Corolla* : one male, the other hermaphrodite ; proper, each bivalve ; valves lanceolate, acuminate, concave, awnless ; the interior one smaller. *Stamina* : to each three filamenta, capillary, length of the corolla ; antheræ sagittate. *Pistil* : germen of the hermaphrodite roundish ; style filiform, length of the stamina ; stigmas two, oblong, hairy, spreading. *Pericarp* : none. *Seed* : roundish. ESSENTIAL CHARACTER. *Involucre* lacinate, echnate, two-flowered. *Calix* : glume two-flowered, one male, the other hermaphrodite. *Hermaphrodite*. *Corolla* : glume awnless. *Stamina* : three. *Seed* : one. *Male*. *Corolla* : glume awnless. *Stamina* : three. —The species are,

1. *Cenchrus Racemosus* ; *Branching Cenchrus*. Panicle spiked ; glumes muricated with ciliary bristles.—Native of the southern parts of Europe, the coast of Egypt, and the East Indies. It flowers in July and August.

2. *Cenchrus Lappaceus* ; *Bur Cenchrus*. Branches of the panicle very simple ; corollas hispid backward ; calices three-valved, two-flowered ; culm branching, even.—Native of the East Indies.

3. *Cenchrus Muricatus*. Spike muricated ; scales various, mucronated ; culm procumbent, a short span in length, branching, leafy.—Native of the East Indies.

4. *Cenchrus Capitatus* ; *Oval-spiked Cenchrus*. Spike ovate, simple. The culm is only three or four inches high, and has only one joint.—Native of the south of France, and Italy.

5. *Cenchrus Echinatus* ; *Rough-spiked Cenchrus*. Spike oblong, conglomerate.—Native of Virginia and Jamaica.

6. *Cenchrus Tribuloides*. Spike glomerate ; female glumes globular, muricate, spiny, hirsute ; culms many, trailing, round, 18 inches long.—Native of Virginia and Jamaica.

7. *Cenchrus Ciliaris* ; *Ciliated Cenchrus*. Spike with setaceous, ciliated, four-flowered involucre. Culm ascending, glossy, the thickness of a thread, a short span in length, with inflected joints.—Observed at the Cape of Good Hope.

8. *Cenchrus Granularis*. Racemes double ; fruits globular, wrinkle-netted ; fruits minute, scarcely so big as a cabbage seed.—Native of the East Indies.

9. *Cenchrus Frutescens*. Heads lateral, sessile ; leaves mucronated ; stem shrubby.—Found by Tournefort in Armenia.

10. *Cenchrus Setosus*. Spike linear, oblong ; involucre bristly ; bristle unarmed, the interior ones villose at the base ; hairs ciliate ; glumes even.—Native of the West Indies.

11. *Cenchrus Purpurascens*. Raceme spiked, simple ; florets surrounded with very long awns ; culm erect, two feet high ; awns purple.—Native of Japan.

Centaurea ; a genus of the class Syngenesia, order Polygamia Frustranea.—GENERIC CHARACTER. *Calix* : common imbricate, roundish ; scales often variously terminated. *Corolla* : compound flosculous, difform ; corollules herma-

phrodite, very many in the disk; females fewer, larger, lax in the ray. Proper of the hermaphrodite monopetalous; tube filiform; border ventricose, oblong, erect, terminated by five divisions, which are linear, erect. Of the females monopetalous, funnel form; tube slender, gradually enlarged, recurved; border oblong, oblique, unequally divided. *Stamina*: in the hermaphrodites: filamenta five, capillary, very short; antheræ cylindric, tubular, length of the corollule. *Pistil*: in the hermaphrodites: germen small; style filiform, length of the stamina; stigma very obtuse, projecting in a point which in many is bifid: in the females; germen very small; style scarcely any; stigma none. *Pericarp*: none; calix unchanged, converging. *Seeds*: in the hermaphrodites solitary; down or egret, in most plumose or pilose; in the females none. *Receptacle*: bristly. **ESSENTIAL CHARACTER.** *Receptacle*: bristly. *Down*: simple. *Corolla*: of the ray funnel-form, longer, irregular.—The numerous species of this genus may be increased without great difficulty: those which are annual, by seeds; and such as are perennial, both that way and by parting the roots. The seeds of the greater part may be sown either in spring or autumn in a bed of light earth, either to remain where they are; and in that case only to be thinned and kept clean from weeds; or to be pricked out when of a proper size, into a bed of fresh earth, about six inches asunder, there to remain till autumn, when they should be planted where they are to continue: most of them are hardy, and none of them very tender, although some require a little protection in this climate.—The species are,

* *Jaceas*: Calices even, unarmed.

1. *Centaurea Crupina*; *Black-seeded Centaury*, or *Bearded Creeper*. Scales lanceolate; leaves pinnate, serrate, subciliate. Stem striated, three feet high, almost quite simple.—Native of the south of France, Tuscany, the Levant, &c. Annual.

2. *Centaurea Moschata*; *Purple Sweet Centaury*, or *Sweet Sultan*. Calices roundish, smooth; scales ovate; leaves lyrate-toothed. This is annual; and has long been propagated in the English gardens, under the name of Sultan-flower, or Sweet-Sultan. It was brought from the Levant, where it grows naturally in arable land among the corn. It sends up a round channelled stalk nearly three feet high, which divides into many branches, with jagged leaves, of a pale green, smooth, and close to the branches; from the side of the branches come out long naked peduncles, each sustaining a single head of flowers, which are purple, white, or flesh-coloured, and have a very strong odour, which is as offensive to some as it is agreeable to others.—The seeds of this species are commonly sown upon a hot-bed in the spring, to bring the plants forward, and in May they are transplanted in the borders of the flower-garden; but if the seeds be sown in a warm border in autumn, they will live through the winter; and these plants may be removed in the spring into the flower-garden, and will be stronger and come earlier to flower than those which are raised in the spring. The seeds may also be sown in the spring on a common warm border, where the plants will rise very well, but will be later in flowering than any of the rest. The autumnal plants will begin to flower in the middle of June, and will continue flowering till September. The spring plants will flower a month later, until the frost stops them. The seeds ripen in autumn. The *yellow Sweet Sultan* is much tenderer than the former; its seeds must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted into a fresh hot-bed to bring them forward; and when they have taken root in this bed, they must have air admitted to them every day, to prevent their drawing up weak, and be sparingly refreshed with water, because they are very apt to rot with much wet.

