Acute salpingitis or inflammation of the right ovary are generally secondary to some other pelvic inflammation which has been diagnosed on account of other symptoms such as a vaginal discharge (p. 185), or pain in the pelvis (p. 167), or some menstrual irregularity such as menorrhagia (p. 385). The skilled gynecologist may, by vaginal palpation, be able to determine the cause, though doubts may very often persist as to whether the condition is one affecting the right uterine appendages on the one hand, or the vermiform appendix on the other, unless laparotomy is performed. This procedure, as a rule, is much less urgent in the case of salpingitis or ovaritis than with appendicitis, and the doubts may therefore remain unresolved even for a period of months. Should the pains in the right iliac fossa be relatively slight in the intermenstrual periods, but severe at the time of the periods themselves, this fact will suggest that the mischief is pelvic and not

appendicular; but even this conclusion is open to fallacy, because when there has been preceding appendicitis with extensive adhesions which may very likely include the uterine appendages, the pains, though primarily the result of appendicitis, may be recurrently worse at each monthly period. An important point, however, is that salpingitis and ovaritis, though possibly unilateral, are much more commonly bilateral, so that the distribution of the pains is likely to be much wider in the case of ovarian or Fallopian tube mischief than it is with or after appendicitis.

Acute stitch generally affects the flank in the lower costal region on one side or the other, but sometimes the muscles over the right iliac fossa are involved instead of the abdominal muscles higher up, or the diaphragm, and acute pain results in the right iliac fossa and the patient may fear appendicitis. The general character of the pain, however, the fact that it appears to be definitely in the abdominal wall, and that it is unassociated as a rule with acute hyperaesthesia or with any swelling or pyrexia, will generally serve to distinguish stitch from appendicitis.

Distention of the colon with faeces or with gas seldom produces very acute pain in the right iliac fossa, but rather a severe grumble; and although in a first attack appendicitis may be feared, recurrence of similar attacks without any obvious illness on the patient's part, and the way the pains are almost immediately relieved if the patient can pass flatus abundantly, or has his bowels evacuated, either naturally, by medicines, or by means of an enema, will generally serve to exclude acute appendicitis at any rate, though doubt may remain as to whether there may not be appendicular or perityphlitic adhesions. In some such cases examination of the bowel with bismuth and the *x*-rays may serve to show the distended condition of the caecum, or on the other hand evidence of deformity from adhesions.

Retention of the right testis is a thing which should not be forgotten, especially when a lad at about the time of puberty complains of acute pain in the right iliac fossa, suggesting appendicitis. The testis at this time swells, and if it is situated at the upper end of the inguinal canal, distention of it may cause acute pain of a character very similar to that of appendicitis, especially as at the same time there may be local resistance suggesting a swelling in the iliac fossa. It is important therefore to examine the scrotum to see whether both testicles are present there or not. There is no pyrexia.

Injury to the right iliac fossa may be followed by acute pain. In most instances the history will indicate the diagnosis clearly, especially if there is local evidence of bruising. Sometimes, however, the patient may have injured himself when he was unaware of doing so, for instance during times of great excitement, or perhaps when he was under the influence of drink, or again during a nocturnal attack of epilepsy, and it may then be very difficult sometimes to tell whether the pains are due to injury or not. The absence of pyrexia and of an increased pulse-rate will be points against acute appendicitis, though there may be local swelling from a deep hematoma, and the injured muscles may be rigid.

Passing on now to a consideration of the differential diagnosis of conditions which may produce subacute, chronic, or recurrent attacks of pain in the right iliac fossa, it is clear that most of the conditions described above need to be borne in mind again, though one need not recapitulate what has already been said in regard to them. Many, if not all, of the additional causes mentioned under the second heading, however, may simulate or be confused with subacute or recurrent appendicitis.

The *ileocaecal kink* of Sir Arbuthnot Lane is now familiar to most physicians and surgeons as a cause of constipation by interfering with the free passage of the intestinal contents from the lower end of the ileum into the caecum, and as a result of this kink discomfort, or a dull grumbling pain, or even an occasional acute pain, may result in the right iliac fossa: it may be very difficult to tell whether there is not some degree of appendicular trouble at the same time, but the diagnosis of the kink itself is relatively easy if a serial examination of the alimentary canal is made with the *x*-rays after the administration of bismuth. The actual narrow point between the bismuth kept in the lower end of the ileum beyond its proper time and the bismuth which has got past the kink into the caecum can generally be seen very clearly: though it is important in making the examination that the patient should not have any paraffin, aperient, or enema during the period of the successive *x*-ray examinations.

Adhesions round the appendix itself, or round the caecum, may be very difficult to

diagnose unless the patient has recurrent pains in the iliac fossa subsequent to a preceding attack of appendicitis but without any recurrence of signs of inflammation, pyrexia, or raised pulse-rate. In some such cases, however, it is only when operation is performed for the relief of the symptoms that the adhesions can be diagnosed with certainty.

Tuberculosis of the caecum is being recognized nowadays with increasing frequency (Fig. 194); it is nearly always associated with chronic phthisis, of which there will be either definite physical signs or x-ray shadows, and the sputum will generally contain tubercle bacilli. When the phthisis is active and extensive the number of bacilli swallowed are generally so numerous that if ulceration of the bowel occurs at all the ulcers are diffused widely through the ileum, caecum, and ascending colon; but even in such a case the post-mortem evidence shows that the maximum incidence of the bowel tuberculosis which results from the swallowing of tuberculous sputum is in the region of the ileocaecal valve, presumably because some delay occurs here in the passage of the motions and gives the

bacilli a better opportunity of attacking the mucous membrane. In cases which are much less acute the bowel tuberculosis is sometimes confined entirely to the ileocaecal valve region, involving perhaps the last inch or two of the ileum, the ileocaecal valve itself, the caput caeci, and the first inch or two of the ascending colon. There may be diarrhoea as a result of this chronic ulceration, but as a rule there is none, and the patient has become so accustomed to his lung condition that he presents himself to the physician complaining of a sense of dull pain in the right iliac fossa with occasional exacerbations. There may or may not be pyrexia owing to the phthisis. On examination an indeterminate fullness or even a definitely palpable mass may be felt in the right iliac fossa, and the first impression will probably be that the patient has chronic appendicitis, or even possibly carcinoma of the caecum. It is the concomitant lung trouble which gives the diagnosis, and possibly tubercle bacilli may also be detected in the faeces by the anti-formin process. A certain number of these cases have now been cured of their bowel trouble completely by excision of the affected parts, accompanied by anastomosis between the healthy lower end of the ileum and the healthy large bowel beyond the ulceration in the caecum.

Fig. 194. Photograph of caecum: tuberculosis of the lower end of the ileum; ileocaecal valve and caecum successively excised in a case of chronic phthisis with symptoms suggesting chronic appendicitis. Patient alive and well seven years after the operation.

A, Normal ileum. B, Dense tuberculous infiltration of the bowel wall. C, Ileocaecal valve, deformed by the tuberculous infiltration. D, Infiltrated caecum.

it is a well-recognized condition which, when it does appear, often baffles diagnosis. In some cases the nature of the mischief in the right iliac fossa is suggested by the fact that the patient has a chronic inflammatory, suppurative, or ulcerative condition either of the jaw or cheek (Plate XX A), or of the pleura and chest wall, or of the liver at the same time, for these, in addition to the caecum, are the sites most usually involved by actinomycosis. The chronicity of the affection is generally pronounced, but the ultimate diagnosis depends upon the discovery of ray fungi from the affected part (Plate XXVIII, p. 614). Were the caecum involved primarily the symptoms would be more or less like those of either chronic appendicitis or of carcinoma of the caecum, and laparotomy would probably be resorted to, though if the nature of the malady were suspected large doses of iodide of potassium would be prescribed with or without actinomycotic vaccine treatment, cure possibly resulting without operation.

PLATE XXI

ACTINOMYCOTIC ULCERATION OF THE JAW

Coloured slide (spoon) from a patient with actinomycotic ulceration of the jaw, which has recently been in the hospital. The case is a typical one. The ulcer is of the type of actinomycotic ulceration, showing the underlying actinomycotic mass, and the typical crater-like appearance. The surrounding livid area represents a typical actinomycotic zone, as defined by the patient. It is a typical example of the course of the disease. The patient is a patient with actinomycotic ulceration. *R. Cross, M.D.*

Reprinted from the Journal of the Royal Society of Medicine

Inflamed iliac lymphatic glands may cause both pain, tenderness, and obscure swelling in the right iliac fossa, and appendicitis may be simulated. There will generally be pyrexia; if the inflammation in the internal glands is due to spread from the femoral or inguinal glands there will generally be some sore place upon the skin in the area drained by the latter to indicate the diagnosis, but the inflammation of the iliac may also occur independently of the inguinal lymphatic glands when the source of the infection is in the pelvis or secondary to periproctal or periprostatic inflammation. Rectal examination will assist the diagnosis.

Tuberculous iliac lymphatic glands generally form part of tabes mesenterica or of tuberculous peritonitis (p. 47), but sometimes the tuberculous deposits occur mainly, or even solely, in the glands in the region of the caecum, in which case it may be very difficult to be sure without operation that the patient has not got chronic appendicitis or alternatively tuberculous lesions in the caecum itself (see above). It is only when one can feel multiple small but firm, tender swellings, as is sometimes possible in a thin person, that the diagnosis of tuberculosis of these glands may be guessed at; as a rule the patient is a child suffering from general deficiency, and the condition is not one in which the symptoms call for urgent laparotomy. Von Pirquet's skin reaction may be positive, though even when it is the diagnosis of tuberculosis of these glands will often remain one of conjecture only. Sometimes the x-rays show multiple shadows in the position which the glands normally occupy, and thus assist the diagnosis.

Carcinoma of the caecum is generally characterized much less by pain in the iliac fossa than by a definite, usually irregular firm mass, at first movable, later more fixed. This mass is distinguished from an accumulation of faeces in the caecum by its greater firmness, by the fact that it cannot be moulded by the fingers, and that it does not disappear when the bowels are thoroughly evacuated. It may enlarge very slowly; in cases of doubt, operation with a view to possible excision will probably be resorted to, and the diagnosis thus confirmed. Sometimes carcinoma of the caecum may be simulated by accumulated faeces, however, when there is obstruction to the bowel further on; there may for instance be adhesions obstructing the sigmoid colon, or a partial volvulus, or a carcinoma of the rectum, or of the sigmoid colon, leading to partial intestinal obstruction and preventing the faeces from leaving the caecum thoroughly even when evacuant measures have been employed. The pain which the patient then complains of may be not at the site of obstruction so much as in the right iliac fossa. A bismuth and x-ray examination may assist materially in detecting the cause of the symptoms in such a case, and careful examination of the rectum with the finger, or of the sigmoid colon by means of the sigmoidoscope, may be required. It is noteworthy that when there is obstruction to the colon in its distal part, it is particularly in the caecum that *stercoral ulcers* are apt to occur, and these may be associated with perityphlitis and pain in the right iliac fossa, more or less simulating appendicitis.

In *dysentery* and *ulcerative colitis* the abdominal pains are usually general, or at least referred now to one, now to another part of the whole colon, so that in these conditions the patient seldom complains mainly of pain in the right iliac fossa; occasionally, however, pain in the right iliac fossa may be more pronounced than over other parts of the colon, though the diagnosis of a more widespread infection will generally be indicated by the history, especially as to residence in the tropics in the case of dysentery, or of recurrent intractable diarrhoea with the passage of blood and mucus in one suffering from ulcerative colitis.

In *typhoid fever* the general symptoms will nearly always be out of all proportion to any pain in the abdomen, but occasionally so mild a case of typhoid fever is met with—the ambulatory type—that the patient has not been ill enough even to go to bed, and in some of these acute pains in the right iliac fossa have been the first thing to call attention to the nature of the disease; in some indeed the patient has had a perforation low down in the ileum, so that a local abscess in the right iliac fossa has formed, and the patient, though suffering from typhoid fever, has been operated upon as an ordinary case of appendicitis until the subsequent course of the pyrexia has indicated that something else was wrong, and it has occurred to one to have the blood tested for a Widal's reaction, which has then been found positive.

Discomfort or actual pain in the right iliac fossa may be the first complaint of patients suffering from a *tumour of the iliac bone*; this tumour may be simple *osteoma* or

chondroma—or it may be malignant *sarcoma*. In either case the diagnosis is arrived at by careful deep palpation, when the tumour will be felt to be firm or even bony hard, and, unlike other tumours in the iliac fossa, completely fixed to the deep parts.

An *aneurysm of the iliac artery* is very uncommon; when it does occur, pain in the iliac fossa may be considerable, and this pain may radiate thence down the right thigh; the diagnosis would be made by careful palpation and the discovery of a tumour with expansile pulsation.

Although both *movable right kidney* and *other lesions of the right kidney*, especially *tuberculosis*, cause pain in the loin to a more pronounced extent than pain in the right iliac fossa, some patients, especially those suffering from unduly movable right kidney, complain of much more pain in the lower right abdominal quadrant than in the loin, and the difficulty of distinguishing between such pains when due to movable kidney only, and a subacute appendicitis occurring in a person who has at the same time a movable kidney, may sometimes be considerable. Careful urine examination should be made; with

renal tuberculosis pus cells and tubercle bacilli may be detected; with movable kidney the urine is generally normal, though sometimes there may be a little albumin or occasionally a trace of blood. With movable kidney, however, there will be no pyrexia, such as one would expect were there also appendicitis, and on careful palpation the patient will tell the examiner that she experiences the pain when he has the kidney between his two hands and not when he presses into the right iliac fossa without touching the kidney.

Herpes zoster is a condition which always needs bearing in mind when pains are unilateral without objective signs, and these pains due to herpes zoster may be present some time before the actual eruption appears, and also in a few cases for weeks or months after the eruption has subsided. It is even probable that in some cases there are pains from herpes zoster without any eruption at all, though then the diagnosis is almost impossible. As a rule, with herpes zoster occurring in such a way as to produce pain referred to the right iliac fossa, the pain will not be confined to this fossa, but will be referred also to the inner side of the upper part of the thigh and to some point in the right

Fig. 195.—Skelogram showing tuberculous disease of 1st and 2nd lumbar vertebrae.
(Skelogram by Dr. C. Thorstein Hollland.)

loin. The characteristic vesicles will also be looked for, or the slight scabs that may be left for some time after the vesicles have dried up.

The remaining conditions in the list above are some in which pain may be referred to the right iliac fossa by lesions at a distance, and it is only by bearing them in mind and looking for evidence of them that they can be recognized. Thus, the fact that a patient who is suffering from *acute pleurisy* at the base of the right lung, or from *pneumonia* in the lower lobe of the right lung, may complain of pain in the lower part of the abdomen rather than in the chest, is familiar; and sometimes it may be very difficult to decide whether the patient's lesion is abdominal or thoracic. Even when there are definite lung signs there may be doubt as to whether there may not be appendicitis as well; acute pleurisy, for example, may result from the rapid tracking up along the posterior abdominal wall of infection from the appendicular region. In such cases it is only by careful judgement that a decision can be come to. As a rule, in such cases there is neither rigidity nor tenderness in the right iliac fossa upon examination, although the patient may put his hand over the

right iliac fossa when indicating where he has the pain. In a similar way chronic pain suggestive of ureteral calculus or of appendicular colic or even a subacute appendicitis may be complained of by persons whose posterior nerve roots on the right side are being irritated by bony or other changes in connection with the lower dorsal or upper lumbar vertebrae, for instance, from *spondylitis deformans* (p. 648) in an early stage; *osteo-arthritis* of the spine; infective changes in the spine of the same nature as *rheumatoid arthritis*; *spinal caries* with or without *psaus abscess*. Such cases will be of chronic duration, and it may be only after much deliberation and repeated examinations that a conclusion will be come to that the pains are referred from the spine and not due to primary trouble in the right iliac fossa itself. The *x-rays* will sometimes be of assistance in detecting the osteoplastic or other bony changes in the vertebrae (*Fig. 495*), and if the patient's complaints can be analyzed successfully, it will generally be found that he has definite localized pain in the back as well as in the iliac fossa. The difficulty of being sure of the cause of the pains in such a case, however, may sometimes be very great, and even after weeks of observation their nature may still remain one of doubtful opinion only.

Herbert French.

PAIN, INTERSCAPULAR.—(See also PAIN IN THE BACK, p. 127.) Pain referred to by the patient as being "in the back, between the shoulder blades," is due in the great majority of cases to simple indigestion, flatulence, or biliousness. Sometimes it is in the middle line, with a maximum intensity at the 5th, the 6th, the 7th or the 8th dorsal vertebra; sometimes it is referred more to one side of the mid-line than the other; often it varies in position, being sometimes near the mid-line, at other times right under the blade of one scapula—particularly on the left side in the case of indigestion and stomach conditions, on the right side when the patient is 'bilious' or his liver is out of order. It is very important, however, not to conclude forthwith that a patient who has this symptom is merely bilious or suffering from dyspepsia, for pain of a similar kind may be the result of more serious lesions, amongst which one must think of:—

Epithelioma of the œsophagus	Aortic aneurysm eroding the vertebrae
Mediastinal sarcoma	Gastric ulcer
Spinal caries	Duodenal ulcer
Sarcoma of the vertebrae	Gastric carcinoma
Carcinoma of the vertebrae	Gall-stones
Infective arthritis of the spine	Hepatic abscess
Fibrositis	Carcinoma of the gall-bladder
Myositis	Carcinoma of the liver.
Spondylitis deformans	

} 'Chronic
rheumatism'

The first step in arriving at a diagnosis will be to examine the bare back very carefully by inspection in a good light, and by palpation. Broadly speaking, the conditions mentioned above divide themselves into two main groups—namely, (1) Those in which the pain is not produced locally, but is referred to the interscapular region from a distance (*Fig. 294*, p. 716); (2) Those in which the pain is definitely of local origin, so that there is tenderness on palpation as well as pain. When the pain is due to local causes, there will generally be some deficiency in the free movement of the spinal column when the patient bends forwards and backwards, or from side to side, or when he twists round; and attempts at such movements will increase the pain in a way which is not the case when the cause is gastric or hepatic.

The maximum amount of rigidity is found in cases in which the bones themselves are involved, whether by *spinal caries*, *new growth*, an *aneurysm*, *spondylitis deformans*, or *arthritis*. The diagnosis of each of these may be clinched by *x-ray* examination in all but a few cases. Skiagraphy will also serve to detect *mediastinal new growth*; or, with the help of a bismuth meal, *epithelioma of the œsophagus*, which is generally suggested by the progressive *DYSPHAGIA* (p. 194) long before it produces pain between the shoulders.

Infective arthritis of the spine, *fibrositis*, and *myositis* are all associated with local tenderness and local stiffness or deficiency in movement as well as with local pain; in only a few cases will the parts affected be the mid-dorsal region of the vertebral column alone; in most instances there will be pains in other parts of the body as well, referred to vaguely as 'neuritic,' together with more or less affection of many joints of the multiple rheumatoid arthritis type (p. 341). All three are closely related to one another, and where fibrositis

or myositis ends and infective arthritis begins is usually impossible to define. Local infiltration may sometimes be recognized on minute palpation, especially by those who have had training in massage. The diagnosis should not be made, however, before caries, aneurysm, and other serious deeper lesions have been excluded by skiagraphy.

When there is no local thickening, tenderness, or rigidity, and no local abnormality to be made out with the x-rays, it will be probable that the interseapular pain, or the pains beneath the blade of one or other scapula, is a referred pain, either of gastric or hepatic origin. In many such cases the diagnosis of FLATULENCE (p. 240), or simple INDIGESTION (p. 315), or of biliousness is guessed at rather than made, and the chances are that the patient will be suffering from one or other of these ill-defined 'simple' conditions rather than from something more serious,—such as gastric or duodenal ulcer, gastric carcinoma, gall-stones, hepatic abscess, or carcinoma of the liver or gall-bladder: especially if he has had similar pains on many previous occasions, losing them completely in the intervals. The severity of the seapular or interseapular pain is no guide, for it may be extreme even when the patient is suffering from nothing worse than flatulence or biliousness. It is important, however, not to jump too readily to the conclusion that the pain is due to these simple conditions, especially if it does not yield easily to simple treatment, such as bicarbonate of soda or a little calomel. Careful abdominal palpation is indicated, lest a gastric or hepatic tumour escape detection: with these the pain will seldom be solely interseapular, however, and here, just as in the case of gastric or duodenal ulcer, hepatic abscess, or gall-stones, there would be pain in the epigastrium or hypochondrium to direct attention to the nature of the lesion, which would be suggested further, perhaps, by such other symptoms as VOMITING (p. 763) or JAUNDICE (p. 324). Nevertheless, in some cases it may only be by watching the patient for a time that an exact diagnosis can be made: and occasionally that which at first appears to be no more than the interseapular pain of dyspepsia or biliousness, proves to have been really due to gall-stones or a carcinoma.

Herbert French.

PAIN IN THE JAW (LOWER)—unaccompanied by any swelling (see SWELLING OF THE JAW, LOWER, p. 683)—is generally due to *dental caries*, i.e., toothache, and it is with this thought in the mind that an examination should first be made. The decayed tooth may be obvious at once, or it may be so hidden as to call for the services of a skilled dentist. Occasionally an unerupted molar may be the cause of the pain, and a skiagram may be needed to complete the diagnosis.

Neuralgia.—Here, pain is the essential feature, and it may be of two kinds. It either follows the course of a nerve such as the inferior dental in the lower jaw, or it affects a considerable part of the jaw without special reference to any nerve. It varies greatly in severity, being sometimes slight, at other times so severe as to call for all the fortitude of the patient to bear it. Usually neuralgia of the inferior dental nerve is combined with neuralgia of the other branches of the fifth nerve, and this in conjunction with the spasmodic character of the pain makes the diagnosis easy. Some cases of neuralgia are embarrassing, especially when sources of irritation in decayed teeth are present as well, and it may be that the true condition can only be settled after all the teeth have been extracted.

Other causes, such as epithelioma or other neoplasm, do not produce pain as a rule until the diagnosis has been arrived at on other grounds.

George E. Gusk.

PAIN IN THE JAW (UPPER).—What has been said above as to pain in the lower jaw being caused by dental caries and neuralgia applies equally to pain in the upper jaw, but there is an important additional cause to be sought for in the latter, and one easily overlooked, namely, inflammatory affections of the antrum of Highmore.

Abscess of the Antrum of Highmore.—The presence of pus within the antrum is indicated by local pain generally dull in character, but sometimes acute. On examination of the jaw, the gums will often be found tender and swollen, and a carious tooth is frequently the source of the infection. So far, the signs are compatible with those arising from a septic tooth, without implication of the antrum, and further evidence is required: the most certain is the periodical discharge of pus, which may run from the corresponding nostril when the head is bent forwards, or trickle down the pharynx when the patient is lying on the back. If the normal opening of the antrum into the nose becomes closed, as

it may from inflammation, this valuable sign is lost, and though local signs of inflammation and general febrile disturbances are present, it may be difficult to arrive at a diagnosis, for the condition is simulated by inflammation in the nasal fosse or suppuration in the ethmoidal and frontal sinuses. It must also be remembered that a growth, either innocent or malignant, starting in the antrum and not yet big enough to cause a swelling, may easily be mistaken. Recourse, therefore, should be had to the method of transillumination, and the antra on the two sides compared (see *Fig. 84*, p. 180). The position of the antrum should be shown by a bright red area, and if instead a shadow is thrown, there is presumably some affection of the antrum. It does not mean necessarily that there is an abscess, for a growth or a thickening of the bone may cast a shadow equally well. In these conditions a skiagram may help. A growth may indicate its presence by pain before the appearance of any swelling, but the differential diagnosis is discussed under SWELLING OF THE JAW, LOWER (p. 683). The only certain method of diagnosis of an antral abscess is by tapping the antrum with an exploring syringe. This can be done through the nose immediately under the anterior part of the inferior turbinate bone. The fluid withdrawn may be subjected to microscopical and bacteriological examination.

George E. Gush.

PAIN IN THE JOINTS.—(See JOINTS, AFFECTIONS OF THE, p. 337.)

PAIN IN THE LEG.—(See PAIN IN THE EXTREMITY, LOWER, p. 438.)

PAIN IN THE LIMBS (General). In the great majority of cases pains in the limbs are the result of some general or systemic disease; in but few instances can they result from symmetrically distributed local lesions. For clinical purposes they may be classified by their duration, according as they are acute or chronic.

1. Acute General Pains in the Limbs occur in—

Rheumatic fever	Hysteria	Inflammations of the lungs, kidneys, etc.
Muscular overstrain	Acute infections such as—	Secondary syphilis
Myositis	Acute coryza	Tropical fevers—
Acute polymyositis	Tonsillitis	Dengue, Malta fever,
Neuromyositis	Febricula or chill	cholera, yellow fever,
Trichinosis	Influenza	dysentery, malaria, etc.
Peripheral neuritis	Acute specific fevers	
Neurasthenia	Rat-bite fever	

2. Chronic General Pains in the Limbs occur in—

Peripheral neuritis	Rheumatoid arthritis	Bronchitis
Tabes dorsalis	Gonococcal arthritis	Emphysema
Chronic rheumatism	Chronic wasting disease, as	Morbus cordis
Myalgia	pulmonary tuberculosis	Severe anaemia
Pernicious anaemia	Gastritis	Malignant disease
Osteo-arthritis	Cirrhosis of the liver	Nephritis.

These general pains may be felt most acutely sometimes in one tissue or part of the limbs, sometimes in another. The muscles, for example, may be the chief seats of pain in a child with rheumatism; in a rheumatic adult the pains are usually worst in and about the joints; in a patient with secondary syphilis the pain is often deep in the bones, the so-called osteocopic pain. General limb-pains are usually made worse by movement, particularly when they are accompanied by inflammatory changes in the joints; but the general pains of chronic rheumatism, or the stiffness and pains left after muscular overstrain, will often pass off if the movements be persisted in for a little time. As a rule, general pains in the limbs are least felt when the patient is at rest, especially when he is at rest in bed; but in some cases rest leads to stiffness and increased discomfort, change of position giving temporary relief; in others—particularly the muscular pains of rheumatism and the osteocopic pains of specific disease—the pains are at their worst as soon as the patient gets warm in bed.

Acute Pain. General pains in the limbs are common in *rheumatic fever*, occurring mainly in the limbs in which there is acute inflammation of the joints. In severe cases the cause will not readily be overlooked; it is in the comparatively mild cases in children that failure to make the proper diagnosis is likely to occur, when the general pains in the

limbs may be set down as merely 'growing pains.' There is no doubt that 'growing pains' occur in healthy children, quite independently of rheumatism; but any complaint of growing pains should lead to a careful investigation of the patient's history, and of the condition of his heart; a family history or past personal history of either rheumatism or chorea will often be made out; and not rarely, examination of the heart will lead to the discovery of valvular disease. The joint-affections of rheumatism are far more prominent in adults than in children; in children the non-arthritic lesions are the most conspicuous—endocarditis, pericarditis, pleurisy, chorea, inflammations of the fibrous tissues generally and of the skin, sore throats. The way in which both the pains and the pyrexia are relieved by salicylates may often assist the diagnosis; if both are relieved within forty-eight hours after salicylate treatment is begun, acute rheumatism is probable, whilst conversely, if the pains persist in spite of salicylates, acute rheumatism is not probable (*Fig. 150, p. 338*).

Few people can be unacquainted with the general pains and stiffness due to *muscular overstrain*, the result of some violent and unusual muscular exertion—walking, running, playing games, etc.—undertaken when the body was out of training. The pains are accompanied by local tenderness of the affected muscles, and there may be slight fever.

Myositis, or inflammation of the muscles, is a comparatively rare cause of general pain in the limbs. *Acute polymyositis*, also described as dermatomyositis and as pseudo-trichinosis, is characterized by pain, rigidity, and tenderness in the muscles, œdema of the extremities, and a rash resembling one or other of the exudative erythemas. In addition, there are the general symptoms of malaise, anorexia, general debility, and fever. It must be distinguished from trichinosis, in which the affected muscles are found to contain *Trichinella spiralis*, the face and eyes are œdematous, and the blood shows eosinophilia. A second rare form of myositis is the *neuromyositis* described by Senator, in which the nerves are involved as well as the muscles. In this, sensation is lessened, the reflexes are lost, and vasomotor phenomena are seen in the extremities. The affected limbs are tender on pressure, and painful when movement is attempted.

Trichinosis, or infection with *Trichinella spiralis*, is very rare in Great Britain, though common in countries where pork is eaten uncooked. Its symptoms are due to gastro-enteritis, and to invasion of the tissues of the body, particularly the muscles, by young trichinellæ. For the first week or ten days the main symptoms are gastro-intestinal, and may suggest cholera. Then the second stage comes on with pains and swellings in the muscles, particularly the flexors. The face, neck, and trunk are affected as well as the limbs; the face and eyes become œdematous; profuse perspirations are common, and high fever is not rare; eosinophilia and leucocytosis are usual. If not fatal the symptoms last a month or more, subsiding gradually into the third stage, that of convalescence, as the larval trichinellæ become encysted in the muscles. The diagnosis of trichinosis is likely to be difficult because of its rarity: it is most likely to suggest itself when it occurs in epidemic form. In the early stages, acute gastro-enteritis, enteric fever, or even cholera, will be suspected, the main symptoms arising from the irritation of the alimentary canal set up by the parent trichinellæ breeding in it. Later, rheumatism will be simulated; but the pain and swelling are in the muscles, not the joints, and the occurrence of œdema and of eosinophilia should help in the diagnosis. It may be added, that adult trichinellæ may be found in the stools of a patient with trichinosis, and larval trichinellæ in portions of the affected muscles removed *intra vitam* for microscopical examination; encysted larvæ will also be seen in the infected meat that gave rise to the attack, should any of it have been preserved.

Aching pains all over the limbs or body, or both, are quite common at the onset of many of the *acute infectious disorders*, or of acute diseases that mainly affect one or another of the organs of the body. Associated with these pains are other general symptoms, in most instances, such as malaise, headache, anorexia, and more or less fever. Thus, a severe *acute coryza* or *tonsillitis* may be ushered in by general pains in the limbs; so may the obscure and elusive acute attack known as a *febricula* or a *chill*, in which the fever and general symptoms persist for a day or two, but no localizing signs or symptoms can be detected to give evidence as to "where the chill has settled." Such febricula may really be abortive attacks of pneumonia or rheumatism, the onset or recrudescence of pulmonary tuberculosis, instances of undetected sore throat, acute gastro-intestinal upsets, cases of larval enteric, scarlet fever, measles, or what not. If they are associated with much pain

or prostration, there is a great tendency to apply the term 'influenza' to them indiscriminately, quite apart from considerations of fact—evidence of infection with Pfeiffer's bacillus; or of probability—the detection of any source whence influenzal infection could have been derived. But, however satisfactory it may be to the patient, the diagnosis of *influenza* should not be made without further evidence, such as is furnished by the discovery of Pfeiffer's bacillus in the patient's nasal or bronchial secretions, or by the occurrence of the attack as one of many in an influenzal epidemic. Influenza is well known to be a protean disorder. In many instances its main symptom is a severe coryza, with headache, lachrymation, pyrexia, and much prostration. In others the type is respiratory, bronchitis with cough and viscid expectoration taking the place of the coryza, and leading up to a bronchopneumonia or lobar pneumonia that not infrequently results in death. A third variety of influenza is the abdominal and gastro-intestinal: abdominal pain, vomiting, diarrhoea, and perhaps jaundice, being the main phenomena. In all of these the pains, depression, and prostration come on very rapidly, and appear severe out of all proportion to the objective signs of the disease, while the fever is usually of short duration. The diagnosis of epidemic cases should not be difficult, but in the sporadic cases it may be far from easy, and must be made on the general lines indicated above.

It is not necessary to refer in detail to the many other acute infections or inflammatory processes in which general pains occur in the limbs. In *measles, scarlet fever, or small-pox*, for example, the pains often occur at the outset, but the diagnosis will be made on the other symptoms, and confirmed by the appearance of the characteristic rash. Recurrent attacks of high fever with pains in the limbs are characteristic of the little known and rarely recognized *Rat-bite Fever* (see p. 598). Various febrile disorders of the lungs, such as *bronchitis, tuberculosis, or pleurisy*, may begin with similar pains; so may *gastro-intestinal infections, or acute inflammations of the kidneys*. The diagnosis in these instances will be made from the special symptoms developed in each; the pains in the limbs will rarely be the only or the most prominent complaint.

In *peripheral neuritis* of the symmetrical multiple type, the amount of pain is very variable—great in some cases, little in others. The peripheral nerves contain motor, sensory, and vasomotor fibres; in peripheral neuritis, therefore, motor and vasomotor symptoms are habitually present, as well as sensory. Alcoholism is the commonest cause of multiple symmetrical peripheral neuritis; the chief complaints are of numbness and tingling in the extremities, 'pins and needles,' sensations of 'dead fingers,' cramps in the legs, and severe gnawing or aching pains in the limbs. Beginning in the hands and feet, they tend to spread to the trunk; motor weakness comes on, the skin develops hyperaesthesia, the limbs become very tender to pressure. The deep reflexes, originally increased, are now lost; the sphincters are hardly ever involved in alcoholic neuritis unless the mind is affected. Mental symptoms are common in alcoholism, taking the form of Korsakow's psychosis; memory for recent events is lost; the patient may forget his name and address, and not know where he is; and in the endeavour to make good the lacuna in his recollections, he is likely to lie freely, and quite without any definite wish to deceive. The physical signs of *arsenical neuritis* are similar to those of the alcoholic form, but inco-ordination and the cutaneous and deep hyperaesthesiae are more marked, and muscular paresis and wasting come on earlier; and there may be other arsenical symptoms (p. 64). In the neuritis due to acute *lead poisoning* the sensory signs are entirely subordinated to the motor, and pains in the limbs are absent. Peripheral neuritis is a fairly frequent legacy of influenza, and may then be characterized by great severity and persistence; it may also occur as a complication of other infectious disorders—such as diphtheria, tuberculosis, or syphilis. The diagnosis of peripheral neuritis will be suggested, speaking generally, if the pains in the limbs are associated with marked sensory changes—anaesthesia, paraesthesia, hyperaesthesia—with tenderness of the skin, muscles, or along the course of the nerves, and with weakness, atrophy, and the reaction of degeneration in the muscles.

Hysterical and neurasthenic patients sometimes suffer acutely from pains in the limbs that lack any objective basis on examination, and may give rise to much trouble in diagnosis. It is of great importance that organic disease of every kind should be excluded before the diagnosis of hysteria or neurasthenia is given out. The hysterical patient is generally a woman, and is likely to exhibit several of the many phenomena common in hysteria, such as functional aphonia, globus or clavus hystericus, stocking-and-glove

anesthesia, hemianesthesia, variable paralyses often due to the contraction of antagonistic muscle-groups, hysterical seizures, and the like. The signs and symptoms of hysteria change from time to time, the recovery from any particular affection often being as sudden as its onset. The neurasthenic patient, on the other hand, is oftener a man than a woman, usually overworked, run down in general health, and worried. The symptoms are those of 'brain-fatigue' for the most part: inability to attend to or take interest in either work or pleasure; the bodily strength is lessened, and subjective sensations of all sorts may be felt in the back or limbs. Headache is a prominent feature in some neurasthenic patients; dyspepsia or palpitation in others; imaginary sexual disorder in others. Exaggerated knee-jerks accompany plantar reflexes that are still normally flexor, and the temperature is often subnormal.

General pains in the limbs are common in certain diseases of hot countries, of which only two need be considered here. Both occur in Southern Europe, as well as in more tropical regions.

Dengue is an epidemic infectious disease, much like influenza in many respects. Its onset is sudden, with headache and pains all over, fever, sore throat, an initial erythematous rash, and rapid pulse. The pains may be in the joints mainly, or diffused throughout the muscles of the limbs, and are made worse by movement. After two or three days the patient feels better, and begins to get about again; but after an interval of a day or two a slight or severe relapse occurs, with pains as before, fever, and a secondary roseolar rash, which begins on the hands and wrists, later spreading in patches over the whole body. The relapse is soon over; but convalescence may be slow, with persistence of the general pains in the limbs. The diagnosis should be easy in epidemics of dengue; the sudden onset, extent of the pains in limbs, head, and loins, and the characteristic course, should suffice to distinguish sporadic cases from other acute disorders such as measles, scarlet fever, rheumatic fever, etc.

Malta fever occurs mainly in the Mediterranean and on its shores: it is a chronic fever, characterized by perspirations, constipation, and rheumatic pains in the limbs; arthritis, orchitis, and enlargement of the spleen are common. The early symptoms are obscure; but pains in the limbs and general debility, gastric derangements, headache, bronchitis, and continued fever, are the general characteristics when the disease is established. The diagnosis would turn on the discovery of exposure to infection, the milk of goats that are carriers of the *Micrococcus melitensis* being the actual vehicle of infection: the patient's serum shows the specific agglutinating reaction.

Chronic General Pains in the Limbs will often remain after several of the disorders mentioned under the former heading. Thus, the pains due to *peripheral neuritis* may become a chronic affection in cases of chronic alcohol, arsenic, or lead poisoning, after influenza, or in gouty, diabetic, or syphilitic patients. Usually only one or two of the limbs will be affected in these cases; and the diagnosis will not have to be made from the occurrence of the pains, but will have become evident from the development of other signs of disease; a blue line on the gums (p. 34), tophi, and previous attacks of acute gout, sugar in the urine, and so forth.

To certain uncommon cases of *tubes dorsalis* the name *tubes dolorosa* has been given, owing to the severity and extent of the pains. The patient presents the usual symptoms of *tubes* (p. 609); in addition he has frequently repeated lightning pains in the limbs, so severe as to form the dominating element in his disorder from the subjective point of view. The diagnosis will be made from the suddenness and shocking intensity of the pains on the one hand; and on the other, from the discovery of further signs of *tubes*—Argyll Robertson pupil, loss of knee-jerk, ataxia, sphincter troubles, areas or zones of anesthesia. The pains will have a radicular distribution, and the nerve-trunks and muscles will not be tender on pressure.

General pains in the limbs are common in *chronic rheumatism*, occurring particularly in consonance with changes in the weather. In some instances, the muscles are the chief seat of the pain; in others, the joints or the fibrous tissues round them. In most cases, exercise, massage, or movement tend to diminish these pains, if the patient can be induced to submit himself to the discomforts of motion or exertion. Occurring in children, these chronic pains are usually set down as 'growing pains'; but their association with acute rheumatism is so frequent that the patient should always be examined for other evidences

of the rheumatic infection (see p. 464). In adults, on the other hand, chronic rheumatism is less often an inheritance from acute rheumatism, and is not so frequently combined with valvular disease of the heart: but it gives rise to pseudo-ankylosis of the joints, inability to work, and much impairment of the general health. The possibility of gonorrhoeal arthritis, mis-called gonorrhoeal rheumatism, must not be overlooked.

Myalgia, or the so-called 'muscular rheumatism,' is a common affection of certain groups of muscles, and may in some instances affect the limbs generally. It is due to chill, exposure to cold after sweating, sitting in a draught, and the like. Its commoner forms, such as lumbago, stiff neck, pleurodynia, stiff back, need only be mentioned; in the rare cases where the limbs are attacked, the diagnosis of muscular rheumatism will probably be made *faute de mieux*, although there is nothing to show that the affection is rheumatic, and no proof that it is the muscles (and not their sensory nerves, for example) that are affected primarily. It happens occasionally that severe pains in the limbs, or pains all over the body, are felt by patients with *pernicious anaemia*. In some instances these pains are associated with great tenderness of the bones of the limbs and trunk to pressure, which may be connected with the hypertrophic changes taking place in the marrow within them. Similar aches, pains, and tenderness may be found in any of the severe anemias or leukemias.

There remains for consideration the large class of diseases characterized by *chronic wasting or cachexia*, in which general pains in the limbs are often prominent. These pains are due to widely different causes in different instances. In some they may be due to nothing more than exaggerated muscular fatigue or overstrain; the debilitated patient has but little muscle, and that little is exhausted by exertions that would be trilling for a normal subject, so that the cachectic patient becomes the victim of general pains by the mere fact of being up and about. In other cases the pains are connected with peripheral neuritis, set up by the circulation of toxins in the patient's blood, though few or none of the other signs or symptoms of neuritis may be detected on investigation. In others, again, the pains seem to be connected with the occurrence of fever, being lessened or absent when the patient's temperature is normal. In the great majority of cases these pains are lessened by rest, or by any treatment that builds the patient up and increases his strength. Either the lungs, the heart, the liver, and gastro-intestinal system, or the kidneys may be the organs primarily at fault, and bodily wasting and weakness will be among the main symptoms. In cases where the organic disease is deep-seated and out of reach, there is danger lest the patient who is really seriously ill should be suspected of nothing more than functional disease and treated for such. Thus, patients with carcinoma of the stomach may be treated for hysterical vomiting or anorexia nervosa; the victim of a carcinoma or aortic aneurysm invading the spinal canal may receive the treatment usually meted out to the malingerer. It is important, therefore, that the most thorough examination should be made, and deep-seated organic disease of every sort excluded as far as is possible, before the diagnosis of functional disease be made in a cachectic patient. This is all the more necessary because there is no doubt that purely functional disease of long standing may reduce nutrition or bodily strength to a very low ebb.

A. J. Jew-Blake.

PAIN IN THE NECK.—(See SORE THROAT, p. 613; and STIFF NECK, p. 617.)

PAIN IN THE PELVIS. In practice, pelvic pain can usually be classified under four headings, namely: (1) *Deep-seated pain*; (2) *Superficial pain in the skin*; (3) *Spasmodic pain*; (4) *Backache or sacralgia*.

Deep-seated Pain is aching in character, continuous, and may be acute in onset, or may be chronic in duration. It is associated with tension in the pelvic organs, usually the result of overfilled vessels, or, in other words, of congestion. If the result of actual inflammation, i.e., congestion due to infection, it is acute, and very severe. It is elicited by pressure, and thereby made worse. In its worst form it is of peritoneal origin; but it may be due to simple congestion of the uterus, tubes, or ovaries, without infection or evidence of actual inflammation. The presence of adhesions between the pelvic organs is an important factor in the differential diagnosis of this type of pain, making it abundantly clear that there has been a past peritoneal inflammation, and that the tension in the organs is the result of the binding and pressure of new fibrous tissue. Thus it may be caused by:—

Local peritonitis due to infection, recent or remote, caused by salpingo-öophoritis, infection after labour or abortion, ovarian cyst with torsion of the pedicle, extra-uterine gestation, appendicitis.

Simple congestion, caused by retroversion and flexion of the uterus, prolapsed ovaries, sclerosed ovaries, hamorrhagic corpus luteum cyst, endometritis.

Superficial Pain in the Skin.—This is elicited by pinching or touching the skin with the head or point of a pin. It is essentially a referred pain, and may radiate very widely over the abdominal area, down the groins, over the crest of the ilium, and down the thighs. The area on the skin in which referred pain is felt in connection with uterine, tubal, or ovarian disease, is that to which the tenth dorsal nerve is distributed: and the area is that which is commonly known as the 'ovarian region.' It is not, however, ovarian only, and it is not even uterine and tubal only, but may be affected also by lesions of the kidney, ureter, gall-bladder, and some parts of the intestines. Consequently, referred pain in the skin in this so-called ovarian region cannot be taken to indicate disease of the generative organs at all, unless other lesions can be eliminated. The region of the tenth dorsal segment is simply a horizontal band spreading behind from the first to third lumbar spines, and extending round the body with its upper level in front at the umbilicus. All parts of the region are not necessarily affected equally, and there may be points of maximum intensity: one, notably, is midway between the umbilicus and anterior superior spine. This spot, especially on the left side, has often been taken erroneously to indicate pain due to ovarian inflammation. It is interesting to note that referred pain is commonly more marked on the left side of the body, the explanation of which is not quite clear. Referred pain in this segment may not be due to any local lesion at all, but may be a marked manifestation of hysteria in its graver forms. When extreme hyperæsthesia of this area on the left side is accompanied by anaesthesia of the skin of the legs and feet up to the level of the knees, with brisk knee-jerks and absence of the palate reflex, the diagnosis of hysteria is almost certain.

Spasmodic Pain in the pelvis is nearly always due to painful uterine contractions when it is of genital origin. The exception to this is the pain, certainly spasmodic in character, which occurs in connection with *tubal gestation*, as a rule in the week or two preceding tubal abortion or rupture of the tube. In this case it is supposed to be due to contraction of the muscle-coats of the tube, but there is no real evidence that this is a fact. There can be no doubt that, even though a part of the pain is muscular, some of it at least must be due to peritoneal irritation. The only way to diagnose between this tubal pain and that due to uterine contractions, is by a careful consideration of the history of the case, and the finding of a definite tubal swelling by the bimanual method. Even then the diagnosis is exceedingly difficult and often impossible. Spasmodic pain due to *uterine contractions* is caused by: The onset of abortion or labour; deficient development of the uterine muscle in spasmodic dysmenorrhœa (p. 192); expulsion of a growth from the uterus such as a fibromyoma; 'after-pains' following labour; gauze packing of the uterus after operations.

The differential diagnosis of these conditions is fortunately easy: but a much greater difficulty is sometimes met with when spasmodic pain has to be diagnosed which is due to causes which may not be of genital origin at all. The possible *extraneous causes* of spasmodic pain have already been outlined (see DYSMENORRHOEA, p. 192), and are: Appendicitis, intestinal, renal, or hepatic colic, leaking gastric ulcer, ruptured tubal gestation, twisted ovarian pedicle, hæmorrhage into a Graafian follicle, rupture of an ovarian cyst or pyosalpinx, dyspepsia, and flatulent distention of the bowels.

Backache, or Sacralgia, is a very common symptom in all classes of pelvic disorders: and may be present at the same time as deep-seated pain and superficial skin tenderness. It is associated especially with chronic uterine congestion and endometritis, backward displacement of the uterus, downward displacement (prolapse), and impacted uterine or ovarian tumours. Sometimes the only lesion to be demonstrated is a chronic cervical catarrh or a cervical erosion. It is a very difficult pain to explain in all cases: but it is usually regarded as one referred to the roots of the actual nerves which supply the uterus, tubes, and ovaries. In cases of impacted tumours it is possible that the pain is due to actual pressure on the sacral nerves at their exit from the bone, in which case pain will also be felt down the inner side and backs of the thighs. In cases of *carcinoma of the cervix*

backache is complained of, but is always associated with pain in the 'ovarian regions,' inguinal region, and also radiating down the legs. It must not be forgotten that this form of backache is not necessarily of genital origin, but may be the result of many other lesions. Thus, it may be the result of some irritating urinary constituent, like excess of urates and phosphates; also it may accompany a calculus in the ureter or some lesion of the renal pelvis. As a rule, in renal cases, the pain is situated rather higher up. Further, curies of the spine low down, growths of the spine, or of the spinal cord membranes, may give rise to it. Inflammation of the sacro-iliac joint, rectal growths, hæmorrhoids, and ulcers, may be its originating cause. It is clear that a correct diagnosis in any case cannot be made without a complete examination of all these structures, combined with careful urinary analysis.

Thos. G. Stevens.

PAIN IN THE PENIS—is a symptom which occurs frequently in urinary surgery, not only in association with lesions of the penis or urethra, but also as a referred pain with disease of the prostate, bladder, or kidney. The symptom is one which is common to many diseases, so that in the diagnosis of any case due consideration must be given to the other symptoms accompanying it, without placing too much reliance on a single symptom which may point strongly to the urethra or bladder.

Penile pain may be present either during or immediately after micturition, or may be entirely independent of the act. It may be said generally that if pain is felt only during micturition there is some inflammatory lesion of the urethra or prostate; whilst if it occurs immediately after the flow of the urine, it suggests some lesion in the urinary bladder. On the other hand, pain may be present quite apart from micturition, due to various diseases of the penis, bladder, ureter, or kidney.

The term 'pain,' too, is a relative quantity, varying with the nervous susceptibility of the patient, for what is pain in one may be merely discomfort in another, so that the patient's account may have to be discounted to a certain extent by the clinician.

I. CAUSES OF PAIN IN THE PENIS EXPERIENCED DURING MICTURITION.

- | | |
|--|-----------------------------------|
| 1. <i>Diseases of the Urethra</i> | Prostatic abscess |
| Acute inflammations | Prostatic carcinoma. |
| The passage of a calculus or the impaction of the latter | 3. <i>Diseases of the Bladder</i> |
| Stricture of the urethra | Acute cystitis |
| Injury of the urethra. | Vesical calculus |
| 2. <i>Diseases of the Prostate</i> — | Villous papilloma |
| Acute prostatitis | Pedunculated carcinoma. |

Diseases of the Urethra.—By far the most common cause of pain in the penis occurring *during* micturition is acute inflammation of the urethra, usually gonorrhœal, but occasionally septic. In the earliest stages of an acute urethritis, before any marked urethral discharge is apparent, there is usually a sense of smarting or tingling in the terminal urethra, more marked as the discharge increases, when it is of a burning or scalding character. The occurrence of this pain during micturition within a few days of sexual connection is frequently the earliest symptom of urethral infection, whilst a purulent discharge from the urethra is usually present when the case comes under observation.

The *passage of a calculus* through the urethra causes a sharp, cutting pain along the urethra, the cause of which is apparent when the calculus is voided. Occasionally it may happen that micturition occurs in these cases in the dark, or that urine is not passed into a vessel, so that the calculus is not actually seen by the patient; but if there is a history of previous renal descent of a stone or symptoms pointing to vesical calculus, the sharp urethral pain during micturition occurring upon one single occasion is significant of the passage of a calculus. A stone may, however, pass on to the urethra during micturition and become *arrested* at some narrowed portion of the canal, usually at the membranous portion or at the distal end, when a sudden, sharp pain is felt in the urethra, and at the same time the flow of urine is partially or completely stopped before the bladder has been emptied, whilst further efforts fail to re-start the stream. In these cases the presence of a stone should be suspected, and the whole length of the urethra examined by passing the finger along its course, when a stone may be actually felt, or the canal may be illuminated by an endoscope and the calculus seen.

Urethral stricture occasionally causes pain in the urethra during micturition, especially if the calibre is small, and if there is septic infection or ulceration of the urethral mucous membrane behind the stricture. The forced efforts at urination may cause pain in the urethra during micturition, but as a general rule stricture causes but little pain. The gradually increasing difficulty in micturition, the feeble stream, and the dribbling of urine from the meatus after the stream has terminated, are symptoms pointing to stricture of the urethra: the diagnosis will be confirmed readily by the obstruction offered to the passage of a full-sized bougie, or Letter, by direct observation of the urethra by means of the endoscope.

Injury of the urethra may cause pain during micturition. The urethra may be injured by a fall on the perineum, by a kick or blow, or by the faulty or careless passage of instruments: it may also be injured or lacerated in association with a fracture of the pelvis. The urethra may be merely bruised, may be lacerated on one aspect, or may be completely ruptured. If the urethra be injured, there is usually an appearance of blood at the external urinary meatus, together with a contusion in the perineum or along the course of the urethra, if the laceration is caused by direct injury. Any attempt at micturition causes pain in the penis, whilst urine may or may not be expelled from the meatus, depending upon the extent of the injury, or may be extravasated into the perineal or scrotal tissues. As a rule, no difficulty will be experienced in the diagnosis, but in any suspected case the greatest care should be exercised in passing an instrument into the urethra.

Diseases of the Prostate.—*Acute prostatitis* and *prostatic abscess* both give rise to pain during micturition, in addition to increased frequency and difficulty during the act. Both are usually sequelæ of an acute urethritis, and whereas an acute prostatitis is accompanied by a temperature raised to 100° F. or 101° F., a prostatic abscess causes the usual rise and fall in temperature common to septic processes. The diagnosis of the two conditions is made readily on careful rectal examination, when the acutely inflamed gland presents a much enlarged, smooth-surfaced prominence in the rectum: whilst if an abscess be present, a softer area in the inflamed gland can usually be detected. An acute prostatitis may accompany a hæmatogenous bacterial urinary infection as distinct from a venereal urethritis.

Adenomatous enlargement of the prostate gives rise to no penile pain during micturition: neither does the prostate containing tuberculous deposits, but pain in the penis is present during micturition occasionally in cases of *prostatic carcinoma*, owing to the direct infiltration of the urethral mucous membrane. Prostatic carcinoma is by no means uncommon, and whilst in its general symptoms it resembles those of prostatic adenoma, there is a marked difference found on digital examination of the gland per rectum. The carcinomatous gland presents rounded areas of densely infiltrated tissue, in contradistinction to the elastic, uniform feel of the adenomatous variety: the whole gland is fixed and immovable, and in advanced stages distinct infiltration of the lateral pelvic lymphatics may be felt extending laterally from the affected organ.