3. *Centaurea Crucifolia*. Scales lanceolate; leaves lanceolate, somewhat toothed. Root annual; stem a foot high, rough with hairs; corolla bright purple; calices pubescent.

4. *Centaurea Lippii*; *Egyptian Centaury*. Scales mucronate; leaves subdecurent, lyrate-toothed; corollas purple, with a large ray.—Native of Egypt, between Alexandria and Rosetta.

5. *Centaurea Alpina*; *Alpine Centaury*. Scales ovate-obtusate; leaves pinnated, smooth, quite entire, the odd leaflet serrated. Root perennial, striking deep into the ground.—It grows naturally upon the Alps and in Italy.

6. *Centaurea Centaurium*; *Great Centaury*. Scales ovate; leaves pinnated; leaflets serrated, decurrent. The flowers are purple, and come out in June.—This has a strong perennial root, and grows naturally on the mountains of Italy, Spain, and Tartary. It is supposed to be the *tristia centaurea* of Lucretius, and the *graveolentia centaurea* of Virgil, recommended by the latter in disorders of the bees. It may be propagated by parting the roots: as it requires much room, it is not proper for small gardens; but in large open borders, or on the edges of plantations, with other tall growing plants, it makes a good figure.

** *Cyani*: *With Scales of the Calix serrate-ciliated.*

7. *Centaurea Phrygia*; *Austrian Centaury*. Calices recurve-plumose; leaves undivided, oblong, scabrous. Stem somewhat shrubby, upright, from eight or ten inches to a cubit in height, often branched, furrowed, hispid, but not tomentose; corolla a fine red.—Native of Germany, Austria, and Switzerland.

8. *Centaurea Capillata*; *Feathered Centaury*.—Calices recurved, plumose; bottom leaves pinnated, toothed; upper lanceolate. Stem four or five feet high, angular, hard, branching.—Native of Spain and Siberia.

9. *Centaurea Uniflora*; *One-flowered Centaury*. Calices recurve-plumose; leaves lanceolate, somewhat toothed, tomentose. This is a palm or foot in height; corolla purple; leaves very narrow, lanceolate, quite entire, covered with a very white pile.—Native of the south of Europe.

10. *Centaurea Linifolia*; *Flax-leaved Centaury*. Calices recurve-plumose; leaves linear, scattered. Stem a palm in height, often decumbent, branching from the bottom, furrowed, angular, rough with stiff hairs; corolla purple.—Perennial; and a native of Spain and Italy.

11. *Centaurea Pectinata*. Calices recurve-plumose; leaves lyrate, toothletted; branch-leaves lanceolate, quite entire; corollets pale purple, or white, all equal.—Native of Spain, south of France, and Silesia.

12. *Centaurea Nigra*; *Black Centaury*, or *Knapweed*. Calices ciliate, with the little scale ovate; cilia capillary, erect; leaves lyrate, angular; flowers floscular. Stem from two to three feet in height; florets all alike; tube whitish, long, and narrow; border purple. This plant has many provincial names, as *knap-weed*, *knop-weed*, *knob-weed*, *horse-knops*; all from *knob* or *nob*, a head; also *hard-heads*, *hard-irons*, and *matfellow*; in Scotland, *horse-knot*.—It is found in Germany, Austria, and France. It is a bad weed in the English meadows and pastures, being a harsh stubborn plant, seldom touched by cattle either green or in hay, and being very difficult to extirpate.

13. *Centaurea Pullata*. Calices ciliate, vertical, leafy; leaves lyrate, toothed, obtuse. It is a low plant; corolla purplish, with a large ray. It flowers in June and July, and the seeds ripen in autumn.—Native of the south of France, Spain, and the Levant.

14. *Centaurea Montana*; *Mountain Centaury*, *Perennial Blue Bottle*, or *Batchelor's Buttons*. Calices serrate; leaves lanceolate, decurrent; stem quite simple. Root perennial,

running deep into the ground ; corollets in the ray very long, blue, with a white tube, neuter ; in the disk short, purple, fertile.—It flowers in May and June, and is a native of the south of Europe. It is now become a common plant in large gardens, from the facility with which it is increased ; the roots indeed creep so much, that it is apt to become troublesome : it will grow in any soil and situation.

15. *Centaurea Cyanus* ; *Corn Centaury*, or *Annual Blue Bottle*. Calices serrate ; leaves linear, quite entire, the lowest toothed. Stem one to two feet high, angular, slightly tomentose, branched at top.—It is a common weed among corn, flowering from June till August ; the wild flower is usually blue, but sometimes white or purple. Our old English writers, besides *blue-bottle*, a name it has commonly obtained, call it *blue-ball*, *blue-blow*, *corn-flower*, and *hurt-sickle* ; in the Booke of Husbandrye, ascribed to Fitzherbert, it seems to be called *hadods* or *handod* : some modern agriculturists speak of it under the name of *buddle*, which is evidently nothing more than a corruption of *bottle*. It is called *bachelor's buttons* in Yorkshire and Derbyshire, but that name is given to many other flowers : in Scotland, it is called *blue bonnets* ; the Germans, Dutch, Swedes, and Danes, call it *korn-blume* ; the French, *bluet* ; the Italians and Portuguese, *ciano* ; and the Spaniards, *aciano*, and *azuleio*. The expressed juice of the neutral florets makes a good ink ; it also stains linen of a beautiful blue ; but the colour is not permanent in any mode hitherto used. Mr. Boyle says, that the juice of the central florets, with the addition of a very small quantity of alum, makes a lasting transparent blue, not inferior to ultramarine. A water distilled from the flowers of this plant is good in inflammations and weakness of the eyes ; and the leaves which grow on the stems ; fresh gathered and bruised, will stop the bleeding of a wound, even if a large vessel be cut ; their use in such cases, is but little known, but they surpass all other things of the kind, and may often be the instrument of saving life, where a surgeon's assistance is not to be procured in time : it is good for wounds or bruises in the breast, spitting of blood, &c. The juice dropped into old ulcers, cleanses and disposes them to heal. I have known it, says Meyrick, to be made use of by the country people for the jaundice ; and, infused or boiled in white wine, it is an exceedingly good diuretic.—There are great varieties of colours in the flowers of the common annual blue-bottle, and some of them are finely variegated. The seeds are sold under the name of *bottles* of all colours ; they will rise in any common border, and require no other care but to be kept clean from weeds, and thinned where they are too close. If the seeds be sown in autumn, they will succeed better, and the plants will flower stronger, than those which are sown in spring.