Care must be taken not to mistake the hard nodules felt in a prostate containing *calculi* for carcinoma. With calculous disease, the gland is not fixed and is only slightly enlarged, whilst on gentle pressure with the examining finger the calculi may be felt to grate upon each other. During the passage of a catheter through the prostatic urethra, distinct grating may be felt if any calculus has ulcerated the urethral wall.

Diseases of the Bladder may cause penile pain during micturition under certain circumstances, although it is much more common to find that pain in vesical disease follows the completion of micturition. In *acute cystitis*, penile pain is present throughout micturition, due to the intense congestion of the vesical mucous membrane of the trigone and around the internal urethral orifice. The other symptoms of acute cystitis, namely, suprapubic pain, pyrexia, increased frequency of micturition, and the presence of pus and blood in the urine, are sufficient for the diagnosis.

Pain during micturition in other vesical lesions is caused whenever there is any sudden obstruction to the normal flow of urine by the implantation of some body against the internal urethral orifice. This may occur with a small *calculus* or with a *pedunculated tumour*, whether simple or malignant, when during micturition the flow is arrested suddenly, accompanied by a shooting pain in the urethra, whilst after an interval of a few seconds the stream may be re-established. With vesical calculus, the urine may be normal or may

contain pus and blood if the bladder has become infected: there is penile pain after micturition, and the stone may be felt with a sound. With a simple villous papilloma there is no pain unless part of the limbricated portion of the tumour engage in the urethral orifice during micturition, but there are usually recurrent attacks of profuse hæmaturia, whilst with a villus-covered carcinoma there is increased frequency of micturition, with pain following the act, more or less constant hæmaturia, and usually pyuria. Upon rectal or vaginal examination, the base of the bladder may be felt to be infiltrated, but by far the most valuable means of diagnosis between the three conditions is cystoscopy, when a calculus or villous tumour is seen readily, whilst a pedunculated carcinoma appears as a dark red tumour covered with stunted processes. (See *Plate XVI*, p. 284.)

II. PENILE PAIN FOLLOWING MICTURITION.

This symptom is common to many lesions of the urinary bladder, more especially those in which there is ulceration or infiltration of the basal areas. The particular pain felt by the patient is described as a sharp pricking or tingling at the terminal part of the penis on the cessation of micturition, lasting some minutes and causing a desire to squeeze the glans. It has often been described as typical of vesical calculus, but this is far from being the case, for it may be due to almost any affection of the trigone.

The common causes of pain in the penis following upon micturition are:—

- | | | |
|-------------------|--------------------------|----------------------------|
| 1. <i>Vesical</i> | 2. <i>Ureteric</i> | 4. <i>Vesicular</i> |
| Calculus | Calculus in lower end | Acute spermato-vesiculitis |
| Tuberculosis | Descending ureteritis | 5. <i>Rectal</i> |
| Tumour carcinoma | Descending tuberculosis. | Carcinoma. |
| papilloma | 3. <i>Prostatic</i> | 6. <i>Anal</i> |
| Acute cystitis | Acute inflammation | Fissure |
| Bilharzia | Abscess | Inflamed hæmorrhoids. |
| | Calculus. | |

In Diseases of the Bladder.

A *calculus* in the bladder, unless it is trapped in the pouch behind an enlarged prostate, causes pain in the glans penis after micturition. It may exist without causing cystitis, although commonly there is some degree of pyuria when the case is first seen. There is increased frequency of micturition during active exercise or during the jolting of travelling, but not during complete rest unless cystitis is marked. The terminal drops of urine during micturition are often tinged with blood, and on some occasions there may have been a sudden stoppage of the stream during micturition. In some cases there is a history of the descent of a stone from the kidney without the subsequent appearance of a calculus in the urine. Patients subject to vesical stone have usually reached the later part of life, and although the symptoms are as a rule sufficiently marked to render the diagnosis easy, sometimes they may be so few that vesical calculus is quite unexpected, or the symptoms are so like those caused by other lesions of the bladder that error is easy. In such a case it is advisable to examine the interior of the bladder with a cystoscope rather than by the usual vesical sound: with a sound a small calculus, or one contained in a vesical pouch, may be missed, whilst with a cystoscope it is seen readily, its approximate size determined, and any other condition of the bladder accompanying or simulating calculus may be diagnosed with certainty. (See *Plate XVI*, p. 284, and *Fig. 135*, p. 282.)

Vesical tuberculosis may be a primary affection, but is more frequently secondary to tuberculous disease in some other part of the genito-urinary tract. It causes marked penile pain after micturition, together with pyuria and a tinge of blood in the terminal drops of urine: the frequency of micturition is increased during both day and night, and is uninfluenced by rest, thus differing from the increased frequency of calculous disease. Vesical tuberculosis usually occurs in young adults, but it must be distinguished carefully from other vesical infections, and more particularly from renal tuberculosis, in which symptoms referable to the bladder are commonly present before the bladder is attacked by disease. In a young patient in whom increased frequency of micturition, pyuria, and penile pain are present, a search should be made for any tuberculous focus, especially in the testes, prostate, and seminal vesicles, or for marked thickening of the terminal ureter as felt per rectum, whilst a careful search should be made for tubercle bacilli in the urine. A cystoscopic examination may be necessary to determine the extent of the disease (*Plate*

XI, Fig. E, p. 282), but, speaking generally, the less instrumentation that is carried out in these cases the better.

Vesical Tumours.—Carcinoma of the bladder occurs in two forms: the infiltrating epithelioma and the villus-covered carcinoma. Either begins most commonly in the basal portion of the bladder, the muscular planes of which become infiltrated. For this reason, the contraction of the bladder wall during micturition causes pain which is referred to the terminal portion of the urethra. Both forms occur in elderly patients, and give rise to increased frequency of micturition during both day and night, and to hæmaturia. They also often give rise to renal pain when the infiltration has extended to the ureteric orifice in the bladder. The base of the bladder may be found per rectum to be infiltrated, or enlarged glands may be felt in the lateral pelvic space, and a cystoscopic examination will usually clear up the diagnosis (*Plate XVI*, p. 284).

Whereas the carcinomatous growths of the bladder give rise to penile pain after micturition from the direct infiltration of the vesical walls, the pedunculated villus-covered carcinoma and the simple villous papilloma may give rise to sharp penile pain during micturition, from the blocking of the internal urethral orifice with a process of growth. The occurrence of this, together with attacks of profuse hæmaturia, are evidence of a pedunculated growth. On cystoscopic examination the carcinomatous pedunculated tumour is seen to be covered by blunt, stunted processes: it is often multiple, whereas the innocent villous papilloma is single and presents much more delicate fimbriae.

♣ *Acute cystitis* causes tingling pain in the penis after micturition from the inflammatory infiltration of the trigonal area. The mode of onset, the character of the pain, and other symptoms of cystitis will point to the cause of the pain.

Bilharzia hæmatobia gives rise to clinical symptoms very similar to those of vesical tuberculosis. The history of residence in an infected district, the microscopical examination of the urine for ova (see *Fig. 26*, p. 79), and the typical cystoscopic appearance of the bladder (see *Plate XI*, *Fig. K*, p. 284) will render the diagnosis apparent.

♠ *Ureteric lesions* not infrequently produce pain in the glans penis after micturition, and may cause considerable difficulty in the diagnosis from vesical disease.

When a *calculus* becomes impacted in the narrowed terminal or intramural portion of the ureter, symptoms are produced almost exactly similar to those of vesical calculus or tuberculosis, namely, increased frequency of micturition, pain in the glans penis after micturition, and a small amount of pus and blood in the urine. Intimate knowledge of the history of the illness will often be of value in these cases: the first attack of pain is usually described as being sudden, and felt in the renal angle posteriorly, passing forward above the iliac crest and spine, and finally becoming localized at the situation of the external abdominal ring. The calculus may become impacted in the terminal inch of the ureter, when, in addition to this pain, increased frequency of micturition and penile pain are added. In a recent case under the author's care, in which a small oxalate calculus was impacted in the terminal part of one ureter, there were frequent attacks of fairly profuse hæmaturia, suggesting a villous papilloma, but this is probably infrequent. With ureteric calculus there is usually pain in the kidney of the affected side from the dilatation of the pelvis of the latter, due to the increased renal tension. The diagnosis of these cases is not so difficult if a careful inquiry is made into the history and symptoms, and so long as it is remembered that increased frequency of micturition and penile pain may be caused by ureteric impaction of a calculus. A good skiagraphic examination of the pelvic areas may show the shadow of a stone (*Fig. 135*, p. 282), whilst the latter may be felt occasionally as a small, painful nodule above the seminal vesicles upon examination per rectum. A cystoscopic examination also affords valuable information, not only in excluding vesical lesions, but by giving a distinct indication of ureteric calculus by the marked congestion and dilatation of the blood-vessels in the immediate vicinity of the ureteric orifice. A small bougie passed into the ureter may meet with obstruction in its passage, whilst a wax-tipped bougie may be grooved or indented by the stone.

Ureteritis descending from infection of the renal pelvis may give rise to slight penile pain and to increased frequency of micturition, and thus simulate vesical disease before the bladder is actually affected. This is most commonly seen in the *tuberculous* form, but is present in a less marked degree with infection by other organisms, of which the most common are the *Bacillus coli communis* and the *staphylococcus*. In the non-tuberculous form,

the ureter may be felt per rectum to be slightly thickened, but the cystoscopic appearance of the inflamed ureteric orifice is quite distinctive (*Plate XI, Fig C*, p. 282). In *descending tuberculosis* from the kidney, the ureter may be felt as a firm, infiltrated cord on the bladder base, the penile pain and increased frequency of micturition are more marked, the kidney may be felt enlarged and tender, and tubercle bacilli will be found in the urine. Apart from this, typical changes in the ureteric orifice are seen on cystoscopic examination, the orifice being pulled up or retracted or horse-shoe shape, and usually occupying a position slightly above and outside the situation of the normal orifice, due to the actual shortening of the duct by infiltration of the submucous coats (*Plate XI, Fig. D*, p. 282).

Diseases of the Prostate often cause pain in the penis immediately following micturition. This is most commonly seen with acute inflammation or abscess in the gland as a sequela of acute gonorrhœa or septic urethritis. In either case there is penile pain, sometimes associated with erection, but little difficulty will be experienced in the diagnosis on due consideration of the symptoms and upon rectal examination.

Prostatic calculi are not uncommon, and there may be a single calculus or a nest of them in the prostate. They tend to ulcerate into the urethra, so that small calculi may be passed in the urinary stream, or some may pass back along the dilated prostatic urethra into the bladder. If a calculus projects from the prostate into the urethra, it causes pain in the penis after micturition. A diagnosis of prostatic calculus is often made by the grating sensation imparted to a catheter in traversing the prostatic urethra, whilst on rectal examination the calculus may be felt as an isolated, hard nodule in the gland, or, if more than one is present, by the crepitation of one upon another on digital pressure in the rectum.

Diseases of the Seminal Vesicle are seldom present without accompanying disease of the prostate or bladder. Acute vesiculitis may follow a urethritis and give rise to pain after micturition, but in most cases will be associated with prostatitis. Similarly tuberculous nodules in the vesicle will be associated with foci in the epididymis, prostate, or bladder.

Diseases of the Rectum and Anus may occasionally give rise to penile pain following micturition, apart from any infection of the bladder or prostate. Thus, a carcinoma in the anal canal, a rectal fissure, or an inflamed hæmorrhoid may occasionally cause pain in the penis, but in each the local symptoms of the trouble will be the more marked, and little difficulty will be found in the diagnosis if a local examination is made with care.

III. PAIN IN THE PENIS APART FROM MICTURITION.

Under the above divisions the symptom penile pain has been considered in relation to the act of micturition, and it remains to consider some conditions giving rise to pain in the penis *apart from micturition*. These include certain local lesions of the penis and urethra, and also the pains referred from disease elsewhere. Although a local lesion may cause little more than discomfort in many patients, in some it is described as pain, the degree of which depends upon the nervous susceptibility of the patient. Thus, penile pain may be present with *acute urethritis*, with *balanitis* in association with *phimosis*, with *paraphimosis*, or with the *lymphangitis* of the organ due to a septic sore or abrasion of the skin or mucous membrane. In some instances *herpes* of the prepuce or penile skin causes distinct pain. Any infiltration of the cavernous tissue of the penis causes pain during erection of the organ; thus during an attack of acute urethritis the common symptom known as *chordee* arises from this cause, whilst in a chronic form, *cavernitis* may be due to infiltration in association with tertiary syphilis or the gouty diathesis, so that erection of the organ is only partial or confined to the proximal part, and causes pain. Another condition causing the same condition arises from the organization of a *hematoma* in the cavernous tissues of the penis following upon a local injury, either from external violence or during forcible attempts at coitus.

Epithelioma of the penis occasionally gives rise to pain in the organ.

Pain may be felt in the penis in some cases of *renal colic*, in which case it is classed as a referred pain. Thus, in the acute colic accompanying the passage of a calculus, blood-clot, or debris of caseous material, aching pain may be felt in the penis quite apart from the increased desire to pass urine. Penile pain is, however, only a minor detail in the presence of the severe pain in the loin, and is often only lightly alluded to.

Pain in the penis was a prominent early symptom in two recent cases of *acute appendicitis* under the writer's care. In neither case was it associated with micturition, nor was there any increased frequency of micturition, but in both the appendix was found to occupy a very low position, turning down into the pelvis, which in one case contained a foul abscess.

R. H. Jocelyn Swan.

PAIN IN THE PERINEUM—is a symptom often mentioned by patients in giving their history of some affection of the genito-urinary apparatus or of other organs, but usually only as a dull aching, of which little notice is taken, as it is generally of minor consequence in comparison with other more striking symptoms. The complaint of perineal pain *per se* does not convey much information to the clinician, and it is practically never present as the only symptom in a case.

Aching in the perineum is frequently present in diseases of the following organs:—

<i>Prostate</i> —	Calculus	Boil
Acute or subacute inflammation	Carcinoma	Carbuncle
Abscess	<i>Urethra</i> —	Ulcer
Tuberculosis	Injury and rupture	Carcinoma.
Calculus	Stricture with extravasation or urethral abscess	<i>Vagina</i> —
Adenomatous enlargement	Fistula	Acute inflammation
Carcinoma.	Calculus impacted in bulbous portion.	Inflammation or abscess of Bartholin's glands
<i>Seminal Vesicles</i> —	<i>Testicle</i>	Cystocele
Acute inflammation	Congenital misplacement in perineum.	Epithelioma.
Tuberculosis.	<i>Anal Area</i> —	<i>Cutaneous Diseases</i> —
<i>Urinary Bladder</i> —	Hæmorrhoids	Intertrigo
Cystitis	Fissure	Eczema, gouty and diabetic
Tuberculosis		Condylomata.

From the foregoing list it will be seen that aching in the perineum occurs with numerous different lesions, but other symptoms discussed elsewhere are in almost every case more marked.

R. H. Jocelyn Swan.

PAIN, PRECORDIAL.—(See PAIN IN THE CHEST, p. 420.)

PAIN IN THE SHOULDER (see also PAIN IN THE EXTREMITY, UPPER, p. 412) may be due to two entirely different main groups of causes, namely: (1) *Direct causes*, in which the shoulder-joint itself is involved, or the nerves, ligaments, muscles, fasciæ, bursæ, close to it; and (2) *Indirect causes*, in which the pains are referred to the shoulder region when the real seat of disease is at a distance, as in the case, for instance, of angina pectoris, or gastric or hepatic disorders. The conditions to be thought of include the following:—

1. Direct Causes:

Injury	Myositis	Effects of occupations
Arthritis	Nemitis	Subacromial bursitis
Synovitis	Effects of exposure to cold	Muscular paralysis, local.
Fibrositis	or damp	

2. Indirect Causes:—

(a). *Cardiovascular lesions.*

Angina pectoris	Aortic atheroma (syphilitic)	Aortic aneurysm.
Aortic valvular disease		

(b). *Pleural, pulmonary, or mediastinal lesions.*

Pleurisy	Phthisis	Pneumothorax.
Pneumonia	Intrathoracic new growth	

(c). *Gastric lesions.*

Flatulence	Gastritis, acute or chronic	Gastric carcinoma
Indigestion	Gastric ulcer	

(d). *Duodenal lesions.*

Catarrh, with or without jaundice	Duodenal ulcer.	
-----------------------------------	-----------------	--

(c). Hepatic lesions.

Biliousness	Nutmeg liver	}	Hepatitis, acute tropical
Gall-stones	New growth		Abscess,
Cholecystitis			

(f). Nervous lesions.

Hemiplegia	Cervico-dorsal spinal caries	}	Pachymeningitis, syphilitic
Herpes zoster	New growth in cervico-		cervico-dorsal
Acute brachitis	dorsal spine		Cervico-brachial neuralgia.

The term shoulder is not explicit, and a patient may complain of pain in the shoulders when careful inquiry shows that it has widely different situations in different cases: in one it may be mainly in the root of the neck or in the central clavicular region; under the deltoid region in a second; under the lower part of the blade of the scapula in a third; and so on. The first step in making the diagnosis is to locate the pain complained of as definitely as possible.

It is often easy to diagnose its cause with some certainty from this point alone. If, for instance, the pain is mainly under the left shoulder-blade, its origin is likely to be gastric or intrathoracic; if mainly under the right shoulder-blade, duodenal or hepatic. (See PAIN, INTERSCAPULAR, p. 161.) If on the other hand the pain is definitely localized to the region of the shoulder-joint, the mischief is probably within the joint itself, or in the fibrous tissues, ligaments, bursae, muscles, or nerves around the joint.

The next point to investigate is the condition of the parts at and round the shoulder; if there is definite tenderness as well as pain, increased pain on attempted movement, local deformity from swelling or from wasting, or impaired mobility at the shoulder-joint, the trouble is probably local and the pains are not referred from the viscera. It may be difficult to be sure that there is no local tenderness as well as pain, for the patient may have suffered so much that he winces on palpation, from an expectancy of pain, when palpation or attempts at moving the joint are really painless; considerable judgment is required in deciding just how much tenderness is present as well as pain, especially in nervous subjects. If, however, there is definite tenderness as well as pain, the trouble is most likely local; and the same applies when the pain is made materially worse by local movements.

In testing the mobility of the shoulder-joint, it is important not to rely on the patient's statements or on inspection only; careful palpation is required. Frequently the patient may seem to move his shoulder well when, if the angle of the scapula is grasped whilst the patient moves his humerus, it will be found that the shoulder-blade moves synchronously with abduction of the arm, there being little or no play at the glenoid fossa. Normally, when the humerus is abducted, the scapula should remain stationary until the arm is at a right-angle with the trunk; if the upward movement of the extended and abducted arm is continued beyond the right-angle, the scapula normally moves with it. If it begins to move before the right-angle is reached, there is something the matter in or around the shoulder-joint. More often than not the mischief is due to peri-arthritis changes rather than to osteo-arthritis or other intra-articular inflammation; the fixation is due to the muscles being on guard to prevent any movement that would produce pain. Under an anæsthetic mobility may be found to be nearly perfect.

The differential diagnosis between the various conditions that may affect the joint is discussed in the article on JOINTS (p. 337). Fibrositis and myositis are in most respects equivalent to infective peri-arthritis, and it is often a matter of opinion whether any particular infective inflammatory condition around the joint is to be styled infective synovitis, or fibrositis, or myositis. Any of the three may involve one shoulder region only, but more often the patient has signs and symptoms of rheumatoid arthritis elsewhere also.

The effects of injury, exposure to cold and damp, and of occupations, when they involve the shoulder region, are only particular varieties of fibrositis, myositis, and arthritis. The stiffness and pain that may result from sleeping in a damp room with the shoulders uncovered by the bedclothes may be very severe, and they may take weeks or months to pass off. The chief question will be whether the exposure may not have caused actual rheumatoid arthritis, or have brought on a gouty inflammation or neuritis, in addition to mere stiffness and pain of a type allied to stiff neck or lumbago; and the differentiation

will often be a matter merely of opinion. The same applies to the effects of injury: in some cases the bruising or the tearing of ligaments, or the fracture of bones, or their dislocation, may be followed by pain and stiffness continuing to affect the shoulder region for months or years afterwards; in addition, however, the injury may set up actual arthritis allied to osteo-arthritis, and like the latter, more or less permanent. The *x*-rays may help in determining the exact degree of local disease the injury has produced. Occupations involving constant use of the shoulder often result in permanent intra-articular changes also—a sort of osteo-arthritis; the tendency increases with age; and very likely the occupation—such as that of porters who carry heavy weights on the shoulder—determines the site of the first joint to be affected rather than actually initiates the disease. Besides intra-articular changes, however, occupations involving strenuous and constantly repeated use of the shoulders may cause pain in them of the same nature as that of writer's cramp and other occupation neuroses. Rowing men, navvies, stokers, and so on, may suffer in this way. It is often very difficult, however, to distinguish between the occupation neurosis and organic fibrositis, myositis, neuritis, or arthritis.

One well-defined but often unrecognized cause of painful shoulder, in which both recurrent slight injury and occupation play an important part, is *subacromial bursitis*. Outside the upper part of the capsule of the shoulder-joint, between it and the under surface of the acromion process, there is a fairly large bursa. This becomes inflamed from overuse or overstrain of the shoulder in much the same way that housemaid's knee results from persistent kneeling; but with this difference, that the swollen subacromial bursa cannot be seen or grasped as an inflamed prepatellar bursa can. Pain on using the shoulder in certain positions is the chief complaint. The trouble arises from falls or blows upon the apex of the shoulder, or from occupations involving repeated sudden jerks to the shoulders—it is common in golfers, tennis players, bowlers, or in those who throw the cricket ball or put the weight; it also arises when the daily work involves the maintenance of a strain against interrupted resistance, as in the case of certain tools employed in electric steel grooving and the like. The diagnostic point is as follows: on minute palpation of the shoulder region, when the arm is at the patient's side there is a definitely and often acutely tender spot immediately below the tip of the acromion process, but if the patient now abducts the arm as far as he can, palpation of the previously tender spot no longer elicits any tenderness at all; on adducting the arm to the side the tender focus is again discoverable with ease. The explanation of the disappearance of the tenderness on abduction of the arm is that this movement takes the subacromial bursa far enough under cover of the acromion process for it to be no longer open to direct palpation. In cases of this sort *x*-ray examination generally shows a wider clear space between the acromion process and the head of the humerus on the affected than on the normal side.

In any case of doubt *x*-ray examination, not only of the shoulder region but also of the whole thorax, should be resorted to; now and again an unsuspected aneurysm of the aortic arch interfering with the lower part of the right brachial plexus will be found to be the cause of acute pains in the right deltoid region; or a mediastinal new growth, or rarities such as a hydatid cyst in the chest (*Fig. 137*, p. 291) may be discovered when mere arthritis has been alone suspected. *Angina pectoris* is responsible for very acute pain in the left shoulder region, but hardly ever here alone; the attacks, and the spread of the pain from the precordial region to the left shoulder and down the left arm are generally characteristic; and their nature will be confirmed by examination of the heart, including resort to electrocardiograms if need be, and by the influence of amyl nitrite or nitroglycerin on the paroxysms.

Pains referred to the shoulder in cases of *phthisis* are generally of the nature of dull discomfort or of aching than of acute pain; and the patient generally has had cough, wasting, night sweats, and so on, to indicate the diagnosis, which is confirmed by the existence of abnormal apical signs, by the discovery of tubercle bacilli in the sputum, or by *x*-ray examination of the chest (*Fig. 41*, p. 103). *Pleurisy*, *pneumonia*, and *pneumothorax* will hardly ever cause pain in the shoulder as their only symptom, and they will be diagnosed on other grounds.

Gastric, *hepatic*, and *duodenal* lesions causing pain in the shoulder, do so in the subscapular region rather than in the region of the shoulder-joint itself—stomach disorders on the left side, hepatic and duodenal on the right. They are discussed in the article on PAIN.

INTERSCAPULAR (p. 451). The chief difficulties that remain are the nervous causes, direct and indirect. *Herpes zoster* will be recognized by the characteristic eruption (p. 754), and the pains will nearly always extend down the arm and not be confined to the shoulder region. The chief point to bear in mind is that the pains resulting from herpes may persist for months after the eruption has disappeared, and may be severe before the vesicles come out. If there is local wasting of the muscles of the shoulder region, it does not follow that the primary lesion is nervous, because precisely similar muscular atrophy results very rapidly from joint lesions: with the latter, however, there is no R. D. (p. 582), whereas with true *neuritis* there is. It is, however, only when all intrathoracic lesions have been excluded, and when physical and *x*-ray examination point to there being no affection of the shoulder-joint, that neuritis of the circumflex nerve, for instance, should be diagnosed: an inaccurate diagnosis of neuritis is so often made simply because the patient has pains and no apparent cause can be found to account for them. *Acute brachitis* is allied to acute sciatica and acute anterior crinitis: it is diagnosed by analyzing the distribution of the pains carefully, and by excluding gross lesions of other structures in the shoulder region or in the chest. It is often associated with marked muscular atrophy, so that the humerus tends to fall away from the glenoid fossa and the patient invents all sorts of slings or splints for the better support of his arm. When there is no muscular wasting, the same lesion would often be termed *cervico-brachial neuralgia*. Some such cases are due to much more serious lesions, which may baffle diagnosis until the patient has been watched for weeks or months—*new growth* in the cervico-dorsal spine, for example: or cervico-dorsal *tuberculous curies*: *x*-ray examination of the vertebrae may assist in the earlier recognition of these conditions, but sometimes it is not until post-mortem examination is made that the exact cause of the pains—possibly regarded previously as in the main neurotic—is demonstrated. The *hemiplegic* arm is sometimes the site of great pain, especially in the shoulder: the pain is probably referred from the sensori-motor cortex of the cerebrum: the differential diagnosis will be found in the article on HEMIPLEGIA (p. 302). Cervico-dorsal *pachymeningitis* of syphilitic origin may cause no more symptoms than ill-defined though acute pains in various parts of the neck, shoulder, arm, or hand: peripheral neuritis or myofibrositis may be the diagnosis made. In most cases it is almost impossible to diagnose the pachymeningitis with certainty, though it may be guessed at: and in obscure cases of pain in the shoulder, apparently of nervous origin, it is often wise to have a Wassermann test made. If it is positive, appropriate anti-syphilitic treatment may cure the patient: and it is remarkable how often syphilis is found to be at the root of obscure pains and other ill-defined nervous complaints, even when any suspicion of syphilis might seem to be out of the question.

Herbert French.

PAIN IN THE SPINAL REGION. (See PAIN IN THE BACK, p. 427.)

PAIN IN THE STERNAL REGION. (See PAIN IN THE CHEST, p. 430.)

PAIN IN THE TESTICLE—of varying degree may be present in many conditions, and may be discussed under separate headings as follows:

- I. *Diseases of the body of the testis or epididymis.*
- II. *Affections of the coverings of the testicle.*
- III. *Affections of the spermatic cord.*
- IV. *A retained or misplaced testicle.*
- V. *Pain from lesions remote from the testis.*

I. DISEASES OF THE BODY OF THE TESTIS OR EPIDIDYMS.

Inflammatory Lesions may attack the testis proper, or, as is more common, may begin in the epididymis: they rarely remain confined to one part of the organ, however, for the process tends to spread rapidly from one part to the other, so that the whole organ is involved and the result termed an "*epididymo-orchitis*." An inflammatory affection of the testicle may be acute, subacute, or chronic, the latter being the terminal result of the former.

An acute epididymo-orchitis arises most commonly by the direct infection of the organ from the urethra *via* the vas deferens. When any inflammation has reached the prostatic

portion of the urethra, the orifices of the vasa deferentia may become infected, and inflammation spreads rapidly along the duct to the epididymis and testis. Whilst formerly the occurrence of an acute inflammatory condition of the testis, following upon some form of urethritis, was looked upon as "metastatic," it has been shown that this view is no longer tenable, and that we must look upon it as a direct spread of infection *via* the vas deferens.

Causes of Acute Epididymo-orchitis :—

Causes of urethral origin :— Gonorrhœal urethritis Septic urethritis Passage of catheters Urethral instrumentation	Ulceration behind a stricture Ulceration about an impacted calculus or a prostatic calculus. Injections into the posterior urethra.	General causes :— Fevers—Parotitis (mumps) Enterica Scarlet fever Injury Influenza Gout and rheumatism In hæmatogenous urinary infections.
--	---	---

Acute epididymo-orchitis begins as a painful thickening of the epididymis associated with febrile symptoms. Before any actual pain is noticed in the testis there is often a sense of discomfort and weight over the external abdominal ring and inguinal canal due to the inflammatory process extending along the vas deferens. The swelling of the epididymis increases, and with it the tubules of the testis proper become infected, causing swelling of its body and increase of pain. The whole organ thus becomes enlarged, and it is often exquisitely tender, the touch of the clothes or the most gentle examination causing pain. The swollen gland is often flattened on the outer and posterior aspect from pressure against the adductor muscles of the thigh; the vas deferens and tissues of the spermatic cord are thickened.

By far the most common cause of an acute epididymo-orchitis is an *acute gonorrhœal urethritis*. During the third week of the disease the prostatic portion of the canal frequently becomes infected, when the orifices of the ejaculatory ducts may share in the inflammation, and infection be conveyed by the vas deferens to the testicle. Similarly, but less frequently, infection may arise from a *septic posterior urethritis*, contracted during connection with a woman the subject of a vaginal leucorrhœa. The gonorrhœal form of acute epididymo-orchitis usually resolves slowly, and shows very little liability to suppurate, whereas the inflammation resulting from a staphylococcal or a streptococcal infection may break down into a testicular abscess.

Acute epididymo-orchitis may also arise from *septic processes* in the urethra following upon the *passage of catheters, of instruments* for vesical operations, such as lithotripsy, from ulceration behind a *urethral stricture* or about a *calculus* in the prostatic urethra, and occasionally after the *instillation of strong solutions* into the posterior urethra in the treatment of a chronic urethritis. In any case the onset of pain and rapid swelling of the testis should always lead to the suspicion of urethral infection, and attention should be directed to the urethra with that in view. Bacteriological examination of any urethral discharge is essential (see DISCHARGE, URETHRAL, p. 181).

Acute epididymo-orchitis occasionally arises *without any preceding urethral infection*, and uncommonly occurs as a complication of *acute specific parotitis* (mumps), *enterica*, *scarlet fever*, *influenza*, or as a complication of a urinary infection by *B. villis coli* or other organisms. The testicle becomes painful, and enlarges rapidly in the same manner as in acute inflammation from urethral infection, and under appropriate treatment gradually resolves. Less frequently testicular inflammation may occur with *gout* or *acute rheumatism*, or after a direct injury to the organ, such as a *blow* or *squeeze*.

The pain in an acute inflammation is generally of an aching character at first, felt not only in the testis, but at the external abdominal ring, and often as a heavy dragging pain in the loin of the affected side. As the testis enlarges, the local pain becomes more severe, so that the swollen gland is exquisitely tender to pressure or to the touch. After a few days the pain subsides to a large extent, but remains as a dull ache until the swelling becomes greatly reduced, and usually disappears some time before the organ returns to the normal size. In a few cases in which a fibrous scar remains in the epididymis, pain may remain and cause some difficulty in the diagnosis from a commencing tuberculous lesion, but the earlier history of acute inflammation will help in forming an opinion. In other cases the persistence of the pain and swelling may indicate the formation of an abscess

in the testicle, when, after decrease at first, the swelling increases, the skin covering it becomes reddened, and a soft area becomes evident in one or other side of the organ.

Tuberculosis of the Testicle is comparatively common, occurring as a primary disease or secondary to tuberculous disease of the kidney, bladder, or prostate. It begins as a localized deposit in almost all cases, causing a rounded, firm nodule in the epididymis. It frequently arises in the upper pole of the epididymis, whereas the inflammatory affections secondary to urethral infection begin in the lower pole. This nodule may remain unaltered for many months, or may enlarge, soften, become adherent to the skin and coverings of the testicle, or actually ulcerate through them to form a discharging fistula in the scrotum. The small commencing nodule in the epididymis is usually painless at first and may be found by accident, but later, as it gradually enlarges, it causes an aching pain in the organ. Other nodules may be formed in the epididymis, or the body of the testis may become involved, whilst commonly small shot-like thickenings may be felt in the course of the vas deferens. In the most advanced stages, nodules may be felt upon rectal examination in the seminal vesicles or prostate, or there may be some in the epididymis of the other side.

Tuberculous disease of the testicle usually presents little difficulty in the diagnosis. In an early case the occurrence of one or more nodules in the epididymis, which are painful on pressure and which have not resulted from a preceding acute epididymo-orchitis, should always suggest a tuberculous focus, and a careful search should be made for any other tuberculous lesion in the body. Should none be found, the estimation of the opsonic index of the blood to tubercle, or one of the several clinical tests for tubercle, such as von Pirquet's tuberculin skin reaction, may clear up the diagnosis. In later stages the diagnosis is less difficult; the gradual enlargement of the nodules, their craggy or bossy feel, the infection of the vas or other genito-urinary organs with tuberculosis, and above all, the tendency of the focus in the epididymis to soften and to become adherent to the serotal coverings, are points to be looked for; whilst if it should have led to the formation of a fistula, tubercle bacilli may be detected in the discharge.

Syphilitic Disease of the Testis causes very little pain in the organ, but there is often a sense of dragging or heaviness, and for this reason it must be considered.

Syphilis may attack the testicle in several different ways, producing:—

In Acquired Syphilis:—
Diffuse interstitial orchitis
Gummatous orchitis
Epididymitis.

In Congenital Syphilis:—
Interstitial orchitis
Gummatous orchitis.

The outstanding feature of syphilitic disease of the testicle is that it affects the body of the testis rather than the epididymis, thus differing in a marked degree from tuberculous disease. In the interstitial form there is thickening of the intertubular connective tissue, with an infiltration of spindle cells, which, forming young connective tissue, yield fibrous tissue when untreated. The subsequent contraction of this fibrous tissue may cause atrophy of the testis. The testis may, on section, show small gummata in addition to the diffuse orchitis, or if the inflammation is more localized, gummata may be the main feature, these varying in size from that of a pea to that of a walnut, or larger. The epididymis is affected but rarely, though cases are on record of a nodular swelling in the epididymis during the secondary stage of syphilis, which disappeared rapidly under antisyphilitic treatment.

In congenital syphilis, both the interstitial and gummatous forms exist; they usually occur in childhood or in young adult life, and in many cases the affection is bilateral. Syphilitic inflammation of the testicle may be accompanied in either the acquired or the congenital form by a vaginal hydrocele.

There is a sense of weight in the scrotum rather than pain, and often an aching or dragging feeling in the inguinal or lumbar region. On palpation, the body of the testis feels enlarged and nodular with the gummatous deposits, but the epididymis can usually be distinguished from the testis and be found to be unaffected. The tissues of the cord remain unthickened.

The diagnosis of syphilitic disease of the testis is usually simple. There may or may not be a history of syphilis, but other signs of the disease should be looked for—thus, in the acquired form, any scar of previous ulceration or periosteal thickening, or in the congenital variety, signs in the teeth, eyes, or ears. If any doubt remains, a positive

Wassermann reaction of the blood or the behaviour of the swelling when treated with large doses of potassium iodide and mercury, or salvarsan, should be noted. Syphilitic disease is distinguished from *tuberculous disease* of the testis by the fact that the epididymis is usually free from infection; that the cord, prostate, and vesicles remain normal; and by the comparative absence of pain in the testicle upon pressure being made upon it. Tuberculous deposits tend to soften and to involve the scrotal coverings in spite of treatment. From *chronic orchitis* it is differentiated by the history of injury and by the absence of the history or signs of syphilis. From *malignant tumours of the testis* it is distinguished by the history of syphilis, the tendency of syphilitic disease to be bilateral, the slow enlargement, and a positive Wassermann reaction. In malignant disease, the increase in the size of the testicle is more rapid, whilst the tumour often shows areas of varying consistence; the cord is often enlarged in malignant cases.

Malignant Tumours of the Testis may give rise to pain in the organ, but as a rule pain is only experienced in the later stages of the disease. Both carcinoma and sarcoma may arise in the testis, but embryoma is more common, exhibiting both epithelial structures and a combination of several forms of connective-tissue type—cartilaginous, myxomatous, etc. Clinically, without microscopical examination, a soft carcinoma and a sarcoma can rarely be differentiated, and as their symptoms and history are so similar, they may for convenience be considered together. A testicle that is the seat of a malignant growth enlarges rapidly, but as pain is at first absent, there may be nothing to arouse the patient's suspicions. As long as the tunica albuginea remains intact the swelling retains the shape of the testis, but when perforation of the fibrous covering takes place nodular projections appear and render the tumour irregular. These projections are softer than the remainder of the growth, and form a valuable point in the diagnosis. A rapidly growing sarcoma or carcinoma of the testis may be so soft as to appear to be a fluid collection in the tunica vaginalis. Generally, however, although a growth may be accompanied by a small amount of fluid in the tunica vaginalis, the more solid mass can be felt through the fluid on careful examination; this fluid is often bloodstained. The epididymis may become incorporated in the growth so that it cannot be distinguished, and the tissues of the cord become thickened. The coverings of the testis become stretched over the tumour; the mass does not become adherent to the scrotal skin until late in the disease. In both carcinoma and sarcoma, the iliac and lumbar glands become enlarged, and may be felt in a thin subject at the brim of the pelvis, and pain due to the pressure of these glands upon nerve structures may become marked. The inguinal glands are usually not enlarged unless the scrotal skin is affected. The diagnosis of malignant disease of the testis may be quite easy in the case of rapidly growing tumours, but in others, especially in the early stages, it may present great difficulty.

Between *sarcoma* and *carcinoma* it may be clinically impossible to distinguish. In quite early life the tumour is more likely to be a sarcoma; the cord is thickened earlier in carcinoma, but with rapidly growing tumours it may be quite impossible to say whether it is a sarcoma, carcinoma, or embryoma until a piece is examined under a microscope.

Orchitis may be confused with the more slowly-growing forms of sarcoma. In both the swelling may have followed an injury, and in both there may be a syphilitic history. Orchitis is, however, either more acute or more chronic, it retains more the oval shape of the testis, and does not present the rounded, slightly raised bosses which are commonly present in a sarcomatous testis. In orchitis the epididymis is usually distinguished more easily, and the cord is not so thickened as with a growth. Finally, the result of treatment with strapping and with mercury and iodide will often show the disease to be of a non-malignant nature.

Chronic torsion of the testicle is not very uncommon amongst habitual horse-riders, and sometimes, if there is no clear history as to the relationship between the swelling and a saddle injury, the nature of the painful tumour may be so uncertain that operation and histological examination are resorted to.

Tuberculous disease is usually diagnosed easily from malignant disease by the tendency of tubercle to attack the epididymis, to caseate, suppurate, and to become adherent to the scrotal skin comparatively early. Tuberculosis occasionally attacks the body of the testicle first, however, forming an oval, smooth tumour of the organ; the epididymis and vas deferens may be unaffected for a time, and if no deposit is found in the prostate or

vesicles, the differential diagnosis between tubercle and growth may be far from easy before operation.

Hæmatocele.—The diagnosis between a hæmatocele and a malignant tumour of the testis may present considerable difficulty. In both the swelling may date from an injury, whilst the indistinct fluctuation obtained in the soft areas of a growth, accompanied sometimes by some fluid in the tunica vaginalis, may simulate a hæmatocele. The latter feels heavy to the hand, but is usually softer in its whole mass and more regular than a growth. Care must be taken not to place too much reliance upon the withdrawal of a few drops of blood from the tumour by means of a trocar and cannula, a result which may happen equally with growth or hæmatocele. A hæmatocele may cease to enlarge, or even diminish in size, whereas, in growth, increase in size is progressive. The cord remains unaffected with hæmatocele, and testicular sensation is more likely to be lost in growth. If any doubt exist, it is advisable to make an exploratory incision rather than a puncture, when, if necessary, a radical operation can be proceeded with.

Hydrocele.—A hydrocele of very long standing, with an irregular, nodular surface, and absence of translucency due to the thickened tunica vaginalis and the thick contents of the sac, may simulate a new growth, but the long history of the case, and the absence of progressive increase in size of the swelling, will prevent a mistake of this kind.

Cysts of the Testis occur most frequently in connection with the epididymis, very rarely with the body of the testis. These cysts are quite different from hydrocele of the tunica vaginalis, and are often spoken of as encysted hydrocele of the epididymis or testis, or as a spermatocele, although all do not contain spermatozoa. They cause a swelling of varying degree in the serotum, and usually an aching in the testicle, groin, or lumbar region. They may arise as retention cysts of the tubules of the epididymis or from one of the fœtal remains which occur about the globus major of the epididymis, namely, the organ of Giraldes, the hydatid of Morgagni, or the vas aberrans of Haller. These cysts are usually placed above and to the outer side of the testis, occasionally behind it. They move with the organ, and can usually be distinguished from the latter by the test of translucency. Their increase in size is very slow, but they may cause aching pain in the testicle by pressure upon, or stretching of, the tissues of the epididymis. They can be distinguished from hydrocele of the tunica vaginalis by the position of the swelling relative to the testicle, and by the fact that the fluid contained in them is colourless or slightly opalescent from the contained spermatozoa, in distinction to the straw-coloured fluid of a vaginal hydrocele.

II. AFFECTIONS OF THE COVERINGS OF THE TESTIS CAUSING PAIN IN THE ORGAN.

The only common lesions of the coverings of the testis are *hydrocele* and *hæmatocele*; new growths of the testicular tunics are so rare as to render them surgical curiosities.

Hydrocele may occur occasionally as an acute affection accompanying an acute epididymo-orchitis, injury to the serotum, or in the course of acute specific fevers such as small-pox, rheumatism, or mumps. Recently acute hydrocele has been described in conjunction with acute lesions of other serous membranes—multiple serositis or poly-orrhoeitis. The more usual form of hydrocele is the chronic variety, which may be due to some disease of the testicle, but for which, in the majority of cases, no ascertainable cause can be found.

A hydrocele may cause some aching in the testicle, but more frequently it causes a dragging sensation in the loin from the mechanical effect of its weight. It forms a swelling on one side of the serotum, oval with smooth uniform surface; it gives a distinct sense of fluctuation. The swelling is limited distinctly above from the cord or external abdominal ring, and gives no sense of impulse on coughing; with a good light it can be found in most cases to be translucent, the testicle occupying a posterior and low position in the swelling.

The diagnosis of hydrocele is usually easy, but occasionally, when in old-standing cases the walls are much thickened, difficulty may be experienced. A hydrocele must be diagnosed from (1) A serotal hernia, (2) Hæmatocele, (3) New growth, and (4) An encysted hydrocele of the testis.

Scrotal Hernia.—Usually a hernia gives an impulse on coughing, can be reduced into the abdomen with a sudden slip or gurgle, and varies in size with the position of the patient. A hernia comes down from above and descends into the serotum. In a large irreducible

hernia, some part of it is usually resonant from the contained intestine, the swelling is not limited above, and the testis can be distinguished at the bottom of the scrotum. A hydrocele is distinctly limited above, gives no impulse, is translucent, and the spermatic cord can be distinguished easily. The testis in a hydrocele cannot usually be distinguished in the scrotum as in a hernia. Difficulty may arise between the two conditions when the hydrocele extends along the inguinal canal, and thus gives an impulse on coughing, or if the translucency is lost owing to the thickness of the walls or contents of the sac. A scrotal hernia in an infant may be translucent.

Hæmatocele is distinguished from hydrocele by the absence of translucency, the greater weight, and the suddenness of the onset, usually after an injury or puncture. If any doubt exist, an incision may be made into the swelling, permission being obtained to proceed to any form of cure that may be found desirable.

New Growths of the Testis.—A hydrocele is of much slower rate of increase in size, of smooth surface and uniform consistence, and is translucent.

Encysted Hydrocele of the Testis (see above).

Hæmatocele may occur as the result of tapping a hydrocele, from puncture of a vein in the sac or of the testicle, or by the occurrence of bleeding into a hydrocele. It may occur quite independently of a hydrocele, usually after direct injury. As a rule there is a rapid onset of swelling in the scrotum following the injury, with ecchymosis of the scrotal skin; the resulting tumour resembles a hydrocele in its clinical symptoms, save that it is not translucent. In other cases the swelling arises more slowly, when a pyriform or oval swelling is present in one side of the scrotum covered by normal skin; the surface of the swelling is smooth, and gives a sense of fluctuation and elasticity. There is no translucency, and, on tapping, dark blood-stained fluid is withdrawn.

The diagnosis in the less acute cases often presents a difficulty, especially with regard to *malignant disease of the testicle* (see above). From *hydrocele* it is distinguished by the absence of translucency; from *hernia* by the same points, except translucency, mentioned above in the diagnosis between hydrocele and hernia.

III. AFFECTIONS OF THE SPERMATIC CORD CAUSING TESTICULAR PAIN.

An inflammatory affection of the cord secondary to urethral infection is not uncommon. Similarly, tuberculous infection of the cord is practically never present without corresponding infection of the testis or epididymis. New growths of the cord, lipomata, myxolipomata, and sarcomata or hydroceles of the cord, cause no pain in the testis. A *varicocele*, especially if large, in a pendulous scrotum, is a frequent cause of a dull, aching pain in the testicle. The characteristic feel of the enlarged veins of the cord in the erect position, and the slight impulse on coughing, will readily point to the correct diagnosis.

IV. THE RETAINED OR MISPLACED TESTIS.

This, in its various situations, may give rise to pain, and may cause some difficulty in the diagnosis of the condition present. A testis may be arrested in its descent at the external abdominal ring in the inguinal canal, may remain inside the abdomen, or may pass (1) into the perineum after traversing the inguinal canal, (2) to the upper part of the thigh *via* the crural ring, or (3) to the root of the penis in front of the pubes.

In the various situations in which an undescended or ectopic testicle is placed, it may be attacked by the several diseases which affect the normally placed organ, and thus give rise to pain; but in addition, owing to the effect of constant muscular strains and the comparative immobility of the organ, it is particularly liable to recurrent attacks of traumatic inflammation, especially when the testis is retained in the inguinal canal; in the intra-abdominal position it remains protected from muscular injury, whilst ectopic testicles have a greater range of mobility than has one that is retained in the inguinal canal. The inflammation of an undescended testicle may be so acute as to lead to gangrene of the organ, with or without torsion of the cord.

The pain may be complained of first when the testes begin to swell at puberty, at which time an undescended right testicle may produce symptoms easily mistakeable for appendicitis.

The diagnosis of undescended testicle rests upon the following points: the fact that

one side of the scrotum is empty, the outline and situation of a swelling in the inguinal canal or elsewhere, the testicular sensation upon pressure, and the recurrent attacks of pain. An undescended testicle may give rise to acute pain from inflammatory lesions or from acute torsion of the organ, and may, if placed in the inguinal canal, give rise to symptoms suggestive of a strangulated hernia. It must be remembered also that a partially descended testicle is often accompanied by an inguinal hernia. It is also stated that the misplaced testis is prone to become the seat of malignant disease.

V. TESTICULAR PAIN FROM LESIONS OTHER THAN IN THE TESTICLE.

It is necessary to mention this class of case, in which complaint is made of testicular pain, when on clinical examination the testis is found to be normal. After an acute inflammation of the organ, even when no palpable nodule remains, the resulting cicatrization may cause an aching in the organ, especially after *sexual excitement* or prolonged desire. Apart from former testicular disease, pain may be felt in the organ if a *calculus* be present in the *pelvis of the kidney* or *upper ureter*, with a marked degree of *oraburia*, or from *stimulation of the peripheral nerves by carcinoma of the bodies of the lumbar vertebrae* or the pressure of an *aneurysm* in this situation. Pain in the testicle is occasionally present in *appendical inflammation*, when the appendix turns down into the pelvis.

R. H. Jocelyn Swan.

PAIN IN THE THIGH. (See PAIN IN THE LOWER EXTREMITY, p. 438.)

PAIN IN THE THROAT. (See SORE THROAT, p. 613.)

PAIN IN THE UMBILICAL REGION.

Pain associated with External Swelling. This may be due to the following causes:—

Umbilical Hernia. This is common in young infants, and also in fat, middle-aged people, particularly women who have borne children. Attention is often called to the protrusion first by the pain. In the early stages, while the hernia is yet small, it may easily be overlooked, especially if the patient is obese. The swelling is usually globular in shape, has an impulse on coughing, and may or may not be reducible. In a very large proportion of cases the hernia is irreducible, and it nearly always contains omentum.

Schaeffer's Cyst. This is not uncommon at the umbilicus. It presents itself as a small spherical swelling, which might be mistaken for a small irreducible umbilical hernia. There is, however, no direct impulse on coughing, and the swelling is attached to the skin. There is generally but little pain unless the cyst has become injured or inflamed.

Nec Growth. Occasionally the umbilicus is the seat of a small secondary nodule of growth which has been brought by the vessels in the round ligament from the neighbourhood of the liver. It may furnish a clue in making the diagnosis of an obscure abdominal ailment. *Epithelioma* is the only likely primary growth here: it has to be distinguished from a mass of *simple granulation tissue* here, and from *tuberculous ulceration of the skin* at the umbilicus: all three are uncommon: in some cases the diagnosis between them may be obvious almost at sight: in others the distinction may be so difficult that microscopic examination of a portion of the mass has to be resorted to.

Eczema Intertrigo.—Very obese people of uncleanly habits may suffer from this trouble at the umbilicus.

Divarication of the Recti Muscles.—A patient lying in the recumbent position may show no evidence of this condition. Diffuse pain is complained of about the umbilicus, and the divarication is made evident at once if the patient is asked to lift the head.

Cyst of the Omphalo-mesenteric Duct, a rare condition, may be found at birth.

Pain associated with Internal Swelling.

Tuberculous Peritonitis with formation of a localized abscess is the commonest cause of pain and a swelling situated inside the abdomen at the umbilicus. The patient is usually a child, and presents well-marked signs of chronic abdominal disease.

Carcinoma of the Pylorus or *Carcinoma of the Colon* may present as an umbilical tumour, especially if it has become fixed by adhesions, but it can usually be diagnosed without difficulty on account of the special symptoms arising in each case.

Pain without Swelling or other Localizing Symptoms.

The causes of umbilical pain are so numerous and varied, that in order to mention

all it would be necessary to enumerate nearly all abdominal complaints. This cannot be done here, but one should bear in mind the following as possible causes in patients in whom no trace of abdominal disease can be found, and who still complain of pain at or about the umbilicus.

Tubes Dorsalis.—The only complaint of the patient may be of abdominal pain, often referred to the region of the umbilicus. The typical gastric crises may be replaced by a much more diffuse pain, and more than one person has been operated on, and a gastro-enterostomy performed, under a mistaken diagnosis. A systematic examination of the knee-jerks, pupil-reflexes, etc., should be made in all cases.

Lead Poisoning.—Severe attacks of cramp-like abdominal pains referred to the umbilicus may be the chief, or even the only, symptom of plumbism. The patient's occupation may suggest the diagnosis, or other characteristic signs of lead poisoning may be found (p. 31.)

Tumour of the Spinal Column or Cord, Spinal Caries, and Compression Myelitis.—Though a less common source of error, these must be borne in mind. Owing to its situation, a growth in the spine may be very hard to locate; a skiagram may be of service.

Phthisis.—In this disease gastric pains are a common symptom, and the pains may even be referred to the umbilicus. George E. Gask.

PAINFUL COITUS.—(See DYSpareunia, p. 193.)

PAINFUL MICTURITION.—(See MICTURITION, ABNORMALITIES OF, p. 393.)

PAINFUL SWALLOWING.—(See DYSPLAGIA, p. 194.)

PALLOR.—(See ANEMIA, p. 21.)