16. *Centaurea Paniculata* ; *Panicled Centaury*. Calices ciliate ; scales flat ; leaflets bipinnate ; branch-leaves pinnatifid, linear. Stem panicled, almost woody, stiff, striated, or angular, whitish, branched, from a foot to eighteen inches and two feet in height ; florets flesh-coloured, or pale purple.—Native of the south of France, Switzerland, Germany, Austria, Carniola, Italy, and Spain : annual.

17. *Centaurea Spinosa* ; *Prickly-branched Centaury*. Calices subciliate ; branches spinous. The whole plant is tomentose.—Native of the island of Candia.

18. *Centaurea Ragusina* ; *Cretan Centaury*. Calices ciliate ; leaves tomentose, pinnatifid ; leaflets obtuse, ovate, quite entire, the outer ones larger. Leaves white, as it were papous, pinnated with rounded lobes ; flower solitary, peduncled, bright yellow. As this plant retains its leaves, which are extremely white, all the year, it makes a pretty variety

in a garden.—Native of the island of Candia, and of several places on the coasts of the Mediterranean, both in Europe and Africa. This, and the two following species, may be propagated by slips, or by planting the young branches which do not shoot up to flower, in a shady border, any time during the summer ; in the autumn they may be removed into warm borders, or put into pots to be sheltered in winter. This species will endure the cold of our ordinary winters in the open air, if it be planted in dry lime rubbish.

19. *Centaurea Cincreria* ; *White-leaved Mountain Centaury*. Calices ciliate, terminal, sessile ; leaves tomentose, bipinnatifid ; lobes acute. Stems nearly three feet high, branching from a perennial root ; flower purple, with white styles ; rays scarcely longer than the rest of the corolla. The flowers come out in June, and in favourable seasons the seeds are perfected in autumn.—It grows naturally in Italy, on the borders of the fields.

20. *Centaurea Argentea* ; *Silvery Centaury*. Calices serrate ; leaves tomentose ; root-leaves pinnatifid ; leaflets earless. Stem next the root very tomentose ; flowers yellow ; leaves white. Perennial ; flowering in July.—Native of Candia, or Crete.

21. *Centaurea Sibirica* ; *Siberian Centaury*. Calices ciliate ; leaves tomentose, undivided and pinnatifid, quite entire ; stem declined. Stem quite simple, sometimes, but rarely, having one small branch, pubescent, somewhat grooved, usually one flower ; corolla purple, sometimes flesh-coloured, with a large barren ray.—Found by Gmelin in Siberia.

22. *Centaurea Sempervirens* ; *Evergreen Centaury*. Calices ciliate ; leaves lanceolate, serrate, substipuled at the lowest tooth ; lower leaves hastate. Stem round, pubescent, gray at bottom ; flowers flosculous. It is a perennial plant, and the leaves continue in verdure through the year : it flowers in June and July, and in warm seasons the seeds ripen in September.—Native of Spain and Portugal.

23. *Centaurea Scabiosa* ; *Scabious Centaury*, or *Great Knapweed*. Calices ciliate ; leaves pinnatifid ; pinnae lanceolate. Stem nearly cylindrical, upright, alternately branched, leafy, striated, two feet high ; leaves roughish, and slightly hairy ; flowers solitary, terminating.—Native of most countries of Europe, except the southernmost parts, being found in meadows, on the borders of corn-fields, and by road-sides : it is perennial, flowering in July and August, and is called the *great horse-knobs*, in Yorkshire.

24. *Centaurea Tatarica* ; *Tartarian Centaury*. Calices ciliate ; leaves pinnate ; pinnae lanceolate, undivided. Perennial.—Native of Siberia.

25. *Centaurea Stœbe*. Calices ciliate, oblong, leaves pinnatifid, linear, quite entire. Root perennial ; stems nearly three feet high, branched, with a single leaf at each joint ; flowers solitary, terminating ; they appear in June, and the seeds ripen in August.

26. *Centaurea Acaulis* ; *Stemless Centaury*. Calices ciliate ; leaves lyrate ; stem scarcely any. The flower is yellow ; the root sweet and esculent.—Native of Arabia. It is called *Toffs* by the Arabs.

*** *Rhaponctica* : with the Scales of the Calix dry and scarioso.

27. *Centaurea Orientalis* ; *Oriental Centaury*. Calices scarioso-ciliate ; leaves pinnatifid ; pinnae lanceolate. The stems rise nearly five feet high, dividing at top into many smaller branches ; flowers solitary, terminating, yellow ; they come out from June to August, and the seeds ripen in autumn.—Native of Siberia.

28. *Centaurea Behen*. Calices scarioso ; radical leaves lyrate ; lobes opposite ; stem leaves embracing, decurrent.

Root perennial; stem a foot and a half high, smooth, leafy, with simple branches; flowers yellow, terminal, solitary.—Found at the foot of Mount Libanus, in shady watery places.

29. *Centaurea Repens*; *Creeping Centaury*. Calices scariose; leaves lanceolate, subtitled, toothed; peduncles filiform, leafless. Stem angular, branched, even.—Perennial; and a native of the Levant.

30. *Centaurea Jacea*; *Common Centaury* or *Knapweed*. Calices scariose, lacerate; leaves lanceolate; radical leaves sinuate-toothed: branches angular; stems eight inches to three feet high; leaves scattered, acute, often a little cottony, and whitish; flowers purple and terminal. There are several varieties not worth enumerating.—Perennial; native of the north of Europe, and the south of France.

31. *Centaurea Amara*; *Bitter Centaury*. Calices scariose; leaves lanceolate, quite entire; stems decumbent. Stem panicled.—Native of Spain and Switzerland.

32. *Centaurea Alba*; *White-flowered Centaury*. Calices scariose, entire, mucronated; leaves pinnate, toothed; stem-leaves linear, toothed at the base.—Native of Spain and Switzerland.