PALPITATION signifies the sensation experienced by a person who is conscious of his heart beats. It is not necessarily associated with pain. It may be due to many different causes, of which the following are the chief:—

1. **Valvular Heart Disease, especially:—**

Mitral stenosis	Aortic stenosis	Pulmonary stenosis.
Mitral regurgitation	Aortic regurgitation	
Mitral stenosis and regurgitation	Aortic stenosis and regurgitation	

2. **Heart Affections associated with very High Blood-pressure:—**

Arteriosclerosis,	Granular Kidney.
-------------------	------------------

3. **Myocardial Affections:**

Fatty heart	'Blacksmith' heart	Senile changes with atheroma
Fibroid heart	Cloudy swelling	Congenital deformity.
Primary alcoholic heart	Pericarditis	
	Adherent pericardium	

4. **Lung Affections leading to Failure of the Right Side of the Heart:—**

Chronic bronchitis	Fibroid lung
Emphysema	Large pleural or pleuritic effusions

5. **The Effect upon the Heart of certain Drugs, etc.:—**

Tobacco	Alcohol	Cocaine
Tea	Absinthic	Digitalis
Coffee	Morphia	Thyroid extract

6. **Heredity, Nervousness, and Allied Causes:—**

Fright or other emotion	Paroxysmal tachycardia	Epilepsy
Graves's disease	Neurasthenia	Tabes dorsalis.
	Hysteria	

7. **Anæmia from whatever cause, but particularly**

Chlorosis	Pernicious anæmia.
-----------	--------------------

8. Mechanical Interference with the Heart by:—

Mediastinal new growth	Ascites
Chronic mediastinal fibrosis	Pregnancy
Thoracic aneurysm of large size	Ovarian cyst or other large intra-abdominal tumour.
Tympanites	

9. Dyspepsia: especially that which is associated with flatulence and with stoutness from lack of exercise.

The majority of patients who complain of palpitation jump to the conclusion that they have something the matter with the heart, and, although the above list is a long one, the diagnosis resolves itself in all but a few cases into deciding whether the palpitations are cardiac or gastric in origin. A routine examination of the various systems will very often indicate the correct diagnosis at once.

Valvular heart disease will be indicated by the history of rheumatic fever, scarlet fever, chorea, syphilis, or the like, and by the alteration in the size of the heart, together with the various bruits. Mitral stenosis is sometimes more difficult than the others to diagnose on account of the possible absence of a bruit or of enlargement of the left ventricle, but it may be suggested by the patient's malar flush, by the history of acute rheumatism, and by the loud, sharp, snapping character of the first sound at the impulse. Aortic regurgitation is sometimes present without a bruit, but it can generally be detected in these cases by the typical collapsing character of the pulse; if there is still doubt, and the patient is able to take exercise, it is frequently possible to bring out an aortic regurgitant bruit by asking him to take a few steps briskly.

High blood-pressure conditions are best detected by means of a sphygmomanometer; the diagnosis will be confirmed by the big heart, the albuminuria with tube-casts, and perhaps by retinitis.

Of the *myocardial affections*, pericarditis and cloudy swelling are both acute conditions, often associated with fever and with sufficient general illness to confine the patient to bed, so that the palpitations are a minor part of the malady. The diagnoses of fatty or fibroid heart and of adherent pericardium are discussed on pp. 53, 54. Palpitations due to heart-muscle affection are sometimes most difficult to distinguish from similar palpitations due to dyspepsia. This applies particularly to fatty changes in the heart. Not a few middle-aged persons suffer from palpitations which, by some observers, will be attributed to gastric trouble, whilst by others both the palpitations and the dyspepsia will be attributed to fatty heart; nor can the diagnosis be made by watching the effect of slight exercises upon the pulse-beat, for in typical dyspeptic persons without fatty heart, the general condition is usually sufficiently lacking in tone for the pulse-rate to be increased readily by exercise. If material benefit results from the giving of digitalis, from the adoption of Schott's Nauheim treatment, or some modification of the latter, the argument will be in favour of some myocardial degeneration; but in many instances of flatulence and palpitation the diagnosis between fatty heart and mere dyspepsia will remain largely a matter of opinion. Electrocardiograms may throw light upon the nature of some cases of myocardial disease the nature of which is not obvious to percussion and stethoscopic examination only; auricular fibrillation may be found, for example (*Fig. 196*), though there may be no valvular disease.

Lung affections causing strain of the right ventricle, and thus leading to palpitations, are detected as a rule by physical examination, but here again there may be so much difficulty in interpreting the physical signs that when a stout, middle-aged person, with obvious emphysema, and with wheezing and shortness of breath on exertion, complains of dyspeptic symptoms and also of palpitations, it may be very difficult indeed, except by watching the effect of different lines of treatment, to say whether the actual cause of the palpitations is emphysema with secondary dilatation of the heart, or dyspepsia with reflex palpitations or the result of fatty changes in the heart muscle of a dyspeptic person of sedentary occupation who is both stout and emphysematous.

Tobacco is a very important cause for palpitations in a patient who may seem to be perfectly healthy; the degree to which different individuals can smoke tobacco with impunity varies enormously, and whereas some may smoke from morning to night and develop no untoward symptoms at all, others develop some ill effects from what are

relatively quite small quantities. Cigarettes seem to be the greatest offenders in this respect, particularly cheap cigarettes sold in packets of considerable numbers for a penny. In bad cases the heart becomes absolutely irregular; in all cases of the kind any extra exertion, such as trotting a hundred yards, causes a rise in the pulse-rate out of all proportion to what it should; the pulse may rise, for instance, from 70 to 150 or 160 per minute as the result of slight exertion which in an ordinary individual would only increase it to 90 or 100. These patients may have palpitations at any time of the day or night, but particularly when they first get into bed, when violent thumpings may cause them considerable alarm. Similar thumpings of the heart, closely allied to but hardly identical with palpitations, are complained of by elderly men, particularly those of the gouty habit, probably with atheromatous degeneration of their coronary arteries. Another condition in which the heart may produce similar symptoms is *epilepsy*, in which disease, quite apart from the major attacks, there are innumerable accessory symptoms of which cardiac thumpings in bed at night are one. In that particular variety of epileptic convulsions which is associated with a sudden halving of the pulse-rate and coma—sometimes spoken of as *Stokes-Adams syndrome*—palpitations may also be a prominent symptom; the diagnosis is established best by obtaining electrocardiographic records of partial or complete heart-block (*Fig. 37, p. 83*). *Tea, coffee, alcohol, and absinthe*, as causes of cardiac irregularity and consequent palpitations, can be diagnosed best by the history and by the

Fig. 196.—Electrocardiogram to illustrate auricular fibrillation. Ventricular beats are marked R. The auricular beats are unmarked except in the central part of the middle curve, where three of them are marked x x x. The ventricular beats (R) do not recur at equal intervals, so that the pulse was irregular in time; but the average ventricular rate was 100 per minute. The auricles were not beating regularly; but where marked x x x the beats occurred approximately one every fifth of a second, the auricular rate at this point being about 300 per minute.

effects of stopping the drugs in question. *Morphia* and *cocaine*, if taken over periods sufficiently long to lead to palpitations, will generally be indicated by the presence of multiple prick-marks upon the body or limbs. The palpitations and other cardiac symptoms are worse, not while the drug is being taken, but when it is being intermitted. *Digitalis* and *thyroid extract* will be recognized as the cause at once if they are being prescribed by the medical attendant.

When palpitations are due to *nervousness, fright, or other emotion*, they are transient and not difficult to diagnose; if they keep on recurring from apparently trivial causes in a person who has not hitherto been nervous, it is important to bear in mind the possibility of *Graves's disease*, for although exophthalmos and enlargement of the thyroid gland are important symptoms of this disease, it is not at all uncommon for them to be absent, especially in the early stages, and for the only sign of the malady to be undue nervousness of the patient with a tendency to tachycardia and palpitations. Any condition in which the nervous system seems to be lacking in force or in control is liable to be termed *neurasthenia* nowadays, and if neurasthenia be defined in this broad sense, then one variety of it has palpitations for a chief symptom: the making of a diagnosis of neurasthenia in such cases, however, is equivalent to saying that the palpitations are of purely nervous origin, so that all one has really done is to exclude organic changes. The same applies to *hysteria*, though it should be borne in mind that modern authorities distinguish between *hysteria*

and *neurosis*, confining the word *hysteria* to those cases in which the symptoms are directly controllable by suggestion. *Locomotor ataxia* may give rise to symptoms referable to almost any of the viscera, and there seems no reason why cardiac crises should not occur as much as laryngeal, gastric, or intestinal; they are, however, rare, and when cardiac symptoms develop in a patient suffering from locomotor ataxia, syphilitic affection of the heart would be a safer diagnosis than would cardiac crises.

Anæmia, when it produces palpitations, is usually obvious from the patient's appearance, and it can be confirmed by blood examination. As a rule, palpitations in anæmic patients are entirely absent while the patient is at rest in bed, occurring mainly when she exerts herself and causes temporary dilatation of the anæmic heart. The palpitations disappear when the anæmia is cured.

Palpitations due to *mechanical interference with the heart*, by masses of fluid or wind displacing it, can generally be relegated to their correct cause by physical examination of the chest and abdomen; mediastinal new growth, tympanites, ovarian cyst of large size, and the other conditions referred to above, generally make their presence obvious before they are of sufficient size to produce palpitations. Herbert French.

PAPULES may be defined as solid, circumscribed elevations of the skin, not larger than a pea. Similar formations exceeding that size are classed as nodules or as tumours. From **VESICLES** (p. 753) they are distinguished by their solidity: if a papule is punctured, nothing but blood exudes: but in many instances papules, especially those of an inflammatory kind, are transitional lesions, passing into (*a*) vesicles, (*b*) pustules, (*c*) scales, or (*d*) breaking down into ulcers, (*e*) undergoing hypertrophy, as warts, or (*f*) atrophying. If the transformation into pustules or vesicles is only partial, the lesions are described as papulo-pustules or papulo-vesicles, and if this is characteristic of the greater number of the lesions, the eruption is said to be papulo-vesicular, vesiculo-papular, or papulo-pustular. If the lesions, originating as erythematous macules, do not take on the full character of papules, they are said to be maculo-papular or erythematopapular.

In *size*, papules may vary from a pin's head, as in lichen scrofulosorum, to a pea, as in lichen ruber planus. The most typical *shape* is that of the papule of lichen planus, flattened and with an irregular base: but they may be rounded or oval, as in prurigo, or cone-shaped, as in pityriasis rubra pilaris, or triangular, or umbilicated, as in lichen planus. In *colour*, they may be pink or rose-coloured, as in the inflammatory papules of urticaria papulosa, violet or purplish as in lichen planus, bright red as in eczema, dark or coppery as in syphilis, yellow as in xanthoma, whitish as in milium, almost black, as in infiltration sometimes met with in sarcoma, or simply skin-coloured, as in prurigo or verruca plana. They may be discrete, as in prurigo, or may occur in patches, as in lichen scrofulosorum; sometimes they form round a hair follicle, as in eczema folliculorum and pityriasis rubra pilaris: they are also met with in connection with the sebaceous glands, the sweat-glands, or the papillæ. They may be inflammatory, as in eczema, or non-inflammatory, as in severe goose-skin, or when they are the result of retained secretion, as in acne, or of excessive cornification round the mouths of hair-follicles. Usually, inflammatory papules give rise to itching; with the non-inflammatory kind there are seldom marked subjective symptoms.

Papules may occur in the epidermis, as in verruca plana, or in the derma, when they may be oedematous, as in urticaria, or infiltrated, as in lichen scrofulosorum: or they may affect both structures, as in lichen planus and the strophulus papule of acute prurigo. The epidermic papule may be recognized by its solidity, its hardness and dryness, and its superficial elevation; the oedematous dermic papule by its pinkish colour and its momentary yielding to pressure; the infiltrated dermic papule by its redness, induration, and elasticity; the epidermo-dermic papule by its union of some of the characters of the other varieties.

The multiple small papules which occur in *papular eczema* are usually conical with rounded base and bright-red colour: owing to rupture by scratching they are covered with a tiny dome of blood-crust: there is usually intense itching. Eczema of this type may resemble *lichen ruber planus*, but in that affection the papules, as a rule, are flat or umbilicated, with an irregular base, dark-red or violaceous colour, and glistening surface: there is no discharge or crust-formation: the papules are not transitional, and they leave brownish stains, while those of eczema frequently pass into vesicles and seldom produce

discoloration. Confusion between the plaques of lichen planus and those of scaly eczema may be obviated by attention to the differences in colour and in definition; in the former the plaques are generally dark-red or purplish, and sharply defined; in the latter, bright-red and not clearly marked off from the surrounding skin. Under the lens, a minute vesicle can often be seen on the top of each papule in eczema papulatum, which is not the case in lichen planus. Yet another point of distinction between the two is that in lichen planus characteristic discrete papules can usually be found at the margin of the patches. This feature serves, too, to differentiate lichen planus, in its turn, from *generalized psoriasis*, which is marked also by more scabiness and less thickening.

Lichen scrofulosorum is a papular dermatosis which clinically bears some resemblance to lichen planus, but it has no right to the designation lichen, and belongs rather to the tuberculides. The papules are seldom larger than a pin's head, are usually flattish but occasionally conical, very slightly resistant, sometimes smooth and shiny but more often covered with a tiny scale which is but slightly adherent; occasionally the summit is occupied by a pustule instead of by a scale. The prevailing colour is red, but it varies from a pale-yellow through red to violet. At first the lesions are disposed in groups, forming patches of various sizes. Others are arranged in arcs of circles, which are usually seen about the orifices of the sebaceous glands. The eruption shows a distinct predilection for the trunk—the lower part, and the back of the abdomen; but occasionally it extends to the beginnings of the limbs and may invade the face. If the affection becomes generalized by the spread and coalescence of the scattered groups of papules, the whole skin is covered with thin scales and is of a dirty reddish-brown hue. Itching is absent, or so slight as to be negligible. The eruption begins insidiously and may last for several months; and, having disappeared, leaving behind it no trace, it may reappear again and again over a period of several years. In the great majority of cases the disease is associated with some form of tuberculosis—phthisis, or necrosis of bone, or scrofulous ulceration of the skin; but much more commonly with enlarged glands, submaxillary, cervical, or axillary. Its usual subjects are children and adolescents; it is uncommon after the age of twenty. The characters of the papules—their homogeneity, situation on the trunk, flattish shape, arrangement in groups, painlessness, and chronicity—with the absence of itching, and the youth of the patient, are generally sufficient to determine the nature of the affection. In papular eczema the papules are not limited to the trunk, are bright red, and there is troublesome itching; moreover, in many cases there are vesicular or papulo-vesicular lesions as well as papules. From *miliary papular syphilides* lichen scrofulosorum can be distinguished by the absence of any other sign of syphilitic affection, and by the usually restricted distribution of the lesions.

In *keratosis pilaris*, or *xerodermia*, the papules do not form groups or patches as in lichen scrofulosorum, and usually they appear on the limbs, most frequently the thighs; they consist of projecting hair-follicles, which convey to the hand the sensation of a nutmeg-grater. This affection has, in turn, to be distinguished from *goose-flesh*, in which the elevations, besides being evanescent, are not rough or scaly. Keratosis pilaris is one form of *ichthyosis*; another form, sometimes met with in association with xerodermia, but more often alone, is *ichthyosis hystrix*, in which the lesions consist of small papillary papules with horny tops, which stud the skin as with minute nail-heads, and sometimes develop into large warty masses. The condition, dating back to infancy, or at least to early childhood, is easy of identification.

The same may be said of the ordinary wart (*verruca vulgaris*). The small flat wart (*verruca plana juvenilis*) may sometimes suggest lichen planus, but it is smaller than the papule of that affection, it has not the dark colour, it gives rise to no itching, nor is there any tendency for the growths to run together into rough, scaly, infiltrated patches.

In *psoriasis rubra pilaris*, papules form at the orifices of the hair-follicles, usually following in the wake of an eruption of scaly patches, or of a dry eruption covered with eczematous-looking crusts. The papules, when they appear, are small, red, and dry, harsh to the touch, more or less conical, and the centre of each is pierced by a single atrophied hair, which is surrounded by a sheath that penetrates into the follicle. The surface of the integument, thus roughened, has been likened to the skin of a newly-plucked fowl. At first the papules are discrete, but later they tend to run together into patches which present the aspect of pale yellowish-red areas covered with papery scales resembling mica.

They mostly affect the limbs, especially the surfaces where hair is most abundant; if they encroach upon the trunk they are usually found at the waist and the lower part of the abdomen. Itching is sometimes absent, and when present is always insignificant. When the patches are covered with mica-like scales and are met with in the situations most common to psoriasis—the tips of the elbows, fronts of the knees, and the extensor surfaces of the limbs—there is some danger of confusion with that disease; but at the edge of each patch the characteristic conical papule with its single hair plugging the mouth of a follicle is always to be seen. The best place to look for the papule is on the backs of the fingers. In psoriasis, again, the lesions grow by peripheral extension instead of by the accretion of new papules. The fact that the general health is not affected suffices to mark off pityriasis rubra pilaris from other forms of *exfoliative dermatitis*, in which also there is rarely any appreciable thickening of the skin, while the colour is redder than in pityriasis and the scaldiness more marked. From lichen ruber planus, pityriasis rubra pilaris is distinguished by the absence of itching and of impaired nutrition, and by its irresponsiveness to arsenic. In lichen planus, too, the papules are flattened, and often umbilicated.

In *acne vulgaris*, the papule forms the primary lesion. If the obstruction is at the mouth of the sebaceous gland-duct, the plug appears on the surface as a small black point—the comedo; if it is in the gland itself, the obstructing material is seen as a tiny whitish mass in the substance of the skin—the milium. The lesion may not develop beyond this stage, but usually it grows into a reddish papule about the size of a pea, and in many cases the papule passes into a pustule. Acne can usually be recognized by the distribution of the lesions—on the face, especially the cheeks, nose, forehead and chin, and less frequently the back of the neck, the back between the shoulders, and the chest—their discrete character, the presence of comedones or of milia, and the patient's age, for the affection is essentially one of puberty. Usually, too, the several stages through which the lesions pass are present at the same time—the comedo or milium, the papule, the pustule. *Rosacea* differs from acne in that it chiefly affects the flush area of the face, is marked by much congestion, and is most common in middle life. (See also PUSTULES, p. 557.)

In *erythema multiforme*, papules, tubercles, vesicles, bullæ, nodules, macules may all be present at the same time. Any one of these lesions may be predominant in a particular case or at a given time; but the type of eruption most frequently met with is that which consists wholly or predominantly of papules—*erythema papulatum*. This, too, is usually the first stage of the eruption in cases which go on to other types. The papules are generally, at the beginning, no larger than a pin's head, bright-red in colour, and flattish, sometimes umbilicated. If grouped closely together they may coalesce and form raised patches as large as a threepenny or a sixpenny piece; each patch has a sharply defined border, and is surrounded by an areola of congested skin: the tint in the centre soon deepens to violet, and afterwards to purple. The favourite sites are the dorsal surfaces of the hands and forearms; sometimes, too, the legs, feet, and the face are involved. Papular erythema multiforme is, as a rule, easy of recognition. Urticaria of the papular variety—the *strophulus* or *prurigo simplex aigu* of French dermatologists—in which the wheals are no larger than a lentil, and leave papules when they subside, occasionally offers some resemblance to it; but the two affections differ in that the lesions of erythema papulatum are much more persistent, are not white in the centre, do not give rise to itching, but do leave stains. One of the most marked of these differences is that which concerns itching, for in papular urticaria this symptom, though variable, is frequently severe. In urticaria, too, it is chiefly the covered portions of the body, and especially the lower lumbar region, that are attacked, and the affection is met with mostly in children.

Papules like those of urticaria papulosa are often met with in prurigo, both in *prurigo ferox* of Hebra, the severe form of the affection, and in *prurigo natus*, the mild and ordinary form. The characteristic lesion is an eruption of discrete, firm, very slightly raised papules, more or less hemispherical in shape, with a roundish, sometimes oval contour, and a glistening surface. At first the papule is of the same colour as the skin, but afterwards it becomes red, yellowish, or brownish, increases in size, and is frequently covered by a blood-crust. In structure, according to Darier, it is a localized acanthosis. Most abundant on the extensor surfaces of the limbs, and rarely seen on the flexor aspects, or on the face, the papules occur not infrequently on the chest, the lower part of the abdomen, the sacral region, and the buttocks. The itching is intense, and mixed with the secondary changes

produced by scratching, there may be found others not unlike those of eczema. Pustules and sores are common, often accompanied by great enlargement of the axillary and femoral glands. In prurigo ferox the papules are much larger and more numerous, and in parts the skin feels to the touch like very coarse brown paper or a nutmeg-grater. The changes secondary to the inflammatory process in prurigo are summed up by French dermatologists in the term *lichenisation* or *lichenification*. The skin is thickened and rugose, and owes its peculiar aspect to an exaggeration of the fine striae of the normal integument, so that it becomes quadrillated into a network of which the meshes are square, lozenge-shaped, or polygonal, with a flat surface which often, as Darier says, presents the aspect of glossy and brilliant facets, as of a mosaic. Sometimes it is covered with fine scales. The skin is less supple than normal skin, and though in colour it may undergo no change, it is more often greyish or brownish. The condition has to be distinguished from the lichenization met with in other dermatoses. In eczema and psoriasis, the thickened and rugose skin is red, has no glistening facets, and the margins are clearly defined. In lichen planus the plaques are formed by confluent papules and are surrounded by characteristic papules.

Apart from these secondary characters of prurigo, the diagnosis is made by excluding other itching affections, such as *scabies* and *pediculosis*, on account of the absence of the lesions characteristic of those conditions, and by the positive characters—the origin of the affection in infancy, and its persistence, the poor general health, the preference the papular eruption shows for the extensor surfaces of the limbs, the freedom of the bends of the joints, and the glandular enlargement, especially in the inguinal region.

In *syphilis*, papules are met with frequently in association with macules, but they may occur independently. They may be divided into two main classes: (1) *Miliary papular*, and (2) *Flat papular syphiloderms*.

1. *Miliary*, or *follicular*, *papular syphilides* are the result of infiltration around and beneath the pilo-sebaceous follicles; they are rough to the touch, and feel like small shot; they vary in size, from a pin-head upward, and may be either acuminate or rounded. The sites of election are the trunk, back, shoulders, and loins, but the limbs may be invaded, and also the face. Very frequently the lesions appear in groups which run into each other; and they are sometimes disposed in rings. The characteristic colour is that of raw ham, but at first they may be pink or red. Involution proceeds slowly, the stain left behind is long in dying away, and is sometimes succeeded by a shallow depression which may last for years. There is often a slight scale on the surface of the papule, and not seldom a tiny vesico-pustule or pustule may be detected on the summit. Sometimes there is overgrowth of the papillae; and if the lesion is situated in a moist part the warty growth is covered with sodden white epithelium, when the lesion is known as a *mucous papule*. A more marked degree of hypertrophy transforms the moist papule into a *mucous tubercle* or *condyloma*, distinguishable from a wart in that the overgrown papillae are welded into a coherent mass by swelling of the intervening tissue, while in the wart they are free.

2. *Flat*, or *lenticular*, *papular syphilides* vary in size from a pin-head to a bean, and the small or the large lesions may predominate in a given case. They may develop directly out of macular syphilides. In contour they are almost perfectly round, with a flattened top, are but slightly elevated, and in colour usually brownish-red. The whole body is affected pretty impartially; there is little tendency to agmination; sometimes the lesions form a kind of circle on the brow round the margin of the hair (the *corona veneris*). In some cases, ring-like patches (the circinate or annular syphiloderma) appear on the chin, around the lips or nostrils, or sometimes on the vulva; they are made up of small yellowish-red papules, with fine scales; elsewhere the papules, in the same case, are of the ordinary kind. In other instances, the flat lenticular papules of this group become seborrhœic; these are characterized by their obduracy to treatment. When there is marked scale-formation, the papules being covered with a dry, dirty-grey scale, they are styled papulo-squamous. Favourite situations for papulo-squamous syphiloderms are the palms and the soles, where they may be mixed with maculo-papular and papulo-tubercular lesions. Syphilides in these sites are often rounded or irregular in shape, have but slight elevation, are at first brownish-yellow or brownish-red, but presently become of a dirty grey, and on the disappearance of the scales have the characteristic colour of raw ham. When the scales are more abundant than usual, they form the *syphilides cornues* of French dermatologists.

The small papular syphilides may in some cases be difficult to distinguish from a widely diffused lichen ruber planus; but in this affection the rash is uniform, the papules generally have a linear arrangement, and there is usually severe itching. The papules of syphilis are most likely to be confused with psoriasis—the squamous papules with the ordinary form of psoriasis, the papules in rings with annular psoriasis. Attention must be paid to the polymorphism of the syphilitic eruption, the coppery colour, the enlarged glands, the sore throat or tongue, and the distribution of the lesions, no such partiality for the elbows and knees being shown as is observed in psoriasis, and the papular syphilide having a preference for the flexor surfaces of the limbs, while psoriasis affects rather the extensor aspects. The syphilitic scales, too, are thin and dirty-white, while those of psoriasis are heaped up in layers and have a silvery sheen. In psoriasis, the subject will usually have a history of previous attacks to relate; and often the affection can be traced back to early life, whereas in syphilis a particular lesion is seldom repeated. The palmar and plantar syphiloderms described above, which occur symmetrically as secondary and unilaterally as tertiary lesions, may be confused with the dry chronic eczema of those regions; but in eczema there are heat and itching, and usually, in the case of the palms, the fingers also are involved, and at some point or other the process is vesicular or moist. Palmar syphilides may be distinguished from eczema seborrhoeicum by the fact that in the latter there are coincident lesions in the common situations—the scalp and eyebrows, the neighbourhood of the beard, the naso-labial folds, the sternal and interseapular regions; nor do they usually assume the form of crescents or segments. Whenever the diagnosis is doubtful, recourse may be had to Wassermann's serum test.

Malcolm Morris.

PARÆSTHESIA. (See SENSATION, ABNORMALITIES OF, p. 604.)

PARALYSIS OF BOTH LEGS. (See PARAPLEGIA, p. 510.)

PARALYSIS, CROSSED.—(See HEMIPLEGIA, p. 302.)

PARALYSIS, FACIAL. This term is applied to complete or partial paralysis of the muscles supplied by the 7th cranial nerve. One or both sides of the face may be involved, the unilateral being more common than the bilateral. It is in some cases the result of a morbid process limited to the 7th nerve, known as *Bell's palsy*; in other instances it is one of the signs of more complex, or more remote, disease. In complete unilateral facial palsy, whatever its origin, the asymmetry of the face may be so marked that the diagnosis can be made at sight. Less severe facial weakness may be overlooked unless the means for its detection are employed. It is well, therefore, to recall the evidences of facial palsy before pointing out the features which characterize its various forms.

Even with the face at rest there are certain appearances on the affected side which attract attention. The natural lines and wrinkles are less marked, and, with the obliteration of the naso-labial fold, the cheek has a somewhat flattened or, in old persons, baggy aspect. If the patient is unconscious or asleep the flabbiness of the tissues may be emphasized by the flapping of the cheek with respiration, especially if breathing is laboured or stertorous. The palpebral fissure is wider than its fellow, and the corner of the mouth may droop.

When the facial muscles are thrown into action by attempts to raise the eyebrows, to close the eyelids, or to expose the teeth (*Fig. 197*), the difference between the two sides is rendered more obvious, the movements on the parietic half of the face being carried out with less power and more slowly than those of the healthy half. The ability to whistle or to move one nostril may also be impaired, and even with slight degrees of paresis, a person who has previously been able to close the eye of the affected side, the other eye

Fig. 197. A case of complete paralysis of the 7th cranial nerve. The patient is shown with the teeth bared. The right side of the face is paralyzed. (Photograph by Dr. S. A. K. Watson.)

remaining open, is no longer able to perform the feat. The same difficulty is experienced in making movements of the ear, by patients who have formerly possessed that accomplishment.

Having established the presence of some facial weakness, it is necessary, in order to take full advantage of its diagnostic value, to make certain careful observations with a view to determining the site of the lesion which is responsible for the defect. Thus, facial paralysis may be brought about by: (1) A lesion anywhere in the course of the pyramidal fibres passing from the lower end of the precentral gyrus in one cerebral hemisphere to the facial nucleus on the opposite side of the pons Varolii (*supranuclear paralysis*); (2) A lesion involving the facial nucleus itself (*nuclear paralysis*); and (3) A lesion of the 7th nerve between its origin in the nucleus and the point where it divides in order to supply the various facial muscles (*peripheral paralysis*).

Supranuclear Paralysis.—Owing to the fact that the fibres of the pyramidal tract concerned with facial movements cross the mid-line of the brain-stem only a very short distance above the 7th nucleus, the facial paralysis is on the side opposite to the lesion. Occasionally these fibres are involved alone; more often those destined to the corresponding arm and leg suffer as well, in which case the facial palsy forms part of a hemiplegia. In this type of paralysis the difference between the two sides is not nearly so marked in the upper as in the lower half of the face. For instance, the patient is able to elevate both

Fig. 198.—Post-paralytic contracture of the left side of the face. At a first glance the appearance suggests that the right side is the seat of paralysis.

Fig. 199.—Post-paralytic contracture. The same patient closing her eyes and showing the over-action of all the facial muscles on the affected left side.

Fig. 200.—Post-paralytic contracture. The same patient smiling, with an involuntary wink.
(Photos by Dr. S. A. K. Wilson.)

eyebrows and to close both eyes, although it will be found, on testing, that he is not able to resist an attempt on the part of the observer to open the eye of the affected side with the same degree of success as attends his efforts on the healthy side. (Figs. 198, 199, 200.) In the attempt to expose the teeth, the facial asymmetry is more striking, the lip remaining immobile or retracting slowly and feebly on the parietic side, and the contrast between the depth of the naso-labial folds on the two sides becoming clearly emphasized.

Notwithstanding the impairment of voluntary movement on one side, the face may present perfect symmetry when it responds automatically to emotional or reflex impulses. In laughing or crying the lines and wrinkles are developed equally, while protective closure of the eyelids is accomplished as well on one side as the other in response to any threatened violence to the eyes. The preservation of these automatic movements depends on the integrity of a facial reflex centre in the mid-brain. When this centre is involved at the same time as the fibres of the pyramidal system, the emotional movements are lost or impaired along with those of voluntary origin.

The corneal reflex can generally be elicited in this form of facial paralysis, provided there is no co-existent diminution of sensibility within the area supplied by the trigeminal nerve of the same side. In sharp contradistinction to what obtains in the nuclear or peripheral types of palsy, the nutrition and electrical excitability of the facial muscles undergo no alteration when the lesion is situated above the nucleus.

Bilateral supranuclear paralysis, such as is seen in cases of cerebral diplegia and pseudo-bulbar paralysis, is characterized by a general impairment of the natural movements, and tends to the production of a stiff, expressionless physiognomy (*Fig. 201*). With the consequent defective inhibition of the reflex centre, emotional movements are often uncontrolled, and with little provocation the patient betrays in his face degrees of mirth or distress which he is very far from feeling. This condition can be distinguished from true bulbar palsy by the preservation of the nutrition and the normal electrical excitability of the muscles, and by the absence of accompanying atrophic paralysis of the tongue, masseters, etc.

Reference must be made to the occurrence of cases, the result of mid-brain lesions, in which the emotional movements are lost and the voluntary movements are preserved on one side of the face. Asymmetry is then only noticeable when the patient smiles or cries.

Finally, it must not be forgotten that in long-standing cases of infantile hemiplegia, facial weakness may be associated with spontaneous athetoid movements similar to those observed in the arm and leg.

Nuclear Paralysis. Lesions of the facial nucleus may be slight or severe, and the resulting facial paralysis may consequently be partial or complete. As a rule, all the muscles supplied by the nerve are affected more or less equally, and the impairment of movements obtains whether they are voluntary, emotional, or reflex in origin. In cases of complete nuclear palsy certain additional effects are produced. The inability to close the eye, and the drooping of the lower lid, lead to imperfect protection of the eyeball, and to the overflow of tears on to the cheek (epiphora). Conjunctivitis and blepharitis may result. Paralysis of the lip muscles allows of saliva escaping from the corner of the mouth, and may interfere materially with the articulation of labial consonants. Paralysis of the stapedius muscle disorganizes the control of tympanic tension, so that the patient suffers from excessive sensitiveness to deep tones (hyperacusis) and perhaps from tinnitus. Unlike supranuclear paralysis, the nuclear form is accompanied by atrophy and alteration in the electric excitability of the facial muscles. In slow degenerative (usually bilateral) processes affecting the facial nucleus, the electrical response shows a quantitative modification: in acute destructive (usually unilateral) lesions of the nucleus, the facial paralysis is followed rapidly by the reaction of degeneration.

Owing to the situation of the facial nucleus in the pons, unilateral nuclear palsy may be associated with paralysis of the external rectus muscle of the same side and paralysis of the opposite arm and leg ('crossed' paralysis).

Peripheral Paralysis. The clinical picture of a peripheral facial paralysis resembles in its most important details that which has already been described under the heading of nuclear paralysis. All the muscles supplied by the nerve are affected in more or less equal degree, and the palsy is associated, within a short time of its onset, with atrophy and alterations in electrical excitability of the muscles concerned. The diagnosis between the two types depends chiefly upon the presence of additional symptoms resulting from interference with the function of neighbouring tissues, and this varies again with the exact site of the lesion in the peripheral course of the nerve.

A lesion affecting the fibres within the pons is likely to produce, in addition to the facial paralysis, external rectus palsy, together with other symptoms in proportion to the extent of the destructive process.

A lesion between the surface of the pons and the internal auditory meatus will probably interfere with the vestibular and cochlear parts of the 8th nerve, and so give rise to vertigo and impairment of hearing.

At the level of the geniculate ganglion, the chorda tympani is unlikely to escape, and the taste fibres coming from the anterior two-thirds of the tongue lose their function. At the same time, irritation of the ganglion may provoke an herpetic eruption on the auricle and around the external auditory meatus.

Fig. 201. Bilateral facial palsy.
The photograph shows absence of all lines, and sagging of both corners of the mouth.

In the upper part of the Fallopian canal a lesion produces complete facial paralysis and loss of taste on the anterior part of the tongue; in the lower part of the canal the resulting symptoms are the same, with the exception that paralysis of the stapedius, with its consequent hyperacusis, does not occur. The nerve to the stapedius leaves the facial nerve between these two points. Involvement of the chorda tympani may also cause deficiency in the salivary secretion of the submaxillary and sublingual glands of the same side.

At the stylomastoid foramen, the effects of a lesion are limited to the facial nerve, the taste fibres being no longer in close apposition to the latter.

From the above data the site of any lesion causing peripheral facial palsy can be determined approximately, and it is only necessary to add that the term *Bell's palsy* is generally limited to cases in which the exciting cause, probably an acute inflammatory process, operates at some point within or just below the Fallopian canal.

From the diagnostic standpoint it is important to remember that a condition which often results from a long-standing Bell's palsy may produce a facial asymmetry capable of erroneous interpretation, unless the observer is familiar with it. This is the so-called *post-paralytic contracture*, which emphasizes the folds and lines on the affected side in such a way that the opposite side of the face may appear at first sight to be the weaker (*Fig. 198*). It will be noticed, however, that an attempt to close the eye is imperfectly carried out, and that the angle of the mouth is strongly, although involuntarily, retracted at the same time. Similarly, on asking the patient to show his teeth, he can only do so slowly and with effort, while the eye is almost closed on the same side by a powerful associated contraction of the orbicularis palpebre. The only complaint of a girl suffering from a slight degree of this contracture was to the effect that she was unable to smile without at the same time giving the impression that she was winking.

Fig. 202.—Hemiatrophy of the left side of the face in an early stage. This condition is sometimes mistaken for facial palsy.

Hysterical facial spasm is another condition which may suggest weakness of the opposite side of the face, but the nature of the defect will be made obvious when the whole face is put into action.

Facial hemiatrophy often simulates facial paralysis (*Fig. 202*); it may be differentiated by the fact that not only the muscles, but all the tissues of the face on the affected side, undergo atrophic changes.

E. Farquhar Buzzard.

PARALYSIS OF THE HAND.—(See PARALYSIS OF ONE EXTREMITY, UPPER, p. 500; CLAW-HAND, p. 109; ATROPHY, MUSCULAR, p. 59; and HEMIPLEGIA, p. 302.)

PARALYSIS, LARYNGEAL.—Laryngeal paralysis is to be distinguished from interference with the vocal cords by inflammatory or ulcerative lesions, fixation of the arytenoid joints, and other affections which mechanically prevent free movements of the cords. The distinction can scarcely be made without careful examination of the parts with the laryngoscope.

In some cases, especially when bilateral abductor paralysis comes on suddenly, the symptoms may be urgent and extreme; in others, there may be no definite symptoms at all, particularly if there is but partial paralysis of one vocal cord, the other being freely movable and able to cross the middle line so as to meet its fellow for purposes of speech or coughing. In most cases the symptoms which point to paresis or paralysis of a vocal cord are a change in the character of the patient's voice, as noticed by himself and his friends, and difficulty in coughing effectually when need arises, the act of coughing being sometimes associated with a peculiar sound described by the terms 'brassy cough' or 'bovine cough.'

For purposes of differential diagnosis laryngeal paralysis may be divided into three main groups, namely: (1) *Functional*; (2) *Unilateral organic*; (3) *Bilateral organic*.

1. Functional Paralysis of the Vocal Cords has for its main symptom aphonia

without pain or discomfort, the patient nearly always being a young woman, or a girl over the age of puberty, who complains that she has almost suddenly become quite unable to speak otherwise than in a whisper. There may have been other functional nerve symptoms, the commonest being perhaps difficulty in swallowing owing to globus hystericus. This form of loss of speech is due to functional adductor paralysis during vocalization: but when the patient is asked to cough she does so with ease, and thus demonstrates that the adductor paralysis is not real, for one cannot cough properly without adducting the vocal cords. If the larynx is examined with the laryngoscope, the cords will be seen to move perfectly both with respiration and when the patient retches, though they may remain in the abductor position if the patient is asked to make any particular voice sound. The condition always gets well: it may pass off almost instantaneously as the result of local electrical application or of treatment by suggestion.

2. Unilateral Organic Affection of a Vocal Cord is obvious on laryngoscopic examination. It is nearly always the result of interference with the corresponding recurrent laryngeal nerve, and owing to anatomical differences between the two, the left is affected more commonly than the right. It may be paralyzed by pressure from, or infiltration by, an *aortic aneurysm*: a *mediastinal new growth*: *secondary deposits* in the deep cervical or mediastinal lymphatic glands—for instance, in a case of squamous-celled carcinoma of the œsophagus: *lymphadenoma*: *gumma*: or *mediastinal fibrosis*, particularly, though not very commonly, in association with syphilis, or with *fibroid phthisis* affecting the upper part of the left lung. Two rare causes are *mitral stenosis*, in which the over-distended left auricle sometimes compresses and paralyzes the left recurrent laryngeal nerve, and *lobar pneumonia* of the left upper lobe: extreme stridor has been known to result during convalescence from the latter in consequence of the cord paralysis. The differential diagnosis between these various conditions will be found discussed elsewhere: x-ray examination of the thorax may be helpful. In the absence of special indications, paralysis of the left vocal cord in a man of about forty-five is always suggestive of an aneurysm of the distal portion of the arch of the aorta, particularly if the patient has had syphilis, has not been an abstainer, and has undergone strenuous physical exertion.

3. Bilateral Affections of the Vocal Cords are seldom due to thoracic aneurysm, but some of the other diseases mentioned in the preceding paragraph may extend far enough up into the root of the neck on the right side to reach and involve the right recurrent laryngeal nerve as it passes beneath the right subclavian artery, as well as the left recurrent laryngeal nerve as it turns round the arch of the aorta to the left of the left subclavian artery. Careful examination of the chest for evidence of new growth or of syphilitic or tuberculous fibrosis is necessary, therefore, before one is in a position to diagnose the more common cause for bilateral paralysis of the vocal cords, namely *degeneration of the nerve cells in the vagus centres* in the medulla oblongata. It should also be remembered that some particularly malignant *enlargements of the thyroid gland*, and also *secondary deposits in the deep cervical lymphatic glands*, or even extensive infiltration of the latter by *tuberculous processes*, may involve both recurrent laryngeal nerves as they lie on either side in the sulcus between the trachea and œsophagus, and thus cause bilateral paralysis of the vocal cords. When the paralysis is due to degeneration in the vagal nuclei there is generally abductor before combined abductor and adductor paralysis: when the affection is symmetrical from the beginning the bilateral adductor spasm may result in acute dyspnoea simulating acute suffocative œdema of the larynx and requiring immediate tracheotomy. More often, fortunately, one vocal cord passes through the stage of abductor paralysis into that of complete paralysis before the other is affected, so that the dangerous condition of simultaneous abductor paralysis of both vocal cords is avoided. The diagnosis depends upon the alteration in, or the loss of, voice, together with the inability to cough efficiently, except with the sound which simulates the coughing of a cow (bovine cough): upon observation of the bilateral paresis of the cords with the laryngoscope: upon the exclusion of gross lesions within the thorax, or in the neck; and upon the co-existence of other indications of changes in the central nervous system. These in younger people are generally the result of syphilis, often taking the form of strabismus, or of locomotor ataxy, or general paralysis of the insane: whilst in older people there may be vascular degeneration associated with evidence of cerebral softening with or without albuminuria, glycosuria,

thickened arteries, an enlarged heart, and a high blood-pressure. Only in very rare cases is the symptom due to hæmorrhage or neoplasm in the medulla oblongata, for with these the patient does not usually survive to show signs of the laryngeal paralysis.

Herbert French.

PARALYSIS, OCULAR.—(See STRABISMUS, p. 649; PUPIL, ABNORMALITIES OF THE, p. 551; and DIPLOPIA, p. 174.)

PARALYSIS OF ONE EXTREMITY (LOWER).—The diagnosis of the conditions in which paralysis of both legs occurs is dealt with under PARAPLEGIA (p. 510); the present article refers only to cases in which paralysis of one leg is complained of. It is, however, a common experience for the clinician to find signs pointing to a bilateral affection when the patient is only aware of disability affecting one lower extremity. A notable and common example of this is afforded by many cases of disseminated sclerosis. The patient complains of weakness in one leg, and the physician finds exaggeration of both knee-jerks as well as extensor plantar responses on both sides, and is led to the conclusion that both pyramidal tracts are affected, although one may be damaged more severely than the other.

The various types of crural monoplegia may be divided roughly into two classes, one of which includes those cases without muscular atrophy, and the other those which present greater or less degrees of muscular wasting.

Paralysis of One Leg without Muscular Atrophy.—The cases in this class may be sub-divided into two groups, the first comprising those in which the pyramidal tract is affected, and the second those in which there is no evidence of pyramidal affection.

Spastic paralysis of one leg may result from a lesion of the pyramidal tract in any part of its course, but for anatomical reasons it is more likely that the paralysis will be confined to one side when a lesion affects the opposite cerebral hemisphere above the pons, that is to say, above the level at which the two pyramidal tracts run in close proximity. Spastic paralysis of one leg may, however, result from a lesion at any level, and the diagnosis of the level must be made from a consideration of other symptoms. In all cases the condition of the leg is qualitatively, if not quantitatively, the same. A spastic leg is characterized by a certain amount of weakness and rigidity, exaggeration of the knee- and ankle-jerks, and the extensor type of plantar response. It is useful to remember that the weakness in a spastic leg does not affect all the movements to the same extent. If the movements at the various joints are tested against the observer's resistance, it will generally be found that dorsiflexion of the ankle and flexion of the knee are affected more than other movements. It is for this reason that the patient tends to drag his toes more on the affected side than on the other, and evidence of this is often forthcoming in the fact that he tends to wear away the toes of his boot. The muscles of a spastic leg show no localized wasting, and present no alteration from the normal in their response to electrical stimulation.

In the attempt to diagnose the level of the lesion which gives rise to spastic paralysis of one leg certain considerations are of particular importance. If the lesion is situated immediately above the lumbar enlargement of the cord, the abdominal reflexes can be obtained. If the lesion is situated at the level of the 10th dorsal segment, the lower abdominal reflex on that side will be absent, while the epigastric reflex remains intact. A lesion of any of the upper dorsal segments causes abolition of all abdominal reflexes on the corresponding side. A lesion above the cervical enlargement will lead probably to some, even if slight, weakness in the corresponding upper extremity, in which the tendon-jerks will be exaggerated. A lesion of the higher part of the pons or of any level between the pons and the cerebral cortex will produce some asymmetry in the facial movements as well as weakness in the arm and leg.

Disseminated sclerosis has been mentioned already as a disease in which spastic paralysis of one leg may result from a lesion situated in the spinal cord. In all probability evidence of other patches of disease will be discovered in such cases if a careful examination is made. Some intention tremor in one or both hands, nystagmus, diplopia, optic atrophy, and sphincter troubles are among the signs which may be forthcoming. Less commonly, a one-sided affection of the spinal cord above the lumbo-sacral enlargement is due either to some intramedullary disease, such as a patch of *myelitis*, a *gumma*, or a *new growth*. When this occurs there may arise a symptom-complex to which the term *Brown-Séquard paralysis* is applied. In this condition there is spastic paralysis of the leg on the same

side as the lesion, together with loss of sensibility, especially of thermal and painful sensibility, in the opposite leg. The physical signs in Brown-Séquard paralysis are represented in greater detail in the accompanying diagram:—

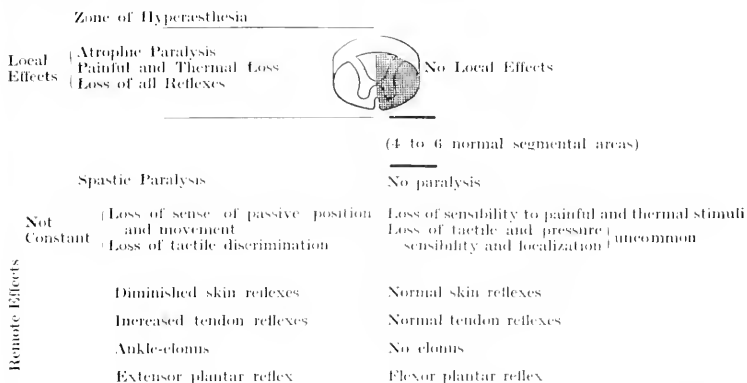

Fig. 203.—Diagrammatic representation of the results of a one-sided lesion of the spinal cord—Brown-Séquard Paralysis

Hysterical paralysis of one leg usually does not afford much difficulty in diagnosis. The affected limb may be either rigid or flaccid: in either case there is no true muscular atrophy and no alteration in the muscular response to electrical stimulation. The condition of the reflexes provides the most important information. In the hysterical form of paralysis the knee and ankle-jerks may be exaggerated, but they are never lost. A true ankle-clonus is never obtained, and the plantar reflex is either absent or of the flexor type. As a general rule the tendon reflexes in the opposite unaffected limb will be found to be equally brisk. In contradistinction to spastic paralysis resulting from a pyramidal lesion, in which it has already been pointed out that dorsiflexion of the ankle and flexion of the knee are the movements most profoundly affected, the movements of the leg in a case of hysterical paralysis are found to be more or less equally deficient at all joints and in all directions. Certain attitudes and certain types of gait are almost characteristic of hysterical paralysis of one leg. In one form the whole leg is kept rigidly extended, and the foot strongly inverted, so that the patient walks on the outer plantar edge with a stiff leg. In another form, the leg is flaccid and is dragged behind the opposite limb with the toes scraping the floor. In some cases, examination of the limb when the patient is at rest in bed reveals little or no paralysis, but in the attempt to stand or walk the limb appears to be quite useless. Hysterical paralysis of a leg may of course be associated with similar palsies of the opposite leg, or of the arm on the same side (hysterical paraplegia, hysterical hemiplegia). More often than not a leg which is the seat of hysterical paralysis also presents complete insensibility to

Fig. 204.—Brown-Séquard paralysis is due to an intramedullary one-sided lesion of the lower thoracic cord. The shaded area was insensitive to deep and superficial pain and to all degrees of temperature, but sensitive to touch. The sense of passive movement and position and tactile discrimination were disturbed in the right foot. There was spastic paralysis of the right leg only.

all forms of stimulation, and the upper limit of such anæsthesia may correspond to the line of the knee, the groin, or the umbilicus.

In the early stages of *paralysis agitata* a patient may complain of loss of power in one leg, and the diagnosis may present considerable difficulty if the characteristic tremor of this disease has not made its appearance. Examination of the limb may show little abnormal. Some slight paresis and slight stiffness to passive movements may be detected, but no alteration in the character of the reflexes will be observed. The diagnosis must depend more upon the general aspect and the attitude and gait of the patient. Some loss of facial expression, the general slowness of his movements, and the tendency to shuffle with the affected leg, are points which may lead the observer to form a correct opinion.

Paralysis of One Leg with Muscular Atrophy.—In a case which presents atrophic palsy of one leg, the first essential for making a diagnosis is to ascertain the exact distribution of the atrophied muscles, and to review this distribution in the light of what we know with regard to the central and peripheral innervation of the muscles of the lower limb. (See table below.)

Single nerve palsies are not so common in the lower extremity as in the upper, but they may occur, especially as the result of injury. Isolated *paralysis of the anterior crural nerve* and of the *obturator nerve* are quite uncommon, and when they do occur are generally the result of compression of the nerve within the abdominal cavity, either by growths or during the act of parturition. In affections of the anterior crural nerve, the movements of flexion of the thigh on the trunk and extension of the leg upon the thigh may both be impaired or lost. Wasting of the anterior thigh muscles, and diminution or loss of the knee-jerk, are other obvious signs of this condition. When the *obturator nerve is injured*, the patient can flex his hip but cannot adduct the thigh, and so, when sitting, he can raise his knee but cannot throw it across the other leg. He can walk about with no obvious disturbance of gait, but he cannot rotate the thigh either outwards or inwards, with any degree of force.

TABLE SHOWING THE MUSCLES TO WHICH THE VARIOUS NERVES OF THE LUMBAR AND SACRAL PLEXUSES ARE DISTRIBUTED.

<i>Nerve.</i>		<i>Muscles.</i>
Obturator (L. 2, 3, 4)	{	Obturator externus Adductor magnus

	{	Gluteus minimus
Inferior gluteal nerve (L. 5, S. 1, 2)	{	Gluteus maximus

Paralysis of the main trunk of the sciatic nerve, which would include paralysis of all the muscles supplied by the internal and external popliteal nerves, points to disease or injury affecting the pelvis. It may be brought about by a fracture of the pelvis or of the upper end of the femur, or by injuries to the hip-joint; on the other hand, the sciatic nerve may be compressed by tumours or inflammatory masses within the pelvis. Such an extensive palsy has considerable effect on the patient's gait, as he is unable to flex the knee, and consequently has to use the leg as a stiff, extended support; the disability is increased by the absence of all movements at the ankle-joint. The sensory loss in such a condition includes the outer side of the leg and the whole of the foot, except a small area on its inner and upper aspect.

Palsy of the *external popliteal nerve* is the commonest isolated nerve palsy in the lower extremity. Not only is it particularly exposed to injury in its course through the popliteal space, and as it winds round the fibula, but a primary neuritis of it is by no means uncommon, especially in cases of diabetes mellitus and lead poisoning. Isolated paralysis of the external popliteal nerve has been observed frequently in tabes dorsalis. Its most obvious result is the dropped foot to which it gives rise, and the high-stepping gait which is necessary if the patient is to clear the ground with his toes.

Injury to the *internal popliteal nerve* is very much less common, but it may be involved by tumours or the products of inflammation in the upper part of the leg. Paralysis of the calf muscles is the chief consequence, preventing the patient from extending his foot and standing on tip-toe, or from making any springing movement in the attempt to walk or run. The paralysis of the interossei and the unopposed contraction of the long extensors may lead to CLAW-FOOT (p. 109).

In addition to these peripheral nerve palsies of the lower limb, we have to consider paralysis due to lesions of the roots leaving the lumbo-sacral region of the cord, and forms resulting from disease of that part of the spinal cord itself (see table above); atrophic palsy of one leg is not commonly the result of *spinal curies*, although it may occur when the curies affects the lower lumbar or sacral region. On the other hand, paralysis of one leg, generally associated with acute pain of root distribution, is not a very rare early symptom of *malignant disease of the lower part of the vertebral column*. In the absence of any obvious deformity, the diagnosis in such cases is often difficult, and much may depend on the use of skiagraphy or upon the history of a growth elsewhere which may have been removed, from the breast for instance, even years previously. In some cases a good deal may be learnt from observing loss of the natural spinal curve, and from a suggestion of shortening in the stature of the patient, and particularly by noticing the diminished interval between the lower ribs and the iliac crests. These are signs of collapse on the part of the softened vertebra, and constitute a condition to which the name 'entassement' is applied.