33. *Centaurea Splendens*; *Shining Centaury*. Calices scariose, obtuse; radical leaves bipinnatifid; stem-leaves pinnated; teeth lanceolate. Stems three feet high, angular, hard, smooth, branched, many-flowered; flowers purple, with a beautiful silvery calix, consisting of dry round scales, ending in a harmless awn. Biennial; flowering in July: the seeds ripen in September.—Found in transalpine Switzerland, Spain, and Siberia.

34. *Centaurea Rhapontica*; *Swiss Centaury*. Calices scariose; leaves ovate-oblong, toothletted, entire, petioled, tomentose beneath. Root thick, round, black, wrinkled, and irregular; it strikes deep into the ground, and when dry is aromatic. This is a handsome plant; flowers solitary, large; floscules purple, very numerous, without any neutrals.—It flowers in July, and is found in Switzerland, and about Verona. The root of this plant, and of several of the species allied to it, are bitter and astringent, and were formerly much given in cases wherein Jesuit's bark is now administered; the plant also will dye yellow. Neither this nor the thirty-seventh species, perfect their seeds in England; they must therefore be procured from their native countries; they are perennial, and hardy; and when once obtained, may be increased by the root.

35. *Centaurea Babylonica*; *Babylonian Centaury*. Calices scariose; leaves subtomentose, decurrent, undivided; radical leaves lyrate; corolla yellow. Perennial.—Native of the Levant.

36. *Centaurea Glastifolia*; *Wood-leaved Centaury*. Calices scariose; leaves undivided, quite entire, decurrent; root perennial, striking deep into the ground; flowers yellow.—Native of the Levant and Siberia; flowering from July till August.

37. *Centaurea Conifera*; *Cone Centaury*. Calices scariose; leaves tomentose, next the root lanceolate, on the stem pinnatifid; stem simple; root perennial, single, sending out in the spring several entire leaves, and afterwards a single stalk, more than a foot high; at the top comes a scaly head, like a pine-cone, taper at the top, surrounding the florets, which are of a bright purple colour, and appear in June.—Native of the south of Europe.

**** *Stœbæ*: *With the Spines of the Calix palmated.*

38. *Centaurea Sonchifolia*; *Southistle-leaved Centaury*. Calices palmate-spiny; leaves subdecurrent, spinulous, repand-toothed. Stem simple, angular.—Found on the coast of the Mediterranean.

39. *Centaurea Seridis*. Calices palmate, spiny; leaves decurrent, tomentose, oblong, the lowest sinuate-toothed. A tomentose plant, hardly a foot high, with the stems branching a little; ray of the flower purple; disk whitish, with few florets; perennial.—Native of Spain.

40. *Centaurea Romana*. Calices palmate-spiny; leaves decurrent, unarmed; radical leaves pinnatifid, the end-lobe largest. Root biennial; stems three feet in height; flowers large, red, appearing in July, and ripening seed in September.—It is a native of the Campania of Rome.

41. *Centaurea Sphærocephala*. Calices palmate-spiny; leaves ovate-lanceolate, petioled, toothed; root annual; leaves woolly.—Native of Spain and Barbary.

42. *Centaurea Isnardi*. Calices palmate-spiny; leaves lyrate-toothed, hispid, almost stem-clasping; flowers sessile, terminal; root perennial; flowers purple, solitary, appearing in June and July.

43. *Centaurea Napifolia*; *Turnip-leaved Centaury*. Calices palmate-spiny; leaves decurrent, sinuate, spinulous; radical leaves lyrate. Root annual; flowers terminating, corolla radiate, purple.—Native of the Archipelago. This species may be increased and treated in the same manner as the common annual blue-bottle.

44. *Centaurea Aspera*; *Rough Centaury*. Calices palmate, three-spined; leaves lanceolate, toothed.—Found about Montpellier, in Tuscany, and in Portugal.

***** *Calcitrapæ*: *with the Spines of the Calix compound.*

45. *Centaurea Benedicta*; *Blessed Thistle*. Calices double, spiny, woolly, involucred; leaves semidecurrent, toothletted, spiny. Root annual; stem erect, roundish, channelled, rough, one or two feet high, often branched towards the top; leaves long, elliptical, rough, bright green above, whitish underneath.—Flowers from June to September, and is a native of Spain and the Levant. This plant obtained the appellation of *Benedictus*, from its being supposed to possess extraordinary medical powers; for, exclusively of those qualities usually ascribed to bitters, it was thought to be a powerful alexipharmic, and capable of curing the plague, and other malignant febrile disorders; it was also reputed to be good against worms, as well as against all sorts of poison. Simon Paulli declares, that it has no equal in consolidating putrid and stubborn ulcers, and even cancers. He relates the case of a woman, whose breasts were wasted by a cancer to the very ribs, and yet was cured by washing them with the distilled water of this plant, and sprinkling them with the powder of its leaves. And Arnoldus de Villa Nova relates, that he saw the putrid and hollow ulcers of a man, who had all the flesh of his legs consumed to the very bone, and who had tried all other medicines in vain, cured by the following recipe: take the bruised leaves of this plant, and boil them with some generous wine, then add some melted hog's lard: let them boil a little more, and then put in some wheat flour, stirring it about all the while with a spatula, till it comes to the consistence of an ointment, which is to be laid warm upon the ulcers twice a day. However, notwithstanding all these high commendations, we do not find this plant considered as of any great importance in the modern materia medica. In loss of appetite, where the stomach has been injured by irregularities, it is allowed that the good effects of the infusion of this plant have been often experienced. The decoction of it also in water, or posset-drink, still maintains its popular reputation as a gentle vomit, for which purpose it is to be drunk in pretty large quantities. Many persons mistake the Milk Thistle for this plant. Meyrick says, that the leaves of this species are bitter and stomachic, and that an infusion of them, taken in large quantities, excites vomit-

ing; and is good in smaller doses, to excite an appetite, and prevent sickness: when dried and powdered, they are good against worms. The surest method of cultivating this plant, is to sow the seed in autumn, and when the plants come up, to hoe the ground, cut up the weeds, and thin the plants; and in the following spring to hoe it a second time, leaving the plants a foot asunder: they will ripen their seeds in autumn, and soon after decay.

46. *Centaurea Eriophora*; *Woolly-headed Centaury*. Calices double-spiny; woolly; leaves semidecurrent, entire, and sinuate; stem proliferous. It flowers in July.—Native of Portugal.

47. *Centaurea Ægyptiaca*. Calices double, spiny, somewhat woolly; leaves sessile, lanceolate, entire, and toothed; stem proliferous, a foot high; corolla white; antheræ yellow, reddish at the tip. Annual.—Native of Egypt.

48. *Centaurea Calcitrapa*; *Star Thistle*. Calices sub-double, spiny, sessile; leaves pinnatifid, linear, toothed; stem hairy; root annual.—Native of England, Switzerland, and the southern parts of Europe.

49. *Centaurea Calcitrapoides*; *Phœnician Centaury*. Calices subdouble, spiny; leaves stem-clasping, lanceolate, undivided, serrate.—Found at Nismes, and in Palestine.

50. *Centaurea Solstitialis*; *St. Barnaby's Thistle*. Calices double, spiny, solitary; branch-leaves decurrent, unarmed, lanceolate; radical leaves lyrate, pinnatifid, acuminate; flowers terminal, solitary, bright yellow. Annual.—Native of the south of Europe. Discovered by Mr. Rowe, in a grassy field at Arminghall, two miles from Norwich.

51. *Centaurea Melitensis*; *Cluster-headed Centaury*. Calices double, spiny, crowded, terminal; leaves decurrent, lanceolate, sinuous, unarmed. Annual.—Found about Montpellier, and in the island of Malta. This plant is what we commonly call the *solstitialis*.

52. *Centaurea Sicula*. Calices ciliate, spiny, terminal; leaves decurrent, lyrate, unarmed, hoary. Perennial.—Native of Sicily.

53. *Centaurea Centauroides*. Calices ciliate, spiny; leaves lyrate, pinnate, quite entire, the end division largest.—Native of Italy, Spain, and Montpellier.

54. *Centaurea Collina*. Calices ciliate, unarmed, spiny; radical leaves bipinnatifid; stem acute-angled; florets yellow. Perennial.—Native of Montpellier, Spain, Carniola, Italy, &c.

55. *Centaurea Rupestris*; *Rock Centaury*. Calices ciliate, spiny; leaves bipinnate, linear. Perennial.—Native of Italy.

******Crocodiloidea*: *Spines simple*.

56. *Centaurea Verutum*; *Dwarf Centaury*. Calices mostly simple, spiny; teeth two, opposite; leaves lanceolate, entire, decurrent. Root annual; stem erect, eighteen inches high; corolla yellow.—Native of Palestine.

57. *Centaurea Salmantica*; *Lyre-leaved Centaury*. Calices smooth, with a subspiny setule standing out; leaves lyrate, runcinate, serrate; flowers terminal; corollas white or purple. Perennial.—Native of the south of Europe.

58. *Centaurea Cichoracea*; *Succory-leaved Centaury*. Calices setaceous; spiny; leaves decurrent, undivided, serrate, spiny.—Native of Monte Argentario, in Italy.

59. *Centaurea Muricata*. Calices very simply spiny; lower leaves pinnatifid; upper lanceolate; peduncles very long; stems tender; flowers purple, rayed; spine brown, very sharp. Annual.—Native of Spain.

60. *Centaurea Peregrina*. Calices setaceous, spiny; leaves lanceolate, petioled, toothed at bottom. The stems rise nearly three feet high, with entire leaves at each joint; they are terminated by large single heads of gold-coloured flowers, enclosed in a prickly calix, appearing in July and

August, but never producing seeds in this country. It grows naturally in Austria and Hungary.

61. *Centaurea Radiata*; *Rayed Centaury*. Calices almost unarmed and awned, radiate; leaves pinnatifid.—Native of Siberia.

62. *Centaurea Nudicaulis*; *Naked-stalked Centaury*. Calices setaceous, spiny; leaves undivided, the upper ones a little toothed; stem almost naked, one-flowered, simple; corollas purplish. Perennial.—Native of Provence, Spain, and Italy.

63. *Centaurea Crocodilium*; *Blush Centaury*. Calices scarious, very simply spiny; leaves pinnatifid, quite entire, the outmost division larger, toothed. Annual.—Native of Syria.

64. *Centaurea Pumila*; *Dwarf Centaury*. Calices very simply spiny; leaves tooth-pinnate, villose; stem none.—Found in Egypt, by Hasselquist.

65. *Centaurea Tingitana*; *Tangier Centaury*. Calices spiny at the edge; leaves lanceolate, undivided, serrate, subspiny. Perennial.—Native of Tangier.

66. *Centaurea Galactites*; *White-veined Centaury*. Calices setaceous, spiny; leaves decurrent, sinuate, spiny, tomentose beneath.—Observed by Ray, in Sicily, Malta, Italy, and about Montpellier.

******New Species*.

67. *Centaurea Triumphetti*. Calices serrate, with white cilia; leaves deeply pinnatifid, with two pinnae for the most part, decurrent. Perennial.—Found upon Mount Cenis.

68. *Centaurea Kartschiana*. Calices ciliate, spiny; leaves pinnate; pinnae sessile, lanceolate, decurrent, ending in a point. Stem smooth, branching, angular; florets reddish.

69. *Centaurea Alata*; *Upright Wing-stalked Centaury*. Calices ciliate; scales flat, oppressed, ciliate at the end; stem-leaves oblong, decurrent. Perennial.—Native of Tartary.

70. *Centaurea Intyfacea*; *Succory-leaved Centaury*. Calices ciliate; scales flat, obtuse, ciliate at the end; leaves pinnatifid; disk equal to the ray. Stem two feet high, upright, hard, striated, branched; flowers terminating, purple, flesh-coloured, or white. Perennial.—Native of the borders of fields and dry pastures in the south of Europe.

71. *Centaurea Diluta*; *Pale-flowered Centaury*. Calices ciliate; scales acuminate, somewhat thorny; leaves oblong and pinnatifid; floscules of the ray longer than the disk.—Native of the south of Europe.

72. *Centaurea Strobilacea*. Calices scarious, spiny, serrate, ciliated; leaves dotted beneath, pinnate; pinnae lanceolate, falcated, erect. The calix closes during the night: the flowers are of a pale yellow colour; the plant has a bitterish taste, but no smell. Perennial.—It may be raised from seeds sown in the spring, on a gentle hot-bed; but in autumn the plants must be placed under the shelter of a glass-case: it may also be propagated by parting the roots.