Syphilitic meningitis, involving the roots of the lumbo-sacral cord, is another not very uncommon source of crural monoplegia. The diagnosis depends upon the history of syphilis, a positive Wassermann serum reaction, the results of an examination of the cerebrospinal fluid, and the fact that both the motor palsy and the sensory loss follow a root distribution.

* The muscles which afford the most useful landmarks are printed in italics.

Probably more common than any other cause for atrophic paralysis of one leg is the disease known as *acute poliomyelitis* (p. 512).

Tumours of the spinal cord and syringomyelia are very much rarer causes of paralysis of one lower extremity, although the possibility of their occurrence may sometimes need to be taken into consideration.

Various forms of *progressive muscular atrophy*, of either spinal or primary muscular origin, are more important causes of PARAPLEGIA (p. 510) than of unilateral paralysis. As a general rule they are symmetrical, or approximately symmetrical, in their onset and progress, but every now and then one may meet with cases in their earliest stage, when the complaint of the patient is referred to one limb only. A good example is afforded by the case of a lad who was brought to me on account of weakness

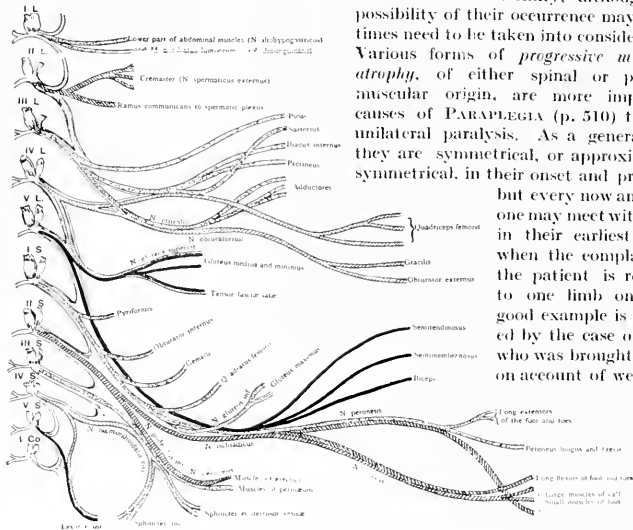

Fig. 205.—Diagram to illustrate the lumbosacral plexus and its branches (after Kocher).

in one foot, which had appeared quite insidiously and was tending to progress. The affected limb showed atrophic palsy of the long extensors of the toes and of the peroneal muscles. The diagnosis of *peroneal muscular atrophy* (p. 60) was confirmed by the appearance of similar physical signs in the other leg some months later. In addition to their early symmetrical distribution, these progressive degenerative diseases can be distinguished from gross diseases of the spinal cord and its envelopments by the absence of pain in the course of their evolution.

E. Farquhar Buzzard.

PARALYSIS OF ONE EXTREMITY (UPPER).—The word 'paralysis' has come, by general use, to include partial as well as complete palsies, and to embrace all varieties of impaired voluntary movement. It is in this sense that the word is used for the purpose of this article. No other interpretation would be of value in discussing diagnosis, because the latter depends, not upon the degree of paralysis, but upon its nature, distribution, and associated phenomena. Accurate diagnosis is often most difficult, although perhaps more important from the point of view of successful treatment, when the limitation of voluntary movement is only slight. Before discussing the various forms of paralysis met with in the arm, some reference must be made to a few practical points which are important in the proper investigation of cases complaining of inability to use an arm.

The medical man must not be satisfied with the patient's statement that he has lost power or that he is weak in his limbs. Tests must be employed to ascertain whether this is really the case. The movements at each joint, of flexion, extension, pronation, supination, must be investigated, and if necessary their power measured against the observer's resistance. It may be found that the grasp is powerful in a patient who is unable to use his hand on account of loss of control over the finger movements. In such a case there is not paralysis, but inco-ordination (see ATAXY, p. 55). Similarly, there is certain to be

difficulty in carrying out delicate movements if there is loss of cutaneous sensibility. Without tactile sense it is impossible to handle a pen in a proper manner. Sometimes a patient will complain of loss of power, when investigation shows that the ability to execute movements is inhibited by the pain in a muscle or joint evoked by the attempt. In other instances, mechanical limitation of movement by arthritic changes, without pain, may lead the patient to believe that there is loss of power. He finds he cannot lift his arm, and ascribes the disability to paralysis instead of to ankylosis of the shoulder-joint. On the other hand, it must be remembered that pain and loss of power may be associated in some forms of neuritis. If the patient says, "My arm is so painful that I cannot lift it," examination must be directed to ascertain whether the inability is due only to painful inhibition or to real paralysis in addition.

Stress must be laid upon the necessity for obtaining a careful history, and especially an accurate account of the duration of the trouble, whether its onset was sudden, rapid, or slow and progressive, and whether the loss of power was accompanied or preceded by pain, numbness, or tingling. The family and previous history must not be neglected. In examining the paralyzed arm, care should be taken that the whole of *both* upper limbs, as well as the neck, upper part of thorax, and shoulders are stripped, so as to be inspected easily and the two sides compared. It will also be necessary, in the large majority of instances, to investigate the functions of the cranial nerves and the reflexes, etc., of the trunk and lower extremities. This is often imperative even when no complaint is made of loss of power or other symptoms in any part of the body except one upper limb. The importance of this full examination is perhaps obvious, but it may be illustrated by reference to two points. A lesion of one internal capsule may give rise to paralysis of the opposite arm, but it will be likely to cause, in addition, some alteration in the abdominal and leg reflexes of the corresponding side. Similarly, a lesion of the 8th cervical or 1st dorsal spinal segments, or of their corresponding spinal roots, will also affect the fibres leaving the cord at that level and passing, *via* the cervical sympathetic, to the eye of the same side. In this way atrophic paralysis of the muscles of one hand may be associated with a small pupil and a small palpebral fissure on the same side, a coincidence which at once points to the cord or roots as the site of the lesion, and acquits the peripheral nerves of being concerned in the production of the palsy. In such a case the further investigation of the abdominal reflexes, the knee-jerks, and plantar responses, will help to decide whether the lesion is intramedullary or extramedullary: in the former event the abdominal reflex on the same side would be absent, the knee-jerk would be increased, and the plantar response would be of the extensor type, while in the latter, unless the lesion exerted considerable pressure on the cord, the reflexes below the arm would be normal.

Any attempt to enumerate, let alone discuss, all the possible lesions which can give rise to paralysis in the upper extremity, is out of the question, and we must be content to consider the broad principles of diagnosis in connection with the more familiar instances of brachial palsy. For this purpose a classification based chiefly on the presence or absence of muscular atrophy will be adopted. This will be of practical use because the mere inspection of a paralyzed limb generally enables the observer to detect whether a case belongs to the one category or the other.

PARALYSIS WITHOUT MUSCULAR ATROPHY.

This heading embraces cases in which there may be general impairment of nutrition, and perhaps muscular wasting, due to disuse, but in which there is no localized muscular atrophy and no alteration in the response of the muscles to electrical stimulation. The cases may be divided into two groups: (1) Those in which there is some affection of the upper motor neuronic system (pyramidal lesions), and (2) Cases without lesion of the pyramidal tract.

Paralysis due to Pyramidal Tract Lesions. The most familiar example of this group is afforded by cases of brachial monoplegia due to a *vascular lesion (thrombosis, hemorrhage, or embolism) in the internal capsule* or other part of the pyramidal tract in its course through the brain. In the diagnosis of this condition the points of importance are: The presence of some cardiovascular condition capable of producing the lesion, such as disease of the heart, kidneys, or arteries; the sudden or rapid onset of the symptoms, with or without loss of consciousness or other cerebral disturbance. The arm retains its natural

contours, and the muscles are not atrophied, although they may appear, after some time has elapsed, to be smaller than those of the other arm. The paralysis may affect the whole limb and include inability to shrug the shoulder; or the movements of the hand and fingers may be more impaired than those of the elbow and shoulder. There is a tendency for the arm to exhibit more and more resistance to passive movement, that is to say, to develop spasticity. At the same time, if left to itself, the limb will adopt a fixed position, which includes adduction of the upper arm to the trunk, flexion and pronation of the forearm, and flexion of the wrist and fingers. If any movements are possible, they will be those of flexion rather than of extension at the various joints. The muscle tone is increased, and the tendon-jerks, such as the ulnar and radial wrist-jerks, the triceps, biceps and supinator jerks, are exaggerated when compared with those of the opposite limb. Eventually contractures may develop, and it will be found impossible to extend the upper arm, forearm, hand, and fingers into one straight line.

Such is the clinical picture afforded by spastic paralysis of the arm, and one case will differ from another only in the degree of spasm and the degree of paralysis; but the amount of spasticity and the paresis do not always correspond. In one patient the rigidity forms the chief obstacle to voluntary movement; in another the arm, though powerless, shows comparatively little increase in tone.

The fact that the pyramidal fibres destined for the face, trunk, and leg run in close proximity to those for the arm, is sufficient reason for suspecting that, even if no other paralysis is complained of, there may be signs of disturbed function in other parts. The side of the face corresponding to the paralyzed arm may not move so quickly or so powerfully as the other side in a voluntary effort to show the teeth, although no difference may be detected when the patient smiles. The corresponding abdominal reflexes may be found wanting. The knee-jerk may be increased; ankle-clonus and an extensor plantar response may be elicited; all on the same side.

This spastic arm, in all degrees of severity, may result not only from a vascular lesion in the brain, but also from a *cerebral abscess*, a *cerebral tumour*, or *cerebral inflammation* (encephalitis). The arm will present identical features, so that the diagnosis must be made from a consideration of other data. Thus a *cerebral abscess* only becomes likely when there is some infective process either in the bones of the skull (mastoid or frontal sinus disease) or in a distant part such as the heart or lungs (ulcerative endocarditis or bronchiectasis). Headache, vomiting, and optic neuritis, with a slow pulse, slow respiration, and subnormal temperature, may help in the diagnosis. In cases of *cerebral tumour* the development of the brachial palsy is nearly always slow and progressive, spreading from one part of the limb to another, and again there may be headache, vomiting, and optic neuritis. It should be remembered, however, that these signs of increased intracranial pressure are not always present, and that the presence of a tumour is always to be suspected when a spastic paralysis of one limb comes on in a slow and progressive manner. Some tumours grow at the expense of neighbouring tissues in such a way that pressure is raised but little or not at all. *Encephalitis* will need to be considered when there is a history of acute constitutional disturbance with fever, vomiting, headache, and perhaps convulsions preceding or attending the onset of the paralysis. The latter, however, is not progressive. It reaches its maximum within a few hours, and shows a general tendency to improve after the acute symptoms have passed off.

Disseminated sclerosis is another disease in which a spastic monoplegia is not uncommon. The diagnosis is easy if it occurs late in the disease, when nystagmus, optic atrophy, spastic paraplegia, and sphincter trouble are already present, or if there is a history of previous transient palsies affecting other limbs. When, however, paralysis of one arm is the first symptom, as it may be, the diagnosis may be difficult. The rapid onset of the palsy in a healthy young adult without constitutional disturbance, severe headache, or vomiting, and perhaps the discovery of absent abdominal reflexes and an extensor plantar response, should direct suspicion to the possibility of a patch of disseminated sclerosis being responsible for the trouble.

Diseases of the *pons*, *medulla*, and that part of the spinal cord which lies above the cervical enlargement, whether vascular, inflammatory, or neoplastic, may cause spastic palsy of the upper limb, but it is rarely a monoplegia. The arm and leg on one side, or both arms and both legs (double hemiplegia), are much more likely to be involved simultaneously.

and the site of the lesion is inferred from the knowledge that the two pyramidal tracts are in close proximity in those regions.

Paralysis without Lesions of the Pyramidal Tract. It is not uncommon for a patient in the earliest stage of *paralysis agitans* to complain of loss of power in one arm. This sometimes leads to a wrong diagnosis, the trouble being described vaguely as due to neuritis, or even hysteria. This mistake will be avoided if notice is taken of the fact that the limb is not only weaker than its fellow, but that it is somewhat stiff and conspicuously slow in carrying out movements. A lack of expression in the face, or tendency to carry the arm in a flexed position across the trunk, and perhaps some hesitancy in the gait, should guide the observer to a correct diagnosis even if tremor is absent, as it often is at this stage of the malady. This form of paralysis is unattended by changes in the reflexes.

Children suffering from *chorea*, and especially hemichorea, are often brought to a doctor with the complaint that he or she has lost the use of an arm. Examination will show that there is really some weakness of the affected limb, which is demonstrated, not so much by the poorness of the grasp, as by the fact that the child is unable to maintain a steady pressure. He will grasp the observer's fingers, but quickly release the pressure, although urged to continue the squeeze. In the same way, when asked to put out his tongue he will do so, but withdraw it at once. When required to extend his arm in front of him with the palm of the hand facing downwards, it will generally be noticed that the wrist is slightly flexed although the fingers are extended. These are points which may be useful in coming to a right conclusion when choreic movements are not conspicuous; but attention must also be paid to the condition of the heart and to any history of rheumatism. No information of value can be obtained from the reflexes unless perhaps the choreic form of knee-jerk is present (p. 359).

Hysterical brachial palsy may resemble one due to a pyramidal lesion in presenting a marked amount of rigidity, or, on the other hand, the whole limb may be flaccid and limp. Some general wasting of the muscles may be present, but there is no alteration in their electrical reactions. Organic pyramidal lesions must be excluded by an examination of the reflexes. The supinator, biceps, and triceps jerks may be tried, but they will not be appreciably more brisk than those of the opposite limb. The abdominal and leg reflexes will be natural. If the limb is rigid the observer will probably be able to overcome the rigidity by steady pressure, and to extend the arm, forearm, hand, and fingers into one straight line. When the patient is asked to perform a certain movement, the observer can often see that in the effort to carry it out the antagonistic muscles are put into action rather than, or as well as, those which are necessary for its execution. Thus the triceps will contract as well as the biceps when the patient is requested to flex the elbow, with the result that the forearm is moved very little or not at all. This may also be demonstrated when the observer resists the movement of flexion by grasping the wrist and then unexpectedly relaxes his resistance; in an organic palsy this will be followed by further uncontrolled flexion at the elbow, whereas in a hysterical patient the contraction of the triceps maintains the forearm in its former position. Another important point in distinguishing a palsy of cerebral origin from one which is hysterical is that in the organic case, even when no voluntary movement whatever can be carried out by the fingers, the latter may move involuntarily in association with energetic movements in the opposite limb. Thus, when the patient is asked to grasp some object as tightly as he can with the sound hand, flexion of the fingers may be detected in the paralyzed side. The same phenomenon is seen in connection with involuntary movements, such as yawning. The writer remembers being requested to see a case in which there was paralysis of one arm, and in which the diagnosis between organic and functional disease was in doubt. The first question he asked the patient was whether he could open his hand and extend his fingers; the patient replied in the negative, but immediately volunteered the statement that the fingers became extended whenever he yawned. This settled the point in dispute at once, because such associated movements do not occur in hysterical palsies. In many, if not most, cases of hysterical palsy of an arm, the limb is also anæsthetic, and this anæsthesia can generally be recognized as hysterical on account of its complete character. In a cerebral palsy there may be some loss of sensibility to light touches and some impairment of pain sense, but the hysterical patient is usually insensitive to all forms of stimulation, even pinching or a strong faradic current. Moreover, the distribution of the anæsthesia does not correspond

to any form seen in organic disease, and is frequently of a glove or sleeve type with a very sharp line of demarcation.

PARALYSIS WITH MUSCULAR ATROPHY (OR ATROPHIC PALSY).

In this category are included all cases of brachial palsy in which there is true muscular atrophy associated with some alteration in electrical reactions, either the typical reaction of degeneration or quantitative diminution of excitability to galvanic and faradic currents. In all such cases there is some organic lesion affecting some part of the lower motor neurons: there must be some disease involving (1) the spinal segments from the 5th cervical to the 1st dorsal, (2) the corresponding anterior spinal roots, (3) the brachial plexus, (4) the peripheral nerves of the arm, or (5) the muscles themselves.

In addition to atrophy and alteration in electrical response, each paralyzed muscle tends to lose its tendon-jerk. For instance, the tendon-jerk of an atrophied biceps cannot be obtained, and in all probability direct percussion of the muscle itself will also fail to elicit a contraction, or will give rise only to an abnormally slow contraction. Muscles which are undergoing atrophy may also exhibit fine fibrillary contractions of a spontaneous kind, but these are seen only when the disease affects the nerve fibres, and not when the muscles themselves are affected primarily. These fibrillations are very rarely seen in the group of muscular atrophies to which the name of 'myopathy' is given.

When making a diagnosis of the site of the lesion in cases of atrophic brachial paralysis, it is essential to analyze carefully the distribution of the atrophied muscles. This must be done in order to answer the questions: Are all the atrophied muscles supplied by one peripheral nerve, or are they innervated by one or more spinal segments, or by one or more anterior spinal roots? The diagnosis will be comparatively simple when it is found, for instance, that all the atrophied muscles are supplied by the musculospiral nerve, and that all the muscles supplied by that nerve are atrophied and paralyzed. A lesion of that nerve can then be diagnosed and its nature inferred from other data, such as the use of a crutch or the history of a fractured humerus, with the detection of callus involving the nerve at the site of the fracture.

Let us now consider briefly some of the various conditions giving rise to atrophic palsy of the upper extremity, and the features which are most characteristic for the purpose of their diagnosis.

In cases of *neuritis* there may be paralysis of the muscles supplied by one nerve only, or of muscles supplied by several nerves (multiple neuritis). In the former case the correct diagnosis of the lesion depends on a knowledge of the muscles innervated by each of the chief brachial nerves, and this may be gleaned from the following list:—

Nerve.	Muscles.
Posterior scapular (C. 5)	Levator anguli scapulae Rhomboides minor Rhomboides major
Long thoracic (C. 5, 6, 7)	Serratus magnus
Suprascapular (C. 5, 6)	Supraspinatus Infraspinatus
Anterior thoracic (C. 5, 6, 7, 8, D. 1)	Pectoralis major Pectoralis minor
Musculo-cutaneous (C. 5, 6)	Biceps Brachialis anticus Coraco-brachialis
Median (C. 6, 7, 8, D. 1) forearm	Pronator radii teres Flexor carpi radialis Palmaris longus Flexor sublimis digitorum Flexor longus pollicis Pronator quadratus Flexor profundus digitorum (outer half)
hand	Abductor pollicis Opponens pollicis Flexor brevis pollicis (superficial head) Two outer lumbricals
Ulnar (C. 8, D. 1) forearm	Flexor carpi ulnaris Flexor profundus digitorum (inner half)
hand	Palmaris brevis Flexor brevis minimi digiti Abductor minimi digiti Opponens minimi digiti Interossei Two inner lumbricals Adductor obliquus pollicis Adductor transversus pollicis Flexor brevis pollicis (deep)

	Extensor ossis metacarpi pollicis
	Extensor longus pollicis
	Extensor brevis pollicis
	Extensor indicis
	Latissimus dorsi

When several nerves are involved in neuritis, the condition is one of *multiple neuritis* and, being generally due to some toxic cause, tends to be bilateral and symmetrical. Multiple neuritis is further characterized by the facts that the peripheral muscles are more affected than the proximal, that the extensors of the wrist and fingers suffer out of proportion to the flexors, and that there are often pain and tenderness in the paralyzed muscles. These features are present in *alcoholic neuritis*, the most common form (p. 66). In *lead palsy* the extensors of the wrists and fingers are particularly susceptible, although other muscles supplied by the musculospiral nerve—such as the supinator longus and triceps—may escape altogether. The association of dropped wrist with a blue line on the gums, and other signs of plumbism (p. 34), is diagnostic of this form of brachial palsy. In some cases of multiple neuritis it is impossible to identify the causative toxin, but glycosuria, mercury, and arsenic, in addition to alcohol and lead, must be remembered in this connection. Leprosy may produce a precisely similar condition (Fig. 206), but it is rarely met with in Great Britain. (See also ATROPHY, MUSCULAR, p. 59.)

In most cases of single nerve palsy the diagnosis, based on the distribution of the muscular atrophy and paralysis with altered electrical reactions, can be confirmed by the detection of sensory loss in the cutaneous area supplied by the same nerve. In other cases the sensory fibres appear to offer more resistance than the motor to the exciting cause of the neuritis, and little or no disturbance of sensibility can be found. (For areas supplied by the peripheral nerves, see *Plate XXI*, p. 608, and SENSATION, SOME ABNORMALITIES OF, p. 604.)

Reference may be made to one or two of the single nerve palsies which present special points in relation to diagnosis.

In *paralysis of the serratus magnus* (Fig. 207) due to injury or neuritis of the long thoracic nerve, the patient may complain of general weakness of the arm, and particularly of inability to raise it above the horizontal position. The trouble arises from the fact that the scapula is no longer held against the thoracic wall, and cannot be rotated with the movements of the limb. The origin of this disability may be overlooked if the arm only is examined. If, however, the position of the scapula is observed when the arm is moved in different directions, the correct diagnosis can be arrived at. When the arm hangs at rest by the side, the scapula is seen to be slightly raised and displaced outwards, with the inferior angle inclining towards the vertebral column and perhaps somewhat separated from the chest wall (Fig. 207). When the arm is raised forward to the horizontal position and pressed against some resistance, the inner border of the scapula projects

Fig. 206. Atrophy of the arm due to peripheral neuritis in an atrophied case of leprosy (note mass thence in a Norwegian). (From a photograph by the late Dr. Hansen, Inspector-General of Leprosy in Norway.)

backwards and presents a 'winged' appearance. This deformity ought always to suggest paralysis of the serratus magnus.

The movements of the upper limb are also hampered somewhat in cases of neuritis or injury to the *suprascapular nerve*, and the patient may complain of difficulty or fatigue in writing. Examination will show flattening of the infraspinous fossa and weakness in rotating the humerus outwards against resistance. The infraspinatus muscle may show the reaction of degeneration, but the supraspinatus is not accessible, being covered by the trapezius.

Adhesions within the shoulder-joint, with secondary wasting of the deltoid, may simulate paralysis in the distribution of the *circumflex nerve*, owing to the difficulty in abducting the arm; but a little care in examination and electrical testing of the deltoid muscle will suffice to make a diagnosis. In circumflex palsy, moreover, some sensory loss may be found in the skin over the upper and outer aspect of the arm.

In cases of *musculospiral paralysis* it must be remembered that the injury to the nerve may be above or below the points where branches leave to supply the triceps and supinator longus muscles, and that these muscles may therefore escape. Sensory symptoms are often absent, but some anesthesia is sometimes found on the radial border of the hand.

Fig. 207.—Photographs illustrating the deformities produced by palsy of the right serratus magnus. It is often associated with weakness of the lower trapezius fibres, and is found most commonly in carpenters and sawyers.

In connection with traumatic affections of the *median nerve*, the distribution of the paralysis depends on the site of the wound: the branch which supplies the muscles of the hand may leave the main nerve in the forearm, and thus escape injury when the wound is at the wrist.

Ischemic paralysis of the hand (Volkmann's contracture, Fig. 58, p. 141) must not be forgotten in cases of injury to the forearm when there is a history of the patient wearing a splint, and the condition must not be mistaken for ulnar or median paralysis. The diagnosis depends partly upon the history, but chiefly upon the rigid contracture of *all* the flexor tendons of the wrist and fingers with wasting of the muscles and other trophic changes. The electrical excitability of the flexor muscles is sometimes impaired.

Paralysis of one arm due to a *lesion of the brachial plexus* is a common event, the most frequent cause being some injury. When the whole plexus is damaged, complete brachial palsy, with atrophy of the muscles and extensive sensory loss, results. The diagnosis of such a lesion is simple, because it would be impossible for the spinal cord to be damaged sufficiently to bring about such a paralysis without giving rise to symptoms of atrophic palsy in the opposite arm, and spastic paralysis, with disturbances of sensibility, in the trunk and legs.

In addition to a lesion of the brachial plexus as a whole, two forms of partial palsy are not uncommon, and have received special names. The first is known as *Erb's palsy*, and is due to a lesion of the upper trunk of the brachial plexus, composed of fibres from the 5th and 6th cervical roots. The paralyzed muscles include the spinati, deltoid, biceps, supinator longus, and to a less extent the extensors of the wrist and fingers. The arm hangs by the side, and the forearm remains pronated owing to weakness of the supinator muscles, and especially of the biceps. There is sometimes, but not always, anaesthesia over the outer aspect of the forearm and hand. This form of palsy is usually produced by a fall on the shoulder of such a kind as to separate the latter forcibly from the head, and so to exert sudden and severe traction on the upper part of the brachial plexus. A similar lesion is often seen in infants as a result of injury during birth, and has been called *Duchenne's palsy*, after the observer who first described it. In both Erb's and Duchenne's palsy, the grouping of the paralyzed muscles resembles that which may follow an injury to the 5th and 6th cervical segments of the spinal cord, but in the latter case bilateral symptoms are practically certain to be present, as well as more extensive disturbances of

sensation of the trunk and limb, probably of the dissociative type. (See SENSATION, SOME ABNORMALITIES OF, p. 604.) In spinal cord lesions, moreover, we may see an atrophic paralysis of the muscles supplied by the 5th and 6th cervical segments, together with a spastic paralysis of the remaining muscles in the arm—that is to say, of the muscles innervated from the 7th and 8th cervical and 1st dorsal segments. This mixture of atrophic and spastic paralysis in the upper limb can only be brought about by some injury or disease of the spinal cord.

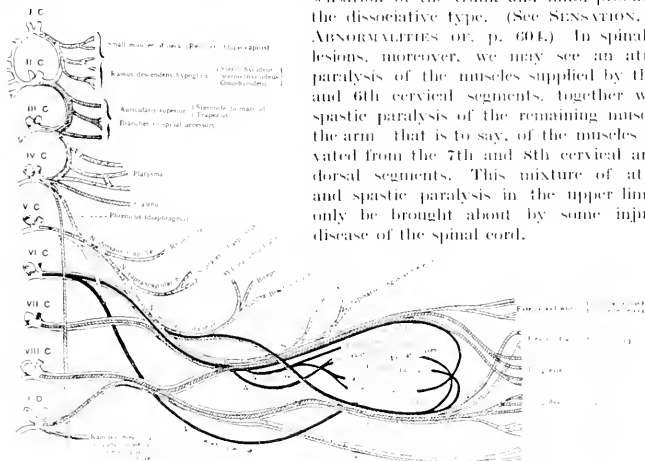

Fig. 208.—Diagram to illustrate the cervical brachial plexus and its branches (after Koehler).

The other form of partial brachial plexus palsy, *Klumpke's palsy*, depends on a lesion of the trunk formed by the 8th cervical and 1st dorsal roots. The flexors of the wrist and fingers, and the intrinsic muscles of the hand, undergo atrophy, and although the patient can carry out all movements at the shoulder and elbow, he is unable to use his fingers. The area of anaesthesia in this form involves the ulnar border of the forearm and hand from the elbow downwards. This condition may be distinguished from a spinal-cord lesion affecting the 8th cervical and 1st dorsal segments, not only by its limitation to one upper extremity, but also by the absence of the oculo-pupillary symptoms which are nearly always present in spinal lesions of that level: a lesion of the spinal segments in that region, or of the corresponding spinal roots in their intravertebral course, produces a diminution in the size of the pupil and a narrowing of the palpebral aperture on the same side. Such a pupil does not dilate to shade, nor when the skin of the neck is pinched, nor when a cocaine solution is dropped into the eye. Although the presence or absence of oculo-pupillary symptoms affords a point of differentiation between lesions of the 8th cervical and 1st dorsal segments of the spinal cord, or of their corresponding roots on the one hand, and a lesion of the lower trunk of the brachial plexus on the other, in the majority of cases in very severe injuries to the neck the lower roots of the plexus may be actually torn away

from their connection with the spinal cord, in which case the oculo-pupillary symptoms mentioned above will be present.

Amyotrophic lateral sclerosis is a condition dependent on a gradual degeneration and disappearance of the anterior cornual cells of the spinal cord, associated with sclerosis of the upper motor neuron tracts. The muscular atrophy begins insidiously and progresses gradually. It often begins in the intrinsic hand muscles (Aran-Duchenne type), less commonly in the shoulder and upper arm muscles. The loss of power is in proportion to the amount of atrophy. The alteration in electrical reactions is usually more a quantitative diminution of excitability to both currents than a true reaction of degeneration. Fibrillary contractions are common. The atrophy usually begins in one limb before the other, but soon becomes more or less symmetrical. The tendon-jerks of all muscles which are not atrophied are exaggerated. The abdominal reflexes may be absent, and the plantar reflexes may be of the extensor type. There are no pains, no sensory loss, and no oculo-pupillary phenomena.

In *syringomyelia* the spinal changes frequently begin in the cervical enlargement of the cord, with the result that atrophic paralysis is first noticed in the upper extremity, generally in the intrinsic muscles of the hand and the flexor muscles on the ulnar aspect of the forearm. The onset is insidious and the progress gradual. One limb is generally affected many months, perhaps years, before the other. Manual deformities are common. (See CLAW-HAND, *Fig.* 45, p. 110.) The electrical reactions vary like those of amyotrophic lateral sclerosis. The knee- and ankle-jerks are increased as a rule, and spastic paralysis of the lower extremities usually develops in the later stages, with extensor plantar responses. Pains shooting down the arms from the neck occur, but are not common. Trophic changes develop in the skin, subcutaneous tissues, and joints. There is sensory loss of a dissociative type, i.e., loss of sensibility to pain, heat, and cold, with preservation of tactile sensibility. Oculo-pupillary phenomena and nystagmus are common. Spinal curvature, in the form of a dorsal scoliosis, is another frequent physical sign. It is not necessary that all these signs and symptoms should be present for making a diagnosis. The combination of muscular atrophy, dissociative anaesthesia, and trophic changes in the skin is usually sufficient.

Fig. 209.—Atrophic palsy of right hand associated with long 7th cervical rib of that side. Note the marked wasting of the abductor pollicis as compared with the other muscles of the thenar eminence. According to S. A. K. Wilson this is a common feature of these cases, but it is not pathognomonic.

(Photo by Dr. P. W. Saunders.)

sometimes shooting into the little and ring fingers. The pain is worse after exertion, and often relieved by placing the hand behind the head. Muscular atrophy begins in the hand muscles (*Fig.* 209), the interossei, thenar, and hypothenar eminences, and often involves the flexors of the wrist and fingers. It develops gradually and does not spread beyond the distribution just described. There is often sensory loss in regions corresponding to the cutaneous areas supplied by the 1st dorsal and 8th cervical spinal roots. The loss is usually less marked to touch than to painful and thermal stimuli. The atrophied muscles show reaction of degeneration. There are no oculo-pupillary phenomena and no signs of disease in other parts of the body. The condition is usually one-sided, occasionally bilateral, and the chief point in diagnosis is the discovery of the ribs by means of skiagraphy (*Fig.* 187, p. 443). At the same time it must not be concluded that the absence of a rib shadow in an x-ray photograph is in all cases a contra-indication to the diagnosis. A ligamentous band, undetected by the skiagraphic examination, is sometimes found to occupy the position of a supernumerary rib and to be responsible for similar results in the way of pain and atrophic palsy. (See also PAIN IN THE EXTREMITY, UPPER, p. 442; and CLAW-HAND, p. 109.)

A cervical rib may be responsible for atrophic palsy in the upper extremity. Paralysis is usually preceded by pain, chiefly referred to the inner aspect of the arm, and fingers.

Another disease in which atrophic palsy of the intrinsic hand muscles is a prominent feature is *peroneal atrophy*. As the name suggests, the muscular atrophy and paralysis generally begin in the lower, before they affect the upper, extremities, and further details concerning the condition may be found under PARALYSIS OF ONE EXTREMITY, LOWER, p. 498; and ATROPHY, MUSCULAR (Figs. 20 and 21, p. 60).

The diagnosis of muscular atrophy in the arm dependent on a preceding *acute poliomyelitis* (Fig. 19, p. 59) is not difficult if an accurate history can be obtained. The onset was acute, with constitutional disturbance, varying from a transient and perhaps overlooked malaise to a pyrexia up to 104 F., with generalized pains all over the body, vomiting, and convulsions. It is almost invariable that the initial paralysis was more extensive than that which remained permanent. Attention to the distribution of the paralysis shows that it is irregular and different in every case, but there is more liability on the part of the shoulder and upper arm muscles to suffer than those of the forearm and hand. If both arms are affected there is little likelihood of any great degree of symmetry in the distribution of the atrophy. With regard to the electrical reactions, much will depend on the stage at which the case comes under observation. Some muscles may show the reaction of degeneration, others may respond fairly well, and others show no response whatever to either faradism or galvanism. Vasomotor changes, general defects in the growth of the limb, deformities, and contractures are common, but no sensory changes and no oculo-pupillary phenomena are to be observed. Only those reflexes are altered or lost which are concerned with atrophied muscles.

Hæmorrhage into the spinal cord, or *hamatomyelia*, due to injury, occurs more often at the level of the 8th cervical and 1st dorsal segments than at any other. The resulting paralysis has much the same distribution as that described in Klumpke's palsy (p. 507), but the diagnosis may be made from the fact that the former also produces spastic paralysis of the trunk and legs, and frequently gives rise to areas of dissociated anaesthesia. Oculo-pupillary phenomena are usual as well in cases of hamatomyelia at this level. Injuries to the cord result in bilateral symptoms, whereas Klumpke's palsy is confined to one arm.

Various forms of root palsies may be caused by *tuberculous or malignant disease of the vertebrae*, and also by *pachymeningitis*, frequently syphilitic. The diagnosis of the nature of such lesions depends on examination of the vertebral column and of the cerebrospinal fluid. The symptoms are more often bilateral than unilateral, and may be complicated by the results of pressure on the spinal cord, leading to spastic paralysis of parts below the level of the disease.

Tumours originating in the meninges or in the spinal cord at the level of the cervical enlargement are rare, but they may produce atrophic paralysis of the arm muscles, with spastic paralysis of the trunk and lower extremities. These phenomena may be more marked on one side at first, but they tend to become bilateral with the gradual growth of the tumour.

In the group of diseases to which the name *myopathy or muscular dystrophy* is applied, the arm is often more or less completely paralyzed. The diagnosis of this condition depends on a consideration of various factors. The gradual onset and the bilateral symmetry of the affection, the marked involvement of the shoulder and upper arm as compared with the forearm and hand, are important characteristics. The absence of fibrillary contraction and of the reaction of degeneration are also to be noted, while the history of a similar affection in other members of the family, and the presence of muscular atrophy or muscular pseudo-hypertrophy in other parts of the body, serve to confirm the diagnosis.

TABLE SHOWING THE MUSCULAR DISTRIBUTION OF THE VARIOUS NERVE ROOTS OF THE BRACHIAL PLEXUS.*

C. 5.	<i>Deltoid, Spinati, Teres minor, Rhomboids, Diaphragm, Biceps, Supinator longus, Serratus magnus, Pectoralis major, Brachialis anticus, Coraco-brachialis.</i>
C. 6.	<i>Biceps, Coraco-brachialis, Brachialis Anticus, Supinator longus, Deltoid, Spinati, Teres major, Serratus magnus, Pectoralis major, Subscapularis, Pronators of forearm, Extensors of wrist.</i>
C. 7.	<i>Triceps, Extensors of wrist and fingers, Pronators of forearm, Pectoralis major, Subscapularis, Latissimus dorsi, Teres major.</i>
C. 8.	<i>Flexors of wrist and long flexors of fingers, Interossei and lumbrales, Muscles of thenar and hypothenar eminences.</i>
D. 1.	<i>Muscles of the thenar and hypothenar eminences, Interossei and lumbricales, Flexor carpi ulnaris, Oculo-pupillary fibres.</i>

* Those muscles which are the most useful "limb-arms" for individual segments are printed in italics.

A glance at this list shows that nearly all muscles derive innervation from more than one spinal segment, generally from two or three. The table does not purport to give a complete anatomical list of all the muscles of the arm, but provides a guide to clinicians in their endeavours to localize spinal or root lesions from the distribution of atrophic muscular paralysis.

E. Farquhar Buzzard.

PARAPLEGIA implies partial or complete paralysis of both legs, with or without part of the trunk. It does not, however, include inability to walk owing to mechanical defects, such as old fractures, joint disease, and so forth; it is due, as a rule, to changes either in the brain, the spinal cord, the peripheral nerves, or in the muscles themselves, though sometimes it is caused by errors of function without any structural change in the neuro-muscular system. For clinical purposes, although naturally a paraplegia that has arisen in childhood may persist into adult life and thus cause overlapping of the classification, paraplegia in children may be discussed separately from paraplegia in adults. Let us suppose that the patient is a child, and that the chief complaint is weakness or paralysis of both legs. The following table indicates some of the causes that may produce this condition:—

I. THE CAUSES OF PARAPLEGIA IN CHILDREN.

(A). *Conditions in which there is no definite local disease, though there may be some general pathological condition:—*

(1) Simple delayed walking; (2) Rickets; (3) Cretinism; (4) Idiocy.

(B). *Paraplegia associated with a definite upper neuron nerve lesion:—*

1. Infantile diplegia due to: (a) Congenital defect of the cortex; porencephalus; (b) Infantile encephalitis; (c) Injury, for example by forceps at delivery; (d) Superior longitudinal sinus thrombosis; (e) Meningitis; (f) Congenital or acquired hydrocephalus.
2. Congenital malformation, such as meningocele, spina bifida, or spina bifida occulta.
3. Spinal caries, with compression of the spinal cord.
4. Friedreich's ataxy.

(C). *Paraplegia due to a lesion of the lower neuron type:—*

1. Acute anterior poliomyelitis, leading to infantile paralysis.
2. Tooth's peroneal type of progressive muscular atrophy.
3. Peripheral neuritis.

(D). *Paraplegia of the primary muscular type:—*

1. Pseudo-hypertrophic muscular paralysis.
2. The infantile type of primary muscular dystrophy.
3. The juvenile type of primary muscular dystrophy.

In arriving at the diagnosis, the first point to pay attention to is the history; the case will belong to one or other of two main groups, the first containing those that have never been able to use the legs properly, the second those that have lost the use of the legs after having been at one time able to walk, or otherwise use them efficiently.

To the first group belong all cases of congenital malformation, such as *hydrocephalus* or *meningocele*, and most cases of *infantile diplegia*. Before diagnosing any of these, however, it is necessary to exclude *rickets*, *cretinism*, *idiocy*, and *simple delayed walking*, as causes of an apparent rather than real paraplegia. These cannot be the sole diagnosis if there is absolute flaccidity on the one hand, or if there is spasticity upon the other. It is important to remember how deceptive the reflexes may be; almost any illness in an infant or young child bronchopneumonia for example, or simple diarrhoea may so depress the knee-jerk that it is often unobtainable until the patient's general health is restored; the plantar reflex is normally more often extensor than flexor in infants; ankle-clonus, however, does not occur except when there is degeneration of the lateral columns. If there is neither absolute flaccidity nor intermittent spasticity, and if the limbs are moved spontaneously, the mere fact that the child is late in walking by no means necessarily indicates nerve disease; the delay may commonly extend to the second year, and occasionally even to the third or fourth. The main factor in making a diagnosis in such

a case is time, for, until with the lapse of time the little patient begins to walk, it may sometimes be difficult to exclude organic paraplegia. If there are definite signs of rickets, or if the patient is a cretin or an idiot, the diagnosis is more obvious. The good effects of giving thyroid extract over a prolonged period may be the only conclusive means of distinguishing cretinism from idiocy, and this remedy should be employed in all such cases, however hopelessly idiotic the infant may seem to be. If there is congenital optic nerve blindness, the case is one of idiocy and not cretinism.

Having excluded the above, the next thing to consider is whether there is any congenital malformation of the brain or cord. Cases of *meningocele*, *myelocele*, or *spina bifida* will generally be obvious enough; even *spina bifida occulta* will often suggest itself from the presence of a pigmented or hairy mole over the lower part of the lumbar spinal region, and the diagnosis may be confirmed by careful palpation there. Congenital *hydrocephalus* makes itself evident from the characteristic enlargement of the head, which in extreme cases can be mistaken for nothing else, and which in lesser degrees can be distinguished from the enlargement due to rickets or to congenital syphilis by the fact that it is more uniform, and that the bones are fragile and thin, and separated at the sutures. The only doubt that arises in a case of infantile hydrocephalus is as to whether it is truly congenital or was caused by an early but post-natal posterior basal meningitis. There is increasing evidence to show that the majority of these cases are not really congenital, that the head is not large at birth, and that the enlargement follows some febrile illness, with or without convulsions—really a meningococcal meningitis.

Congenital defect of the cortex would suggest itself as the cause of infantile diplegia in a case in which delivery had taken place without difficulty and without the use of forceps, the head and spine not being hydrocephalic or deformed, and yet the limbs being paralyzed from birth; they may be flaccid or they may be spastic, and there is no constant type of reflex, though there is a tendency to increased knee-jerk, ankle-clonus, and extensor plantar reflex. Intelligence will very likely be defective at the same time. In rare cases the kidneys may be so large and cystic that they can be palpated, and the brain may then be cystic also—*porencephalus*.

Paraplegia due to *injury at birth*, either by the use of forceps or by excessive compression in a contracted maternal pelvis, is a diagnosis that can only be made when there has been an unusual amount of difficulty at birth, for it is remarkable to what extreme degrees the child's head may be squeezed and altered in shape without apparent detriment. Seeing that it is the lateral aspects, especially the arm areas of the Rolandic cortex, that will be most affected by forceps, these instruments are more likely to cause bilateral arm paralysis than ordinary paraplegia. Just the converse of this is true of *superior longitudinal sinus thrombosis*, for the leg areas of the brain lie close up against either side of this sinus, whilst the arm areas, being more distant from it, are likely to be less affected. The symptoms of superior longitudinal sinus thrombosis, of acute encephalitis, and of meningitis, may be so similar—pyrexia, general head symptoms, vomiting, and convulsions—that it is almost a matter of guess-work to choose between them when they are actually in progress; if death occurs in a few days, suppurative meningitis is likely; if in a few weeks, tuberculous meningitis; if the patient lingers for many weeks before dying, or if recovery occurs with hydrocephalus, posterior basal or cerebrospinal meningitis; if recovery occurs without hydrocephalus, it may be almost impossible to decide between meningococcal meningitis, acute encephalitis, and superior longitudinal sinus thrombosis; nor is the distinction material, except in so far that it is important to remember always that a favourable issue may occur even in a case that seems to be hopelessly comatose and dying—a diagnosis of meningitis may have been made erroneously when the condition was really one of acute encephalitis only. If it seems to be of great importance to arrive at the accurate diagnosis in the acute stages, it may be justifiable to perform lumbar puncture. A cytological examination of the cerebrospinal fluid may show many polymorphonuclear cells in a suppurative case, or many lymphocytes in a tuberculous case. Of more value than the cytological examination, however, is the bacteriological test, which may succeed in isolating the causal organism.

If one is able to exclude the infantile diplegias, and the conditions which simulate them, the probability is that the patient will have shown obvious signs of being able to use the legs, or may even have been able to walk before the paraplegia set in. In that

case, if the paralysis is of the upper neuron type, with spasticity, no wasting except such as may be due to disuse and non-development, no reaction of degeneration, increased knee-jerks, extensor plantar reflexes, ankle-clonus, and probably bladder and rectal trouble—especially if there is anaesthesia in the legs at the same time—by far the commonest cause for the condition is *spinal caries* with compression of the cord.

If, on the other hand, the patient develops a lower neuron type of paralysis, with wasting of the affected muscles and reaction of degeneration, the chances will be greatly in favour of *acute anterior poliomyelitis* followed by infantile paralysis, particularly if diphtheria can be excluded, and if a clear history can be obtained that the child was perfectly well until he developed an obscure febrile complaint, which may at first have been regarded as of gastric origin, but which, in a day or two, led to one or more limbs, possibly all four, becoming limp and paralyzed, with rapid subsidence of the fever and great improvement in the paralysis during the next few weeks. It is possible for a child to have had absolute paralysis of all four limbs from acute anterior poliomyelitis, and yet for complete recovery to occur: more often, however, one or another group of muscles remains weak: in a typical case, the extensors of the toes and ankle are affected permanently, the consequent contraction of the unparalyzed calf muscles leading to talipes equinus or equino-varus. Weakness of other groups of calf muscles leads in a similar way to other forms of club-foot, such as T. calcaneus, T. valgus, and so on. In other cases, the muscles below the knee recover completely, but some other group is involved—the quadriceps extensor femoris for instance, or the adductors of the thigh. It is of course possible for the legs to recover completely, whilst paresis of some group of muscles in the shoulder, arm, or forearm persists. The infantile paralysis which follows acute anterior poliomyelitis is nearly always asymmetrical, but it is by no means necessarily so, and it may cause persistent partial paraplegia. It is important to remember that the knee-jerk is deficient or absent only when the quadriceps extensor femoris muscle is affected: and also that reaction of degeneration is no longer obtainable in the muscles when the disease is of sufficiently long standing for all the degenerate fibres to have become fibrous, by which time the only muscle and nerve fibres that remain are normal, though they are fewer in number than they should be.

Peripheral neuritis in a child is decidedly uncommon, except as the result of *diphtheria*: it should not be diagnosed lightly. Being an affection of the lower neuron type, with wasting of the muscles, flaccidity, reaction of degeneration, and deficiency in the tendon reflexes, it may be difficult to distinguish between it and acute anterior poliomyelitis. It might be urged that the occurrence of pain or other sensory symptoms is in favour of peripheral neuritis and against poliomyelitis, but this is not really the case: the inflammation in poliomyelitis is by no means necessarily restricted to the grey matter of the anterior cornua, and the acute stage of the disease is often accompanied by severe pains referred to the peripheral parts. There may, however, be bacteriological or other evidence of the patient's having had diphtheria during the preceding few weeks, in which case peripheral neuritis would be diagnosed: if there is paresis of the soft palate, as evidenced by the regurgitation of fluids through the nose when the patient tries to swallow them, or by the nasal character of the voice, diphtheritic neuritis would be very probable.

There remains for discussion the following causes of paraplegia in children: *Friedreich's ataxy*, *Tooth's peroneal type of progressive muscular atrophy*, and the primary muscular dystrophies, particularly pseudo-hypertrophic muscular paralysis. There are two points common to all these, namely, that they all are insidious in onset, slowly progressive for years before the end comes as the result of an intercurrent malady; and that they are familial diseases, the family history having an important bearing upon their diagnosis.

Friedreich's ataxy is characterized by paraplegia, often associated with deformity, such as talipes and scoliosis, owing to persistent error of posture, without wasting except such as may be due to disuse or non-development: the knee-jerks are absent, but the pupils react normally: there is no sphincter trouble unless quite late: ankle-clonus is absent, but there is generally a remarkable condition of hallux erectus, which amounts to a sort of permanent extensor plantar reflex: there are no sensory disturbances: the arms may not be affected at all, or they may present some degree of ataxy, with or without intention tremors—that is to say, tremors which are increased when the patient tries to perform

voluntary movements—sometimes even choreiform movements are present; speech is monotonous, nystagmus is sometimes present, and occasionally there is optic atrophy. If progressive paraplegia develops at about 8 or 9 years of age in a child with a family history of similar trouble: if the knee-jerks are absent, whilst the big toes are permanently erect, and if there is neither atrophy nor pseudo-hypertrophy of the muscles, the diagnosis is in all probability Friedreich's ataxy. The patient may survive to puberty or even longer, but is liable to death from phthisis, pneumonia, or other intercurrent malady—the same applying to all the familial diseases now under discussion.

Tooth's peroneal type of progressive muscular atrophy is apt to develop after some simple specific fever, such as whooping-cough or measles. The first point the mother notices is that the child—hitherto normal—is unable to bend the big toes upwards; a condition of permanent plantar flexion of the big toes ensues; inability to extend the other toes follows; and presently the patient cannot dorsiflex the ankles. It is chiefly the muscles supplied by the external popliteal nerve, formerly called the *peroneal* nerve, that are affected; hence the name of the disease. Talipes may result. The lesion is not primarily in the muscles, but in the anterior cornual cells of the lumbosacral part of the cord, so that reaction of degeneration is obtainable in the wasted muscles. The knee-jerks remain normal so long as the quadriceps extensor femoris is unaffected, there is no ankle-clonus, and the big toe may not move at all when the sole is stimulated. A brother or a sister is very likely to have suffered from the same complaint (see *Figs.* 20, 21, p. 60).

In the *primary muscular dystrophies* the nerves are normal, so that there is no reaction of degeneration: if a muscle has become entirely atrophied, there will be no reaction in it at all; but as long as any reaction is obtainable it is of the normal type. The same applies to the reflexes. The most easily recognized of all the primary muscular dystrophies is pseudo-hypertrophic muscular paralysis, the only difficulty being when no family history is obtainable, and when the case is still in too early a stage to be typical. Boys are affected more often than girls, but it is generally inherited from the mother's side. It is possible for some members to have presented atrophic myopathy, whilst others suffer from the pseudo-hypertrophic form. When fully developed, the most striking feature of the case is the marked weakness of the legs, notwithstanding the apparent firmness and great size of the calves. The muscles are really atrophied, their apparent enlargement being due to extensive deposition of intramuscular interstitial fat. Ultimately, if the patient survives, all the muscles in the body become wasted and fibrous; but whereas some of them atrophy from the first, others exhibit marked pseudo-hypertrophy before they atrophy—particularly the gastrocnemii, the solei, the glutei, the deltoids, the supra- and infra-spinati, and portions of the triceps. The muscles of the hands and feet are generally unaffected. The muscles most frequently atrophied are the lower half of the pectoralis major, the latissimus dorsi, the serratus magnus, the biceps, and the flexors of the knee. There are no sensory or sphincter troubles. When the case is well advanced, the way in which the patient gets up from a lying posture is very characteristic: it is generally described as 'climbing up himself.' He first rolls over and rests on his hands and knees; then puts his head between his arms and raises the knees from the ground, so that he is now supported on his hands and feet; he next brings one hand nearer to his toes, and then, swinging his body over first to one side, places his opposite hand on the corresponding knee, straightens that leg, and repeats the performance on the other side, so that he now stands with his legs widely separated and with a hand resting on each knee; he then works each hand alternately higher up his thighs, until finally, by a sudden backward movement of his shoulders, he attains the erect attitude. Another feature of the case is, that if one tries to lift the boy up by putting one's hands under his armpits, his shoulders rise right up to his ears, and he very easily slips through one's hands. He is also unable to stand on tip-toe, and the gait is waddling.

The two other types of muscular dystrophy mentioned above—the infantile and the juvenile—are but different varieties of the same malady; both are characterized by progressive wasting of the muscles without pseudo-hypertrophy; in the infantile form the muscles have been atrophic from the first, whereas in the juvenile form the muscles develop in what seems to be a normal way up to a certain point, and then gradually waste away. The disease is distinguished from peripheral neuritis, (1) by the absence of reaction of degeneration; (2) by the persistence of the reflexes as long as any muscle

tissue is left to respond; (3) by the family history as mentioned above; (4) by the absence of sensory changes; and (5) by the absence of improvement with time. An attempt is sometimes made to classify the primary muscular dystrophies into different kinds, according to the groups of muscles first affected. In the Landouzy-Dejerine type, for instance, the face muscles are first attacked, the trouble slowly spreading to the shoulder and upper arm. It is probable, however, that whatever groups of muscles may be the first affected, the differences are those of degree and type rather than of kind, and that the muscular wasting, wherever it may begin, ultimately becomes widespread, and finally involves all the muscles.

II. THE CAUSES OF PARAPLEGIA IN ADULTS.

We may now pass on to a discussion of the differential diagnosis of paraplegia in adults. It is clear that a paraplegia that has arisen during infancy or childhood may persist into adult life, in which case the diagnosis will be made upon the lines indicated above. It is also possible for some of the causes of paraplegia that usually affect young patients not to do so until they have grown up. The chief causes, however, for paraplegia arising for the first time in adult life are as follows:—

(A). *Causes of the lower neuron type of paraplegia:—*

1. Peripheral neuritis, which may be due to various different causes (p. 63)
2. Anterior poliomyelitis
3. A pelvic tumour interfering with the lumbosacral plexus
4. A tumour affecting the cauda equina
5. Compression of the lumbar enlargement of the cord.