73. *Centaurea Hybrida*. Calices ciliated, ending in a spine; leaves pinnate; branch-leaves linear, lanceolate, undivided, decurrent. Flower terminal, yellow: the whole plant dark green, and roughish.—Found on the hills about Turin: biennial.

74. *Centaurea Nicænsis*. Calices ciliate, spiny; leaves ovate, rough; radical leaves petioled, toothed; stem-leaves embracing, decurrent. Flower terminal, yellow.—Found about Nice: biennial.

75. *Centaurea Cæspitosa*. Calices palmate, spiny; leaves sinuate-toothed; the lower ones petioled, the upper ones half stem-clasping. Roots perennial, woody, dry, perpendicular, black on the outside; the flowers, which are purple, have a strong disagreeable smell.—Native of Italy, forming very thick tufts in the sand upon the sea-shore near Naples.

76. *Centaurea Elegans*. Stem simple; leaves undivided,

linear; axillas one-flowered, and one terminal flower. Height eighteen inches; stem round; flower blue. Annual.—Found by Dana in the vineyards of Unelia.

77. *Centaurea Aurca*; *Great Golden Centaury*. Calices most simply thorned; thorns spreading; floscules equal; leaves hirsute, the lower pinnatifid.—Native of the south of Europe.

Centaury. See *Centaurea*, *Chlora*, and *Gentiana*.

Centunculus; a genus of the class Tetandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-cleft, spreading, permanent; divisions acute, lanceolate, longer than the corolla. *Corolla*: monopetalous, rotated; tube subglobular; border four-cleft, flat; divisions subovate. *Stamina*: filamenta four, almost the length of the corolla; antheræ simple. *Pistil*: germen roundish, within the tube of the corolla; style filiform, length of the corolla, permanent; stigma simple. *Pericarp*: capsule globular, unilocular, opening horizontally. *Seeds*: very many, very small. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Corolla*: four-cleft, spreading. *Stamina*: short. *Capsule*: one-celled, opening horizontally.—The only known species is,

1. *Centunculus Minimus*; *Bastard Pimpernel*. Root annual, fibrous; stem one or two inches high; leaves alternate, egg-shaped, quite entire, smooth; flowers very minute, white; solitary, axillary, sessile.—Native of Italy, France, Germany, Britain, Denmark, Scania; in sandy or gravelly moist places. It is found on Hounslow Heath, on Ashford Common, near Hampton Court, Chislehurst, &c. flowering from June till August.

Cephalanthus; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth common none, but the receptacle collecting many floscules into a globose head; perianth proper one-leaved, funnel-form, angular; border quadrifid. *Corolla*: universal, equal; proper monopetalous, funnel-form; acute, quadrifid. *Stamina*: filamenta four, inserted into the corolla, shorter than the border; antheræ globose. *Pistil*: germen inferior; style longer than the corolla; stigma globose. *Pericarp*: none. *Seeds*: solitary, long, attenuated at the base, pyramidal and lanuginous. *Receptacle*: common globular, villose. ESSENTIAL CHARACTER. *Calix*: common none; proper superior, funnel-form. *Receptacle*: globular, naked. *Seed*: one; lanuginous.—The species are,

1. *Cephalanthus Occidentalis*; *American Button Wood*. Leaves in pairs or threes; heads terminal, forming a kind of raceme. This shrub seldom rises higher than six or seven feet in this country; flowers whitish.—Native of swamps in Carolina. A decoction of the wood or root is used for the bite of venomous animals, and is reported to be efficacious in venereal complaints.

2. *Cephalanthus Angustifolius*. Leaves lanceolate-linear, opposite. This is a middle-sized tree, with ascending branches.—Native of Cochin-china.

3. *Cephalanthus Procumbens*. Stem procumbent; leaves ovate-lanceolate, alternate. This is a thick shrub, with many long funicular branches; flowers violet-coloured; leaves large, quite entire, tomentose, petioled.—Native of Cochin-china.

4. *Cephalanthus Montanus*. Leaves ovate, crenate, alternate. A large tree, with hempen bark, and spreading branches.—Native of China.

5. *Cephalanthus Stellatus*. Leaves stellate, lanceolate-linear. A middle-sized tree, with ascending branches.—Native of Cochin-china.

Cerastium; a genus of the class Decandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate-lanceolate, acute, spreading; permanent. *Corolla*: petals five, bifid, obtuse, erect-expanding, length

of the calix. *Stamina*: filamenta ten, filiform, shorter than the corolla, the alternate ones shorter; antheræ roundish. *Pistil*: germen ovate; styles five, capillary, erect, length of the stamina; stigmas obtuse. *Pericarp*: capsule ovate, cylindrical, or globular, obtuse, unilocular, gaping with a five-toothed tip. *Seeds*: very many, roundish. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: bifid. *Capsule*: unilocular, gaping at the tip.—None of these plants make much appearance, and they are therefore only cultivated in botanic-gardens; some of them are common weeds in most parts of Europe: the smoother sorts are not disagreeable to cattle, and the seeds are useful to small birds. They are all raised from seeds which should be sown in autumn. They require no other care than to keep them clean from weeds.—The species are,

*With oblong Capsules.

1. *Cerastium Perfoliatum*; *Perfoliate Mouse-Ear*. Leaves connate, quite smooth, glaucous; petals smaller than the calix. Root annual; stem about a foot high, cylindrical, leafy, upright, weak; flowers terminal and axillary, white, on short peduncles; calix bell-shaped.—Native of Greece.

2. *Cerastium Vulgatum*; *Common or Narrow-leaved Mouse-Ear*. Leaves ovate; petals equal to the calix; stems diffused. It flowers during the whole summer, from May, on walls, by road-sides, among rubbish, and in meadows. Annual.—Native of England, and other parts of Europe.

3. *Cerastium Viscosum*; *Clammy or Broad-leaved Mouse-Ear*. Erect, villose, viscous. This plant is annual; stem branched at bottom, covered with hairs, each of which is terminated by a gland exuding a viscid juice.—It is found in meadows, on walls, dry banks, and ant-hills, varying in size from three inches to a foot; and flowers in April and May.

4. *Cerastium Semidecandrium*; *Least Mouse-Ear*. Flowers five-stamined; petals emarginate. Stems from two to six inches high, purplish, covered with glandulous hairs. It is annual; flowering early, and soon disappearing.—Found upon walls and heaths.

5. *Cerastium Pentandrium*; *Five-stamined Mouse-Ear*. Flowers five-stamined; petals entire. Very small.—Native of Spain.

6. *Cerastium Arvense*; *Corn Mouse-Ear*. Leaves linear-lanceolate or obtuse, smooth; corollas larger than the calix: root perennial, creeping. The whole plant is often very hairy.—It is found flowering from May and June till September, in corn-fields, dry pastures, heaths, and banks. It has been observed near Croydon in Surry, about Newmarket, Bury, and Norwich, and frequently in Cambridgeshire.

7. *Cerastium Dichotomum*; *Forked Mouse-Ear*. Leaves lanceolate; stem dichotomous, about six inches high, very much branched; capsules erect. The whole plant is clammy.—It grows upon arable land in Spain: is annual; flowering in May, and ripening seeds in July.

8. *Cerastium Alpinum*; *Alpine Mouse-Ear*. Leaves ovate-lanceolate; stem divided; capsules oblong; root creeping.—Found upon high mountains in many parts of Europe; Snowden, and other parts of Wales.

9. *Cerastium Dioicum*; *Spanish Mouse-Ear*. Hairy, viscid: leaves lanceolate; flowers diœcous; petals three times larger than the calix: perennial.—Native of Spain.

**With roundish Capsules.

10. *Cerastium Repens*; *Creeping Mouse-Ear*, or *Sea Pink*. Leaves lanceolate; peduncles branching; capsules roundish. It sends out many weak, trailing stalks, which put out roots at their joints; the leaves are two inches long, and less than half an inch broad, very hoary; flowers from the sides of the stalks upon slender peduncles, white.—It grows naturally in

France and Italy, and was formerly cultivated in the English gardens, under the name of Sea Pink, as an edging for borders, for which it was very unfit, on account of its creeping. The Neapolitans call it *erba lattaria*, or milk-herb, because it is supposed to increase the milk of sheep and cows. It propagates too fast by its creeping roots and trailing branches, to be admitted into gardens; but is very proper for planting upon rock-work, where it will spread and thrive without care.

11. *Cerastium Strictum*. Leaves linear, acuminate, smooth; peduncles one-flowered, subtomentose; capsules globular. Stems smooth, procumbent; leaves stiff, very much acuminate: perennial.—Native of the mountains of Switzerland, Austria, the Vaudois, and Mount Cenis.

12. *Cerastium Suffruticosum*. Stem perennial, procumbent; leaves linear, lanceolate, subhirsute.—It is found in the southern countries of Europe.

13. *Cerastium Maximum*. Leaves lanceolate, scabrous; petals crenated; capsules globular: annual.—Found in Siberia, near the river Jenisca.

14. *Cerastium Aquaticum*; *Water Mouse-Ear*. Leaves cordate, sessile; flowers solitary; fruits pendulous. Root perennial.—Native of moist places, and banks of ditches and rivers, flowering in July and August.

15. *Cerastium Latifolium*; *Broad-leaved Mouse-Ear*. Leaves ovate, subtomentose; branches one-flowered; capsules globular; flowers white, large.—Found upon the high mountains of the Valais, next the Glaciers, and on the highest rocks in Wales and Scotland. Perennial; flowering in May and June.

16. *Cerastium Tomentosum*; *Woolly Mouse-Ear*. Leaves oblong, tomentose; peduncles branching; capsules globular. The whole plant is white, with a thick down.—Native of Granada, Istria, France, Switzerland, and Ripton-wood in Huntingdonshire. Perennial; flowering in May and June.

17. *Cerastium Manticum*. Smooth: stem striated; leaves lanceolate; peduncles very long; capsules globular. Root slender, annual.—Native of the neighbourhood of Verona and the Grisons.

18. *Cerastium Refractum*. Leaves lanceolate, smooth; petioles broken: perennial.—Found upon the higher Alps, Mont St. Bernard, &c.

Ceratocarpus; a genus of the class Monœcia, order Monandria.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth one-leafed, tubular, wider at top, thin, coloured, bifid; the upper segments sharp, the lower emarginate. *Corolla*: none. *Stamina*: filamentum single, capillary, scarce longer than the calix, inserted into the receptacle; antheræ twin, oval, upright. *Female Flowers*, on the same plant. *Calix*: perianth one-leafed, obovate, compressed, keeled on both sides, permanent, two-horned; horns straight, subulate, divaricate. *Corolla*: none. *Pistil*: germen oblong, superior; styles two, capillary; stigmas simple, standing out between the horns of the calix. *Pericarp*: none, but the calix grown larger. *Seed*: oblong, attenuated at bottom, compressed. ESSENTIAL CHARACTER. *Male*. *Calix*: one-leafed, bifid; *Corolla*: none. *Female*. *Calix*: one-leafed, keeled, permanent, two-horned. *Styles*: two. *Seeds*: single, compressed, inclosed in and covered by the calix.—The only species is,

1. *Ceratocarpus Arenarius*. An annual branching plant, with very narrow sharp grassy leaves. Stem about a foot high, villous. Three male flowers sessile in each division of the stem; females solitary, sessile in each axilla of the leaves.—It is a native of the rude deserts of Tartary.

Ceratonia; a genus of the class Polygamia, order Tricœcia.—GENERIC CHARACTER. *Male*. *Calix*: perianth five-parted, very large. *Corolla*: none. *Stamina*: filamenta five, sub-

ulate, very long, spreading: antheræ large, twin. *Female*. *Calix*: perianth one-leafed, divided by five tubercles. *Corolla*: none. *Pistil*: germen lying concealed within a fleshy receptacle; style long, filiform; stigma headed. *Pericarp*: legume very large, obtuse, compressed, coriaceous, with a great many transverse partitions, the interstices filled with pulp; seed solitary, roundish, compressed, hard, glossy. *Hermaphrodite Flowers*, on a distinct tree. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: none. *Stamina*: five. *Style*: filiform. *Legume*: coriaceous, many-seeded. *Diœcous*; male and female separate.—The only species is,