(B). *Causes of the upper neuron type of paraplegia:—*

1. Transverse myelitis.
 - (a). Primary
 - (b). Due to compression by: (i) Spinal caries; (ii) New growth in the vertebrae or meninges; (iii) Injury; (iv) Aortic aneurysm
2. Disseminated sclerosis
3. Amyotrophic lateral sclerosis
4. Primary lateral sclerosis
5. Ataxic paraplegia
6. Combined sclerosis of the cord
7. Syringomyelia
8. Meningitis
9. Haemorrhage into the cord
10. Cerebellar tumour or abscess
11. Bilateral cerebral softening or haemorrhage.

(C). *Causes not conforming either to the lower or to the upper neuron type:—*

1. Tabes dorsalis
2. General paralysis of the insane
3. Landry's paralysis
4. Functional paraplegia
5. Malingering.

The first points which call for attention in making a diagnosis are the history and progress of the case. In only a few of the above conditions is the onset sudden; these are certain cases of acute anterior poliomyelitis, transverse myelitis, meningeal haemorrhage, Landry's paralysis, functional paraplegia, and malingering. If the paraplegia is of sudden onset, of the upper neuron type, and not the result of injury, it is almost certainly due to some form of transverse myelitis. The great majority of cases of paraplegia, however, have an onset that is not absolutely acute, and generally it is quite gradual.

There are certain conditions that can, as a rule, be either diagnosed or excluded at once. If the patient has Argyll Robertson pupils and no knee-jerks, *tabes dorsalis* can be diagnosed at once. It is necessary to remember, however, that the pupil may react neither to light nor to accommodation in some cases of peripheral neuritis, so that, if care be not exercised, the reaction may be mistaken for the Argyll Robertson type of tabes, the latter being diagnosed when peripheral neuritis is the lesion really present. The converse mistake is also possible, especially if the actual strength of the leg muscles be not tested; in both conditions there may be patches of impaired sensation, but in peripheral neuritis with absent knee-jerks, there are absolute wasting, loss of power, and reaction of

degeneration, whilst in tubes there is no trophic wasting, and often no great loss of power in individual muscles, though there is apparent weakness owing to the action of opposing muscles being inco-ordinate, and there is no reaction of degeneration.

Another difficulty in connection with tubes dorsalis arises in anomalous cases in which either the pupil reaction has not yet become typical, or else the knee-jerks are not yet gone. If the reaction of the pupil is of the Argyll Robertson type, tubes may sometimes be diagnosed even in the presence of knee-jerks, if there is an obvious history of other concomitants of the disease, such as lightning pains, gastric crises, or any of the rarer crises—laryngeal, rectal, urethral, vesical, renal, general abdominal, or sweating—marked ataxy, history of syphilis, perforating ulcer of the foot, a Charcot's joint, or bladder or rectal trouble, particularly if the patient be a male who has had much brain wear. The tendo Achillis jerks may disappear before the knee-jerks do, and they should be carefully tested. There is also in many cases a remarkable deficiency or even complete absence of deep tenderness in such organs as the testis, tongue, larynx, or mamma. In certain cases the knee-jerk may still be obtainable on one side after it has been lost upon the other, so that both should always be tested and not one only.

If the paraplegia is obviously of the lower neuron type, with deficiency or absence of the superficial and deep reflexes, atrophy of the muscles, and reaction of degeneration, with or without paræsthesia, the probabilities are that it is due to one of the many different causes of *peripheral neuritis* that are discussed on page 63. If the onset has been sudden, however, and if the paralysis began to clear up again rapidly, except possibly in one group of muscles in one leg, there would necessarily be a suspicion of acute *anterior poliomyelitis* which occurs occasionally in adults.

It is important in all cases of suspected peripheral neuritis to make a rectal examination, lest there should be some pelvic mass, malignant or otherwise, interfering with the lumbo-sacral plexus. Peripheral neuritis may also be simulated closely by either a tumour or a gumma interfering with the cauda equina, an uncommon condition that suggests itself if there is severe pain referred to the lower part of the spinal column behind, or if the paraplegia comes on in such a way as to affect one leg before the other, the pelvis being found free from growth. It is also important to remember that transverse myelitis due to lesions which, if they are situated a little higher up in the cord, cause a paraplegia of the upper neuron type, produces wasting, reaction of degeneration, and loss of reflexes when they affect the cord at the level of the lumbar enlargement.

When the paraplegia is definitely of the upper neuron type, with spasticity of the legs without wasting, with increased knee-jerks, extensor plantar reflexes, ankle-clonus, and perhaps retention of urine with overflow, and incontinence of feces, the first step in arriving at the diagnosis is to determine if there is any sensory disturbance at the same time. The only diseases mentioned under heading *B*, that produce obvious sensory disorders, are transverse myelitis, syringomyelia, hæmorrhage into the cord, and very rarely meningitis or bilateral cerebral softening. The latter can only be diagnosed when there has been an apoplectic seizure associated with hemiplegia, followed after an interval by another cerebral seizure which, by producing hemiplegia of the opposite side to the one first involved, results in paraplegia, or rather diplegia. The arms and face are likely to be affected as well as the legs, and there will be either a history of syphilis to account for endarteritis and thrombosis in a young male, or a bruit, a history of acute rheumatism, or other evidence of a heart lesion, to account for embolism; or senile changes, with or without albuminuria, a high blood-pressure, retinitis, and other signs of renal and arterial degeneration, to account for hæmorrhage.

Hæmorrhage into the cord is hardly ever spontaneous; it may follow an injury, such as a bullet wound or a stab in the back, and then the history will indicate the diagnosis. *Acute meningitis*, whether tuberculous, suppurative, posterior basal, or cerebrospinal, seldom causes complete paraplegia until a late stage of the illness is reached, by which time the nature of the malady will generally be indicated by the cerebral symptoms, particularly headache, vomiting, convulsions, strabismus, and ophthalmoscopic changes such as optic neuritis or choroidal tubercles. Bacteriological investigations of the fluid obtained by lumbar puncture may assist the diagnosis materially. There is a chronic form of meningitis, however, of which the diagnosis is not so easy, and that is the *chronic hypertrophic hæmorrhagic pachymeningitis* which affects chiefly the vertex and the cervical portion of

the cord. The condition is generally caused by chronic alcoholism in syphilitic subjects, especially if there has also been some injury; the diagnosis is difficult, but it may be suggested by the history, and by the degree of pain referred to the nerves that are involved in the meningeal thickening—the chief difficulty being to exclude spinal caries in cases involving the cord. Wassermann's reaction may be positive if no antisyphilitic remedies have been employed. In *syringomyelia*—a very slowly progressive disease that is by no means always associated with paraplegia, the nature of the symptoms depends upon the degree to which the central canal of the cord and the gelatinous substance around it are affected, and also upon the level in the cord at which the changes occur. The diagnostic symptom is that, in some region or another, the skin will be found to have lost its power of distinguishing heat from cold and pain from touch, though it still retains ordinary cutaneous sensibility. It is apt to give rise to skin lesions in the paræsthetic parts (Morvan's disease), and also to acute painless swelling of the joints, with deformity from destruction of the ends of the bones—Charcot's joints—precisely similar to those that may occur in *tabes dorsalis*.

If the patient has marked impairment of all kinds of sensation in both legs, with paraplegia of the upper neuron type, and no paralysis of the arms, the lesion is almost certainly *transverse myelitis* of some kind. The absence of sensory disturbance, however, does not exclude transverse myelitis, for when the conductivity of the spinal cord is interfered with, without being entirely inhibited, the sensory columns are able to transmit impulses longer than the pyramidal tracts, so that paralysis appears before anaesthesia. The same applies to a transverse myelitis that is getting better, the patient recovering sensation in his legs before he is able to move them. The chief difficulty will be to determine the nature of the transverse myelitis. There are two main types: (1) That due to causes outside the cord compressing it—especially *spinal caries*, secondary *growth*, the effects of such *injuries* as fractures of the spine, bullet wounds and stabs, or more rarely erosion of the bones by an *aortic aneurysm*; and (2) That due to softening from thrombosis of a spinal artery, the result of *syphilis*, or a fever such as *enteric* or *scarlet*. One of the first points to attend to is the presence or absence of pain. Lesions, such as thrombosis, which affect the cord but not its posterior nerve roots, are painless, whereas swellings which compress the cord from without almost always produce pain, sometimes a typical girdle pain, on account of their irritating the posterior nerve roots. If, therefore, there is or has been any pain in the back other than what may be due to a known injury, it is probable that transverse myelitis is not primary but due to compression. If the spine presents an obvious Pott's curvature, or if the patient has other evidence of peripheral tuberculosis, such as enlarged or caseating glands in the neck, hip, knee, or other joint disease, a psoas abscess, lupus vulgaris, and so on, especially in a young person who has been in the habit of drinking much milk, compression by spinal caries is fairly certain. The main difficulty arises when the cord becomes compressed without deformity of the spinal column, and with no other tuberculous lesion apparent. Local tenderness over one or more vertebral spines will help to suggest the diagnosis, especially if local pain is complained of in the same region, and if the pain is increased by any jarring of the spine. Growth is fortunately much rarer, and it is to be excluded by a routine examination of all the viscera, most cases of spinal new growth being secondary to a neoplasm elsewhere, especially of the breast; primary growths of the spine are so rare that they are generally taken for caries at first, and the correct diagnosis is not always arrived at before post-mortem microscopical examination has been made. Aortic aneurysm is a still rarer cause of compression myelitis; if there is a distinct pulsatile tumour along the course of the aorta, the nature of the case may be obvious; more often, however, an aneurysm which erodes the vertebrae sufficiently to bulge into the spinal canal, does not at the same time enlarge forward to produce a tumour that can be recognized easily by palpation. The patient will generally be a man in the prime of life who has had syphilis, who is not a life abstainer, and who has worked hard; Wassermann's reaction may be positive. Apart from a pulsatile tumour the symptoms will be very like those of paraplegia from spinal caries.

The relationship of injury to transverse myelitis is not always quite straightforward. If, for example, a patient who has syphilitic endarteritis of his spinal vessels receives a kick in the back from a horse, he may find that, by next day, he is unable to move his legs; it may at first seem obvious that the kick has been the sole cause of the paraplegia, when

the real cause is syphilis—the kick having been the final factor which led to thrombosis in a diseased spinal artery. Transverse myelitis due to syphilis is exactly comparable in its mode of origin to the hemiplegia which results from endarteritis obliterans in a middle cerebral artery. There is no pain and no deformity of the spine, but in other respects the paraplegia presents the same features as does that which is due to compression of the cord. Syphilis is by far the most important cause of this primary transverse softening, but there are a considerable number of other maladies in which a similar result ensues occasionally: almost any infective disease may lead to it: one may perhaps mention typhoid fever, scarlet fever, and influenza in particular. In infective endocarditis there may be an additional factor, namely embolism of the cord, though this is decidedly rare.

If it is found that the arms are affected as well as the legs, it is unlikely that the lesion is transverse myelitis, unless in rare and anomalous cases such as those mentioned on page 62. If the onset has been slow, the course progressive, and wasting is present, with reaction of degeneration in the muscles of the hands or arms, with increased knee-jerks, ankle-clonus, and extensor plantar reflexes, but no anaesthesia, the malady is almost certainly *amyotrophic lateral sclerosis*.

If there are increased knee-jerks, extensor plantar reflexes, ankle-clonus, ataxy, intention tremors in the hands, nystagmus, and a hesitancy in the voice, which may even be of the type described as 'scanning,' the disease is either *cerebellar abscess or tumour*, or *disseminated sclerosis*. If headache and vomiting have been severe, the former is the more probable, and the diagnosis may be clinched by finding double optic neuritis. Abscess will be more likely than tumour if there is otorrhoea or pyrexia. It is not uncommon to find optic atrophy, with either concentric diminution in the fields of vision or else a central scotoma, in disseminated sclerosis, but optic neuritis is uncommon. The difficulty in diagnosing disseminated sclerosis arises mainly when the complaint is in its early stages: the patches of sclerosis may be anywhere in the cord, and before the affected fibres atrophy there is a period when they are sometimes able to conduct impulses, sometimes not: when they are not able to conduct, there are numerous symptoms, and in a day or two, when conducting power recovers, these symptoms are gone again: this variation from day to day nearly always leads to a diagnosis of neurosis for months or years before the true nature of the malady becomes obvious. In some patients a central scotoma may develop early, leading to peculiar symptoms, such as the inability to distinguish a sovereign from a shilling if the light is not good, or the liability to run into people without seeing them when cycling. If ataxy is marked, the staggering gait may lead to a suspicion of alcoholism: the patient staggers alternately to either side in disseminated sclerosis, whereas in tumours of one cerebellar hemisphere the tendency is to stagger constantly to the same side. Bladder and rectal troubles are not common in either case, and yet they may be prominent. Paræsthesia may also develop in disseminated sclerosis, although as a rule there is no sensory disturbance at all.

If a patient has the symptoms of spastic paraplegia and ataxy, without anaesthesia, nystagmus, or changes in the voice, a diagnosis of *ataxic paraplegia* will usually be made. There is really no difference between this and what has been called *combined sclerosis of the cord*: in both conditions there is degeneration of the posterior columns, the crossed pyramidal, and the cerebellar tracts. Some observers use the term combined sclerosis only for syphilitic cases, reserving ataxic paraplegia for similar non-syphilitic cases.

Primary lateral sclerosis was a relatively common diagnosis until it was found that the more careful the examination the greater was the likelihood that more than simple degeneration of the crossed pyramidal tracts would be found. Partial compression of the cord produces spastic paraplegia without anaesthesia, and thus simulates primary lateral sclerosis as described above. Disseminated sclerosis may do so likewise, and so on. Primary lateral sclerosis should never be diagnosed, therefore, till all the other affections in which the lateral columns may be affected have been excluded. There is such a disease as primary lateral sclerosis, however: it is generally syphilitic in origin, and it leads to typical spastic paresis of the legs, with increased knee-jerks, ankle-clonus, extensor plantar reflexes, no wasting, no R. D., no sensory disturbances, and in the later stages, retention of urine with overflow, and incontinence of faeces: the disease is generally progressive, but after reaching a certain point it may remain stationary for years, or even improve to a slight extent for a time. When lateral sclerosis is yet in an early stage, a valuable sign

of it is the disappearance of the abdominal reflexes; the diagrams (*Figs. 210, 211*) may be of assistance in locating the level of the cord at which a lesion may be present.

The causes of paraplegia that remain for discussion are Landry's paralysis, general paralysis of the insane, functional paraplegia and malingering.

Landry's paralysis is probably not a distinct entity, but rather a very acute type of perhaps more than one variety of paraplegia. It is rare. It affects young adults, who,

hitherto strong and well, become rapidly affected by paralysis which starts in the legs and quickly ascends to the trunk and arms, and may even involve the neck and cranial nerves. It either gets well quite rapidly, or else kills the patients in a few hours or days by affecting the intercostal muscles and diaphragm, with consequent asphyxia. There may be slight pains in the affected parts shortly before paralysis sets in, but sensory symptoms are generally slight, or absent. The nature of the malady is obscure, but if one were to regard it as a very acute and widespread anterior poliomyelitis, one could account both for its main symptoms, its rapid fatality in some cases, and its equally rapid recovery in others. Moreover, seeing that the patient either dies or recovers so quickly, it is not surprising that there is no time for the development of obvious muscular wasting or reaction of degeneration.

Paraplegia in cases of *general paralysis of the insane* does not arise until the third stage of that malady is reached; by that time the diagnosis is generally obvious; the paraplegia is part of a general and extreme weakness, and the patient is bedridden.

Functional paraplegia and *malingering* should never be diagnosed until all organic causes—particularly disseminated sclerosis and spinal caries—have been excluded. Malingering may be suggested by the particular circumstances of the case—the patient may be a nervous, self-conscious girl who desires to attract sympathy, or an out-of-work who wants to get a night's shelter in a hospital; careful observation generally leads to the detection of the fraud. Functional paraplegia is less easy to be sure of, and in many patients that which may at first be regarded as functional ultimately turns out to be organic; this is especially true in the case of disseminated sclerosis. The paraplegia is never of the primary muscular, or the lower neuron type, there being no wasting and no R.D. The muscles remain of good bulk as they do in the upper neuron type of paraplegia, but although the knee-jerks may be unduly brisk, the plantar reflexes remain flexor, and there is

Fig. 210.—Diagram of sensory localization in the spinal cord.

Fig. 211.—Diagram of localization of reflex centres in the spinal cord.

no maintained ankle-clonus. If there is anaesthesia, the distribution of the latter is sometimes obviously functional; it may, for instance, start sharply at the knee and cease suddenly at the ankle, or in some other way indicate that it corresponds neither to the

segments of the spinal cord nor to the distribution of the peripheral nerves. It is by anomalies of this kind, which make it impossible to fit in the case with any organic lesion, that functional paraplegia is diagnosed by a process of exclusion. *Herbert French.*

PARASITES, INTESTINAL. Tape-worms. The commonest symptom of the existence of a tape-worm is the passage of the detached terminal segments per rectum in longer or shorter tape-like strips. The only condition for which these might be mistaken is muco-membranous colitis, in which long, narrow, white mucous casts of the bowel may be passed with the motions (*Fig. 172, p. 398*). It is easy to distinguish these, however, if the suspected material is floated in water, for in the case of a cast of the bowel a central lumen will be found which is not present in the tape-worm. There is, moreover, no regular segmentation in the case of muco-membranous colitis, whereas tape-worms are obviously segmented. If any doubt remains, examination with a lens will show the glandular structure of the uterus in the tape-worm segments, and no such structure in the strips of mucus in muco-membranous colitis. It is sometimes stated that picking of the nose and a voracious appetite are symptoms of the presence of some kind of intestinal parasite; but this is hardly ever the case; if constitutional symptoms develop at all, they take the form of deficiency of appetite, with more or less anæmia, which may become profound; there is often considerable **EOSINOPHILIA** (p. 218). The three forms of tape-worm that occur in the human intestine are *Tænia solium*, *T. mediocanellata*, and *Bothriocephalus latus*, the commonest in Great Britain being the *T. mediocanellata*, the cystic stage of which is spent in cattle. *T. solium* is derived chiefly from pig-meat, whilst *Bothriocephalus latus* occurs mainly in those who live much on fresh-water fish. It may be possible to make the diagnosis of *T. mediocanellata* by holding the segments up against a bright light and seeing a median streak or water-channel, in addition to one down either edge of each strip, this middle water-channel giving the name to the parasite. The ultimate proof of the nature of the tape-worm, however, is afforded by the characters of the head, that of *T. solium* having four sucking discs, with a rostellum surrounded by thirty-four hooklets (*Figs. 212, 213*); that of *T. mediocanellata* four circular sucking discs and no hooklets

Fig. 212. Head of Tænia solium, showing four sucking discs and thirty-four hooklets, alternately long and short. Medium power. (From a specimen in the possession of Mr. Pillsbury, New Bond Street, W.)

Microscopical Examination of Faeces. One of the best ways of preparing faeces for microscopical examination for the ova of parasites or for other solid particles, is to put about as much as would cover a shilling into a test-tube, filling the latter two-thirds full of normal saline solution (1½ dr. of salt to a pint of water), corking the tube, and shaking it vigorously in order to break up the faeces as much as possible; on allowing to stand for twenty minutes, the upper part of the fluid remains opaque with fine debris, whilst the heavier particles, including the ova of

parasites, have sunk to the bottom; the supernatant opalescent or opaque fluid may now be poured off, and the more definite residue again shaken up with normal saline and allowed to stand for another twenty minutes; this process is repeated until the supernatant fluid becomes clear after it has stood for the twenty minutes, and then, when as much of the fluid as possible has been poured away, a drop of the sediment is taken up in a pipette, transferred to a microscope slide, covered, the excess of fluid removed with filter paper, and the specimen examined either with the $\frac{2}{3}$ in. or $\frac{1}{4}$ in. objective, preferably with the mechanical stage. Such a specimen exhibits all sorts of vegetable cells, keratin particles, and so forth, which may at first be regarded as ova, but when the actual ovum of an intestinal parasite is seen, there is seldom any doubt about it.

Fig. 216.—Ovum of *Trichostrongylus axei*, semi-diagrammatic. (High power.) (From French's *Medical Laboratory Methods*.)

Round-worms.—The only round-worm that occurs in Great Britain is the *Ascaris lumbricoides*. This parasite may or may not give rise to symptoms; if it does so, they take the form of slight and obscure nervous and gastro-intestinal disorders. More often the diagnosis is quite unsuspected until one of the worms is found in the bed, having crawled out per anam, especially when the patient, generally a child, falls ill of some febrile malady. If round-worms have been found previously, and if the existence of others is suspected, the diagnosis may be confirmed by discovering the typical ova (Fig. 217) in the faeces: their chief characters are their relatively large size, oval shape, and irregular membranous envelope outside the chitinous shell. This worm does not produce eosinophilia as a rule, but in exceptional cases it may do so.

Thread-worms. *Oxyuris vermicularis*, if present at all, usually occurs in hundreds, and can be detected immediately by examination

Fig. 217.—Ovum of *Ascaris lumbricoides*. (High power.) (From French's *Medical Laboratory Methods*.)

of the faeces with the naked eye. Each parasite is rather more than $\frac{1}{4}$ in. in length, without any colour; its extremities project from the faecal mass, and move about slowly, like threads waving in the air. These parasites produce no eosinophilia. The patients are nearly always children, and there may be no symptoms at all; but more often there is considerable irritation around the anus, and in young girls about the vulva. Gonorrhoea has before now been suspected when the vulvar infection was really due to the *Oxyuris vermicularis*.

The **Whip-worm** (*Trichocephalus dispar*) is in itself an entirely unimportant parasite occurring in the caecum and large intestine (Fig. 218), and producing no symptoms whatever. The worm with its tail is about $1\frac{1}{2}$ in. in length, and it is often coiled up watch-spring-wise. Its appearances are unmistakable: its ovum (Fig. 219) looks more or less like a running-cork, and, with its deep brown central parts and clear ends, it is quite characteristic. Whip-worms are present to the extent of nearly 10 per cent of all the inhabitants of some cities. They produce no eosinophilia, blood-changes, or symptoms.

The **Hook-worm** (*Ancylostomum duodenale*) (Fig. 220).—This is not a general parasite in Great Britain, but has affected many persons in certain districts as the result of introduction from abroad, particularly amongst lead-miners in Cornwall. Outbreaks also

Fig. 218.—Whip-worms (*Trichocephalus dispar*) at the caecum and ascending colon. (From a specimen in the Gordon Museum, Guy's Hospital.)

introduction from abroad, particularly amongst lead-miners in Cornwall. Outbreaks also

occurred in the workers in the St. Gotthard tunnel, and the disease is prevalent in many parts abroad, especially in India, Egypt, Brazil, and Jamaica. The infection is carried from faeces to soil, from the soil to the hands, thence to the mouth, and so to the alimentary canal. The symptoms are for the most part those of progressive anaemia and asthenia, inability to continue with work, oedema of the lower extremities, anasarea, shortness of breath, and the occurrence of boil-like skin eruptions, described popularly as the 'flowers' of the disease. The appearance of the patient may suggest pernicious anaemia, and the blood-count may sometimes seem to confirm this diagnosis at first; for whereas a great many of the patients have a severe chlorotic type of anaemia, some have a marked reduction of the red corpuscles and a slightly less reduction of the haemoglobin, so that there is a high colour-index such as is characteristic of pernicious anaemia. There is generally no leucocytosis, but the differential leucocyte-count may suggest the diagnosis at once, for nearly all the patients present a considerable degree of eosinophilia. The administration of anthelmintics such as thymol may lead to the evacuation of the mature worms, which may be recognized in the faeces (Fig. 27, p. 79), each being from $\frac{1}{2}$ to $\frac{2}{3}$ in. in length. The ova (Figs. 28 and 29, p. 80) are oval, with a clear transparent shell and coiled-up embryo parasite. Melena is another symptom which may be prominent in some of these cases.

The two intestinal parasitic affections which produce the most serious anaemias and other toxic effects in man are *Ancylostomum duodenale* and *Bothriocephalus latus*. Herbert French

PARESIS. (See PARALYSIS, p. 491, et seq.)

PENIS, DISCHARGE FROM.—(See DISCHARGE, URETHRAL, p. 181.)

PERISTALSIS, VISIBLE.—The importance of visible peristalsis lies in the fact that it is always pathological except in a few cases in which its unimportant nature is immediately obvious. The two chief conditions which render the normal movements of the bowels visible are *divarication of the abdominal recti muscles*, and *ventral herniation of a laparotomy scar*. The latter is obvious at once; the former is best detected when the recumbent patient, who is generally a multiparous woman with a soft flabby abdomen, tries to raise her head and thorax from the couch without the use of her arms: the contracting recti come together then, and close over the gap in the middle line in which, under the stretched and unsupported skin, the bowel movements had been seen. In almost all other circumstances visible peristalsis is pathological: it may then be divided into two types—gastric, and intestinal.

Gastric Peristalsis takes the form of a comparatively large swelling in the upper part of the abdomen, coming and going, generally appearing from under the region of the left

FIG. 27. *Ancylostomum* of the shadblow. (From a specimen in the Gordon Museum, Guy's Hospital.)

ribs, progressing slowly downwards and to the right, where it fades away and disappears: it corresponds more or less with the greater curvature of the stomach. It is often stated that a return wave, passing along the lesser curvature from right to left, can also be made out, but this is exceptional. Sometimes, instead of progressing, it comes and goes almost in the same spot, varying in shape but scarcely in position. The exact site of the wave must depend mainly upon the size and position of the stomach. It indicates *pyloric or duodenal obstruction*, and its presence serves to exclude atonic gastrectasis. There may or may not be other signs of dilated stomach, particularly a widely distributed succussion

splash, vomiting of large volumes of fermenting fluid at relatively long intervals, and a greatly increased bismuth x -ray shadow. Whether the pyloric stenosis is simple or malignant has to be decided upon other grounds.

Visible Intestinal Peristalsis is, with the limitations discussed above, one of the surest signs of grave intestinal obstruction. There are almost certain to be abdominal distention, vomiting, and constipation along with it, and the discussion of the differential diagnosis of the different causes of these symptoms will be found elsewhere. The great importance of visible peristalsis is seen in those doubtful or obscure cases in which the patient seems hardly ill enough to be suffering from intestinal obstruction. It may be thought that colic, the result of some indigestible article of diet, is a more likely diagnosis, and that a dose of castor oil will cure the malady. Rather than wait for increasing severity of the symptoms to clinch the diagnosis in these cases, it is most important to arrive at a diagnosis of the necessity for laparotomy at the earliest possible moment if life is to be saved. If the small intestine alone is involved, the waves are multiple, and they run more or less transversely across the abdomen—the ladder-rung type: when the colon is obstructed, vertical waves, especially in one or both flanks, are the chief form the peristalsis takes. Definite and visible intestinal peristalsis is, so far as any single sign can be relied on, an almost infallible indication of the need for laparotomy in any case in which the other symptoms and the history point to a possibility of intestinal obstruction.

Herbert French.

PERSPIRATION, ABNORMALITIES OF.—(See SWEATING, p. 654.)

PHOSPHATURIA.—This is a term the precise significance of which is by no means clear; the meaning it conveys to one observer is not always that which it implies to another. Some restrict it to conditions in which the total quantity of phosphates in each day's urine is greater than the average maximum. Others use the term when there is a spontaneous deposit of phosphates in the specimen glass. Others would include cases in which, on applying the boiling-test for albumin, a cloud of phosphates comes down. So loose is the application of the word phosphaturia that it is generally used whenever anything arises to remind the observer ocularly of the fact that the urine contains any phosphates at all.

What is really required is a series of *different* terms to express the following conditions:—

1. Circumstances in which a greater quantity of phosphates is habitually passed in the urine than is the average maximum in health.
2. The spontaneous deposition of phosphates in a urine that has stood in a specimen glass until cold.
3. The spontaneous deposition of phosphates in the bladder, so that the urine is thick and milk-like when it is being passed.
4. The deposition of phosphates as a white cloud when the urine is heated.

Absolute Phosphaturia.—The phosphoric acid in the urine is chiefly exogenous, i.e., derived from phosphates in the food. It is chiefly in inorganic combination as salts of the alkalis and alkaline earths. There is a certain small percentage of urinary phosphorus derived from the katabolism of nuclein and lecithin, but the amount derived from these in healthy persons is very slight as compared with that which comes direct from the food, so that the phosphates almost disappear from the urine during starvation. There are wide variations in the amounts excreted by normal persons: the average is 3.5 grams per diem, but the healthy limits are as far apart as 1 gram and 8 grams.

It has been asserted that persons whose business entails great wear and tear of the nervous system excrete more than the average amount of phosphates, and the same has generally been held to be true of sufferers from certain nervous disorders of the hysterical or neurasthenic type, particularly when sexual matters are in question. There is very little evidence, however, to show that there is any real increase in the urinary phosphates in these cases. There is often a very abundant deposit of phosphates on applying the heat test to the urine, and this may give the impression that the total quantity of phosphates present must be above the normal: but the impression has not been confirmed by exact analysis. There is only one well-defined condition in which there is absolutely and persistently more phosphate in the urine than healthy limits would allow, and that is *phosphatic diabetes*—a very rare condition of which the main features are thirst, emaciation, aching

in the loins and back, and polyuria without sugar but with an absolute excess of phosphates in the urine.

Physiology of Phosphatic Deposits.—In nearly every case the deposition of phosphates is a purely physiological process. A molecule of phosphoric acid, H_3PO_4 , contains three hydrogen atoms. Each of these can be replaced separately by an atom of any monobasic metal, such as sodium. Three types of salts are formed, according as one, two, or three of the hydrogen atoms have been replaced, as in the following examples :

NaH_2PO_4	-	-	Sodium dihydrog phosphate
Na_2HPO_4	-	-	Sodium monohydrog phosphate
Na_3PO_4	-	-	Sodium phosphate

These salts may all be present in the same urine, the proportions of each varying with the amount of phosphoric acid present, on the one hand, and the total amount of bases (i.e., sodium, potassium, etc.), and the total quantities of other acids present in the form of chlorides, sulphates, and so forth, on the other. The greater the quantity of chlorides and sulphates, the greater will be the amount of the metallic bases required to form them, and consequently the less will be the amount of bases left to combine with phosphoric acid; the result must then be a relative excess of NaH_2PO_4 . Conversely, the scantier the chlorides and sulphates, and the more abundant the bases, the greater will be the proportion of Na_2HPO_4 and Na_3PO_4 .

Now the three sodium salts differ from one another in at least two physical respects — their action upon litmus, and their solubility in water. Sodium dihydrogen phosphate (NaH_2PO_4) turns blue litmus red—in other words, it is an acid phosphate. The acidity of ordinary urine is mainly due to it. Sodium monohydrogen phosphate (Na_2HPO_4) is also an acid salt technically speaking, and there are some colour tests which exhibit the acid reaction with it; litmus, however, is not one of these, for Na_2HPO_4 turns red litmus blue. When a given urine contains more Na_2HPO_4 than NaH_2PO_4 , the reaction of that urine to litmus is alkaline; that is to say, it turns red litmus blue and does not turn blue litmus red. Some urines have what is known as an amphoteric reaction—they turn red litmus bluish and blue litmus reddish—a different thing from neutrality of reaction, in which neither red litmus nor blue is turned in colour at all. The cause of the amphoteric reaction of a urine is the even balance in that urine of the Na_2HPO_4 on the one hand and of the NaH_2PO_4 on the other.

Now the dihydrogen phosphate is much more soluble in water than is the monohydrogen phosphate, whilst the tribasic phosphates are as a rule far less soluble still. When it is stated, therefore, that phosphates are more soluble in acids than they are in alkalis, it must be remembered that it is not a question of a difference of solubilities of the *same* salt of phosphoric acid, but of an acid urine containing the bulk of its phosphates in a salt *different* from the one present in an alkaline urine. The very fact of a urine being alkaline means that there is relatively little of the more soluble NaH_2PO_4 present, and relatively much of the less soluble Na_2HPO_4 and Na_3PO_4 . Conversely, the fact that a urine is acid implies that the phosphates are relatively more abundant in the soluble NaH_2PO_4 form than they are either as Na_2HPO_4 or Na_3PO_4 . As a matter of fact, the three degrees of phosphates of sodium, potassium, and ammonium are all so soluble that they practically never become precipitated spontaneously, nor do they take part in forming calculi. It is the phosphates of calcium and magnesium that form precipitates, but what has been said above of sodium phosphate applies equally to calcium and magnesium phosphates. The less acid a urine is, the more will the less soluble varieties of calcium and magnesium phosphate preponderate, and it is on this account that phosphates come down in alkaline or neutral rather than in acid urines.

Again, it is often stated that phosphates are less soluble in hot urine than they are in cold, and this is given as the reason for the cloud of precipitated phosphates that so often forms when a urine that is not already very acid is boiled. This, however, does not express the real reason for the cloud; the heat does not precipitate the same phosphate as the cold urine contained, but leads to the formation of a different, and less soluble, phosphate. The calcium monohydrogen phosphate dissociates into calcium dihydrogen phosphate and normal calcium phosphate; it is the latter which is so insoluble that it comes down:

Milky Urine.—The urine of many healthy people, especially children, and eaters of large public dinners, is sometimes milk-like when it is passed soon after a full meal. Many a person has become alarmed at the sight, and has feared some grave disorder of the sexual organs or functions, especially either gonorrhœa or spermatorrhœa. The condition is physiological. It results from increased quantities of hydrochloric acid being required in the stomach at the time. The result of this is that the urine temporarily contains such an abundance of bases in proportion to acids that the less soluble monohydrogen phosphates exceed the more soluble dihydrogen phosphates, and they may become precipitated even in the urine that is still within the bladder. The commonest salt to come down is calcium monohydrogen phosphate, CaHPO_4 , which is either amorphous, or else assumes the form familiar as 'stellar phosphate.' MgHPO_4 may come down with it in the form of amorphous particles, or as needles.

The alternation between oxaluria and phosphaturia exhibited by some individuals is discussed on p. 424.

Ammonio-magnesium Phosphate.—This, generally known as triple phosphate, MgNH_4PO_4 , is comparatively insoluble, and when precipitated it nearly always assumes the form of prisms—the familiar 'knife-rester' or 'collin-lid' crystals (*Fig. 221*). It is clear that these will come down only when the urine contains ammonia. The latter may of course have been produced by ammoniacal decomposition of urea after the urine was passed. If urinary decomposition after passage can be excluded, however, it is usually stated that the presence of ammonio-magnesium phosphate crystals indicates a purulent lesion in the urinary tracts, especially in the bladder. It is quite true that ammoniacal urines from cases of cystitis often abound in crystals of triple phosphate. The diagnosis is given by the pus cells and so forth, however, and not by the triple phosphate crystals. It is important to remember, moreover, that each day's urine normally contains enough ammonia for ammonio-magnesium phosphate crystals to occur in an absolutely healthy urine, even apart from decomposition on standing. This fact detracts very greatly from the value formerly attributed to the detection of triple phosphate crystals in the urine.

Indeed, the importance of phosphates in the urine lies almost entirely in the fact that errors of interpretation may arise unless their physiological behaviour is clearly understood. Microscopically they are often amorphous, but the three well-defined forms of crystals shown in *Fig. 221* may be recognized microscopically. The chief chemical test is the addition of dilute acetic acid, which causes a precipitate of phosphates to clear up. The main importance of recognizing them correctly is to avoid mistaking phosphates for pus in the case of a spontaneous deposit, for spermatozoa, or gonorrhœa, when the urine comes milky from the urethra, and for albumin in the case of the boiling-test for the latter.

Herbert French

PHOTOPHOBIA, or intolerance of light, may be due to three main groups of causes namely:

1. Causes in the Eye itself:—

Foreign body
Injury
Conjunctivitis
Ophthalmia
Keratitis
Ulceration of the cornea

Iritis
Cyclitis
Glaucoma
Retinitis
Retrolinbar neuritis

Eye-strain from close work in those suffering from uncorrected errors of refraction, especially astigmatism and hypermetropia.

2. Certain Occupations:

Involving work under eye-straining conditions, such as affect furnace stokers, electric steel welders, workers in strong sunlight, those who are exposed to the dazzle of snow in strong sunshine, those who come out into strong daylight after prolonged work in the dark, as in coal pits; those who work much with x-rays. Some persons are unable to stand any strong light, whether of the sun, gas, or electric.

3. Causes not primarily in the Eye itself:—

(a). *Some fevers, especially* :—

Measles		Influenza		Typhus.
---------	--	-----------	--	---------

(b). *Intracranial lesions* :—

Tuberculous menin-		Epidemic cerebrospinal men-		Syphilitic pachymeningitis
gitis		ingitis		Cerebral tumour.
Suppurative menin-		Acute encephalitis		
gitis				

(c). *After the administration of some drugs* :—

Arsenic		Potassium iodide		Potassium bromide.
---------	--	------------------	--	--------------------

(d). *Functional conditions* :—

Migraine		Tic douloureux		Hysteria		Sick headache.
----------	--	----------------	--	----------	--	----------------

(e). *Supra-orbital herpes zoster.*(f). *Severe anaemia* (see ANÆMIA, p. 20).(g). *Secondary to dyspepsia or constipation.*(h). *Malingering.*

Some idea of the cause will generally present itself as soon as the patient gives an account of how the trouble began and how it has progressed. By itself photophobia is seldom a symptom of diagnostic significance, and nearly always there will be other symptoms to assist one. The eyes should be examined carefully in the first place, to find or exclude a local cause, especially glaucoma, which is the most serious of the local lesions; it is associated in acute cases not only with severe photophobia, but also with acute pain in the eye (see EYE, ACUTE INFLAMMATION, *op.*, p. 231). Retinal changes will be discovered by ophthalmoscopic examination (see OPHTHALMOSCOPIC APPEARANCES, p. 415). *Retrolubar neuritis* may not cause any visible changes in the optic disc, at any rate not until several days have elapsed, by which time optic neuritis may be visible; but it may be suggested by the rapid onset of impaired vision without increased intra-ocular tension as in glaucoma, going on perhaps to temporary complete blindness (p. 760).

Eye-strain from errors of refraction requires special ophthalmic knowledge for its exact determination, though it may be suggested by the circumstances of the case.

Occupation photophobia will be likely if the patient works under peculiar conditions of light, though it will be necessary to exclude organic lesions in the eyes by a thorough ophthalmic examination. When local eye conditions have been excluded definitely, the cause of photophobia will generally be either pretty clear at once or soon, or else open to so much doubt that the actual cause may be one of conjecture only.

It will not be the photophobia, but other symptoms, such as the rash, the fever, and the course of the disease, which will give the diagnosis in cases of *measles*, *influenza*, or *typhus fever*; headache, vomiting, optic neuritis, and the results of lumbar puncture or the Wassermann test in the case of *meningitis*, *encephalitis*, *cerebral tumour*, or *syphilitic pachymeningitis*; knowledge of the drug given and cessation of the photophobia when it is stopped in the case of *arsenic*, *potassium iodide* or *bromide*, or *quinine*.

Migraine and *tic douloureux* are so characteristic in their attacks that they are both diagnosable as a rule from the patient's story; photophobia may be severe in either, or even extreme in *tic douloureux*, in which, during the exerting paroxysms of facial pain, the patient will often desire to remain for days in an absolutely darkened room; exposure to any light may bring on a paroxysm.

Supra-orbital herpes is generally obvious from the eruption of groups of vesicles on a reddened base along the course of one supra-orbital nerve; and the photophobia is generally unilateral; it may persist however for weeks or months after the eruption has subsided, and then its origin may be overlooked.

Malingering can be diagnosed only by catching the patient unawares and discovering that when he is not watched he is able to read in an ordinary light notwithstanding the photophobia he complains of. *Dyspepsia*, *constipation*, and *severe anaemia* are somewhat problematical as causes of photophobia, but might be regarded as its origin in a patient who, suffering from any of the three, also had photophobia without any other discoverable

cause, especially if the photophobia disappears when the patient is cured of the constipation, the dyspepsia, or the anemia, respectively.

Sick headache is a periodic malady of many women and some men. Headache of great severity is the chief symptom, lasting a whole day or even longer; gastric functions are in abeyance during the attack, so that food in the stomach remains undigested and medicines unabsorbed; the patient may feel ill enough to have to stay in bed; towards the end of the attack vomiting occurs once or several times, and by the next day the patient feels perfectly well again. Dislike of any but a dim light is common during the attack. The diagnosis is generally based upon the patient's familiarity with similar symptoms on many previous occasions. The malady is often hereditary; possibly it is related to migraine.

Biliousness is a very common ailment, due to many different causes, especially injudicious eating or drinking, or to deficient fresh air or exercise. Some cases of recurrent biliousness are closely allied to sick headache and to migraine. During an attack the tongue is coated and the bowels inactive. The precise pathology of the condition is little understood, but the diagnosis is not difficult, although it is important to make a routine examination to exclude more serious lesions. Photophobia, though common in a minor degree in bilious attacks, is seldom very marked.

Hysterical photophobia is met with only occasionally, but when it occurs it may be extreme; that is to say, the patient may mimic—not intentionally, as in the case of a malingerer, but without at all wishing to do so—so extreme a degree of intolerance to light that she may cover her eyes with deep-tinted glasses, or even cover her whole head with an impervious dark robe; and may perhaps require to be led about when she walks, like a person totally blind. It is this over-doing of the part that may give the clue to the diagnosis. Naturally a thorough examination, particularly of the eyes, will be required to exclude organic disease, but if functional photophobia appears to be the diagnosis in a particular case, the suspicion may be confirmed by the way the symptom can be made to disappear by sufficiently bold suggestion.

Herbert French.

PIGMENTATION IN THE MOUTH generally consists of flecks, streaks, or spots of pale brown or pale sepia discoloration of the mucosa, especially upon the inner aspect of the cheeks along a line roughly corresponding to the level of the closed teeth; with or without similar pigment spots, streaks, or patches upon the mucous surface of the lips, seen best when the latter are everted in a good light; upon the roof of the mouth, generally upon the soft palate or upon the posterior part of the hard palate rather than more anteriorly; upon the gums occasionally; and sometimes upon the sides of the tongue (*Plate XXI*). Such pigmentation of the buccal mucosa immediately suggests *Addison's disease*, especially if there is generalized pigmentation of the skin at the same time, extreme asthenia, a low blood-pressure, a tendency to vomiting or to fainting attacks on any exertion, with inability to maintain any effort, mental or physical. Unfortunately, however, although such buccal pigmentation is highly suggestive of Addison's disease, it is not pathognomonic, for it has been noted in a variety of other conditions also.

Thus, it is an almost constant feature in persons who have *negro blood* in their ancestry, even though this be from one great grandparent only. This source of dilliculty in interpretation is commoner, perhaps, in Africa, the West Indies and America, than it is in Britain, but even here it makes it uncertain sometimes whether one is to diagnose Addison's disease or not.

Then in *pernicious anaemia* buccal pigmentation precisely similar to that of Addison's disease is met with occasionally (*Plate XXII*, p. 528), and unless the blood-count is very definite (p. 24) it may be difficult, even up to the time of post-mortem examination, to say which of the two conditions the patient is suffering from. Probably the right course to follow then would be to treat the case with salvarsan and arsenic, and watch the effect; pernicious anaemia rallies, temporarily, to these remedies much more certainly than Addison's disease does.

Arsenic itself may cause pigmentation, not only of the skin, but also within the mouth, as was shown by some of the cases in the Manchester epidemic of arsenic in beer poisoning. Some have supposed that the buccal pigment in pernicious anaemia is due to the arsenic employed in treatment; that this is not so, however, is shown by the fact that some cases

PLATE XXI

PIGMENTATION OF TONGUE AND MOUTH IN ADDISON'S DISEASE

FIGURE 1. Pigmentation of the tongue in Addison's disease.

FIGURE 2. Pigmentation of the lower lip and chin in Addison's disease.

of pernicious anæmia exhibit pigmented spots inside the mouth even before any arsenic has been given; the patient from whom *Plate XXII* was taken was an instance in point.

One has also seen pigmentation of the buccal mucosa, suggesting Addison's disease, in *chronic cachectic conditions* in which the suprarenal capsules have proved to be healthy at autopsy. In a case of *phthisis* recently, for example, so pigmented was the mouth that it seemed reasonable to diagnose that the tuberculous process was affecting the suprarenals as well as the lungs; yet after death the suprarenals were normal, and one can only suppose that the buccal pigment resulted from the phthisical cachexia which had caused a general tendency to pigmentary degeneration everywhere. In another case Addison's disease was diagnosed during life for the same reason, but at autopsy a *carcinoma* of the splenic flexure of the colon was found, with secondary deposits in the liver; there had been asthenia and general cachexia, and apparently it was the latter which was responsible for the pigment changes. In a third case the patient was both anæmic and cachectic, without any other definite symptoms, and there was extensive pigmentation in the mouth. The blood-count showed extreme anæmia with a colour index that was approximately 1. The doubts during life lay between Addison's disease and pernicious anæmia; both suggestions proved wrong, for at autopsy syphilitic gummata of the liver were found, together with *tertiary syphilitic amyloid disease*.

Fortunately, buccal pigmentation from cachectic states such as phthisis, cancer, and syphilis is rare, though the possibilities have to be kept in mind. In the great majority of cases, however, if pernicious anæmia, arsenic, and negro blood can be excluded, Addison's disease will be diagnosed correctly if the patient is clearly asthenic and ill without any very definite physical signs, but with marked pigmentation within the mouth. *Herbert French.*

PIGMENTATION OF THE SKIN.

—Anomalies of the natural pigmentation of the skin, on the side either of excess or deficiency, may be due to irritation of the abdominal sympathetic, and particularly the solar plexus, leading to *general* pigmentation, or to the exudation or extravasation of the colouring matter of the blood, producing *local* pigmentation. Local pigmentation may be brought about by the action of irritants, may result from a condition of hyperæmia, or may be a sequela of skin eruptions. The most familiar errors of pigmentation are covered by the term *chloasma*. This may be either idiopathic or symptomatic. *Idiopathic chloasma* is usually caused by counter-irritants, such as vesicants, or some other form of external irritation, especially scratching, as in *vagabond's disease—phthieriasis*; but in some cases it is impossible to trace the cause. *Symptomatic chloasma* is a sequela or an accompaniment of cutaneous eruptions, or is the result of abnormal conditions of the uterus or of other abdominal viscera, or of cachexia. It is most often met with as *chloasma uterinum*, which may occur not only in connection with pregnancy, but also in association with any form of uterine irritation. The smooth yellowish-brown patches are seen most commonly on the forehead, but almost the entire face may be involved—and also the trunk and limbs. Somewhat similar irregularities of pigmentation occur in *rheumatoid arthritis*, *pernicious anæmia*, *Hodgkin's disease*, *Graves's disease*

Fig. 222. —A case of (1) idiopathic chloasma, illustrating general pigmentation of the skin in this disease.

(Fig. 222), abdominal tuberculosis, constipation, chronic intestinal stasis, and other disorders of the abdominal viscera, and in cases in which *arsenic* has been given over long periods. In Addison's disease there is a general bronzing of the skin, together with pigment deposits in the mucous membranes of the mouth (Plate XXI), anus, vulva, and urethra; buccal pigment, however, does not by itself prove that Addison's disease is present, for precisely similar pigmentation in the mouth is observed in some cases of pernicious anaemia (Plate XXII), of phthisis without suprarenal disease, and of malignant disease; whilst negro blood in the ancestry often causes buccal pigmentation in perfectly healthy persons.

Pigmentary abnormalities of the skin occur also in *cachexia* associated with malaria, cancer, nodular leprosy, and secondary syphilis—in malaria, a yellowish-brown to black; in cancer, a sallow tint; in nodular leprosy, a fawn colour early in the disease, and a general bronzing at a later stage; in secondary syphilis, an earthy tint affecting the face. In the rare condition known as *ochronosis*, the skin, cartilages, and sclerotics are blackened, as

Fig. 222.—Extensive syphilitic leucodermatitis.

Fig. 221.—The same case as Fig. 222, seen from behind.

the result in some cases of alkaptonuria, in others of the prolonged absorption of carbonic acid. In *hæmochromatosis*, another rare condition, apparently due to diseases of the alimentary tract and liver, the patient may be pigmented from head to foot, the prevailing colour being a deep blue-grey slate tint. The diagnosis of *urticaria pigmentosa seu nigricans* is generally clear. Pigmentary deposits in the skin form only part of the skin changes characteristic of *Kaposi's disease*. The pigmentation of *bronzed diabetes* can scarcely be misinterpreted if, when the urine is examined, glycosuria be found; most cases of this form of diabetes have cirrhosis of the liver as well, so that there is a non-rectotal history.

The diagnosis of the various forms of chloasma is usually easy, though the particular cause of the pigmentation can only be deduced, of course, from the general symptoms.

PLATE XXII

PIGMENTATION OF MOUTH IN PERNICIOUS ANÆMIA

Pigmentation of the mucous membrane of the lips, cheeks, and palate. History of pernicious anemia (Waldenstrom's case) had not yet been told. Addison's disease was excluded. (For further details, refer to case of this case, continued by autopsy.)

Chloasma can be differentiated from *chromidrosis*, by observing that in the latter condition the colour, which is derived from the exuded secretions, disappears if washed with ether or chloroform. In *linea versicolor*, and some other fungous diseases which resemble chloasma, the patches are not smooth but scaly, and the discoloration can be scraped off. The *pigmentary syphilide*, which may take the form of a diffused brownish hue, brownish spots, or dappled patches, is seldom met with except on the neck, but sometimes it may take the form of widespread leucomelanoderma (Figs. 223 and 224). Question may arise between chloasma and *leucodermia* (vitiligo) when in the latter condition the white areas have spread over the greater part of the body, and are taken for the normal colour; but in leucodermia the border of the area is concave, whereas in chloasma it is convex. Moreover, in leucodermia the history is that of the formation of white patches, surrounded by a pigmented border, which may spread until large areas, and even the whole surface of the body, are affected.

Leucodermia has in its turn to be distinguished from sclerodermia, morphea, macular leprosy, pigmentary syphilide, and partial albinism. The skin is not stiff and thickened as it is in *sclerodermia*. The edges are not streaked with small dilated vessels, making a pink or violet border, as in *morphea*, nor is there any intermingling of atrophic striae. The patches are not destitute of sensation as in *nerve-leprosy*, nor, though it has been styled 'white leprosy,' has leucodermia any other resemblance to that affection save the colour of the patches. Doubt as between leucodermia and a congenital condition like *partial albinism* could only arise by disregarding the history. Of albinism itself, whether partial or universal, nothing more need be said here; for though it is an abnormality of pigmentation, its true character can never be in question. Nor need I speak of jaundice, for that condition forms the subject of a separate article.

Discoloration of the skin may be due to the prolonged administration of drugs. Thus picric acid may turn the skin and the conjunctivæ yellow, arsenic may cause a peculiar greyish, brownish or freckle-like pigmentation (Fig. 225, and Plate VII, p. 64), nitrate of silver may set up the condition known as *argyria*, in which the integument and the mucous membrane, particularly in situations exposed to light, take on a bluish-grey or greyish-black colour, especially on the face and the flexor aspects of the limbs. This condition may closely resemble hæmochromatosis and similar abnormalities, but the history of protracted use of the drug will make the diagnosis clear. Since, however, arsenic may be derived from some unsuspected source, as was the case in the peripheral neuritis epidemic in and around Manchester due to beer containing it as an impurity, chemical analysis of the hair should be made, for arsenic becomes stored up in the hair that grows whilst this is being taken.

Fig. 225. Pigmentation of skin from arsenic in a case of pernicious anaemia.

Malcolm Morris.

PLANTAR REFLEX, EXTENSOR.—(See BABINSKI'S SIGN, p. 68.)

PLEURAL EFFUSION.—(See CHEST, p. 102.)

PNEUMATURIA—or the passage of gas per urethram, either along with or independently of urine—is a rare symptom, but when it does occur it is very striking, particularly in males.

It may be due to one or other of two entirely distinct groups of causes, namely :

D

1. Communication between the rectum, cæcum, vermiform appendix, or other part of the alimentary canal and the bladder, ureter, or renal pelvis: either directly, or *via* an intermediate gas-containing abscess cavity.

2. Infection of the bladder or other part of the urinary tract by micro-organisms that produce gas, without there necessarily being any breach of surface of the mucosa.