1. *Ceratonia Siliqua*; *The Carob Tree*, or *St. John's Bread*. It sometimes grows to a considerable size; leaves pinnate; leaflets roundish, entire, thick, rigid, nerved, dark green above, paler beneath, three inches in breadth, and somewhat more in length. Its fruit when ripe has a tolerably pleasant sweetish taste, and is eaten in times of scarcity, but is apt to disorder the bowels. As a medicine, it has the same properties as Cassia, but in a less degree. The pulp, which has the consistence of a blackish syrup, mixed with liquorice root, dry raisins, and other fruit, forms the sherbet of the Turks. Its leaves are of an astringent nature, and may be used in tanning.—Native of Syria, Palestine, Egypt, Cyprus, Candia, Sicily, Apulia, and Spain. Ignorance of Eastern manners and natural history, induced some persons to fancy, that the locusts on which John the Baptist fed, were the tender shoots of plants, and that the wild honey was the pulp in the pod of the Carob; whence it had the name of St. John's bread: there is better reason to suppose that the shells of the Carob pod might be the husks which the prodigal son desired to partake of with the swine.—This tree is propagated by seeds, which, when imported fresh in the pods, will grow very well, if they be sown upon a moderate hot-bed in the spring; when the plants come up, they should be carefully transplanted, each into a separate small pot filled with light earth, and plunged into another moderate hot-bed, observing to water and shade them until they have taken root; after which air must be admitted in proportion to the heat of the weather. In June they must be inured to the open air by degrees, and in July they should be removed off the hot-bed, and placed in a warm situation, where they may remain till the beginning of October, when they should be removed into the green-house, placing them where they may have free air in mild weather; for they are pretty hardy, and only require to be sheltered from hard frosts.

Ceratophyllum; a genus of the class Monœcia, order Polyandria.—GENERIC CHARACTER. *Male Flowers*: *Calix*: perianth many-parted; divisions subulate, equal. *Corolla*: none. *Stamina*: filamenta double the number of divisions of the calix, sixteen to twenty, hardly conspicuous; antheræ oblong, erect, longer than the calix. *Female Flowers*, on the same plant with the males. *Calix*: perianth many-parted; divisions subulate, equal. *Corolla*: none. *Pistil*: germen ovate, compressed; style none; stigma obtuse, oblique. *Pericarp*: none. *Seed*: nut ovate, unilocular, acuminate, ESSENTIAL CHARACTER. *Male*. *Calix*: many-parted. *Corolla*: none. *Stamina*: sixteen to twenty. *Female*. *Calix*: many-parted. *Corolla*: none. *Pistil*: one; style none. *Seed*: one, naked.—These plants can be cultivated in gardens, no other way than by sowing the seeds or planting them in ponds, muddy streams, or in pots or boxes with earth at the bottom, and filled with water.—The species are,

1. *Ceratophyllum Demersum*; *Prickly-seeded Hornwort*. Leaves two-fold, dichotomous; fruits three-thorned. Root perennial, striking deep in the mud; stem much branched; flowers few, in the bosoms of the leaves.—Found in ditches and slow

streams, flowering in August and September; also in Japan: it is common in Jamaica, where they call it *Morass-weed*, and use it to cover fish, &c. when to be carried to any distance.

2. *Ceratophyllum Submersum*; *Smooth-seeded Hornwort*. Leaves three-fold, dichotomous; fruits thornless.—It is found in the ditches on the side of the road, from Chichester to the Isle of Selsey.

Cerbera: a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved, acuminate, spreading; leaflets ovate-lanceolate. *Corolla*: monopetalous, funnel-form; tube clavated; border large, five-parted; divisions oblique, obtuse, more gibbous on one side than the other; mouth of the tube pentagonal, five-toothed, converging in the form of a star. *Stamina*: filamenta five, subulate in the middle of the tube; antheræ erect, converging. *Pistil*: germen roundish; style filiform, short; stigma headed, bilobate. *Pericarp*: drupe very large, roundish, fleshy, excavated on the side by a longitudinal furrow, and with two specks or points. *Seed*: not two celled, four-valved, retuse **ESSENTIAL CHARACTER.** Contorted. *Drupe*: one-seeded.—These plants must be propagated from their nuts, which must be procured from the countries where they naturally grow. They should be put into small pots filled with light earth, and plunged into a hot-bed of tanner's bark in the spring, and treated in the same manner as other tender exotic seeds, giving them now and then a little water to promote their vegetation. When the plants are come up about two inches high, they should be transplanted into a separate pot, filled with light sandy earth, and plunged again into a hot-bed of tanner's bark, observing to shade the glasses in the heat of the day, until the plants have taken new root; they must also be frequently refreshed with water, but not in large quantities. As the summer advances, they must have air admitted to them in proportion to the warmth of the season; and when they have filled these small pots with their roots, they should be turned out, and transplanted into those of a larger size. In the winter they should be placed in a warm stove, and have but little water. The following spring they must be shifted to larger pots, and plunged into the bark-bed again. When by any accident the tops of these plants are injured, they frequently put out shoots from their roots, which, if carefully taken up and potted, will become good plants.—The species are,

1. *Cerbera Alouai*; *Oval-leaved Cerbera*. Leaves ovate.—It grows naturally in the Brasils, and in the Spanish West Indies; and also in the British islands of America. It rises with an irregular stem to the height of eight or ten feet, sending out many crooked diffused branches; leaves three inches long, thick, and succulent; flowers in loose bunches at the end of the branches, cream-coloured, with long narrow tubes. Every part of the plant is very full of a milky juice: it flowers in July and August, but never produces seeds in England. The wood of this tree stinks most insufferably, and the kernels of the nuts are a deadly poison. The Indians are not acquainted with any antidote to it; nor will they use the wood for fuel. They put small stones into the empty nuts, string them, and fasten them about their legs when they dance.

2. *Cerbera Manghas*. Leaves lanceolate; nerves transverse. This is a milky tree; corolla white; drupe ovate, the size of a goose's egg, with very minute white drops, compressed on one side, and with an obscure suture, inclosing two seeds resembling two large chestnuts, poisonous and vomiting.—Native of the East Indies, some parts of the Spanish West Indies, and of the Society Islands.

3. *Cerbera Thevetia*; *Linear-leaved Cerbera*. Leaves linear, very long, crowded. This is an elegant shrub or small tree,

about twelve feet in height; the stem is round, unarmed, abounding in a poisonous milky juice. Flowers large, specious, nodding, yellow, smelling very sweet.—Native of the West Indies, in woods or coppices near the coast. Mr. Miller informs us, that he received it from our islands there, by the name of *French Physic-nut*, and that it flowers here in July and August, but never produces fruit in England.