When the cause lies in the first group, the patient is very liable to pass fecal material at the same time as the gas, and the differential diagnosis between the various possible lesions is discussed under *FÆCES PASSED PER URETHRAM* (p. 238). It should be added, however, that the passage of gas without feces per urethram by no means excludes there being a fistulous communication between some part of the alimentary canal and the urinary tract; the fistula may be tortuous, so that gas gets along it, but not feces. It may happen, moreover, that a lesion such as appendicitis has led to the formation of a local abscess which, owing to its infection by the *Bacillus coli communis*, contains gas; this abscess may open into the bladder and cause the discharge of pus and gas, but no feces, per urethram. The same applies to other abscesses which, though not arising primarily in connection with the bowel, nevertheless occasionally contain gas from infection by the *B. coli communis*—a suppurating hydatid or ovarian dermoid cyst, for instance, or a pyosalpinx.

Sometimes there may be serious doubts as to whether the gas is finding its way into the urinary passages from some external source, as above, or whether it is being produced *in situ*. In the absence of any rectal or other pelvic or abdominal evidence of disease outside the bladder, it will be remembered that certain organisms produce gas when they grow in urine: notably the *Bacillus coli communis*, and in glycosuria cases, various yeasts. The urine will be examined for sugar, and if it be present, a catheter specimen will be obtained to see if saccharomyces are present in the bladder-urine: if so, and if there is no pus or evidence of infection by other micro-organisms, the nature of the pneumaturia will be clear: as a rule, in these cases the patient voids urine that is bubbly rather than distinct and separate from the gas. If, on the other hand, no sugar is present, a catheter specimen will be cultivated to find out whether the *B. coli communis* is present, and if so, in what quantity. If it is, and if no sign of any fistulous communication between any part of the bowel, or a gas-containing abscess cavity, and the urinary tracts, can be made out, the presumption will be that the pneumaturia is due to coli bacilluria, although the latter is far commoner without than with pneumaturia. The urine in these cases may contain very little obvious pus and only a trace of albumin: it may be acid, and not foul smelling or ammoniacal; on the other hand, it may sometimes be so foul and feculent as to cause serious suspicions of a communication between the colon and the bladder, even when there is none. A cystoscopic examination will serve to exclude a fistulous opening into the bladder, but it may be much more difficult to exclude a similar communication with the higher parts of the urinary tract, especially the renal pelvis. The latter condition is so rare, however, that it is wiser to diagnose coli bacilluria only unless there is direct evidence of a cause for communication between the bowel and the renal pelvis, such as a carcinoma coli.

Herbert French.

PNEUMOTHORAX, or gas in the pleural cavity, may exist with or without clear fluid, pus, or blood in the lower part of the pleura at the same time. If there is any kind of fluid in the cavity along with the air, the fact is generally made obvious at once, when the patient's thorax is auscultated whilst it is being actively or passively shaken, so as to produce the typical succussion splash, often followed by the ringing sounds made by drops of fluid falling from the compressed lung into the pool of fluid beneath. The nature of the fluid—hydro-pneumothorax, pyo-pneumothorax, or hæmo-pneumothorax, as the case may be—can seldom be diagnosed except by means of an exploring needle and syringe. Whether the pneumothorax is or is not associated with any of these fluids, the diagnosis is generally easy on account of the deficiency in movement of the affected side of the chest, the displacement of the heart in the opposite direction, and hyper-resonance to percussion, together with remarkable deficiency or complete absence of the vesicular murmur and voice sounds. The coin-tap sound, obtained by placing one silver coin on the chest wall, tapping it with another silver coin, and listening through the stethoscope for the ringing echo produced, when the sign is positive, may serve to confirm the diagnosis, but it is not

essential. Partial pneumothorax, in which complete collapse of the lung is prevented by adhesions, is proportionately more difficult to diagnose, but the same type of physical signs, including the coin-tap sound or *bruit d'airain*, will generally be found in these cases, though in less degree than when the pneumothorax is complete. The *x*-rays show an abnormal clearness corresponding to the air in the pleural cavity (Fig. 226.) It is not sufficient, however, merely to diagnose pneumothorax; its cause has to be determined from amongst the following:

Phthisis: (a) early, (b) late.

Rupture of an emphysematous bleb.

Gangrene of the lung with necrosis of the pleura.

Empyema ruptured through the lung.

Instrumental: e.g., after tapping a pleural effusion.

Stabs, or gunshot wounds of the chest wall.

Epithelioma of the œsophagus ulcerating into the pleura.

Gastric ulcer or carcinoma ventriculi, leaking so as to produce a gas-containing subdiaphragmatic abscess, which in its turn may perforate the diaphragm and cause a pneumothorax.

Infection of the pleural cavity by gas-producing organisms, such as the *Bacillus coli communis*.

Fig. 226. Skiagram of a right-sided pyopneumothorax (left side of the skiagram). Note the horizontal upper level of the pleva (black) and the clearness of the pneumothorax above it. (Skiagram by Dr. Lindsay Locke.)

The commonest cause by far is *phthisis*; and when the occurrence of the pneumothorax does give rise to symptoms, it is generally due to comparatively early phthisis; indeed, when it comes on acutely with sudden lancinating pain in one side of the chest, associated with rapid shallow breathing, and cyanosis with or without hæmoptysis in a young apparently healthy adult, it is almost certain that the patient has a tuberculous focus at one apex, even though, as frequently happens, there have been no abnormal symptoms previously, such as cough or night sweats, and even though absolutely no abnormal physical signs can be detected at the apex of the other lung. There may be a little sputum, and in this tubercle bacilli may be detected.

When pneumothorax is attributed to *rupture of an emphysematous bleb*, there must always remain in the physician's mind a serious doubt as to whether it is not really due to

a bleb in the immediate neighbourhood of an undiagnosable tuberculous deposit, and the case should be treated as one of potential phthisis.

If the tuberculous process in the lung has made considerable advance pneumothorax is far less common, because there will almost certainly have been pleurisy with thickening and adhesions sufficient to prevent pneumothorax occurring; nevertheless, in some such cases pneumothorax does develop, and the diagnosis of its cause is easy both on account of the abnormal physical signs and of the sputum with the tubercle bacilli in it. In a later stage still, the occurrence of pneumothorax may cause very little additional disturbance, on account of the extent of lung already diseased, and although its cause would be obvious enough, the occurrence of the pneumothorax often escapes detection.

When the patient has had a *pleuritis* or *pleural effusion* tapped, detection of air free in the pleural cavity next day is by no means uncommon: it does not follow that this air has leaked in through the tapping instrument, for it is quite as commonly derived from the rupture of superficial alveoli which have been re-expanded rather too rapidly in the withdrawal of fluid by the aspirator. The air generally becomes reabsorbed in a few days, and the temporary pneumothorax is of little significance.

Similar escape of air into the pleural cavity, as the result of cuts, stabs, fractured ribs, or gunshot wounds, is remarkably rare: this rarity depends upon the fact that the two layers of pleura tend to cohere in a way similar to that which makes two thin sheets of Indian paper difficult to separate, so that when an injury from outside penetrates one layer it nearly always perforates both, and air from within the lung escapes into the subcutaneous tissues instead of into the pleural cavity, and produces surgical emphysema instead of pneumothorax. It rarely happens that an injury separates a sufficient area of the two layers of pleura one from the other to cause a pneumothorax.

All the remaining causes of pneumothorax in the list above are uncommon, and none of them will arise without there having been other symptoms to indicate the nature of the malady. It is possible for an *empyema* to rupture into a bronchus, and so lead to the sudden expectoration of much foul pus, without any pneumothorax arising, or at least none of any extent, because for such an empyema to rupture into the lung it must have been shut off all round by firm pleural adhesions. When pneumothorax results from *gangrene of the lung* due to any cause (p. 259), it is but a terminal factor in an already serious disease, and may even pass without recognition on account of the severity of the symptoms already existing in the case. *Gas-containing abscesses beneath the diaphragm*, such as may either perforate directly into the pleural cavity or lead to infection of that cavity by the *Bacillus coli communis* or other gas-forming organism, never arise suddenly, but are preceded by a simple or malignant ulceration of either the stomach, duodenum, or colon, the symptoms of which will generally have existed for days, weeks, or months: so that if the possibility of gas appearing in the pleural cavity in this way is borne in mind, the diagnosis of its origin need not be difficult. The x-rays may serve to show a large gas bubble below the diaphragm as well as gas in the pleural cavity, and that the gas bubble is not intragastric may be demonstrated by filling the stomach with a bismuth meal and finding that the gas bubble does not become blackened.

Herbert French.

POLYCYTHÆMIA is the term used to denote a material increase of the red corpuscles above their normal number per cubic millimetre of blood. In males they should average 5,000,000 per c.mm.; in females, 4,500,000. Any considerable increase above these figures, for instance up to 6,000,000 per c.mm., or more, constitutes polycythæmia. Figures as high even as 14,000,000 are reached sometimes. The following are some of the conditions in which polycythæmia occurs:—

1. Congenital heart disease of the type spoken of as *morbis coruleus*—generally due to pulmonary stenosis (see *Fig. 16*, p. 111, and *Fig. 67*, p. 157.)
2. Persons who live in high altitudes.
3. Patients afflicted with chronic shortness of breath, with a tendency to periodic cyanosis, particularly cases of (a) mitral stenosis, (b) fibroid lung with and without bronchiectasis, (c) chronic bronchitis and emphysema, (d) spasmodic asthma, (e) some renal cases.
4. Patients who have recently lost a quantity of fluid from the tissues, the result of such conditions as (a) severe vomiting, e.g., the uncontrollable vomiting of pregnancy;

(b) severe diarrhoea, e.g., the summer diarrhoea of infants, cholera, ptomaine poisoning, arsenic: (c) inability to obtain fluid to drink, especially if there exists already a disease tending to polyuria, such as diabetes mellitus, diabetes insipidus, or granular kidney.

5. From the prolonged use of certain drugs, especially acetanilide, veronal, and some others of the type that may cause methæmoglobinuria (p. 284).

6. Splenomegalic polycythæmia.

As a rule, the diagnosis of the cause of polycythæmia in a given case is not difficult. When it is due to *congenital heart disease* it is nearly always associated with an extreme degree of cyanosis without proportionate dyspnoea, and with clubbing of the fingers, both these dating from birth or early childhood. The patient is generally young, though some survive into adult life. There is not always a cardiac bruit, and the precise lesion will then be obscure: often, however, percussion shows increased cardiac dullness to the right of the sternum, and upwards towards the second left rib, indicating increased size of the right auricle and ventricle: and in most cases there is either a loud rumbling or blattering systolic bruit of pulmonary stenosis, heard loudest in the second left space close to the sternum, but also audible over the greater part of the precordial region, and often over both sides of the chest in front and behind: or else a very similar universal systolic bruit, differing chiefly in having its maximum intensity either behind the sternum between the two fourth ribs, or else in the fourth left intercostal spaces close to the sternum, indicative of patent septum ventriculorum. These two lesions may both be present in the same patient, and they are the commonest cause in cases of *morbus ceruleus* that survive infancy. The red corpuscles seldom number less than 6,000,000 per c.mm., and in some cases they have been no fewer than 14,000,000 per c.mm. The percentage of hæmoglobin is also increased greatly, but usually to a less degree than are the red cells, so that the colour index falls below 1. This applies to nearly all causes of polycythæmia. There is no simultaneous increase in the number of leucocytes per c.mm., and the differential leucocyte count falls within the normal limits. It is noteworthy that cases of persistent ductus arteriosus seldom present either cyanosis, clubbed fingers, or polycythæmia.

Residence at *high altitudes* often causes polycythæmia. The increase is seldom extreme, but the red cells not infrequently reach 6,000,000 or more per c.mm. This rule is not by any means universal, however, though upon the whole the higher the altitude the higher the normal average number of red cells per c.mm., particularly in those who have resided long and continuously in the mountains. The individuals are not ill: it is merely that their red cells stand at a higher figure normally than do those of dwellers nearer sea level.

Quite apart from the presence or absence of anæmia, patients suffering from chronic lesions which tend to produce dyspnoea are also very apt to have polycythæmia, particularly when the lesion causes marked redness of the lips. This is well seen in many cases of *mitral stenosis* when there has been a tendency to failure of compensation for some time past. There is no similar polycythæmia in aortic cases unless mitral disease is present as well, and the red cells are much less increased in mitral regurgitation than in mitral stenosis. In the latter they often reach 6,000,000 or even 7,000,000 per c.mm., and it would seem to be an attempt on nature's part to try and compensate for the failing circulation by distributing the hæmoglobin over a larger corpuscular area. The same explanation probably accounts for the similar polycythæmia due to *morbus ceruleus*, and to high altitudes, and to certain cases of *fibroid lung*, *bronchiectasis*, *emphysema*, *chronic bronchitis*, *renal disease* with chronic dyspnoea, and *spasmodic asthma*, in which some degree of polycythæmia, though not the rule, is sometimes met with, just as it is in mitral stenosis. The colour index is less than 1, for although the hæmoglobin is increased, it is less so than are the red cells. The leucocytes remain unaltered. The polycythæmia will seldom if ever be the most prominent symptom in the case, so that the diagnosis will nearly always have been made upon other grounds—the presystolic bruit at the impulse: the displacement of the heart towards that side where the lung presents an impaired note, with or without crackling râles and bronchial breathing: and so on. The maintenance of the polycythæmia is important, however, and therapeutic measures should be directed to this end, for many cases of mitral stenosis with 5,000,000 red cells per c.mm. are relatively anæmic: they should have 6,000,000 or more.

The effect of *cholera*, *ptomaine poisoning*, *arsenic*, *summer diarrhoea* of infants, *severe thirst* that cannot be assuaged, the *toxæmia of pregnancy*, and so on, in concentrating the

blood by withdrawing or withholding fluid from it, and thus producing some degree of polycythæmia, is an acute condition which is to be counteracted by continuous saline infusion or some similar method of restoring fluid to the tissues. The polycythæmia seldom reaches any marked degree except in quite early stages, for instance, in cholera; later, the red cells disintegrate more rapidly than they are replaced. In measuring the concentration of the blood in these conditions, it is of less value to count the red cells than to measure the specific gravity. This is done most readily by the chloroform and benzene method. The specific gravity of chloroform is high, that of benzene is low, and by mixing the two in different proportions it is possible to obtain fluids of every intermediate specific gravity. A mixture of the two of the normal specific gravity of the blood, viz., 1056, is made, and poured into a specimen glass of sufficient depth to allow a urinometer to float in it. For strict accuracy, certain corrections in the readings of the ordinary urinometer are required, but for emergency use the instrument will serve. The lobule of the patient's ear is pricked, a large drop of blood is allowed to fall into a suitable small cup or other receiver containing some of the chloroform-benzene mixture, and thence transferred to the main bulk of the fluid in the specimen glass. If the blood-drop sinks, more chloroform must be added; if it floats, more benzene; ultimately a point is reached at which the blood-drop neither sinks nor floats; the specific gravity of the chloroform-benzene mixture is then the same as that of the blood. In cases of collapse from loss of fluid there is a rise in the specific gravity of the blood even when there is no polycythæmia,—and the greater the rise, the greater the need for infusion.

Spleno-megalic polycythæmia is a somewhat rare condition that is also termed *erythræmia*, or *erythrocythæmia*. Its name suggests its main features, which are: Enlargement of the spleen, increase in the red cells up to as many as 10,000,000 per c.mm., or even more, and duskiness or lividity of the face (*Plate XXIX*, p. 634) and of the extremities. The nature of the malady is still obscure, though some regard it as due to disease of the bone-marrow. It affects adults and females rather than children and males, and its course is chronic. It only remains to add, that whereas to be typical the spleen must be enlarged, there are cases, probably of the same affection, in which, without the spleen becoming palpable, the only definite clinical signs are progressive lividity and polycythæmia. *Herbert French*.

POLYDIPSIA.—See THIRST, EXTREME, p. 719.)

POLYURIA. The term polyuria signifies the passage of more than the average amount of urine per diem. It may be either (I) *Transient*, or (II) *Continued*. It is important not to mistake frequency of micturition for polyuria, for although the latter almost necessarily causes the former, there are many conditions that lead to frequency of micturition without polyuria—for example, tuberculous ulceration of the bladder, enlargement of the prostate, or urethral stenosis, in all of which urine may be passed frequently, but in small quantities at a time. In case of doubt the total amount of urine passed in each period of twenty-four hours should be measured. The normal limits are very wide, the average being about 50 ounces per diem, more being passed in cold weather than in warm, during rest than after exercise, waking than sleeping, and after drinking than after taking little fluid by the mouth. The point at which polyuria begins is arbitrary; if a patient passes 70 ounces or more per diem it is almost certain to attract attention, and therefore to merit the term polyuria. In degree, the polyuria due to causes in Group I seldom exceeds 100 ounces a day; some of the causes in Group II, especially diabetes mellitus and diabetes insipidus, may cause polyuria to the extent of 200 ounces, or even 300, 400, 500, 600, or more, per diem.

In arriving at the differential diagnosis of the cause in any given case, one of the first points to note is whether the polyuria is persistent; or whether, even if recurrent, it is transient. Any of the causes that usually give persistent polyuria may in some individuals produce the symptom intermittently, but upon the whole one may classify the causes of polyuria as follows:—

I. CAUSES OF TRANSIENT POLYURIA.

1. After drinking abundance of water or other fluid.
2. After drinking fluids containing diuretic principles, such as alcohol (wine, malt liquors, spirits); caffeine (tea, cocoa, coffee); citrates or tartrates (artificial lemonades).

3. As the result of nervousness, or of nervous attacks, such as :—
 - (a) Medical examination for life assurance
 - (b) Preparation for some physical or mental competition
 - (c) Hysteria, especially during recovery from an acute outburst
 - (d) Neurasthenia
 - (e) After an epileptic attack
 - (f) After migraine
 - (g) After an asthmatic attack
 - (h) After an attack of angina pectoris
 - (i) Periodic polyuria, apparently without cause.
4. Hydronephrosis, with periodic emptying of the renal sac.
5. The cold stage of a malarial attack.
6. In some cases of convalescence from a febrile illness, such as enterica.
7. As the result of the clearing up of extreme œdema or serous effusions,—for instance, during recovery from acute nephritis; mitral stenosis, with heart failure; cirrhosis of the liver, and so on; especially if the fluid clears up quickly after giving diuretic remedies, such as blue pill, digitalis, calomel, copaiba resin, potassium salts, diuretin, sodium-theocin-acetate, uva ursi, broom tops, or dwarf elder.

When the cause lies in Group I its nature is generally obvious, though it is essential to examine the urine carefully for sugar, albumin, and renal tube-casts, for purposes of exclusion. Nevertheless, the diagnosis may be in doubt until the course of the symptom has been watched for a while. For instance, polyuria may seem to be due to profuse drinking, when really the kidneys are granular and contracted; or in a life insurance case, nervousness may seem to be the cause, when there has really been a bout of drinking; or, again, the drinking may be secondary to the extreme thirst produced by diabetes insipidus.

Excessive Drinking.—When due to drinking water, tea, wine, spirits, or artificial lemonades, the polyuria ceases when the drink in question is limited.

Nervousness. The history and circumstances of the case, together with the absence of signs of gross disease of heart or kidneys, will be the main factors in deciding whether the polyuria is caused by excitement, nervousness, hysteria, or neurasthenia.

Epilepsy.—The character of the convulsive seizures, their recurrence at intervals, and the influence of bromides upon them, will serve to diagnose epilepsy, for polyuria in association with the latter nearly always follows immediately after an attack of grand mal. It may, however, be associated with petit mal, or even be the chief phenomenon in some cases of epilepsy.

Migraine. The diagnosis of migraine depends on the history of the case and the absence of optic neuritis and other evidence of gross intracranial disease.

Asthma.—Asthma is sometimes easy to diagnose, sometimes very difficult: it may be mistaken for recurrent bronchitis, cardiac dyspnoea, renal dyspnoea or uræmic 'asthma,' mediastinal new growth, thoracic aneurysm, thymic 'asthma,' laryngeal papilloma or fibroma, foreign body in the air-passages, syphilitic stenosis of a bronchus, goitre, or hysteria. It so frequently develops into emphysema and bronchitis that one is apt to forget that the essential symptom of asthma is dyspnoea, and not cough. To diagnose a difficult case it may be necessary to examine the chest with the x-rays to exclude aneurysm and new growth; to examine the larynx and vocal cords; the heart, the retina, and the urine to exclude renal and cardiac mischief; and even then, doubt may remain unless there is a clear and typical account of the nature of the earlier attacks in a patient who has had recurrences for years, and who is relieved by cocaine sprays to the nose, by ethereal tincture of lobelia, by inhalations of stramonium fumes, by injections of small doses of adrenalin, or by other anti-asthmatic remedies: *EOSTROPHILIA* (p. 218) is more likely to be found during an attack of asthma than as the result of any of the other conditions that may simulate it. The polyuria occurs in by no means every case; when it does so, it generally follows immediately after an attack, and this applies also in cases of *angina pectoris*, the diagnosis of which is not difficult when the acute attacks of precordial pain radiate upwards and outwards to the left shoulder and down the left arm, and when there is evidence of an aortic lesion, or of atheroma and arteriosclerosis with high blood-pressure.

Periodic Polyuria, apparently without cause, is a condition which is regarded by some as a clinical entity; the diagnosis must always be difficult to be sure of, however, and the more carefully a cause is looked for, the fewer will be the cases remaining in this category; it will be found that some are due to epilepsy; others to secret drinking; others to granular kidney; others to hydronephrosis, and so on.

Hydronephrosis, with periodic emptying of the renal sac, is the chief cause of typically periodic polyuria. The diagnosis is arrived at by having the urine measured carefully each day, and by palpating the loins bimonthly for evidence of renal enlargement. When a kidney swelling can be detected, and when this increases in size at the same time that less urine is being passed, whilst it materially decreases on the days when the polyuria occurs, the diagnosis of hydronephrosis or pyonephrosis is clear; and the distinction between the two depends on whether there is or is not pyuria. The commonest causes for hydronephrosis are movable kidney and renal calculus; and the x-rays often serve to distinguish the latter from the former.

Fevers. The polyuria that occurs during the cold stage of a malarial attack is replaced speedily by the opposite condition when the hot stage is reached; the diagnosis is afforded by the circumstances of the case, such as residence in a malarial district and previous attacks of the malady; by the discovery of malarial parasites in blood-films; by the absence of leucocytosis, the relative increase in the large lymphocytes in the differential leucocyte count, and by the beneficial effects of quinine upon the disease. Polyuria during convalescence from other fevers, such as enterica or pneumonia, is not uncommon; it is a phenomenon that may attract some attention at the time, but it seldom gives rise to difficulty in diagnosis.

Edema and Diuretics.—The considerable polyuria that often results in renal or cardiac cases when edema is clearing up under treatment is noteworthy, but the diagnosis is not, as a rule, difficult. If the polyuria is due merely to the excretion of accumulated fluid it will cease when there is no longer any edema; whilst if it is due to granular kidney, or other underlying malady, it will continue even after the edema has gone.

II. CAUSES OF CONTINUED POLYURIA.

1. Diabetes mellitus.
2. Red granular contracted kidneys.
3. Arteriosclerosis.
4. Pale granular contracted kidneys.
5. Lardaceous or amyloid kidneys.
6. Cystic kidneys.
7. Diabetes insipidus:
 - (a) Due to no gross nervous lesion
 - (b) Due to tumour or injury of the medulla oblongata.
8. Incurable drinking of beer or spirits.
9. Phosphatic diabetes.
10. Azotic diabetes.
11. Some cases of acromegaly.
12. Some cases of myxedema.

Diabetes Mellitus.—A very important step in the diagnosis is to examine the urine carefully. If sugar is present, a diagnosis of diabetes mellitus will be made, especially if diacetic acid and acetone are also present, and the specific gravity is between 1035 and 1045. Some authorities distinguish in kind as well as in degree between what they term true diabetes mellitus on the one hand, and alimentary glycosuria on the other, though others hold that these differ only in degree; it is chiefly in severe diabetes of young people that polyuria is marked, something between 100 and 600 ounces of urine being passed per diem; in elderly people with glycosuria the polyuria is often slight; in these cases the specific gravity need not be above the normal, and diacetic acid and acetone are generally absent. If no sugar is present upon one occasion it may be on another, so that several examinations may be required.

Albuminuria.—If albumin is present, and the polyuria cannot be attributed at once to anything so obvious as the clearing up of edema or the administration of a diuretic,

a careful microscopical examination of the centrifugalized deposit for renal tube-casts should be made; if the latter are absent, and if the patient is a young adult male, who seems to be in good health, whose heart and other organs present no abnormal physical signs, and whose polyuria troubles him chiefly at times of excitement, for instance when he is in for an examination, the diagnosis is very likely to be that of 'functional' or 'physiological' albuminuria, in which case repeated tests will show that the urine is often quite free from albumin, especially the first thing in the morning, and the blood-pressure would not be raised. If, on the other hand, more than an occasional renal tube-cast was found, and the albumin and polyuria were persistent, the diagnosis of red granular contracted kidney, arteriosclerosis, pale granular contracted kidney, lardaceous kidney, or cystic kidney would suggest itself. The differential diagnosis between these is discussed under ALBUMINURIA (p. 6, et seq.).

Diabetes Insipidus. If neither albumin nor sugar is found, even on repeated testing, and if the polyuria is extreme and persistent, whilst the specific gravity of the urine is constantly low (1001 to 1008), a diagnosis of diabetes insipidus will suggest itself. Before this diagnosis is made finally, however, precautions must be taken to determine that the patient's thirst and polyuria are not due to habits of drinking to excess; it may be difficult to decide this in cases in which alcoholic beverages are consumed; but when the patient is a water-drinker, and yet cannot do with less than 8 or 10 pints a day, the drinking is probably a necessity, and not a habit; and diabetes insipidus is the probable diagnosis. In cases of doubt, the difficulty can be decided by restricting the intake of fluid and determining the specific gravity of the blood. This should be about 1056, and in a case where polyuria is due to drinking habits, restriction of fluids will not alter it materially; in a case of diabetes insipidus with restricted intake of fluids, however, the drain of the latter from the blood still goes on, and the specific gravity rises to 1060, or 1065, unless the patient is allowed fluid by the mouth again.

There are two classes of diabetes insipidus, according as there is, or is not, a gross lesion of the central nervous system. If the malady follows on a fractured base of the skull, or if there are vomiting, headache, optic neuritis, or other symptoms of cerebral tumour, there is probably a gross lesion of the base of the brain in or near the medulla oblongata—thrombosis, softening, hæmorrhage, small aneurysm, gumma, glioma or other neoplasm. In other cases, the complaint arises after a fright or shock, or even without any apparent cause, and there seems to be no gross lesion to account for it.

Phosphatic and Azotic Diabetes. Another point that needs investigation in a case suspected to be diabetes insipidus, is the amount of solids excreted daily in the urine. In ordinary diabetes insipidus the total solids are normal, the only increase being in the water. There are rare cases in which, in addition to polyuria, there is a great increase in the total solids in the urine also—so-called *bururia*. Rare though these cases are, they have been divided into two types, namely, those in which the inorganic salts are most increased—phosphatic diabetes (p. 522), and those in which the nitrogenous constituents are augmented mainly—azotic diabetes. The diagnosis here depends mainly on quantitative estimation of the various urinary substances.

Acromegaly and Myxœdema. It only remains to add that symptoms not unlike those of diabetes insipidus have sometimes arisen in cases of acromegaly and in myxœdema. There is probably a nervous factor in both cases, coupled in myxœdema with dryness of the skin, and consequent deficiency in perspiration; whilst in acromegaly there is the tumour-like enlargement of the pituitary body which may cause polyuria like any other lesion near the medulla oblongata. The diagnosis of acromegaly may be confirmed by the *x*-rays, which will show the great enlargement of the bones of the hands, feet, and head, or even perhaps of the pituitary fossa itself; whilst in myxœdema, if the general symptoms, the pseudo-œdema of the legs, the acquired dullness of intellect, the increasing weight, and the broadening of the features (*Fig.* 101, p. 234), the fingers, and the hands, do not at once indicate the nature of the complaint, the beneficial effects of treatment by thyroid extract may serve to clinch the diagnosis.

Herbert French.

PRECORDIAL PAIN.—(See PAIN IN THE CHEST, p. 430.)

PRIAPISM signifies erection of the penis, continual, of troublesome degree, and not necessarily accompanied by sexual desire. Though generally spoken of in connection

with the male sex, a precisely similar affection may occur in the female clitoris. The symptom is not often by itself of diagnostic importance, though it may be due to a considerable number of different causes. Most of the latter need be little more than enumerated, for if they are borne in mind they will nearly always lead to a speedy diagnosis. Two in particular merit special mention, however. The first is priapism in elderly men. In some such cases there may be enlargement of the prostate, or local inflammation such as gouty urethritis, but in many the priapism seems to occur, without pathological cause, as a sort of final outburst of sexual energy before the onset of senile impotence.

The other special condition under which priapism may be extreme is after injury to the upper dorsal region of the spinal cord. The damage may be so serious as to have produced a fracture dislocation of the spine with paraplegia, in which case the diagnosis will be obvious; short of this, however, there may have been only a minor degree of injury, with contusion and perhaps multiple small hemorrhages into the substance of the cord, in association with which priapism may in some instances be very pronounced and last for weeks or months before recovery occurs.

For the rest, the causes of priapism may be summarized briefly according to age periods, the chief being:—

Priapism in infancy:—

Phimosi8	Posthiti8
Oxaluria	Calculus, urethral or vesical
Worms, especially oxyuris vermicularis	Certain conditions of mental deficiency
Balaniti8	Circumci8ia.

Priapism at puberty:—

The changes in the genital organs associated with the onset of puberty.

Priapism in young adult life:—

Sleeping on the back	Fracture of the dorsal spine
Non-emptying of the bladder when full	Transverse myelitis of the upper dorsal region
Ill-fitting trousers	Spinal meningiti8
Sexual excitement	Certain aphrodisiac drugs:—
Gonorrhoea	Cantharides
Epilepsy	Turpentine
After circumci8ion	Alcohol, especially port wine in some persons, champagne in others
Masturbation	Strychnine
Convalescence from an acute disease	Cannabis indica
Tetanus	Camphor
Hydrophobia	Phosphorus
Leukemia	Damiana.
Thrombosis of the pampiniform plexus	

Priapism in older men:—

The male menopause	
Local irritation as the result of:—	
Gouty urethriti8	Hemorrhoids
Enlarged prostate	A loaded rectum.
Hemorrhage into the middle lobe of the cerebellum	
Lesions of the pons varolii	

Very seldom indeed will priapism be the only symptom in the case; the diagnosis will be made from the history and from the other symptoms. *Herbert French.*

PROLAPSE OF THE UTERUS.—As a matter of practical fact, the uterus only descends as a result of a much wider displacement of all the movable structures which go to make up the pelvic floor. This is composed of a movable or pubic portion, and a fixed or sacral portion, and it is descent of the pubic portion which produces the actual lesion known as prolapse of the uterus. In other words, the uterus only descends because it is a part of the pubic portion of the pelvic floor. The uterus, bladder, and anterior vaginal wall are normally kept in position chiefly by the connective-tissue sheaths which accompany the blood-vessels supplying them, and it is injury and stretching of this connective tissue which allows of descent of the organs named. There is no doubt, however, that injuries to the fixed portion of the pelvic floor, the perineal body, and levatores ani muscles

and their fasciæ, will contribute something to the facility with which the structures mentioned may descend. In practice, therefore, prolapse of the uterus and descent of the pelvic floor lead to the appearance of a swelling at the vaginal orifice. There are other swellings which come down the vagina and appear at the vulva, and from them, therefore, prolapse of the uterus has to be diagnosed. These swellings are: (1) *Hypertrophic elongation of the cervix uteri*; (2) *A tumour protruding from the vagina*; (3) *Inversion of the uterus*; (4) *Cystocele and rectocele*; (5) *Extroversion of the bladder*.

Hypertrophy of the Cervix may be of the vaginal, the intermediate, or the supravaginal portion. The first is always congenital, and consists of elongation of the portio vaginalis. It may protrude from the vaginal entrance, but the vaginal fornices will be found unaltered at their usual level, and the sound will pass an increased distance proportionate to the length of the portio. The os uteri forms the apex of the protrusion. The fundus remains at its usual level. In hypertrophy of the intermediate portion the anterior fornix of the vagina is carried downwards with the cervix and may be obliterated, whilst the posterior fornix remains at its usual level, because the elongated portion lies between the insertion levels of the anterior and posterior vaginal walls. The sound passes an increased distance, and the os uteri forms the apex of the protrusion. The fundus remains at its usual level. In hypertrophy of the supravaginal portion *both* fornices are carried down with the cervix, and both may be obliterated. The bladder is displaced downwards, but the rectum does not descend. The fundus uteri will be found on bimanual examination to be at its usual level, whilst in true prolapse the fundus uteri descends as a whole with the rest of the uterus. It is common for some prolapse of the uterus as a whole to accompany elongation of the cervix, and this can be appreciated only by a careful bimanual examination.

A Tumour protruding into or from the vagina is most commonly a *fibromyoma of the uterus*. It may be a pedunculated growth either of the cervix, or protruding through it, in either case hanging free in the vagina. It may grow from the cervix in the connective tissue in front, between the uterus, bladder, and anterior vaginal wall; or behind, between the uterus, rectum, and posterior vaginal wall; in either case the vaginal wall is stretched over the growth. The uterus will be felt high up. When the pedunculated growth is protruding from the os the hard ring of the cervix is felt encircling the pedicle. In the case of sessile interstitial growths, the cervix is high up in front or behind the growth, as the case may be, and if the tumour is a large one, may be out of reach altogether. In any case there is no descent of the uterus, and it may even be higher than usual. The growth may be a *fibroid growing from the vaginal wall*, a *mucous polypus of the cervix*, or a *malignant growth*.

Inversion of the Uterus may be chronic, or may occur immediately after labour as an acute condition which could hardly be mistaken for anything else, except perhaps extrusion of a fibroid immediately after delivery. In the latter case the tumour protrudes through the cervix, whilst the whole uterus can be felt above it bimanually, whereas in inversion the uterus turns inside-out, partially or completely, a cup-shaped depression is felt above instead of the rounded fundus, and a finger or the sound will only pass a short way by the side of the mass, or not at all if inversion is complete. Both conditions may be accompanied by hæmorrhage, but that with inversion may be exceedingly severe. Acute inversion is always accompanied by great shock, whilst extrusion of a fibroid is not. Chronic inversion is more likely to be mistaken for prolapse or a polypoid fibromyoma. It is distinguished from prolapse in that the uterus does not necessarily descend as a whole, the cervical ring is felt high up in its usual position, and the sound will only pass a short distance all round the protruding mass, according to the degree to which the uterus is inverted. A cup-shaped depression, instead of the rounded fundus, is felt in the vaginal vault by a hand on the abdominal wall.

Cystocele and Rectocele more often accompany prolapse of the uterus, but may occur independently of it. They are essentially bulgings of the anterior or posterior vaginal walls towards or through the vaginal entrance, the bladder or rectum being attached, and following them of necessity. A sound passed into the bladder, or a finger in the rectum, will directly enter the bulging vaginal wall, whilst the uterus will be felt bimanually above in its normal position.

Extroversion of the Bladder can occur either through a congenital defect in its

wall, or through an injury to its basal portion : for instance, in removing a growth from the vaginal wall a gap may be left in the bladder through which extroversion may occur. The mucous membrane will be exposed in the vagina, and on it will be seen the two orifices of the ureters, with urine issuing by intermittent jets. The uterus in such a case may have its normal position.

Thos. G. Stevens.

PROPTOSIS.—(See EXOPHTHALMOS, p. 229.)

PRURITUS.—Itching may occur without visible lesions of the skin, save those due to scratching, or may be associated with various cutaneous eruptions. It is to the former condition that the word 'pruritus' should be restricted. The diseases of which itching is a symptom may be either neuroses, such as hysteria, hypochondriasis, and other affections of the nervous centres, or general nutritive disorders affecting the nervous system secondarily, such as arthritis and diabetes mellitus ; or the irritation may be set up by the attacks of parasites, or by definite skin lesions. Itching varies in character : it may be interpreted by the patient as a tingling, or pricking, or as a formication—a feeling as of insects crawling on the skin. It varies also in degree, from a mild sensation which is welcome to the patient from the pleasure he finds in scratching, to an irritation so severe and persistent as to endanger his life from sleeplessness, or his reason from the nervous irritability which it sets up. The affections in which itching is slight are seborrhœa, erythema, pityriasis rubra pilaris, and pemphigus ; it is more severe, in varying degrees, in eczema, prurigo, some cases of psoriasis, dermatitis herpetiformis, dermatitis gestationis, application dermatitis, lichen planus, lichenization, lichen urticatus, pityriasis rubra, mycosis fungoides, pityriasis rosea, cheilopompholyx, chilblain, prickly heat, tinea marginata, urticaria, scabies, the various kinds of pediculosis, flea-, mosquito-, and bug-bites, jelly-fish and other stings. Even in the affections in which it is usually severe it varies much in degree in different cases. Itching seldom has any distinct diagnostic value, but in cases in which the cutaneous lesions may admit of more than one interpretation, its presence or absence may suffice to turn the balance. Syphilides hardly ever itch.

Pruritus proper may be general or local. Of general pruritus there are four varieties—pruritus universalis, pruritus hiemalis, pruritus senilis, and bath pruritus. The local varieties affect chiefly the anus, the vulva, and the serotum, but the nares, the palms of the hands, and the soles of the feet may be the seat of the irritation. One of the most curious forms of pruritus is that which is associated with bathing. According to Stelwagon, who has made it a subject of special study, it most commonly affects the legs from the hips downwards ; but the forearms also may be involved, and it may have even wider range. It is an affection of adolescence and adult life, and is more frequent in males than in females.

If no lesions of the skin are present save those which can be accounted for, directly or indirectly, by the scratching, the diagnosis of pruritus 'imposes itself.' Care must, however, be taken to exclude all possible sources of parasitic irritation ; and it must always be remembered that lice and acari sometimes find harbourage in the most unexpected quarters. If the scratches are on the shoulders, or in the genital region, the presence of lice must be suspected ; if on the wrists and between the fingers the burrows of the *Acarus scabiei* must be sought for. Some patients, without developing actual urticaria, suffer from severe itching after the ingestion of certain foods, notably strawberries, or crab. After serum injections pruritus may be extreme, especially about the ninth day, though urticaria generally accompanies it. Pruritus from the irritation of sugar (grocer's itch), or of primula obconica or rhus toxicodendron (gardener's itch) ; or of satin wood sawdust (carpenter's itch) ; or of some kinds of soaps ; or of the hairs of some caterpillars, may or may not be associated with objective evidence of dermatitis. Only when careful investigation fails to reveal any local source of irritation should the case be diagnosed as one of pruritus pure and simple.

Malcolm Morris.

PTOSIS is the term applied to drooping of the upper eyelid with inability to raise it to the full extent (*Figs. 227, 228, 229, 230*) ; it must not be confused with the inequality of the palpebral apertures sometimes observed in people accustomed to screw up one eye.

It is usually caused by *paralysis of the third nerve*, in which case it may also be

associated with paralysis of other ocular muscles, either external or internal (*Fig. 228*). Sometimes it is accompanied by paralysis of other motor cranial nerves. The 7th for instance (*Figs. 229 and 230*), in which case the multiple cranial nerve paralyzes immediately suggest a syphilitic cause, which may be verified in many cases by means of Wassermann's serum reaction.

PARALYSIS OF THE LEFT THIRD NERVE.

Fig. 227.—The patient's face at rest; there is complete ptosis from paralysis of the left levator palpebræ superioris. Note the scar of the healed gummy on the left cheek near the left angle of the nose.

Fig. 228.—The patient is trying to look to his right; the left eyelid is being held up to show that the left eye is unable to look to the right owing to paralysis of the left internal rectus muscle.

LEFT-SIDED NUCLEAR AND INFRAOCULAR 7TH NERVE PARALYSIS AND COMPLETE PTOSIS FROM PARALYSIS OF THE LEFT THIRD NERVE, THE RESULT OF CEREBRAL SYPHILIS.

Fig. 229.—At rest.

Fig. 230.—When voluntary effort was made to show the teeth and close the eyes.

In *paralysis of the cervical sympathetic*, slight ptosis may be associated with diminution in the size of the pupil on the affected side, and retraction of the eyeball or enophthalmos. It may also occur in *myasthenia gravis* (*Fig. 111*, p. 235).

Ptosis of the lids, associated with much oedema and infiltration of the lids, is also found in all *inflammatory affections* of the conjunctiva, in *angioneurotic oedemas* (*Fig. 178*, p. 112), and is a very constant symptom in *trachoma*.

Congenital ptosis is usually bilateral, and associated with smoothness of the upper lids and absence of all the usual cutaneous folds. The levator palpebræ is absent or ill-developed, and efforts to open the eye are made by the occipito-frontalis muscle. *Herbert L. Eason.*

PTYALISM denotes excessive secretion of saliva. It is not easy, however, to determine in every case whether there is really excess, or whether the patient is not merely allowing the normal saliva to dribble from the mouth. It is difficult to draw an absolute distinction, therefore, between dribbling of saliva and ptyalism, though in practice the nature of the case may be obvious enough. One has but to consider the various conditions under which trouble with the saliva may arise to see how in some cases the difficulty is solely one of swallowing the normal secretion, as in bulbar paralysis and in babies; how in others there is both excess of secretion and difficulty in swallowing it, as in mercurial stomatitis; and how in others, again, there is too much secretion but no difficulty in swallowing it, as in functional or hysterical ptyalorrhœa. The first step in arriving at the diagnosis of the cause is to inquire carefully as to any *medicine* or *drug* the patient may be taking orally or applying externally, especially:—

Mercury	Bromide	Aeonite
Pilocarpine	Phosphorus	Chlorate of potash
Jaborandi	Arsenic	Cantharides
Iodide	Antimony	Copper salts.

Mercury is the most important of these: its effects are most serious when the mouth is not kept scrupulously clean, particularly when there is also nephritis, as is not uncommon in severe secondary syphilis. The saliva is also apt to have peculiar effects when mercury is being taken; thus, in repairing submarine cables it is customary to use saliva in completing the process of covering in the central core, and it has been found that if the repairer is taking mercury medicinally the repaired part of the cable speedily becomes defective again, in a way which does not result when the repairer is a healthy man taking no medicine.

If the salivation is not due to any drug, it may be the result of one of the many forms of *general stomatitis*:—

Apthous	Variolous	Due to angina Ludovici
Dyspeptic	Diphtheritic	„ canerum oris
Septic	Syphilitic	„ pernicious anæmia
Suppurative	Tuberculous	„ hæmophilia
Ulcerous	Due to pyorrhœa alveolaris	„ sprue
Malignant	„ necrosis of the jaw	„ scurvy.

The exact nature of a severe stomatitis will be diagnosed by making a careful local examination, ocular and digital, assisted by the history and, if need be, by bacteriological examination of swabbings from the mouth, by Wassermann's serum reaction for syphilis, or by microscopical examination of a fragment of the affected tissues. Tuberculous stomatitis is one of the rarer forms, but when it occurs it is severe: it may be primary, but more often is associated with obvious phthisis.

If drugs and general stomatitis can be excluded, local examination may still serve to detect a local cause acting by reflex irritation of the fifth nerve, especially:—

A jagged carious tooth	A ranula
A rough filling	A gumboil
A stump left beneath a tooth-plate	An epulis
A broken or ill-fitting tooth-plate	A myeloid sarcoma of the jaw
A foreign body, such as a fishbone, impacted in the gum	A salivary calculus
Neuralgia of the fifth nerve	An eschar left by some recent irritant or corrosive substance, or injury.

If careful examination serves to exclude all these, the salivation, apparent rather than real, may be found to result from *mechanical difficulties in swallowing*, the effect of such lesions as:—

Mumps	Fixation of the jaw, as by osteo-arthritis of the temporo-maxillary joint
Acute tonsillitis	Painful affections of the larynx, pharynx, or œsophagus.
Quinsy	
Fracture of the jaw	
Dislocation of the jaw	

In the absence of any obvious structural lesion locally, it may yet be clear that inability to swallow, owing to paralysis of some kind, is the cause of the apparent salivation, for instance in cases of: -

Bulbar paralysis		Myasthenia gravis		Paralysis agitans
Pseudo-bulbar paralysis		Hypoglossal nerve paralysis		Hydrophobia.
Bilateral facial paralysis		Diphtheritic paralysis		

The differential diagnosis of these conditions is discussed elsewhere, and of them all it is only in bulbar and pseudo-bulbar paralysis that the dribbling of much saliva is a prominent symptom. The sequence of events summarized by the term labio-glossopharyngolaryngeal paralysis is sufficiently characteristic as a rule: pseudo-bulbar paralysis, being of cortical instead of medullary origin, has not the wasting of the tongue that is prominent in the latter.

The salivation that results from *gastric* or *hepatic reflexes* is almost physiological, though sometimes it reaches a pathological degree in certain cases of: -

Dilatation of the stomach	Acute dyspepsia		Biliousness
Gastric ulcer	Acute gastritis		Hepatic disorder
Duodenal ulcer	Gastric carcinoma		Pancreatitis.

Mere slovenliness and lack of proper cerebral control are responsible for the slobbering and salivation of: -

Idiots	;	Imbeciles	;	Demented and other mental cases.
--------	---	-----------	---	----------------------------------

Finally, a remarkable degree of salivation can sometimes be attributed to nothing but functional disorder *ptyalorrhœa*. It can scarcely be called hysterical, because it may occur in men as well as in women, generally in later life rather than at a time when hysteria is commonest. The condition is a sort of salivary neurosis, which may come on suddenly and without obvious cause, or as the result of some worry, shock, or mental emotion. It may possibly be a functional affection of the 5th nerve analogous to the far more distressing tic douloureux. It is sometimes prominent amongst the neuroses that are apt to accompany pregnancy. It can only be diagnosed when a careful examination has served to exclude any likelihood of organic disease, when the history is suggestive, and when the excessive salivation ceases after a time almost as suddenly as it began. In some male cases, notwithstanding the diagnosis being 'functional,' a high blood-pressure will be found, with other signs of arteriosclerosis, suggesting that errors in the circulation involving the vasomotor and other brain centres are responsible for the symptom.

Herbert French.

PULSATING TUMOURS. (See SWELLING, PULSATILE, p. 693.)

PULSATION, UNDUE ABDOMINAL AORTIC. Excessive pulsation of the abdominal aorta may occur in cases of aortic regurgitation, when all the arteries throughout the body may pulsate with undue violence. Apart from aortic regurgitation, however, it is nearly always an entirely functional disorder of the aorta. It occurs much more frequently in women than in men, the patients generally being unmarried or childless, between 20 and 40 years of age. They complain of pain in the abdomen, especially in the epigastrium; a feeling of discomfort and distress; a sensation of pulsation and throbbing over the abdominal aorta; nausea, retching, sickness, and constipation; they are usually thin, anemic, extremely nervous, often hysterical, and sometimes decidedly hypochondriacal. There may be nothing else the matter with them at all, or they may be suffering from some other complaint of which much nervousness is a feature, exophthalmic goitre for example. The condition is frequently associated with movable kidney and enteroptosis; the symptoms may suggest some organic disease, such as gastric ulcer, appendicitis, or ovaritis, without any of these being present.

On palpation of the abdomen the pulsation may be found to be forcible; but the normal cylindrical outline of the aorta can generally be felt to be quite free from any sacular bulging or fusiform dilatation; there is no thrill over it; on applying a stethoscope lightly to the pulsating region no murmur will be audible, but firmer pressure, sufficient to compress the aorta slightly, will bring out a systolic bruit. The heart, lungs, and urine are usually normal. The knee-jerks are apt to be much exaggerated, though the

plantar reflexes remain flexor, and there is no ankle-clonus. The chief importance of the condition clinically is that it is apt to be mistaken for an aneurysm of the abdominal aorta. Abdominal aneurysm is so extremely rare in women, however, that it should never be diagnosed unless the pulsation can be made out to be definitely expansile, or unless, in addition to pulsation, a definite swelling of the aorta can be felt.

Herbert French.

PULSE, IRREGULAR. No advance in clinical medicine is more striking than the change which has come over our view of the arrhythmic pulse during the past decade. Formerly we felt that our duty was finished when we had recorded the main facts: as to whether the force or the frequency varied, or both, and so forth. Now, however, it is possible to refer almost every type of irregularity to a definite cause, and thus to gain information of the utmost value for prognosis and treatment. To this end it is advisable that each case should be investigated by means of the recording polygraph, and the jugular and arterial curves compared.

The Mackenzie ink polygraph, the best of these instruments, consists of (1) A clockwork machine drawing a band of paper at a uniform rate over a flat surface; (2) Tambours for application to different parts of the body where there is superficial pulsation; (3) Levers connected by tubing with these tambours, carrying pens at their free ends which write upon the travelling paper; (4) A time-marking lever, also driven by clockwork, and marking five times per second. One of the tambours is applied to the radial artery, and the other to the internal jugular vein at the root of the neck as a rule. The result is a synchronous record of (i) time in one-fifth second intervals, (ii) the movements of the radial artery, (iii) the movements of the jugular vein. In the records from this last, each cardiac cycle exhibits three principal waves. By comparison

FIG. 231.—An electrocardiogram record showing ventricular extrasystoles. P, Auricular systolic phase, F, Main ventricular systolic phase, T, Terminal systolic phase, R', Ventricular extrasystolic phase. This movement is premature, and its form (diphase) indicates that only a part of the ventricle has contracted instead of the whole.

with the radial trace the identity of the ventriculo-systolic wave (*c*) is established. The wave immediately preceding this is the auriculo-systolic (*a*), and the interval between its origin and that of the ventriculo-systolic, normally about $\cdot 2$ second, is spoken of as the 'a-c interval.' It constitutes an index of auriculo-ventricular conductivity. The third, or *r* wave, arises at the end of ventricular systole. The chief value of the method lies in the accuracy with which it enables us to study the time relations of auricular and ventricular systole.

A still newer method, of great value in differential diagnosis, is by means of electrocardiograms. This method depends on the fact that contracting muscle is an electrical battery, the currents in which can be appreciated and their movements recorded by a sufficiently delicate galvanometer. The contracting heart thus generates currents which are led off to an extremely sensitive galvanometer, and the photographic records made from this can be interpreted in terms of cardiac movement (*Fig. 231*). Practically every one of the large medical schools throughout the country has one of these electrocardiographic outfits, so that there are few patients to whom this method cannot be applied if the practitioner feels that the accuracy of the information derived is so valuable as to justify the expenditure of time, trouble, and money involved. Many practitioners, however, are obliged to learn what they can about their patient's heart without these means, and in what follows this has been borne in mind.

First, it must be remembered that the heart generates its own stimuli; that these normally arise at the sino-auricular node, a relief of the primitive cardiac tube lying at the junction of the sinus venosus with the right auricle; that thence they pass through the auricular walls, and are conducted along the auriculo-ventricular bundles, narrow strips of muscle—also reliefs of the primitive cardiac tube—into the ventricular walls, one branch from the stem of the main bundle running to each ventricle; and that each portion of the cardiac muscle contracts as this stimulus provokes it to do so, the result being a co-ordinated and economical movement of the whole heart.

Pulse irregularities may be (1) *Perversions of the normal rhythm*; (2) *Rhythms originating abnormally*. Under the first heading fall (a) Irregularities of the whole heart—'sinus arrhythmias'—due to extra-cardiac influences acting through the vagus on the sino-auricular node; (b) Irregularities due to interference with the conduction of impulses through the heart, and especially with their passage from auricle to ventricle—'heart block'; and (c) Irregularities in the response of the musculature to the stimuli reaching it, of which the outstanding example is the 'alternating pulse.' Of abnormally originating rhythms there are three chief examples: (a) The simple extrasystole or premature contraction; (b) Paroxysmal tachycardia, and (c) The totally irregular pulse of auricular fibrillation.

1. Perversions of the Normal Rhythm:—

(a). *Sinus irregularities* are specially common in children and nervous subjects, in convalescence and acute illness, and in the presence of increased intracranial pressure. The difference in length between two sequent beats is never great, and sufficiently prolonged observation is nearly always rewarded by the discovery of a 'dominant rhythm'—i.e., a normal rhythm—from which the pulse departs from time to time. This type of irregularity is singularly apt to be exaggerated by excitement, and by bidding the patient swallow or hold his breath. As it does not depend on intra-cardiac causes, physical examination of the heart detects no sign of disease. It is generally possible to distinguish it from other forms of irregularity without instrumental help; but sometimes it is difficult to be quite sure that the arrhythmia is of this type, and if a tracing be taken it shows that auricular and ventricular systole are following each other in normal sequence.

(b). *Heart-block* is of various grades. The mildest type is that in which the interval elapsing between the start of auricular systole and that of ventricular systole is prolonged (*Fig. 232, xx*); this of course can only be detected by graphic records of the arterial and

Fig. 232.—Incomplete heart-block. Note at *x*: (i) The radial pulse misses a beat entirely, (ii) The jugular pulse shows an *a* wave without a sequent *c* wave. This means that auricular systole occurred at the normal interval after the preceding cardiac cycle, but that ventricular systole failed to follow; the reason being that disease implicating the conducting paths hindered the normal transmission of stimuli from auricle to ventricle. Note at *xx*: The long *a-c* interval (about 0.4 second) indicating considerable though incomplete hindrance to transmission of the impulse from auricle to ventricle.

venous pulses. The next grade, in which some of the descending impulses are completely 'blocked' in their passage from auricle to ventricle, reveals itself in ordinary observation of the pulse as a dropping of beats; a gap, equivalent in length to two whole pulse-beats, separates one beat from that which preceded it. Here the auricle has contracted in the ordinary way, but since the stimulus which provoked that contraction has not passed into the ventricle, the latter has failed to contract (*Fig. 232, x*). This proves that there is some disease or disorder of the conducting apparatus. In higher grades of block, every third or every other stimulus, or even two out of three, or three out of four, may fail to pass over from auricle to ventricle (*Fig. 233*); so that the auricle may be beating 72 to the minute while the pulse counted at the wrist comes to 48, 36, 24, or 18 only. In the highest grade of all the auricle is completely dissociated from the ventricle, which assumes a rhythm of its own, usually at 30 to 40 per minute; thus the auricle is

beating regularly at one rate and the ventricle at another quite independent of that of the auricle.

To make sure that a dropped beat, or a slow regular pulse, is due to heart-block, it is therefore necessary to prove that the auricle contracted while the ventricle failed to follow suit. The only means of such proof, apart from the use of the polygraph, is furnished by observation of the venous pulse in the neck. If this can be seen to continue regularly, during the radial pauses, as well as immediately before the radial beats, then it is safe to assume that the condition is one of heart-block. It must be confessed, however, that this is very often difficult, and sometimes impossible, and that the observer is on much firmer ground if he obtains solid proof of his suspicion in the form of a graphic record. This will show that in the intervals when the pulse failed at the wrist, the wave which represents auricular systole made its appearance at the proper moment in the jugular curve (see Fig. 232). It is particularly desirable to obtain graphic evidence when it is a matter of accounting for occasional failures of the radial beat; for, as will be shown below, this grade of block may be simulated by extrasystoles too feeble to reach the wrist (see Fig. 234), and also in extreme exhaustion of contractility.

In the higher grades of block the patient often suffers from severe syncope and epileptiform attacks, the coincidence of which with heart-block constitutes the Stokes-Adams syndrome. In these attacks the pulse usually becomes slower than ever. It is not quite safe, however, to conclude from the coincidence of such attacks with slow pulse that a lesion of conductivity is present; one or two cases have been described in which tracings have proved that the whole heart—auricle as well as ventricle—was slowed; i.e., that the rhythm was altered at its origin at the sino-auricular node and not in its

Fig. 232.—Heart-block. The ventricle only responds to every fourth stimulus descending to it from the auricle. The *a-c* interval is more than twice its normal length.

passage through the heart. The distinction between this condition and that of heart-block is important, for the latter signifies organic disease of the heart, while the former does not; and their distinction cannot be safely founded except on the evidence of graphic records.

If the existence of heart-block be definitely proved, it points practically always to the existence of organic disease implicating the bundle which connects auricle with ventricle. Heart-block may arise in connection with acute infections such as diphtheria, rheumatism, influenza, pneumonia, or ulcerative endocarditis; or as part of a chronic disease such as gumma or atherosclerosis. In any given case the cause of the block can only be determined by a general consideration of all its features.

(c). The term '*pulsus alternans*' is reserved for cases in which beats, equal in length, alternate in force; that is, for an alternation of a large beat with a small beat, but not of a long beat with a short beat. This phenomenon is an expression of exhaustion of the contractile power of the ventricle, and it is therefore of serious import. In some instances it can be detected clearly with the finger on the pulse; a full wave is followed by a small wave, and this again by a full wave, and so on, each beat being of equal duration. Often, however, the difference in the amplitude of the waves is so minute that it can only be detected by a tracing. Where alternation is suspected, confirmatory evidence may sometimes be afforded by a corresponding alternation in the intensity of the first cardiac sound, particularly if it be accompanied or followed by a bruit.

In connection with this form of irregularity, it is important to note that the smaller beat may sometimes be so feeble as to fail to reach the wrist; consequently the pulse appears to drop a beat.

2. Rhythms Originating Abnormally:—

(a). Turning to those forms of irregularity which are due to ectopic generation of stimuli, one finds that the simplest type, the *extrasystole*, is very common. It is associated with nervous states and with coronary sclerosis, and though it is of no great import, it is often productive of uncomfortable sensations which distress the patient; it is therefore necessary to recognize its nature in order that a reassuring statement may be made. The extrasystole is "a premature contraction of auricle and ventricle in response to a stimulus from some abnormal part of the heart, where otherwise the fundamental rhythm of the heart is maintained" (Maekenzie).

The patient sometimes complains of feeling as if his heart had stopped, and then gone on again with a jerk; or it may be that the jerk alone is felt. The observer, with his finger on the radial pulse, feels a small beat occur before its time, i.e., at a shorter interval after the preceding beat than the usual pause between beats. The beat which follows this premature one is generally more forcible than normal; in some cases it follows after a compensatory pause, i.e., a pause of such length that it makes up for the brevity of the premature beat, the two together being equal in duration to two normal beats. It is the small premature beat which signifies the occurrence of an extrasystole (Figs. 231, 234). Confirmatory evidence of its nature may often be found in the heart-sounds; simultaneously with the small premature beat at the wrist, a premature feeble pair of heart-sounds (or in some cases the first sound only) is heard.

It might be argued that if the extrasystole can be thus detected by ordinary methods of examination, and that if it has little positive significance in assisting to a full diagnosis of the case, it is needless to apply graphic methods to its elucidation; and it is certainly

Fig. 231. Ventricular extrasystole. Note at *x* a small premature radial beat—that this coincides with a large wave (*a c*) in the jugular curve. (*a c*) is therefore a ventriculo-systole wave, and as it is not preceded by any auricular movement, it denotes a premature contraction, or 'extrasystole,' arising in the ventricle. Clinically this case simulated 'heart block' until the tracing made the truth plain.

true that it is of all forms of irregularity the one in which tracing is least essential. However, there are one or two considerations which may make a tracing advisable and even necessary: (i) The premature contraction may be so small that its beat is not felt at the wrist; a dropped beat may be thus simulated, especially where the extrasystole is followed by a compensatory pause. In such cases heart-block may be wrongly diagnosed, unless clearer information be sought in a tracing. This will show the fault to be due to a feeble premature beat, and not to a blocked auricular impulse (see Fig. 234). (ii) Extrasystoles may occur in complexes, e.g., at every second or third beat. In the former case an alternation will result: a full beat is followed at a short interval by a small beat, and this after a long interval by a full beat, and so on (pulsus bigeminus). The true nature of such an arrhythmia is much easier to appreciate when it is seen mapped out in a tracing. (iii) A polygraphic record enables the observer to discover whether the premature beat arose in the auricle, in the ventricle, or in the junctional tissues. In the first case the jugular curve shows an auricular wave preceding the premature arterial beat at the proper interval; in the second case there is no such auricular wave; while in the third case, auricle and ventricle contract simultaneously, and the result is an abnormally large wave in the jugular curve. A knowledge of the source of extrasystoles may occasionally be of material value; for instance, in mitral stenosis the final breakdown of the auricle is sometimes heralded by a series of extrasystoles of auricular origin. It is true that as a rule auricular extrasystoles are not followed by a compensatory pause, while those of ventricular origin are; but it is not always easy to appreciate this distinction apart from a tracing, and, moreover, it does not invariably hold good.

(b). In *paroxysmal tachycardia*, as the term is used nowadays, the patient suffers from

attacks of fast but regular cardiac action. The duration of these may vary from seconds to days; what is characteristic is the abrupt transition from the normal to the rapid rhythm and back again, at the onset and offset of the attack. The patient is conscious of discomfort, and indeed there is good cause if the speed be above a certain pitch; for in such a case the auricle gets no time for emptying itself, and becomes over-distended, pulmonary stagnation with cyanosis and venous engorgement resulting. Tachycardial paroxysms may appear on a background of organic disease, cardiosclerosis and mitral stenosis in particular; or the patient's heart may be normal. This form of irregularity has especially to be distinguished from that next to be described, the total arrhythmia of auricular fibrillation, which may manifest itself in paroxysms, particularly in its earlier stages. The distinguishing point is that in true paroxysmal tachycardia the pulse is regular, whereas in the other it is quite irregular.

By means of a polygraph tracing it is possible to discover the source of the rapid rhythm, whether it is auricular or ventricular, in most cases. The complexity of the subject of cardiac arrhythmia is, however, illustrated by the fact that there is a form of paroxysmal tachycardia arising in the auricles, which beat at great speed, up to and even exceeding 300 per minute, in which a certain proportion of the beats is blocked: so that only every second, third, or even fourth impulse passes over into the ventricle. That is to say, the auricle may be in a state of paroxysmal tachycardia, and yet the radial pulse is hastened but little or not at all. The difficulty of diagnosis is heightened by the fact that the auricular beats do not always appear in the jugular curve of a polygraph record, though they are manifest in an electrocardiogram. This form of tachycardia goes by the name of 'auricular friction.'

(c). The last form of irregularity to be recognized is in many senses the most important—the *total arrhythmia* which is associated with breakdown and fibrillation of the auricles. This is essentially a terminal phase of chronic organic disease, especially of mitral stenosis and cardiosclerosis; it may be prolonged for years, but nevertheless it marks a certain 'last state' of the auricular musculature. The features which characterize it are of two kinds: those which mark the disappearance of auricular systole, and the evidences of absolute irregularity of the pulse. To the observer using ordinary methods of examination without apparatus, this latter is the more obvious and striking side of the picture. If the pulse be counted for one or two minutes, it will be found that there is no 'dominant rhythm'; anarchy is complete. The pulse is usually hasty—over 100 per minute—but not always. The heart's action is similarly irregular, and on comparing it with the arterial pulse, a certain number of beats too feeble to reach the wrist will be discovered. Cessation of effective auricular systole is manifested in two ways if the case be one of mitral stenosis: by disappearance of the presystolic thrill and bruit (the diastolic vibration, however, persisting), and by disappearance of the auriculo-systolic wave from the jugular tracing. Of course, if the case be not one of mitral disease, there are no presystolic vibrations to disappear. However, the absolute disorder of the pulse, coupled with evidences of organic disease of the heart and a gravely embarrassed circulation, combine to form a picture so characteristic that there is little fear of a mistake. Nevertheless, there are cases of sinus irregularity so profound that without a polygraph tracing it is difficult to exclude auricular fibrillation; the same may be said of some few cases of multiple extrasystolic irregularity.

SUMMARY OF VARIATIONS IN RHYTHM OF PULSE.

1.—*The radial pulse may be wholly regular, but abnormally slow or abnormally quick.*

A.—**Regular Slow Pulse** may be due to—

1. *Extracardiac* causes (convalescence from acute illness, sinus irregularity, raised intracranial pressure, jaundice). In such, the whole heart is slowed, auricle and ventricle alike; there are no signs of cardiac disease; and there are signs of extracardiac disease.

2. *Intracardiac* causes. (a) *Alternating extrasystoles* may cause an apparent regular slowing of the pulse: if each 'normal' beat is followed by a premature one too small to be felt at the wrist, the radial pulse will appear slow. The real interpretation may be discovered by a polygraph tracing, and by comparing the heart-sounds with the pulse at the wrist: by these means the occurrence of the small premature beat after every normal beat will be observed. (b) *Heart-block*, either partial or complete, will render the radial pulse

slow. If the block be partial but regularly recurrent, the pulse at the wrist will be regular and slow; e.g., if the auricle is beating at 72 per minute, and every other stimulus is blocked in its passage from auricle to ventricle, a regular pulse of 36 per minute will be the result; while if two out of every three stimuli are blocked, the pulse will beat regularly 24 times per minute. If the block be complete, auricle and ventricle will each have its own regular rhythm: that of the ventricle is usually at the rate of 30 to 40 per minute, and this will accordingly be the rate of the pulse. The occurrence of epileptiform and syncopal attacks is to a large extent confirmatory of the diagnosis of heart-block; but this cannot be accepted as proved unless it has been demonstrated that when the auricle contracts, the ventricle sometimes or always fails to follow suit. This evidence is provided (i) by naked-eye observation of jugular, i.e., auricular, movement, (ii) by auscultation detecting auricular sounds during the ventricular pauses, (iii) by polygraph records, which not only afford conclusive evidence, but also facilitate the study of the degree of block present.

B.—Regular Rapid Pulse (and see TACHYCARDIA, p. 702) may be due to—

1. *Extracardiac* causes (tuberculosis and other infections, excitement, Graves's disease, etc.). Here the whole heart is persistently hurried, and the cause is usually manifest; moreover, change to or from a slower rate is gradual and not abrupt.

2. *Intracardiac* causes. The only important intracardiac condition giving rise to a quick but regular pulse is that form of ectopic stimulus production which manifests itself in *paroxysmal tachycardia*. Here there may or may not be other signs of cardiac disease, mitral stenosis and cardi sclerosis being the commonest types; the tachycardia is temporary, its onset and cessation being abrupt.

II.—The radial pulse may show a fundamental regularity, occasionally interrupted by premature beats, intermissions, or periods of irregularity.

A.—Premature Beats may be single or multiple; they may recur at regular or irregular intervals; the pause following them may or may not be compensatory; the beat next following the pause is often increased in magnitude. The premature beat bespeaks an extrasystole; it is a small beat, accompanied by heart-sounds feebler than those coinciding with the normal beats.

B.—Intermission of a beat or beats may be due to one of three causes: a premature extrasystolic beat too feeble to reach the wrist; a blocked auricular stimulus; or a comparative failure in the contractility of the ventricle.

1. If the intermission be due to a *feeble extrasystole*, the imperfect heart-sounds which accompany the premature beat will be audible. A sphygmographic tracing will sometimes bring to light a wave too feeble to be perceived with the finger. The pause due to the intermission is shorter than the duration of two complete beats, if the gap is due to an unperceived extrasystole which is not followed by a compensatory pause.

2. If it be due to a *blocked auricular impulse*, this can only be proved by demonstrating the occurrence of auricular systole without a corresponding ventricular systole following at the usual interval; and it is scarcely possible to do this without a polygraph record of jugular and radial pulses. The auricular systole may be audible, and its effect visible in the jugular vein; but in both cases timing is a difficult matter.

3. If it be due to a *normally timed ventricular systole too feeble to send a wave to the wrist*, other evidences of failing contractile power, among them the alternating pulse, are sure to be detected; indeed, this type of intermission is in reality an exaggeration of the alternating pulse, without which it will not occur.

C.—Short Periods of Irregularity due to a 'sinus disturbance' are very common, especially in children and nervous subjects. The diagnostic features are absence of physical signs of cardiac disease, marked variation of the rhythm with respiration and swallowing, and implication of the whole heart—auricle as well as ventricle—in the irregularity. This latter fact is of course only discerned by means of graphic records; but the diagnosis can usually be made without recourse to these.

Longer periods of total arrhythmia (c. *infra*, IV, .1), sometimes interrupt a normal rhythm.

III.—The radial pulse is arranged in pairs of beats.

A.—The Pulsus Bisferiens is a single beat with a double summit (*Fig.* 235). This can

easily be recognized by the fact that the two summits are very close together, and that one cycle only of heart-sounds corresponds to each pair.

B.—Alternating Extrasystoles cause the pulse to be paired (pulsus bigeminus); each pair consists of a full beat, followed after an abnormally short pause by a small beat. Each beat, whether normal or abortive, is accompanied by a cycle of heart-sounds; though the second sound may fail if the accompanying premature extrasystolic beat be too feeble to open the aortic valves. A sphygmographic or polygraphic record will help to make the nature of the irregularity clear.

Fig. 235.—Pulsus bigeminus. There is a double peak to each radial beat, simulating a pair of beats.

C.—The Pulsus Alternans

is associated with other evidences of inadequate contractile power. Each pair consists of a full beat and a small beat, and each beat is equidistant in time from that preceding and that following. A similar alternation in cardiac force may be detected in the heart-sounds. In many cases

the alternation can only be recognized certainly by means of a sphygmographic tracing.

D.—Blocking of every third Auricular Stimulus results in the ventricular contractions being arranged in pairs. Each beat is of equal force, and the interval separating each pair from that following it is equivalent to the duration of two normal pulse waves.

Beats may fall regularly in groups of three or four if every fourth or fifth beat is either an extrasystole, or missing, owing to auriculo-ventricular block.

IV.—The pulse is totally irregular, no fundamental rhythm being discoverable.

A.—True Total Irregularity is associated with organic disease, either post-rheumatic or cardiosclerotic. The pulse and heart-sounds are altogether irregular, and the circulation is obviously embarrassed. The picture is therefore characteristic: if any doubt be present, discovery of evidences of auricular asystole (loss of presystolic thrill and murmur, failure of auriculo-systolic wave in jugular curve of polygraph tracing) will remove it.

B.—Total Irregularity may be Simulated by extreme sinus irregularity, by depression of conductivity leading to variations in the *a-c* interval, and also by multiple extrasystoles. In any such case all that is needed to establish a diagnosis is a polygraph tracing.

It is clear from this brief summary that most forms of arrhythmia can be recognized without the use of special apparatus; but that in many cases a polygraphic record is valuable on account of the certainty which it gives to the diagnosis, while in a few it is impossible to be sure of the meaning of the irregularity without such a record.

Carey Coombs.

PULSE, UNDULY RAPID.—(See TACHYCARDIA, p. 702.)

PULSE, UNDULY SLOW.—(See BRADYCARDIA, p. 82.)

PULSES, UNEQUAL.—Inequality of the pulses may be a perfectly natural phenomenon; one frequently finds that the radial arteries of the two sides are not of the same calibre, owing to variable degrees of collateral circulation by an enlarged *comes nervi mediani*. Inequality of the pulses is a much more important sign when known to have developed in a patient whose pulses were formerly normal. In such a case the cause is probably one of the following:—

Thoracic aneurysm	Accessory cervical rib	Atheroma.
Mediastinal new growth	Embolism	

Pathological inequality of the pulses, or definite delay of one behind the other, as gauged by simultaneous palpation of the two radial pulses, is distinctly uncommon, even in cases of thoracic aneurysm; it is true that when very careful simultaneous records are made from the two radial pulses slight differences in size and definite differences in time can be detected, the one being delayed behind the other; but in clinical medicine such minute methods of investigation are seldom applicable; if the aneurysm involves the

origin of the innominate artery, the right pulse will be smaller than the left; whereas if it affects that part of the arch from which the left subclavian artery is derived, the left radial pulse will be smaller than and delayed behind the right. Similar delay or inequality might be produced by *new growth* compressing either the innominate artery on the right side or the subclavian artery on either side; but this is rare.

An *accessory cervical rib* might stenose the subclavian artery, but the condition is generally bilateral so that it rarely produces inequality of the radial pulses; its symptoms are more likely to be those of interference with the lower part of the brachial plexus, with consequent pain, paresthesia or paresis corresponding to the nerves distributed upon the ulnar aspect of the arms and hands (p. 443).

Embolism of one or other radial artery will rather obliterate it altogether than cause it to be less in size than that of the other side. It will almost always be due to fungating endocarditis (p. 34).

Atheroma of the brachial or subclavian artery on one side might cause the corresponding radial pulse to be less than that on the other; but this very rarely happens, and in such a case it would be more probable that atheroma of the aorta with an aneurysmal dilatation would be diagnosed than atheroma restricted to the vessels in the upper arm, unless the *x-rays* exhibited no trace of aneurysmal opacity in the thorax. *Herbert French*.

PUPIL ABNORMALITIES OF THE. Abnormalities of the pupil may be classified into:—I. *Irregularities in shape*; II. *Irregularities in size*.

I. Irregularities in Shape.—The normal pupil is circular or slightly oval. Its outline may become irregular owing to an adhesion between the iris and the lens, the result of *old iritis*. These adhesions are most evident when the pupil is dilated. A similar irregularity sometimes occurs with the *persistence of a pupillary membrane*—a congenital affection. The adhesions due to this cause may be distinguished from inflammatory adhesions by the fact that they arise from the anterior surface of the iris at a slight distance from the pupil and not from the posterior surface and the extreme edge.

The pupil may also become irregular in shape as the result of *injuries*, such as rupture of the sphincter, and tearing of the root of the iris from its ciliary adhesion (iridodialysis); of dislocation of the lens; or of partial adherence to an old perforated corneal ulcer.

II. Irregularities in Movement and Size. Before considering the irregularities in the movements and size of the pupil, it is desirable to remember that its normal size varies during life. In extreme infancy it is small. It becomes larger during young adult and middle life, and ultimately becomes small again in old age. It is also, as a general rule, small in hypermetropic, and large in myopic eyes.

There are also four normal pupillary reflexes: (i) The light reflex; (ii) The reflex to accommodation; (iii) The reflex to sensory stimulation; (iv) Psychic reflexes. The reflexes to light and to accommodation are both constrictive, the constriction in accommodation being more in the nature of an associated muscular action. The sensory and psychic reflexes are both dilatations, the dilatation being caused by either sudden sensory stimuli or some sudden emotion, such as fright or terror.

The pathological variations in the pupil may be classified as follows:—

1. *Loss of the Pupillary Light Reflex*, either with or without constriction of the pupil, but with persistence of the reaction to accommodation, constitutes the Argyll Robertson pupil. It never occurs in healthy individuals, but has been observed most frequently in *tuberculosis dorsalis*, to an extent varying according to different observers from 70 to 90 per cent of all the cases. The condition is usually permanent. It also occurs in *general paralysis of the insane*. The pupil is constricted in nearly all tabetic cases, and the affection is most commonly bilateral.

2. *Loss of Convergent Accommodation Reflex and Retention of the Light Reflex*. This condition is extremely rare, but has been observed in *syphilis*, *basal meningitis*, *myelitis*, and *tumour of the corpora quadrigemina*.

3. *Loss of the Convergence Pupillary Reflex* may be unilateral or bilateral. It occurs, rarely, in *tuberculosis dorsalis*, and after some cases of *diphtheria* and *alcoholic intoxication*.

4. *Loss of all Reflex Movements of the Pupil*.—In this condition there is paralysis of the sphincter of the pupil and of the ciliary muscle, the extrinsic muscles of the eye being unaffected (ophthalmoplegia interna). The site of the lesion must be in the third nerve

nucleus, and it is most frequently unilateral, though occasionally bilateral. *Syphilis* is the most frequent cause. It may also occur after *diphtheria*, *injury*, or in some intracranial diseases.

5. In the condition in which there is a lesion of the optic nerve on one side, between the chiasma and the globe, there will be, as a result, a loss of direct light reflex in that eye, and of the consensual light reflex in the opposite eye.

6. *Loss of Sensory or Psychic Reflex* occurs in lesions of the dilatator pupillary tract, such as *paralysis of the cervical sympathetic*: in which condition it is associated with slight ptosis of the upper lid, enophthalmos, and diminished tension of the globe.

7. *Abnormal Constriction of a Pupil, with Retention of the Light and Convergent Reflexes*, may occur from abnormal stimuli of the sphincter, or paralysis of the dilatator pupillæ as the result of acute *encephalitis*, *intracranial abscess*, or *growth*, in which the lesion irritates but does not destroy the centre for convergence. In all cases of brain disease the constriction is ultimately replaced by dilatation.

8. *Abnormal Dilatation of the Pupil, with Retention of the Light and Convergent Reflexes*, is met with in cases of stimulation of the cervical sympathetic, for instance by an aortic *aneurysm*. It may also be observed in certain mental states, such as *epilepsy*, acute *mania*, or *cataplexy*.

9. *Inequality in the size of the Pupils* is observed frequently, and may have no pathological significance: but pronounced difference in the size of the pupils is nearly always symptomatic of some organic lesion. In cases where the abnormal pupil is the smaller, the condition is usually due to hyperemia of the iris, such as occurs in *iritis*; *paralysis of the cervical sympathetic*; or the use of a myotic drug such as *physostigmine*. In cases where the abnormal pupil is the larger, the dilatation is usually due to stimulation of the sympathetic, the use of a mydriatic, paralysis of the fibres of the third nerve, or increased ocular tension, such as may occur in *glaucoma*.

In cases of inequality of the pupils one may suspect *tubercles*, general paralysis of the insane, a unilateral lesion of the third nerve or cervical sympathetic, trigeminal neuralgia, carotid or aortic aneurysm, a unilateral intracranial lesion, or *glaucoma*.

10. Irregularities in the shape of the pupils other than those mentioned above may occur in *tubercles* and various cases of *insanity*. There is no marked or sharp irregularity, it only being noticed that the pupil is not circular owing to paralysis of certain fibres of the iris.

11. *Hippus*.—This term is applied to a condition in which, when both eyes are shaded, and then illuminated, the pupils will alternately dilate and contract. It is sometimes associated with nystagmus, and occurs also in *disseminated sclerosis*, and in some cases of *brain tumour*. It is observed most frequently when there is a central scotoma in the field of vision, with some injury to the macular or axial fibres of the optic nerve. It is also common in *alcoholic subjects*.

12. *Paradoxical Pupillary Reflex*: pupils dilating under the stimulus of light. This condition is extremely rare, and has only been observed in patients affected with grave lesions of the central nervous system, usually *tubercles dorsalis*.

13. *Hemianopic Pupillary Reflex*: lesions of the brain situated in the optic tract above the corpora quadrigemina may give rise to partial loss of vision, but will not affect the pupil-reflex arc. For example, a lesion in the right occipital cortex may give rise to a left homonymous hemianopsia, but the pupil will react even when a light is thrown on the blind side of the retina (see HEMIANOPIA, p. 300). In cases, however, where the lesion is situated in the optic tract below the corpora quadrigemina, hemianopsia may also occur, but under these circumstances no pupillary reflex for light can be obtained on stimulus of the blind side of the retina, the pupil reacting to light when the opposite side of the retina is stimulated. This reaction is termed the hemiopic pupillary reflex, and is of great value in the localization of intracranial lesions.

Herbert L. Eason.

PURPURA signifies hemorrhage into the skin, and, according to the size of the extravasation of blood, the lesions are spoken of as puncta or spots, vibices or lines, petechiæ or small patches, ecchymoses or bruises. The lesions cannot be obliterated by pressure with the finger, which distinguishes the effused blood from mere congestion. The diagnosis of the actual fact of purpura is seldom difficult: the persistence of the discoloration under pressure differentiates it from erythematous lesions, and the colour generally

serves to distinguish it from pigmentation of the skin other than that due to hæmorrhage. In a case of doubt, the fact that the lesions presently alter in colour and then disappear serves to distinguish purpura from capillary nævi or from pigmentation of the skin, which persist. It may be more difficult, however, to decide what is the nature of the purpura in any given case: the following is a list of its better-recognized causes:—

CAUSES OF PURPURA.

1.—Due to Local Injuries:

Flea-bite	Blows	Rupture of a vein, especially a varicose vein.
Pediculosis	Sprains	
Leech-bite	Rupture of a muscle	

2.—The Effect of Drugs and Poisons:

Antipyrin	Chloral hydrate	Salicylic acid
Iodoform	Butyl-chloral hydrate	Potassium chlorate
Iodide of Potassium	Veronal	Diphtheritic antitoxin
Sulphonal	Mercury	Ptomaine
Copaiba	Arsenic	Snake-bite poison.
Belladonna	Quinine	
Chloral	Ergot	

3.—In Fevers:

Typhus fever	General tuberculosis	Remittent fever
Cerebrospinal fever	Dysentery	Severe malarial fever
Small-pox	Cholera	Blackwater fever
Pyæmia	Yellow fever	Measles
Septicæmia	Weil's disease, or bilious typhoid	Diphtheria
Fungating endocarditis	Plague	Typhoid fever
		Scarlet fever.

4.—In association with Jaundice from whatever cause (see JAUNDICE, p. 321).

5.—Bright's Disease.

6.—Chronic Alcoholism:

Cirrhosis of the liver | Peripheral neuritis

7.—The so-called Blood Diseases:

Spleno-medullary leucæmia	Pernicious anæmia	Barlow's disease.
Lymphatic leucæmia	Splenic anæmia	Hæmophilia
Lymphadenoma	Pseudo-leucæmia infantum	
	Scurvy	

8.—In cases of generalized Malignant Disease, especially:

Sarcomatosis | Chloroma

9.—Peliosis Rheumatica.

10.—Henoch's Purpura.

11.—Purpura Simplex.

Morbus maculosus of Werlhof	Purpura hæmorrhagica	Purpura fulminans.
-----------------------------	----------------------	--------------------

A number of the above conditions require but little discussion, for if they are only borne in mind their diagnosis will generally be easy.

Flea-bites are by far the commonest cause of purpura in the out-patient department of a hospital, and they may sometimes be so numerous as to raise a misleading suspicion that the patient is suffering from some serious disease. The relatively small hæmorrhagic foci, and their prevalence on the parts covered by the clothes rather than upon the hands, face, or exposed parts of the legs, serve to indicate the diagnosis, even in a severe case.

The commonest variety of *pediculosis* to produce purpura is *P. corporis* or *vestimentorum*: the circumstances of the case and the distribution of the purpura itself and of the marks of scratching, particularly in the regions where collars and other constrictions in the dress occur, would indicate the diagnosis.

The hæmorrhage around a *leech-bite* is so characteristic that, once seen, it cannot be mistaken for anything else.

Blows and *sprains*, if sufficiently severe, produce purpura even in the healthy, in whom

the history gives the diagnosis ; it is important to bear in mind, however, that some normal individuals bruise with such ease that there may be no clear evidence of injury unless careful inquiry is made, when some trivial stumble or knock may be recalled to mind by the patient. Such easy bruising may also occur in any of the blood diseases. A case of *epilepsy* may sometimes come under observation for multiple bruises simulating some other kind of purpura, but due to injuries produced during the attacks, which may themselves be unsuspected if they occur during the night. Very extensive purpura on the legs or other parts has sometimes been produced by multiple self-injury in girls suffering from *hysteria* or by *malingers* ; serious organic disease may be feared unless other factors in the case or the distribution of the purpura suggests an artificial origin ; the hæmorrhagic spots and blotches may be abundant on the fronts and sides of the legs, for instance, and not down the backs of them ; no known organic purpura has so selective a distribution.

Spontaneous *rupture of a muscle* leads to extensive purpuric extravasation of blood, but the diagnosis is not difficult if the history is clear, and one can often feel the place where the muscle has given way unless it is too deep-seated to palpate, as in the case of the *plantaris longus*, which is apt to rupture during sudden efforts such as may be made in playing tennis or the organ.

The *purpuric discoloration of the skin around varicose veins* in the legs, together with its resultant dark-brown pigmentation, is familiar to all.

As regards *drugs*, the list above indicates that there are many which may sometimes produce purpura ; it may be said at once, however, that none do so at all commonly. Nevertheless the possibility should be borne in mind, and inquiry made as to the remedies the patient may have been taking. *Antidiphtheritic serum* and *ptomaines* merit particular attention. The commonest eruption resulting from antidiphtheritic serum, or from other forms of antitoxic horse-serum administered hypodermically, is urticaria ; purpura is relatively rare ; either form occurs as a rule about nine or ten days after the serum has been given, and is generally associated with lassitude, muscular and joint pains, anæmia, and more or less pyrexia, lasting from a few hours to two or three days. Ptomaine poisoning is often difficult to recognize with certainty unless it occurs in epidemic form. It is due in most cases to the products of Gaertner's bacillus, and seeing that the blood-serum of patients affected by this bacterium develops agglutinating powers against it similar to Widal's reaction for typhoid fever, this serum test should not be omitted ; if it proves positive the diagnosis is clear ; a negative result, however, does not exclude ptomaine poisoning.

In the majority of *acute fevers*, the occurrence of purpura is of prognostic rather than of diagnostic value ; in diphtheria, for example, even a single well-defined purpuric spot is a sign of grave omen, but it does not assist at all in the diagnosis of the disease, which has to be recognized upon other grounds. The same applies to measles, scarlet fever, and so on ; indeed, the only two fevers in which purpura is of essentially diagnostic value are *typhus* and *cerebrospinal fever*. The former is now very rare in Great Britain, but when it was common and typhoid fever began to be differentiated from it, the point upon which greatest stress was laid was that in true typhus or *gaol fever* there is always more or less purpura, whereas in typhoid fever all the red spots fade upon pressure. It happens occasionally even yet, that typhus fever develops in the poorest parts of cities, and this point is most useful in distinguishing it from typhoid. In the latter, if flea-bites are excluded, purpuric spots are exceedingly rare. *Cerebrospinal fever* presents many characters that are common to it and to other forms of acute meningitis ; but if with these there is a purpuric eruption, it is at once differentiated from the others, though the absence of purpura does not exclude the disease. So characteristic is the purpura in some cases that the malady has earned the title of spotted fever, which used to occur in widespread epidemics, and still does in smaller ones from time to time. The diagnosis may be clinched by bacteriological examination of the cerebrospinal fluid obtained by lumbar puncture.

Small-pox may present cutaneous hæmorrhages of three different kinds ; there may be hæmorrhage *into the pustules* in a late stage, when the diagnosis has already been made and when the prognosis is not thereby made worse ; there may be hæmorrhage *between the pustules*, vesicles, or papules, the diagnosis having already been made, in which case the prognosis is not good ; and there may be a hæmorrhagic eruption either all over the body or in the bathing-drawers region in the *prodromal* stage of the disease, in which case

the patient will almost certainly die before the true small-pox eruption develops, so that if there is not an epidemic at the time the diagnosis may be exceedingly difficult.

Almost any condition in which there are pyogenic micro-organisms or their toxins circulating in the blood-stream may be associated with extensive purpura, and this applies to *pyæmia* and *septicæmia* in general. The diagnosis will be confirmed best by obtaining cultivations from the blood, though should blood-cultures prove negative septicæmia will not be excluded necessarily; there will very likely have been rigors, pyrexia, and other symptoms pointing to the nature of the case. *Fungating endocarditis* is only a variety of pyæmia or septicæmia. Seeing that it is very rare to get purpura in association with chronic valvular disease of the heart if both purpura rheumatica and infective endocarditis can be excluded, the occurrence of purpura in a heart case (*Fig. 236*) may be one of the main symptoms indicating that fungating endocarditis has supervened. So indefinite is the nomenclature in regard to this disease, that the terms malignant, ulcerative, fungating, infected, and infective endocarditis are used indiscriminately by different observers to denote the same condition. The disease may be further indicated by symptoms described on p. 34. *Pyorrhæa alveolaris* is another septic infection which leads occasionally to extensive purpura and other hæmorrhages.

General tuberculosis is not a common cause of purpura, and yet in a few instances extensive purpura has been the first, and for the time being the only, symptom of an obscure illness which has ultimately turned out to be general tuberculosis. The patient has generally been a child, and the diagnosis has only been possible when the course of the case has been watched. The same may be said of *sarcomatosis* in certain cases, though this has been included under a different heading in the above list.

Jaundice should be borne in mind as a cause of purpura, for although the occurrence of the latter does not assist in differentiating one kind

of jaundice from another, one might be misled into diagnosing something more serious than is necessary if one did not bear in mind that any kind of jaundice may produce purpura. Moreover, some of these patients may seem to have been grossly ill-treated if one were to judge only by the degree of bruising that may result from ordinary palpation; the danger of fatal oozing after operation is always to be remembered when surgical measures are thought of in a jaundiced subject. Spontaneous hæmorrhage into the skin is less common here than is hæmorrhage from what otherwise would be trivial causes.

Bright's disease, particularly the chronic varieties, may produce hæmorrhage anywhere in the body. Purpura is not a very common form of such hæmorrhage, but when it does occur it may be extensive. The diagnosis is discussed under ALBUMINURIA (p. 6).

Chronic alcoholism, especially if it has already led to either cirrhosis of the liver or to peripheral neuritis, is occasionally a cause of considerable purpura, though the latter is generally confined to the legs, particularly to the parts below the knees. In many instances the diagnosis is easy, even if the history is not given with perfect honesty; but considerable difficulty sometimes arises in the case of ladies who have contracted the habit of secret drinking, their relatives and friends being entirely unaware of it.

Fig. 236.—From a photograph showing extensive purpura in a case of fungating endocarditis. The limbs were affected more than the trunk. From the same case as *Fig. 270*, p. 610.

Any of the so-called *blood diseases* may present purpura as a prominent symptom, and in some cases, particularly in *lymphatic leukaemia* in children, extensive purpura may be the first symptom that anything is wrong. More often, however, the disease has already given rise to anaemia or to enlargement of the spleen or lymphatic glands, or to some other prominent hæmorrhage, and the diagnosis has already been made by the time the purpura supervenes. (See ANÆMIA, p. 20; SPLEEN, ENLARGEMENT OF THE, p. 628; and LYMPHATIC GLAND ENLARGEMENT, p. 376.)

Scurvy in an adult is relatively rare, but is sometimes met with in those who have been obliged by poverty to live upon a diet containing no fresh vegetables; a man may try to live for a month or more on plain bread, in which case typical scurvy may develop in him, with the spongy heaping up of the gums both inside and outside the teeth, and with the knotty hæmorrhagic swellings in the muscles of the calves, as well as purpura. Children who are fed upon patent foods without sufficient fresh milk, or vegetable food, or fresh meat, not infrequently develop a milder form of scurvy, with marked tenderness of the periosteum of the long bones, pasty pallor, mouth bleeding from spongy gums, and possibly purpura; this is *infantile scurvy*, or *Barlow's disease*, which should not be confused, as it is apt to be, with rickets.

Hæmophilia is generally indicated at once by the history of persistent oozing from slight cuts and scratches, and also by the fact that other members of the family, especially males, have suffered in a similar way.

Chloroma is a very rare disease, in some ways related to sarcomatosis, and in others to lymphatic leukaemia; it produces swellings in connection with the bones, especially of the head, together with enlargement of the lymphatic, lachrymal and salivary glands; it develops in early life, proves slowly fatal, and the diagnosis is confirmed by the green colour of the new-formed tissue—'green cancer.' The blood changes are negative.

Peliosis rheumatica, or *purpura rheumatica*, or *Schönlein's disease*, was formerly regarded as related to acute rheumatism; but it is exceedingly rare for a patient affected by it to present unmistakable signs of valvular heart disease, although there may be a local systolic bruit at the impulse. The reason why it is thought to be related to acute rheumatism is, that in addition to the extensive purpura, which comes out in successive crops and may affect any part of the body, though it is commoner upon the lower limbs than elsewhere, there is considerable pain, redness, and swelling of many joints, which may become affected successively; the temperature rises during an attack to 103° F. or 104° F., the throat generally being sore at the same time. It is not impossible that the purpura is due to the absorption of microbes or their toxins from the acute tonsillitis; but be this as it may, the diagnosis is not difficult when the purpura, the joint pains, and the pyrexia are present together. The disease is little influenced by sodium salicylate; it may be associated with more or less erythema as well as purpura; the malady affects young persons, especially between the ages of ten and thirty, of either sex.

Hænoch's purpura is met with chiefly in children (*Fig. 157*, p. 345), and the same patient may suffer from recurrent attacks, which usually cease at or before puberty. In addition to hæmorrhages beneath the skin, there is generally some tendency to joint pains not unlike those of peliosis rheumatica, but in addition to this the child is seized with more or less severe acute abdominal symptoms, varying from simple vomiting and stomach-ache to severe prostration with agonizing cramp-like attacks of colic, some of which may be followed by the passage of blood and mucus per rectum to such an extent as to simulate acute intussusception; the abdominal attacks are probably the result of submucous intestinal hæmorrhages. There is every degree of the affection, from mild to very severe, but the association of the purpura with the abdominal attacks in childhood suggests the diagnosis at once, especially if there has been a similar attack previously. The chief error to avoid is mistaking for Hænoch's purpura that which is really an acute nephritis; the urine should be examined periodically for albumin and renal tube-casts, even if there is no œdema, though the occurrence of blood alone would not be sufficient to indicate acute nephritis, seeing that hæmorrhage from the kidney may be due to Hænoch's purpura itself.

It is only when every precaution has been taken to exclude all the above causes of purpura that one can be satisfied with any of the remaining three diagnoses, namely *purpura simplex* (*morbus maculosus* of Werlhof), *purpura hæmorrhagica*, or *purpura fulminans*. These differ from each other only in degree; broadly speaking, purpura simplex signifies

hemorrhage into the skin only; purpura hemorrhagica has, in addition, hemorrhages from the mucous membranes, particularly of the mouth, nose, and bowel, less commonly of the urinary passages; whilst purpura fulminans is the term used to denote a condition in which a person may seem perfectly healthy to-day, may be seized with acute purpura and be dead before to-morrow, without developing any other symptoms to indicate the nature of the complaint. These kinds of purpura have sometimes been spoken of as idiopathic, but they must have some underlying cause, if only it can be found. It is better probably to label them cases of purpura of which the exact cause is not yet known, than to be content with such a term as purpura simplex, and it is probable that if bacteriological examinations were made, a bacterial cause would be discovered, particularly in connection with the tonsils, the gums in states of septic gingivitis or pyorrhœa alveolaris, the uterus, the bowel, or the circulating blood itself.

Herbert French.

PUS IN THE CHEST.—(See CHEST, Pus IN, p. 103.)

PUS IN THE STOOLS in sufficient amount to be recognizable by the naked eye, indicates the rupture of an abscess into the intestinal tract. The symptom is rare, however, for even when a large appendicular abscess perforates into the cœcum, the pus either becomes indistinguishable when mixed with the feces, or unrecognizable on account of digestion and decomposition. The less the pus is mixed with other intestinal contents, the nearer to the anus has the site of rupture been; but the diagnosis of the source of the abscess needs to be determined upon other grounds, particularly the history, and the results of general physical examination, including that of the rectum and vagina. Abscesses most apt to cause a discharge of pus with the stools are of the appendicular, cholecystic, perinephric, psoas, pelvic, perigastric, or other local peritoneal types, and pyosalpinx.

Microscopical quantities of pus in the stools may be due to any of the causes already mentioned; they may also be derived, not from lesions outside the intestines, but from affections of the mucous membrane itself: acute or chronic colitis, with or without ulceration; dysentery; cholera; dengue; mucous or mucomembranous colitis; tuberculous, typhoidal, malignant, or venereal ulceration of the bowel. The pus corpuscles may be recognizable as such under the microscope; but it is difficult to determine when the leucocytes derived from the intestinal catarrh are merely leucocytes in excess, and when their numbers become sufficient to merit the term actual pus. Examination with the sigmoidoscope is sometimes invaluable when the diagnosis has not been decided by other methods.

Herbert French.

PUSTULES.—The pustule, one of the primary cutaneous lesions, is an epidemic elevation, either uniloecular or multiloecular, containing a purulent liquid, and differing from a vesicle or a bulla only in the character of its contents. Always a product of inflammation, it may originate as a pustule or may develop from a papule, but much more often it is a transformed vesicle; if the metamorphosis is imperfect the lesion is styled a papulo-pustule or a vesico-pustule. Frequently the transformation from a papule or a vesicle is so swift that the true origin of the lesion may escape notice; but in such cases it is usual to find papules or vesicles intermingled with the pustules. The pustular cavity may be situated in the epidermis, in the derma, or in a follicle; a purulent accumulation *beneath* the derma is either an abscess or a gumma. *Epidermic* pustules may be superficial, as in impetigo, or deep, as in the condition known as cethyma, which I regard as but a severe form of impetigo. *Dermic* pustules, such as the miliary abscesses of new-born children, are seldom met with, while *follicular* pustules, such as those of sycosis, are common. In *colour*, pustules are usually yellowish or greyish, with a red areola; but when the contents are mixed with blood, the yellow may be tinged with red or brown. If a pustule is punctured or ruptured, the liquid is seen to be more or less turbid and yellowish; under the microscope it is found to consist largely of leucocytes and serum as well as cocci. Pustules vary greatly in size; small ones may remain of inconsiderable dimensions, or may become large by excentric extension. The prevalent *shape* is roundish or convex, as in furuncle and acne; but it may be acuminate, as is frequent in sycosis and cœzema, or flat and irregular, as in impetigo and syphilis, while in rare instances, as sometimes in

scabies, it may be oblong, with a tendency to the linear form. In variola and the varioliform syphilide, the pustules may be flattened or concave, either because the fluid may not fully distend the cleft in which it lies, or from laccidity of the sac due to commencing absorption. Pustules may develop slowly, as sometimes occurs in impetigo and in the pustular syphiloderm; but as a rule they run a rapid course, and terminate either by rupture much more often accidental than spontaneous—or by desiccation. In either case, a yellow, brown, or blackish crust, more or less thick and irregular, is formed; but if the termination is by desiccation, the crust has a less pronounced coloration, and is friable instead of firm.

A cutaneous affection in which the pustule plays a leading part is *impetigo vulgaris seu contagiosa*; usually following slight febrile disturbance, small erythematous spots appear, on which form vesicles containing a turbid fluid that quickly becomes purulent; when the pustules break, as they soon do, they discharge a fluid that dries up quickly into scabs that are at first yellowish, and afterwards green. Dotted about among the scabs are pustules, which may coalesce so as to form, on rupture, crusts of considerable size. The eruption may be limited to a few discrete lesions, or may extend over large areas of the body. In parts where the pustules are exposed to friction, as on the limbs, they are generally ruptured at an early stage, and a flat irregular scab, surrounded by an areola, forms over them—the condition known as ecthyma. Sometimes the distribution is annular (*impetigo circinata* or *gyrata*). In the condition known as *impetigo bullosa* the lesions are much larger, and are not always transformed into true pustules. With impetiginous eruptions, though not with these alone, *cutaneous diphtheria* is sometimes associated, especially in children. The most typical form of this affection has the appearance of an impetiginous eczema, associated with conjunctivitis, and occasionally with otorrhœa and rhinitis. No diphtheritic membrane may be present, and if cutaneous diphtheria is suspected, the Klebs-Löffler bacillus should be sought for bacteriologically. Staphylococci, or streptococci and staphylococci together, are the organisms generally found in simple impetigo, but occasionally other germs produce a precisely similar eruption—the *Bacillus coli communis* for example, or the *Bacillus pyocyaneus*.

The differences between *impetigo vulgaris* and *follicular impetigo* are well marked. The latter is pustular from the beginning, and always situated around a hair-follicle. It starts as a round pustule, often pierced by a long or coarse hair, and it may be quite small, or as large as a pea; the pus collects under the horny layer, which it distends and raises. The eruption, usually multiple, has no sites of election, but appears wherever a breach in the horny layer affords entrance to the pyogenic organism. The pustules are more resistant than those of *impetigo contagiosa*, and are less quick to break. When they rupture, yellow crusts, smaller and thinner than those of *impetigo vulgaris*, are formed. The pustules of follicular *impetigo* can hardly be mistaken for those of any other affection. The other form of *impetigo*, however, has in rare cases to be diagnosed from pemphigus. In the latter the lesions start, not as small vesicles but as bullæ, and the fluid they contain is only sometimes inoculable. Usually, too, there is marked systemic disturbance. But it is with *pustular eczema* that *impetigo vulgaris* is most likely to be confused, especially when the pustules of the latter condition have run together into a patch. In *eczema*, however, the pustules are smaller, there are severe itching and burning, there is an inflammatory areola around the crusts, which is seldom the case in *impetigo vulgaris*, and other definitely *eczematous* lesions will usually be found if sought for carefully, including infiltration and thickening of the integument.

Like follicular *impetigo*, *sycosis vulgaris* is a staphylococcal infection. The lesions begin as papules, or as nodules which form round the hairs—usually of the face, and especially of the chin, but sometimes attacking the eyebrows, eyelashes, and the axillary and pubic regions—and presently develop into pustules, each of them pierced by a hair. As the result of suppuration, the hairs are loosened, and if one is pulled out, a drop or two of pus usually exudes. In severe cases the pustules may be packed so closely together as to form infiltrations, which may fungate. The chief diagnostic features of the affection are its inflammatory character, its origin in the hair-follicles, and its limitation to the hairy parts, usually of the face. The differential diagnosis from *tinea sycosis* has been given under FUNGUS AFFECTIONS OF THE SKIN (p. 246). *Eczema* is not limited to the hairy parts, and if the follicles are involved it is only secondarily, nor, as a rule, is the inflammation

so severe as in sycosis vulgaris. Of sycosis vulgaris again, intense itching is not a feature. Sometimes, when the sycosis is widely diffused, the crusts may have to be removed to clear up the diagnosis; when this is done, the follicular implication will soon be perceived. Tertiary syphilitic ulceration is not restricted to the follicles, and behind it there lies a history of earlier specific lesions, as well as of the primary infection, unless this should have escaped notice. Wassermann's serum test may be applied.

If there is ever any doubt as between sycosis vulgaris and acne vulgaris, the presence of the latter on non-hairy parts should of itself suffice to decide the question. The pustules of *acne vulgaris* can scarcely, indeed, be confounded with those of any other affection, except with the lesions of small-pox (see below) and those of bromide and iodide eruptions. In these drug eruptions, however, comedones are absent, the lesions occur on any part of the body, and are generally a brighter red, while the fluid they contain is rather thinner. Drug eruptions, again, occur at any time of life, whereas *acne vulgaris* is essentially a disease of puberty. Pustular syphilides may attack any part of the body, and are generally grouped, which is never the case with the pustules of *acne*.

A *furuncle* is so characteristic that the only lesion from which it can ever require to be differentiated is a *carbuncle*. The pathological process is the same in both; but while in furuncle there is but one point of suppuration and opening, in carbuncle there are several. The only condition from which a carbuncle has in turn to be diagnosed, except a furuncle and malignant pustule, is diffuse cellulitis, in which there is no circumscribed outline.

In *malignant pustule* (anthrax), following itching and burning at the site of inoculation, a livid red papule appears, on which a bulla or pustule forms quickly and breaks, drying up into a black gangrenous eschar. This is fringed with tiny vesicles or pustules, and surrounded by a broad areola of solid oedematous infiltration, the skin over which is tense and violaceous. There are constitutional symptoms, with septic fever. The diagnosis rests mainly upon the presence of a gangrenous patch surrounded by infiltration in a patient whose occupation exposes him to infection with the anthrax bacillus, especially from cattle, hides, or wool. The organism (*Plate XXVIII*, p. 614) may be detected without difficulty under the microscope. It is a relatively large bacillus which generally forms long chains and is Gram-positive. It is only at the outset that the lesion can be mistaken for a carbuncle. The primary lesion of syphilis can be excluded by its indolence, and by the absence of gangrene and of febrile symptoms.

In *glanders*, the cutaneous lesions begin as red spots, which pass through the papular and vesicular or bullous stage into pustules that give rise to widespread ulceration. The condition, with its severe constitutional disturbance and, except in some chronic cases, the peculiar discharge from the nostrils, is usually easy of recognition; and in exceptional cases in which the diagnosis is in doubt, recourse should be had to the mallein injection test, or the *Bacillus mallei* may be isolated from the lesions.

In *scrofulodermia* (tuberculides), usually an affection of childhood and adolescence, pustular lesions take the form which has been styled by Dühring the large flat pustular, and the small pustular scrofuloderm. The former begins as one or more superficial indurations which, becoming pustular, extend peripherally and form a flat, yellowish, crusted pustule of considerable size, surrounded by a violaceous areola. Neighbouring pustules may coalesce. When the crust is removed, a granular serofulous ulcer is seen. The small pustular scrofuloderm is usually a papulo-pustule rather than a fully-developed pustule, the pus being frequently limited to the central part of the summit, while the outer part of the lesion remains hard. The crusting is sometimes a slow process, which may occupy several weeks, and when the crust drops off it leaves indelible scars not unlike those of variola. The only diseases with which scrofulodermia generally can be confused are lupus and syphilis. The absence of 'apple-jelly' nodules and of infiltration will distinguish it from lupus, though the two conditions may co-exist. The syphilitic ulcer is met with in adults, and is usually a much more active process than scrofulodermia, nor has the lesion the undermined border which is characteristic of the latter affection. Concomitant syphilitic signs will usually be present, just as in scrofulodermia there will generally be other tubercular symptoms; Wassermann's serum reaction should be tested.

In *syphilis* the pustule is a much less frequent lesion than the papule (p. 490), and is generally found in association with a cachectic state of health. It appears in two different

forms, the acuminate and the flat pustular syphilide, and in both the lesion may be either small or large. The *small acuminate* or miliary syphilide, not usually much larger than a pinhead, in most instances begins as a papule, and papules will generally be found intermingled with the pustules. When the crusts into which the pustules dry are detached, there may be some scarring, or the lesions may leave no trace except stains, which presently disappear.

The diagnosis of these small acuminate pustules seldom presents any difficulty: but it is not so with the *large acuminate* pustules, the acneiform syphilides, which may be mistaken not only for acne, but also for variola and iodide eruptions. Appearing on a base which may at first be pink, and afterwards copper, they may be pustular from the beginning, or may start as vesicles or as papules; they are more or less generalized, about the size of a pea, disseminated, or grouped irregularly, and while they are predominantly acuminate, some of them may be rounded. Some of the pustules may be dimpled, and occasionally the majority of them display this character. When the crusts fall off, brownish stains are seen, and there may be slight scarring, which, however, is seldom permanent. The grouping which is characteristic of these pustular syphilides, and the drying-up of the pus into scabs, are important points in differentiating them from the lesions of acne, which, further, instead of being generalized, seldom affect parts other than the face, the back of the neck, the chest, and the back between the shoulders. The comedones of acne are another distinguishing feature, the eruption is of a more sluggish and chronic character, and there is no cachexia. The diagnosis as between pustular syphilides and variola is given below. The pustules met with in iodide eruptions are seldom either generalized or profuse.

Small flat pustular syphilides ('impetiginous syphilides') may begin as such, or may develop from macules or papules. They are discrete; but in such regions as the face and scalp may run together. The eruption is of a generalized character, with a preference for the genitals, the scalp, and the face. The crusts into which the pustules quickly dry are frequently adherent; beneath them there is superficial ulceration; occasionally they are surrounded by an areola of the characteristic raw-ham colour. When the eruption is extensive, the patient is often anemic and cachectic. The affections from which these syphilides have to be differentiated are pustular eczema and impetigo. The ulceration which underlies the crusts in the syphilides is not found in either of those conditions, nor is itching present as in eczema. In impetigo, the pustules most frequently affect the face and hands, and are superficial; and the eruption is mild in character and of shorter duration.

The *large flat pustular syphilides* ('ecthymatous syphilides') differ little from the small ones except in size, and the only lesions with which they are likely to be confused are those of severe impetigo vulgaris. The diagnosis from that condition must rest upon the slow development, the greater number of the pustules, the coppery areola and base, the accompanying cachexia, and the pigmented scars. But it should be remembered—and this applies not to pustular syphilides only, but to syphilis generally—that in most cases a sure diagnosis of syphilis can be made only when all the factors of the case are taken into account: the history, character, course and termination of the lesions, and their reaction to salvarsan, mercury, or arsenic and the iodides. The distinctive characters of secondary lesions generally are their symmetry, their coppery colour, the positions in which they occur, their polymorphism, and the absence of itching, together with enlarged glands, sore throat or tongue. In doubtful cases the whole cutaneous surface should be examined for characteristic marks or lesions. If the diagnosis is still uncertain, the Wassermann test should be applied.

Of all diseases of which the pustule is one of the manifestations, *small-pox* is that which presents the greatest difficulty in diagnosis. The lesion, occasionally preceded by a roseolar rash not unlike that of scarlatina, begins as a mere fleck, of pin-head size, flush with the surface and impalpable. In the course of a few hours it swells up into a pink papule, which can be felt embedded in the skin like a small shot. In a few days, the papule undergoes vacuolation, at the same time getting bigger, and becoming grey and translucent. So the papule passes into the vesicle, which is loculated, so that if it is punctured the contained fluid is not entirely discharged. As a rule, the smaller vesicles are hemispherical, the larger flat-topped, and occasionally the crown is indented. After about twenty-four hours the contents become turbid and the covering dull and whitish.

and so the pustular stage is entered upon. While the lesion is undergoing this transition, the grey translucent centre is encircled at the periphery of the crown by a white or yellow ring. By the sixth day from its birth, the lesion has become yellow throughout and the crown dome-shaped: the pustule so attains maturity, and if of full size measures about three-eighths of an inch across. Even in unmodified small-pox, however, the lesions often fail to reach those dimensions. As the pustule develops, the erythematous zone, the areola, which encircled the papule and was biggest and brightest in the vesicular stage, begins to wane, and has disappeared by the time the pustule reaches maturity. This occurs about the ninth day. As the pustules dry up or burst, scabs are formed, which on separation leave dark stains, scars and 'pits,' the number and depth of the pits usually being determined by the severity of the disease. In mild attacks the pustules remain discrete, in severe cases they run together, confluent small-pox (Figs. 237, 238). In bad cases, hemorrhage takes place into the skin and the interior of the pustules. The mucous membranes of the air-passages may be invaded, the extent to which they are involved being determined by their susceptibility rather than by the severity of the attack. In modified small-pox the eruption may resemble that of the unmodified disease, as here described, the difference being that the lesions are less abundant and are seldom confluent.

It has been usual in the diagnosis of small-pox to lay the chief stress upon the solidity and hardness of the papule, the umbilication of the vesicle, and the loculation of its cavity; but in his masterly monograph ("The Diagnosis of Small-pox") to which I owe the following description, Ricketts has shown that the distribution of the lesions is of more diagnostic value than their character, as also is it more easily observed. The parts most liable to the eruption are the face and hands; and of the two, the face is more liable than the hands. Next to the hands in susceptibility come the upper limbs, then the trunk, then the lower limbs. As to the trunk, the rash is thicker behind than in front, and thickest on the shoulders. The incidence is smallest on the great flexures of the body, while the extensor surfaces of the limbs, and especially the elbow, receive a disproportionate share of the rash. The neck fares better than either the head or the shoulders; the back of it suffers more than the front. On the flank the rash is less profuse than on the adjoining parts of the chest-wall, either in front or behind. On the foot, the distribution is marked by great inconstancy. Usually the back of the foot receives more attention than the sole; between the toes, and in the folds beneath the toes, there is comparative immunity; and the parts for which the eruption shows most preference are the instep, especially the tendinous ridges and the bony eminences, the tendo Achillis, the balls of the toes, the toe-pads, and the heels. In the hand, the palm, and especially the hollow of it, suffers little, and the brunt of the attack is borne by the extensor surface; the rash is thickest on the back of the wrist and hand, and over the heads of the metacarpals. To these usual characters the distribution offers exceptions, some of them difficult of explanation; but they are neither so numerous nor so considerable as materially to lessen its diagnostic importance.

Fig. 238.—Confluent small-pox.
(Photo by Dr. D. S. Davies, M.O.H., Br. Med.)

The diagnosis of small-pox from chicken-pox—the disease with which it is most often

confused—and from vaccinia, has been set out under VESICLES (p. 757). The eruptions of measles and of German measles differ from that of small-pox in that, instead of being papular, they are macular, and that they never pass into a vesicular or a pustular stage. In German measles, further, there is enlargement of the posterior cervical glands, which is never the case in small-pox at an early stage. In scarlatina, the 'strawberry tongue' is a sign which is quite different from the condition of the tongue in small-pox. The rose-red lenticular spots which make up the rash of enteric fever are neither so hard nor so prominent as the papules of small-pox, and they appear chiefly on the trunk, and elect the abdomen and chest rather than the back: the arms and legs, and especially the face, almost always escape.

If the pink, slightly elevated macules of simple purpura are mistaken for the eruption of small-pox, the error is soon corrected by the deeper colour which the macules take on; nor, even though the macules may become papules, have the lesions the characteristic hardness of variolous papules. Another point of difference between simple purpura and small-pox is, that in the former affection the face and trunk are seldom attacked, the sites of election being the limbs. In erythema multiforme, although the rash makes its chief attack upon the limbs, it may be widely diffused and may even invade the face. In such

cases, however, the diffusion will usually be less general than that of the variolous eruption, nor is the order of incidence the same. With the involution which the erythematous lesions undergo, the resemblance to small-pox ceases. Even in cases of acute febrile erythema, in which the whole cutaneous surface is covered by a profuse eruption, the distribution is quite different from that of the small-pox eruption.

Confusion between small-pox and syphilis is much more likely to arise when the syphilide is pustular than when it is vesicular or papular. The erroneous diagnosis may be assisted by the fever and aching symptoms which may precede pustular syphilides, and by the fact that the lesions may begin as papules. In syphilis, however, the constitutional symptoms are less severe, the eruption runs a more indolent course, and appears in successive crops, whilst the vesicles which

form on the summits of the papules have an indurated base. Sometimes, too, the syphilitic eruption is indifferent in distribution, and often it comprises various types of lesions, even when it is not distinctly polymorphic, whereas in small-pox the departure from homogeneity is much more limited.

Occasionally, impetigo vulgaris is mistaken for mild modified small-pox (*Fig. 239*), but attention to the points which mark off the former affection from pustular eczema (see above) should prevent the mistake. Further differentiating features as between impetigo vulgaris and small-pox are, that in impetigo there is no fever, and that the lesions begin as vesicles or bullæ and dry up into flat yellowish crusts. In those cases of sudden and acute eczema which may mimic small-pox, guidance is to be found in the small size and superficiality of the eczematous lesions, and the œdema and infiltration of the underlying skin. In scabies, again, the vesicles are superficial, burrows will generally be found, and the heterogeneity of the secondary lesions will aid the diagnosis. In all these affections, the distribution is quite different from that of small-pox, the incidence being partial or patchy. Thus, in impetigo the lesions are frequently confined to the face and extremities, and if the trunk is invaded, it is the front more than the back, the lower part more than

Fig. 239.—Case of septic dermatitis wrongly diagnosed as small-pox. (Photo by Dr. D. S. Davies, M.O.H., Bristol.)

the upper. In scabies, except in children, the face escapes, and the commonest sites are the hands and fingers, buttocks, and feet.

In Ricketts' experience, no affection, except chicken-pox, is so frequently confused with small-pox as *acne vulgaris*, in spite of its chronic, afebrile character, and the absence of subjective symptoms. If, however, the rash is limited to the upper part of the body and a few characteristic *acne* lesions such as comedones are found, small-pox may be excluded.

I have seen copaliba eruption mistaken for small-pox. The absence of constitutional symptoms such as pain in the lumbar region and fever, the mixed character of the lesions, and the history are the chief points in the diagnosis.

It is seldom that bromide or iodide eruptions are mistaken for the rash of small-pox. In doubtful cases, attention must be paid to the larger size of the pustules, as compared with those of small-pox, and to the symmetrical or patchy distribution. *Malcolm Morris*.

PYREXIA, PROLONGED.—A pyrexia may be considered prolonged if it lasts more than ten days. In most cases, no doubt, there are signs and symptoms, or facts in the history, which enable one to make a diagnosis before this; but difficulties often arise from the absence of the distinctive characters of any one of the diseases commonly accompanied by such pyrexia. In most cases such a prolonged pyrexia is the result of one of the infectious diseases, and it is by a careful consideration of the more probable among these that one may often arrive at a definite opinion. The *general infections* most likely to give rise to a long-lasting fever are:—

Typhus fever	Meningitis	Malaria
Typhoid fever	Malignant endocarditis	Syphilis
Paratyphoid fever	Septicæmia from deep-seated foci of disease, such as:	Bacillæmia
Mediterranean fever	Empyema, Cerebral abscess, Pylephlebitis, or other form of suppuration	Bronchopneumonia.
Influenza		
Tuberculosis		

A high temperature of very long duration occurs often in connection with *diseases of the blood and blood-forming organs*, such as:—

Addison's anemia	Leukæmia	Hodgkin's disease.
------------------	----------	--------------------

It also occurs much more often than has been commonly supposed in *sarcoma* and *carcinoma* of different organs, and has been observed in *cirrhosis of the liver*. There are two other forms of pyrexia which should be borne in mind, namely, a *prolonged pyrexia occurring in children*, often very difficult to explain; and so-called *neurotic pyrexias*.

Modern research has a tendency to rely upon its own methods alone, and to ignore the older clinical differences. But this involves a separate investigation for each disease as it comes to be considered; and thus it may happen that one patient may have to undergo, in addition to a thorough bedside examination of all his organs, a lumbar puncture, and the removal of blood for the Widal test or for the cultivation of organisms: and these may have to be repeated. A full knowledge of the history of the illness, of exposure to infection, and of the clinical changes as far as they are manifested, is desirable in order that the researches of the bacteriologist may be directed as early as possible into the right path.

Typhus.—On the score of prolonged pyrexia (*Fig. 268*, p. 638, and *Fig. 269*, p. 639) little need be said of this fever. The eruption is generally distinctive, and shows itself before the fever has attained any duration; but it is capable of being confounded with typhoid fever, and even with malignant endocarditis. The distinction from typhoid fever is given elsewhere; and a confusion with malignant endocarditis is only possible if the latter should produce a very uniformly distributed petechial eruption over the skin while the cardiac murmur is of slight intensity; or if a person already the subject of cardiac murmur should contract typhus, and have an ill-defined eruption. In either case, if the pyrexia were prolonged beyond the twelfth or fourteenth day, typhus would be unlikely.

Influenza.—In most cases of influenza uncomplicated by definite visceral changes, such as pneumonia or gastro-enteritis, the fever is of short duration, but it is often as long as a week or ten days, and sometimes three weeks or more (*Fig. 240*). The longer period,

accompanied as the fever is by few distinctive signs, is sufficient to lead to a confusion with typhoid fever, tuberculosis, or malignant endocarditis, either of which may proceed for two or three weeks, and the last two for many more weeks, without distinctive clinical signs. The constant presence of influenza amongst us, and the great variety in the characters it assumes, make it very difficult to exclude it until positive signs of another complaint have manifested themselves. Equally difficult, however, is it to prove the existence of the disease, since the organism, Pfeiffer's bacillus, is not found easily in the blood; and in the prolonged cases, the rather striking peculiarities of the intense acute attacks, such as severe pain in the head and back of the eye, and in the lumbar region, may be absent. The diagnosis can often be made positively only *via exclusionis*, when the bacteriological tests of typhoid fever and tuberculosis have failed, and if there is an entire absence of rose spots, diarrhoea, or enlarged spleen on the one hand, or of pulmonary symptoms on the other. Especially must we bear in mind that an apparent attack of influenza may only be the pyrexial equivalent of early tuberculous infection, and if at any time during the illness sputum is available, it should be examined for tubercle bacilli.

Fig. 240.—Temperature chart in a prolonged case of influenza in which the pyrexia lasted a month; the diagnosis was confirmed by bacteriological detection of Pfeiffer's influenza bacilli. The case was complicated by influenzal otitis media and transient cardiac bruits.

Typhoid Fever should be comparatively easy to diagnose in the present day. A fever commencing with frontal headache, perhaps with diarrhoea, generally compelling the patient to lie up in bed by the end of the first week, and showing within the first ten days rose spots on the abdomen and a slight enlargement of the spleen, while at that time the temperature is 101° F. or 102° F. in the morning, and 103° F. or more in the evening, and the pulse is relatively slow, namely from 80 to 100 in the minute, should be typhoid fever. The Widal reaction, that is, the agglutination of typhoid bacilli by the patient's blood serum, becomes positive about the tenth or twelfth day. All these signs may fail for a time: spots may be absent, the bowels may be persistently constipated, enlargement of the spleen may be difficult to prove, the Widal test may and often does fail. Examinations of the feces for Eberth's bacillus are not easy; but cultivation of the bacillus from the blood taken from the patient's vein may yield the bacillus, and this at an earlier date than the Widal reaction can be obtained. Apart from such cultivation, the appearance of rose spots from the sixth to the tenth day, with additions to their number every day for five or six days, forms perhaps the most conclusive evidence of typhoid fever; and the diagnosis based on these grounds should not be upset by one or two failures to get a positive reaction with the Widal test. This test may require to be made with two or more strains of Eberth's bacillus, and failing them, paratyphoid bacilli should be used. A positive Widal reaction in a case otherwise unlike typhoid fever must be accepted with caution. If a case is devoid of spots, and gives no Widal reaction, the probability of its being typhoid fever might be asserted from its mode of onset, a characteristic chart of temperature (Fig. 241), with high readings morning and evening in the middle of the second week, and ending in twenty to twenty-five days after wide oscillations; and finally, a pulse always under 100. On the other hand, a pulse of more than 100 does not exclude typhoid, as it is common enough in the severe adynamic forms. Typhoid fever may be confounded

with many acute diseases: as a prolonged pyrexia it is especially pulmonary tuberculosis, malignant endocarditis, a long-lasting influenza, septicæmic processes, and occasionally tuberculous meningitis which will give difficulty.

Fig. 241. Temperature chart of a case of typhoid fever.

Paratyphoid Fever. Of this it need only be said that it presents the features of a benign typhoid fever, in which all the distinctive characters are less marked. Like typhoid, it may be confounded with a mild long influenza, or with early tuberculosis. Its recognition depends ultimately upon the agglutination of paratyphoid bacilli by the patient's blood serum.

Fig. 242. Temperature chart of a case of Mediterranean fever of undulant type.

Mediterranean Fever is one of the most prolonged of the fevers due to one recognized micro-organism: for in the undulant form of the disease successive exacerbations of pyrexia may carry on the illness into the fifteenth or sixteenth week (Fig. 242). It

resembles typhoid fever closely, including the enlargement of the spleen, but is proved to be due to infection with *Micrococcus melitensis*, conveyed, almost invariably, in goat's milk. In British practice its occurrence is unlikely, except in one who has been in the parts of the world where it is rife—namely, the Mediterranean coast and islands, whence it has found its way into Spain, Portugal, and other countries, and even to such distant parts as South Africa. It differs from typhoid fever in the absence of spots and of characteristic diarrhoea, but as these often fail in typhoid fever the distinction is not always available. However, the diagnosis can generally be made by the Widal test, since the blood serum will agglutinate the *Micrococcus melitensis* as early as the fifth day of the disease.

Tuberculosis.—The onset of general miliary tuberculosis, or of miliary tuberculosis of the lung, has often for its only symptom a moderate pyrexia, with accompanying physical weakness and anorexia. Such a condition may continue for weeks without any other sign; the breathing need not be quickened, and there may be an entire absence of abnormal signs in the lungs. The morning temperature is frequently near the normal, while the evening temperature alone is high; and it does not as a rule increase to a maximum and subsequently fall, so as to form the curve which is characteristic of typhoid, but continues nearly at the same level for long periods. In the absence of sputum the detection of tubercle bacilli is not available. Tuberculin tests may, however, be tried, and will probably give positive results. Of these the most suitable is the cutaneous tuberculin test of von Pirquet (*Plate XXXVII*, p. 768). Tuberculous infection in other localities may equally, when not accompanied by striking local signs, and only presenting the pyrexia, be taken for typhoid fever: for instance, tuberculous disease of the kidney, or pyelitis, and especially tuberculous meningitis. Headache and fever occur both in this and in typhoid and may be for a time the only facts in the case, until in the one case spots or loose motions assert themselves, or, in the other, optic neuritis, convulsions, paralysis, or retracted abdomen point to a cerebral localization.

Meningitis.—The duration of a tuberculous meningitis is often three or four weeks, during which there is pyrexia of moderate, or occasionally of severe type. In the sporadic, infantile form of cerebrospinal meningitis, first described as posterior basal meningitis, the fever is often prolonged for five, six, or more weeks. The continuous temperature is not generally very high, but in some cases there are sudden rises to 103° and 104°, followed by a fall to the normal within a few hours (*Fig. 253*, p. 591). These rises of temperature may occur daily, or every other day, or more frequently. As, in meningitis, by the time the pyrexia has become prolonged the cerebral symptoms, such as drowsiness, coma, and retracted head, are usually pronounced, there is not much difficulty in locating the disease in the meninges. To determine whether the inflammation is tuberculous or meningococcal or of other bacterial origin may require a lumbar puncture (p. 304) or blood culture.

Infective or Malignant Endocarditis may be mentioned next, because for days, weeks, or months the only prominent feature may be a continuous pyrexia with evening rises to 101° F., falling in the morning to 99° or 98·4° F. (*Fig. 243*). In most cases a cardiac murmur is present, and then one may, after a certain lapse of time, such as fourteen days, and

Fig. 243.—Temperature chart of a case of malignant endocarditis.

excluding the possibility of typhoid fever, often make a diagnosis with confidence. This is confirmed by the occurrence of other symptoms mentioned on p. 31. An attempt should be made to obtain an organism from the blood by cultivation, but it is not always successful. In the early stages the difficulty is not uncommonly increased by the fact that no murmur can be heard, in spite of the fact that endocardial changes are present. The course of some of these cases of infective endocarditis, which may be called chronic,

is remarkably prolonged, sometimes for six, eight, or twelve months, with little variations in the accompanying conditions. Long before that, of course, typhoid fever and tuberculosis would have been excluded: and after eight or ten weeks the co-existence of cardiac murmur, with uniform prolonged pyrexia, would make the diagnosis certain. Cases in which the brunt of the disease falls upon the brain may actually have meningitis, as in pneumococcal cases; or they may be mistaken for meningitis, or for typhoid fever, or, if petechiæ are present, for typhus. But in such instances the illness is generally a short one, and it would scarcely come into the present category.

Septicæmia.—In any prolonged pyrexia the possibility of a focus of deep-seated suppuration should be considered. In many situations the focus causes pain which at once directs attention to the origin of the trouble; but in some cases pain is absent, and foci in some situations are habitually painless. The disorders to be thought of are *otitis*, *abscesses in the throat*, a *small empyema*, *cerebral abscess*, *deep-seated glandular suppuration*, *suppurative pylephlebitis*, *appendicitis*, *pelvic suppurations* in women, and *umbilical lesions* in the new-born infant. If the blood shows a leucocytosis this will be in favour of a suppurating centre. At any rate, it will exclude typhoid and miliary tuberculosis. Each possible centre of infection must be called to mind, and the locality concerned must be

Fig. 214. Temperature chart of a case of pyæmia, secondary to otitis media and lateral sinus thrombosis. There was a rigor almost daily.

investigated. Suppurative pylephlebitis, in spite of the extent of the lesions and the size of the organ concerned, has frequently been overlooked, and has been mistaken for typhoid fever, pneumonia, peritonitis, or appendicitis. It is relatively rare, but it is a sequel of other suppurative lesions in the abdomen, and should therefore be thought of when appendicitis or other similar affection has been under treatment. Rigors are very inconstant in diseases of this class: if they occur they compel attention to the possibility of pyogenic centres (Fig. 214); but their absence must not be allowed to influence one in the contrary sense. They are most constant in visceral pyæmia, but this illness is not generally prolonged. In some cases the organism is only discovered after repeated cultural examination of the blood, the urine, or even the cerebrospinal fluid, and it may be found to be some rarity such as the *glanders bacillus* or a *leptothrix bacillus*.

Erysipelas, though generally of short duration, sometimes causes pyrexia lasting more than a fortnight (Fig. 215).

Syphilis.—Like other infections, this has its fevers, both in the secondary stage—that is, the stage of generalization of the infection—and in the late stages accompanying

gummata and other local processes. The secondary fever is certainly not present to a marked degree in most cases; a little feverishness there may be, but it scarcely requires special mention. Only occasionally is there a really prolonged pyrexia, with decided evening elevations of temperature. The diagnosis is rarely in question, because the fever only accompanies the rash and sore throat; and the origin in a local infection is generally well known. The same help may be with us in the fever attending gumma-formation; but if the gumma is deep-seated in a viscus such as the liver, even though it should be painful, and recognized by palpation as an abnormal enlargement or thickening, some hesitation may be felt as to the diagnosis unless it is remembered that such pyrexia may be present. Moreover, a pyrexia of this kind has occurred in connection with the lesions of the inherited disease. Syphilitic pyrexia is frequently of decided character, with evening elevations to 103° F. or more, and morning falls nearly to normal, until stopped, as it may be at once, by the administration of potassium iodide. In both these cases the Wassermann reaction is available to make certain the nature of the infection.

Bronchopneumonia.—This may be mentioned because it has sometimes a duration of many weeks, and during the whole time an oscillating temperature is present. The local signs are, however, sufficient to explain the presence of fever, and the difficulty lies only in the fact that a general pulmonary tuberculosis may resemble almost exactly the more curable bronchopneumonia of pneumococcal or streptococcal origin.

Fig. 215.—Temperature chart of a case of facial erysipelas following a septic scratch.

Malaria.—Important as is this disease, its diagnosis may be dealt with briefly here. The non-malignant quartan and tertian fevers produce isolated pyrexias of short duration (*Fig. 6, p. 28, and Fig. 7, p. 29*) which do not come within the scope of this paper. It is only the malignant or subtertian fevers, which do not arise in this country, and are little likely to be seen in other than regions known to be malarious, which cause prolonged continuous pyrexia (*Fig. 11, p. 31*). The diagnosis is based upon a consideration of the symptoms, upon the discovery of the parasite, and upon the results of treatment with quinine. The symptoms chill, fever, and sweating have less value in a continuous pyrexia than in the simple tertian and quartan fevers, and in a quotidian fever the resemblance to septic poisoning is well recognized. An enlarged spleen is present in malaria, but also commonly in typhoid fever. Most reliance is to be placed upon a microscopical examination of blood-films coloured with Romanowsky's or Leishman's stain; for in cases of pernicious malaria, it is rarely that the organisms (*Plate XXI, Fig. E, p. 614*) fail to be discovered by this means. Absence of leucocytosis and an increase of the large mononuclears to 15 per cent in a differential count of the leucocytes in the blood, are also in favour of malaria, at least in the first two weeks; after which the results may be very similar in typhoid fever. The third test is the administration of quinine, which, given in sufficient quantity, will stop malaria; and

on the other hand, if the fever continues in spite of it, malaria is excluded. An adequate dose for this purpose is 3 or 4 gr. every three hours, day and night, for two or three days.

Bacilluria. This is usually due to infection of the urinary passages with *Bacillus coli communis*. The symptoms may be slight or they may be those of cystitis or pyelitis in a marked degree (see BACTERIURIA, p. 69): with these there is a more or less continuous pyrexia (Fig. 193, p. 456). Especially in infants they may be few, or none at all other than the pyrexia, which is variable in degree, generally irregular from day to day, may be accompanied by chills and sweating, and may last several weeks. Hence in an obscure fever in infants the urine should be examined carefully.

Anæmia. The several forms of pernicious, idiopathic, or Addisonian anæmia are frequently accompanied by a moderate degree of pyrexia, which may persist for many weeks (Fig. 246). Such an anæmia might be the manifestation of tuberculosis, of infective endocarditis, or of malignant growths: but an examination of the blood with the discovery of poikilocytosis and a colour-index above unity, the lemon-yellow tint of the skin in some

Fig. 246.—Characteristic temperature chart of a case of pernicious anemia.

cases, and the history, will generally determine the diagnosis, though the differentiation of the particular form of anæmia may still remain to be considered (see ANÆMIA, p. 20).

Hodgkin's Disease. In some, but by no means all, cases of this disease, a very remarkable form of pyrexia occurs. It consists of alternating periods of pyrexia and apyrexia, each of eight, ten, or twelve days' duration, lasting in all for six, nine, or twelve months. During the pyrexial period the temperature, beginning near the normal, becomes day by day higher and higher, till on the fourth or fifth evening it reaches 102° F., or 103° F., its highest point: it gradually declines during the next four or five days to the normal; and then for three or four days it becomes increasingly subnormal till a minimum is reached, and from this point there is a gradual return to the normal, when a second pyrexial curve begins (Fig. 247). If the cervical, axillary, or inguinal lymph-glands, apart from or in company with the spleen, are enlarged, and the condition of the blood is normal or of the simple chlorotic type, the diagnosis of Hodgkin's disease is safely made. If such a temperature is observed without any enlargement of the spleen or of the external glands, a lymphadenomatous enlargement of the internal glands, bronchial or mediastinal, should

be suspected, and endeavours should be made to demonstrate them by palpation, percussion, or x-rays. Leucocytosis should be absent; but its occurrence in a late stage of the pyrexia would not militate against the diagnosis.

Fig. 247.—Temperature chart of a case of Hodgkin's disease.

Leukæmia.—Pyrexia is a common occurrence in the different forms of leukæmia. As a rule the great size of the spleen in one group of cases leads to an easy diagnosis, and in another group the glands are manifestly enlarged, though acute cases occur in which these changes do not appear early; in all these forms an examination of the blood will show the excessive number of leucocytes, of one or other variety (p. 24), a sufficient explanation of the occurrence of pyrexia.

Fig. 248.—Temperature chart of a case of sarcoma of the neck and mediastinum.

New Growths.—New growths are not accompanied by pyrexia as a rule; but many exceptions have been recorded, in regard both to sarcoma and to carcinoma. A case of sarcoma of the neck and mediastinum was accompanied for the four months preceding death by a pyrexia resembling in its variations from week to week that of Hodgkin's disease (Fig. 248), and carcinoma has now frequently been known to be accompanied for weeks or months by fever, especially where there are secondary deposits in the liver (p. 326). The diagnosis is not generally difficult; the tumour is in evidence. A point of importance is that the pyrexia does not help to distinguish between syphilis and cancer.

Cirrhosis of the Liver.—The diagnostic relations of pyrexia in cirrhosis of the liver are on the same footing. It occurs in some cases (Fig. 167, p. 374) and is apparently due to cirrhosis; perhaps because it is an inflammatory process, or because the cirrhosis is due to a toxæmia which may raise the temperature. The fact is of interest when we consider that ascites due to hepatic cirrhosis has often been mistaken for tuberculous peritonitis, and, perhaps less often, tuberculous peritonitis for cirrhosis. The absence of pyrexia might possibly be held to exclude tuberculous peritonitis, but its presence would leave the diagnosis open, since it might be due to either.

The curious pyrexial outbursts in *rat-bite fever* are described on p. 598, and the long-continued low fever of *pellagra* on p. 225.

Neurotic Pyrexia.—This term may be applied to two classes of case: in one the mercury is found at extraordinarily high levels at irregular intervals, often at different levels in different parts of the body, and falling again rapidly to the normal. This may be repeated many days, but hardly constitutes prolonged pyrexia. In the second variety the patient has a genuine pyrexia, lasting two, three, or more weeks, irregular in the elevations reached on successive days, but on the whole resembling the pyrexia of sepsis.

These cases are more often females, and the fever may be associated with symptoms referable to the pelvic organs, or may persist after the entire subsidence of such symptoms, so that skilled obstetric physicians have been unable to find any active local lesion. The neurotic origin of such cases may be open to doubt, but it is supported by the variability of the pyrexia, and by its occasional rapid cessation without adequate explanation, and without any local change. The diagnosis can only be made as a rule *in exclusionis*, and must always be considered provisional as long as there is any probability of an adequate cause being found.

The Unexplained Pyrexia of Children.—This form of pyrexia is in a somewhat similar position to the above. All students of disease in children are familiar with the fact that in patients under nine or ten years of age a mild pyrexia may occur, lasting two, three, or four months, for which no explanation can be found. Since it arises in quite young subjects, a neurotic origin is not so readily suggested, nor so likely, as in the adult female, and yet it is possible that some cases are of this nature. Tuberculosis should be considered carefully, but is often safely and rightly excluded. Gastro-intestinal disturbance, such as constipation; the unsuitable nature of the food; and acute intoxication from the alimentary canal, are other possible explanations of some cases. Since the prognosis is good, it is satisfactory to be able to recognize the clinical condition, even though the causation is obscure; but the diagnosis can only be established after careful exclusion of typhoid fever, tuberculosis, and local inflammatory conditions such as otitis, bacilluria, and other definite lesions or infections.

Frederick Taylor.

PYREXIA WITHOUT OBVIOUS CAUSE. From researches carried out in trying to ascertain the mechanism by which the body maintains in health an average temperature (practically constant) of 98.4 F., and the factors that lead in disease, and also even in health, to a departure from that temperature, a number of general principles have been established, and these must be grasped before we can form a just estimate of the value of the reading of the thermometer in diagnosis. We must briefly state the more important of these without discussion.

1. *Sources of the Actual Production of Heat in Health* in order of importance: (a) Muscles at work; (b) Glands at work; (c) All minor tissues in which katabolic changes are proceeding.

2. *Provisions for the Escape of Heat.* (a) Temperature changes in the air, especially that expired; (b) Escape by the skin, radiation, and evaporation of sweat; (c) Escape by urine and faeces; (d) Warming of food, and anabolic tissue changes.

3. *Mechanisms for Regulating the Distribution of Heat generated Locally.* (a) A main centre for regulating the distribution of the blood, situated in the medulla; (b) Subsidiary centres for the same purpose situated in the cord and (?) elsewhere; (c) The physical properties of the blood, lymph, and tissue juices as regards their circulatory movements and their capacity for absorbing and retaining heat.

These three belong to the province of pure experimental physiology and physics; we have, then, the further observations shared by physiology and clinical medicine:

4. That the temperature in perfect health can be raised considerably (at least to 102 F. Hill) by strenuous physical exertion; such elevations disappear very rapidly, possibly with small oscillations.

5. That in exhaustion from violent effort or exposure (generally both, as in shipwrecks and similar accidents) the temperature can be, and is, very dangerously depressed, this being possibly the sole cause of death.

6. That in every form of microbe invasion of the body, the temperature may be altered. This alteration may be produced in several conceivable ways, e.g., by the direct action of the microbes or their poisons on the seats of the production of heat or on the centres regulating its distribution, or again by the action of the same poisons or microbes on the main sources of loss of heat. The exact and precise cause is very obscure, though extremely interesting to the pathologist.

Lastly, as purely clinical observations we have learnt:

7. That in order that variations in temperature may kill, or indeed of themselves be of very serious import, they need to be very extreme (say 6 or 7 degrees above or below normal) or else very prolonged, the necessary duration varying with the degree of departure from the normal.

8. That in the wards of a hospital where the temperatures are taken and charted at regular intervals, it is scarcely possible to find a chart of chronic disease which does not show some oscillations in temperature, the causes of which are obscure or overlooked.

From these general propositions we may pass to the practical value of thermometric observations in diagnosis. We may again generalize, and say, that standing alone as a primary and isolated observation, the fact of a disturbance in temperature is of little use; but when this observation is controlled by other factors in diagnosis, and we have made a complete diagnosis of a given disease, we are then in the position of knowing by experience approximately the course of the temperature for that disease, and we shall get many useful hints from the thermometer as to complications or the severity of the attack: a point to which we shall refer presently. Hence, it is useful in our present discussion to divide all patients into two main groups: (1) *Those who are well enough to visit their doctor*, and (2) *Those who are too ill to do so*.

Patients who are well enough to visit their doctor. Unless some special complaint or physical sign soon leads to satisfactory diagnosis, let it be an accepted rule to take the temperature: by doing so we shall not infrequently discover, early, a disease which we might otherwise have overlooked until something or some one else had drawn attention to it, greatly to our discomfiture and loss of credit. The three most typical illustrations of this position are perhaps *typhoid*, *phthisis*, and a condition which in our haste we label '*Influenza*.'

A headache lasting four or five days and associated with some degree of pyrexia, is, even standing alone, so suspicious of the first, that the patient must be ordered to bed to be watched. A nasty dry cough, with general anæmia, weakness, tiredness, and malaise, makes us very suspicious of the second, especially if there is also the slightest alteration in the breath sounds anywhere. The third is the recently developed refuge of the diagnostically destitute: it leads to much mortification when suppurating gums or tonsils, gonorrhœal discharges, decomposing urine, or other critical points are discovered later: a position which may be avoided by examining all easily accessible orifices, and if the mouth, throat, and nose all seem healthy, by labelling the trouble fever of uncertain origin, and ordering the patient to bed. In fact, if on examining the patient in the consulting-room no cause for the pyrexia is apparent, I would lay down as a golden rule—*Remove the patient at once from Group 1 and place him in Group 2* for further critical examination of his or her person, blood, and excreta.

Patients who request their doctor to visit them.—It must be admitted that in this group also, pyrexia by itself is not a very strong diagnostic point, for *ex hypothesi* the other symptoms are of considerable severity and importance, and therefore point pretty strongly in some diagnostic direction. Our residuum from Group 1, with a certain proportion of individuals originally in Group 2, will, however, together make up a by no means negligible number of patients in whom the cause of pyrexia is obscure to an ordinary examination. Here it is the first rule to examine systematically every orifice of the body for a possible source of trouble: gums, and especially the roots of the teeth for pyorrhœa, ears, nose, throat, vagina, rectum, and urethra; should all these prove healthy, the fingers and toes must be inspected for overlooked sores; and the bones near joints investigated for a possible osteomyelitis.

The Blood.—It is by now almost certain that some clue will have been obtained, but should none have appeared (in some cases even when a complete diagnosis has been made) we must now proceed to have the blood examined by the best available scientific methods; we may by this means prove that the blood itself is at fault, or that it contains some microbes, thus:—

1. *Leucocytosis* suggests leucocythæmia perhaps, in which disease outbreaks of pyrexia are not uncommon: or some obscure focus of suppuration; or perhaps it proves that an obvious focus requires the surgeon's assistance; or per contra, it provides a slight argument against typhoid or tubercle, and in favour of gross parasitic worms.

2. *Poikilocytosis* suggests a severe anæmia, which, like leucocythæmia, is known to have pyrexial periods.

3. *Widal's Test*, if positive, practically proves the presence of typhoid.

4. *Cultivation* of it may prove a microbial invasion, the name and nature of the invader, and possibly the point of invasion.

5. *Microparasites* of protozoal form (malarial or other) may be recognized in the blood under the microscope.

The Urine may be found to be thick or decomposed, and thus give a clue to tubercle of the genito-urinary tract, to calculous trouble, or to *B. coli communis* invasion. It is well to remember that *B. coli* may exist in what otherwise appears to be a healthy urine (p. 12).

The Fæces may yield information: melæna, fatty stools, gall-stones, or even eggs of parasites may be found, thus clearing up the cause of an obscure pyrexia.

Tests such as Calmette's or von Pirquet's may be tried for *latent tubercle*, but the dropping of tuberculin into an eye is not without its own risks, and in my opinion had better be avoided, especially as by the time tubercle has caused pyrexia it has probably advanced so far as to be discoverable by careful physical examination of the chest. Moreover, the test is alleged to be so delicate as to discover obsolete tubercle, which is not the cause of the pyrexia, and so may lead one astray.

When physical examination, clinical methods of investigating secretions and excretions, and bacteriological aids have thus all been exhausted, there will still remain a few rare cases in which the cause of the pyrexia is undiscoverable. These are chiefly abdominal: thus gall-stones and their complications, pylephlebitis, ovarian abscess, and deep-seated phlebitis have all presented instances to the writer; but he knows of no rules by which such cases can be discovered: time or an autopsy can alone clear them up. Apart, however, from such obscurities, there still remain some interesting and useful observations to be made on certain clinical thermometric measurements.

PYREXIA OR SUBNORMAL TEMPERATURES IN CHILDREN.

In children we know that the heat-regulating function, like other nervous mechanisms, takes time to develop proper and complete connections with, and control over, subordinate centres of regulation, whether these be foci of production or surfaces of loss: hence we are not surprised, still less alarmed, at temperatures above normal in children which in adults may have a very different significance. It is rather the reverse with those below normal, because we know that the growing child requires very large supplies of heat to carry on the anabolic functions of growth and development.

Subnormal Temperature. Suppose we find a child in this condition, the immediate diagnosis is great exhaustion: such temperatures are generally found in marasmic children who have been starved, or its equivalent, i.e., badly fed, or exposed. Subnormal temperatures are also found in summer diarrhoea, or sometimes in conditions associated with intense pain: also, at an interval after convulsions (not immediately), and in many other conditions, the differential diagnosis of which will generally be obvious.

Pyrexia, on the other hand, owns an infinity of causes, of which we can only glance at a few which may give rise to trouble in diagnosis.

Excitement. In children's wards, visiting day almost invariably causes a plentiful crop of high temperatures, even as much as 103° F., and the private practitioner has to remember this when a loving aunt or an injudicious visitor of any sort has come in contact with his little patient at home. A bad night may easily send the temperature up to any height.

Febriçula. This is merely a Latin name for the fact of pyrexia, but before using the term let every system be examined carefully for signs of disease. It may be that there is absolutely nothing else wrong. The following is a useful and ordinary average clinical rule: for each 1° F. the temperature rises we may expect the pulse to increase in frequency 10 beats (or in children 15) per minute, and the respirations 2 to 3 per minute, and if this ratio is maintained it is fairly safe to say that heart and lungs are neither of them specially threatened, and hence, *if there be nothing else to attract attention*, it is safe to say that the child is certainly feverish, and we must nurse and watch it. I have known a delicate boy of 9 or 10 thus to have a temperature of 102.5° to 103.5° for three or four days at a time for no reason that I could ever detect: he ate well, slept well, and felt well; and this aspect of affairs should be remembered. On the other hand, such temporary attacks of pyrexia may be aroused by the presence of some micro-organisms which have hitherto escaped detection, but *quâ* the pyrexia in itself nothing more can be said. Deep-seated tubercle, perhaps in internal lymphatic glands, may be suspected, but it will often be exceedingly difficult to settle the diagnosis.

Convulsions.—These must be remembered as a possible cause of a temperature of even 103° F. if the thermometer be used at once.

Specific Zymotic Diseases.—On discovering a child with fever, suspicion will naturally be aroused that one of these troubles is at hand. The only thing to be said here is: Do not attempt to give a diagnosis on the thermometer alone: the temperature is raised long before a diagnosis is possible. It is well to note that a temperature of 102° F. only, or less, is a point in favour of diphtheria against a tonsillitis of other causation, which frequently has a pyrexia of 104° F. or 105° F. Slight pyrexia, with headache and vomiting, makes us suspect tuberculous meningitis, whereas a temperature of 103° F. or 104° F. with similar associations renders pneumonia probable.

IN CHILDREN AND ADULTS.

Here we may draw attention to some of those cases in which the fever of known average departs from its usual course.

Empyema.—Suggested by the crisis of a pneumonia followed in a few days by intermittent or remittent fever (*Fig. 71, p. 160*).

Endocarditis.—Suggested in rheumatism by a temperature of 100° F. to 100.5° F. or 101° F. following the initial fall from the administration of salicylates; though the absence of such pyrexia does not exclude the existence either of endocarditis or of pericarditis.

Hyperpyrexia.—Met with in rheumatism, typhoid, and other septic conditions: its onset is easy to detect in the latter conditions: in the former, restlessness with less complaint of pain may cause suspicion. The diagnosis must be confirmed by a frequency of registration proportionate to the severity of the initial observation: two-hourly, hourly, or even quarter-hourly observations may be necessary, that treatment may be controlled.

In addition to such obvious causes, it must be remembered that in cerebral diseases and injuries of almost any kind, the temperature may rise to most unusual heights: one over 103° F. almost certainly heralds a fatal event; the same is sometimes found in uræmia.

Attention may be drawn to the fact that *malaria* is not quite extinct in England, and a regular succession of pyrexial attacks at the same time of day suggests this cause.

Sudden Drops in Temperature.—These are met with in many diseases at times, e.g., typhoid, and the patient must be examined carefully for other suggestive factors—blanching, severe abdominal pain, etc., indicative of hæmorrhage, perforation, or other complication. Do not forget that the crisis in pneumonia is a great deal more of a crisis for the patient than it is for his microbes, and be ready with the appropriate stimulants.

Pyrexia and Malignant Disease.—When the nature of a swelling in the liver or elsewhere is being considered, the discovery of a temperature hovering about 101° F., or even higher, does not militate against a malignant growth, for these frequently give rise to pyrexia (*Fig. 145, p. 326*), and so, too, but more rarely, may cirrhosis of the liver (*Fig. 167, p. 371*).

In the differential diagnosis of *cerebral abscess* from *tumour* it must not be overlooked that a subnormal temperature, contrary to the usual rule of suppuration, suggests an abscess rather than tumour.

It is well to bear in mind that *after an operation*, a few degrees of pyrexia, even for forty-eight hours, are not a conclusive proof of infection of the wound.

When the source of a continued pyrexia is being sought for, the heart must be examined carefully every day, or even more frequently, for *infected endocarditis* is by no means an infrequent result of gonococcal and other microbial invasions which may be most difficult to detect.

Fred. J. Smith.

PYROSIS. —(See HEARTBURN, p. 296.)

PYURIA. Pus appears in the urine in all suppurative conditions affecting the urinary tract, and occasionally from the rupture of an extra-urinary abscess into the urinary apparatus. It may be present in large or in microscopic quantities; when in bulk it forms a thick, greyish, tenacious sediment, which must be distinguished from phosphates and from urates; urates are of a pinkish colour, and will be cleared by heating the specimen; phosphates will be dissolved by the addition of acid, whereas pus will remain unaltered by either test.

In alkaline urine, the pus cells tend to run together into a dense viscid deposit, leaving the upper layers of the urine slightly turbid. Microscopically each pus cell is multinuclear, rounded, and about twice the size of a red blood-disc. The contents are granular, but the addition of acid clears the cell and makes the nucleus stand out more distinctly. Urine containing pus will always contain at least some albumin and frequently epithelial cells from some part of the urinary tract. If the specimen containing pus be shaken gently with ozonic ether, a slight effervescence will be produced, or if mixed with liquor potassæ, aropy precipitation occurs.

It is impossible to determine the lesion producing pus in the urine simply by the examination of the latter. Due consideration must be given to the history and the other symptoms of any case, and particular care be taken not to lay too much emphasis upon any symptom which may point to a vesical lesion when in reality the trouble is in the kidney. This is perhaps most likely to occur in a hematogenous infection of the kidney by micro-organisms, in which increased frequency of micturition is a marked symptom, whilst the bladder remains quite free from disease. Occasionally, after pus has been present continuously in the urine for some time, it may disappear entirely, the change being accompanied by increase of pain in the side, by an elevation of temperature, or enlargement of the kidney in a case of pyonephrosis, when the obstruction to the flow of urine from that side has become temporarily complete. Very little help is derived from the character of epithelial cells accompanying pus in the urine. The shapes of the cells of the renal pelvis, ureter, and deeper layers of the bladder are so much alike, that it is usually impossible to differentiate them.

Some assistance in the determination of the origin of the pus in the urine may be gained by instrumental examination :

By Catheter. If a catheter be passed and the bladder washed out with clear solution of boric acid, it will be found that the medium is soon rendered clear if the pyuria is of renal origin, but that it is much more difficult to obtain a perfectly clear medium if the bladder is the seat of the suppuration. If the medium is cleared quickly, but yet, after some ten minutes' retention in the bladder is again found to be turbid, the pus is almost certainly descending from the kidney.

The Cystoscope. Much more certain evidence is gained, however, by a careful cystoscopic examination. By this means it can be determined in the great majority of cases if the bladder is infected or if any ulceration is present. In a few cases the bladder may be so affected that only a small dilatation is allowed, or bleeding is produced so easily that cystoscopy is rendered futile : in these cases there will be little need for an inspection of the bladder. If the bladder be found to be normal, evidence of a suppurative lesion in the kidney may be obtained from the appearance of the ureteric orifices or by the variations in the character of the urinary efflux from them. Instead of the normal forcible flow of

clear urine from each orifice, mixing with the medium in the bladder in a characteristic swirl, urine containing pus may be seen emitted, appearing in the field as a small smoky puff from the orifice (*Plate XI, Fig. B, p. 282*): pieces of muco-pus may be seen to pass from the orifice, or the turbid urine may be seen to leave the orifice in a gentle trickle instead of a jet if the renal secreting function is impaired or if renal dilatation is present.

Apart from the alterations in the urinary efflux from an orifice, the actual appearance of the orifice may show changes which indicate renal disease. Thus, in pyelitis, the margins of the orifice are slightly oedematous and congested, and appear to pour into the bladder (*Plate XI, Fig. C, p. 282*); the mucous membrane of the bladder, immediately below and internal to the orifice, is frequently congested or granular from the effect of the altered urinary flow upon it. If the renal pelvis and ureter are dilated, the orifice is usually elongated and patulous, whilst in tubercle or in diseases in which the ureter is thickened, the whole ureteric orifice is drawn upwards and outwards from its normal situation (*Plate XI, Fig. D, p. 282*), and is seen at the apex of a conical retracted area in the bladder base.

PYURIA CAUSED BY DISEASES OF THE URINARY ORGANS.

Renal Disease. *Diseases of inflammatory origin.*

Pyelitis and *pyelonephritis* may arise as an ascending infection from the lower urinary tract, especially when there is some obstruction to the normal passage of urine. Thus it is common in cases of prostatic enlargement and stricture. When cystitis is present, it is usually bilateral, although one kidney may show much more advanced disease than the other. Any growth or lesion in the bladder which is accompanied by suppurative infection, and which involves the ureteric orifice, such as vesical epithelioma, or the direct involvement of one or both ureters in the spread of uterine cancer, may set up pyelitis in the kidney, the infection ascending either by the ureter or by the peri-ureteric lymphatics.

In this group of cases the primary cause of the disease has usually advanced to a sufficiently late stage to be obvious, and the symptoms of suppurative ascending infection of the renal pelvis or renal tissues are usually overshadowed by the symptoms of the disease causing the obstruction. Aching in the loin, rigors or raised temperature, tenderness on deep palpation in the renal area, or actual renal enlargement, are usually indicative of renal infection. The urine is often increased in quantity, of low specific gravity, and the daily excretion of solids is lessened; the skin is dry and harsh and the tongue glazed.

Pyelitis and pyelonephritis may also arise as an infection of the kidney apart from any other disease in the genito-urinary organs. Infection is conveyed to the kidney by the blood-stream (haematogenous form), and is not uncommon in acute fevers, or with mild forms of suppuration in other parts of the body, or in association with pregnancy. In the less acute forms a pyelitis may result, as in typhoid fever, but in most cases the haematogenous infection produces first a suppurative process in the renal parenchyma, from which infection spreads to the calices and pelvis. This form of disease has been shown by recent work to be due most frequently to the colon bacillus in association with affections of the intestinal canal, less frequently to the staphylococcus, streptococcus, pneumococcus, typhoid bacillus, or *bacillus proteus*. The renal pyelitis which ensues when a calculus has ulcerated into the renal pelvis is truly a haematogenous infection.

Acute haematogenous infection of the renal pelvis without involvement of the renal parenchyma usually begins with slight rigors, tenderness in the loin, and increased frequency of micturition. The urine is faintly turbid and opalescent, does not settle to a pronounced sediment, but remains of a sheeny appearance. It contains numerous bacteria, a little pus, and a little albumin. When the infection first attacks the renal parenchyma as well as the pelvis, the symptoms are much more severe, and the patient may become uræmic rapidly. In the less acute cases, small foci of suppuration occur, which coalesce to form an *abscess*, with the general symptoms of suppuration. Renal abscess may also result from injury when an effusion of blood in the renal tissues becomes infected by pyogenic micro-organisms, or by the breaking down of a renal infarct.

Pyonephrosis—or dilatation of the pelvis and calices of the kidney with pus and urine—is caused when suppuration has occurred in a kidney which is at the same time subjected to some form of obstruction to the normal passage of urine. Pyonephrosis is caused most commonly by renal calculus or tuberculosis, but is by no means uncommon with a chronic cystitis, complicating urinary obstruction from an enlarged prostate or

stricture. Carcinomatous ulceration affecting a ureteric orifice, either primary in the bladder or by direct extension of uterine cancer, is also a comparatively common cause of pyonephrosis. In contradistinction to suppurative pyelonephritis, the symptoms of pyonephrosis are less severe: at first they are those of the obstructive lesion causing the disease, to which are added the general symptoms of suppuration. Pyonephrosis causes a renal tumour of variable size, whilst in the same patient distinct intermittence in size may be observed, a decrease being associated with the discharge of a larger amount of pus in the urine. In pyonephrosis due to calculous disease the urine may contain a large amount of pus, but there may be no lumbar pain suggesting a renal stone. In these cases a large calculus will usually be found in the renal pelvis, and will be shown on *x*-ray examination (*Fig. 133*, p. 279).

The urine in suppurative disease of the kidney and its pelvis requires careful examination. It may be normal with a localized cortical renal abscess or with closed pyonephrosis: in all other lesions it contains pus and micro-organisms. If the pus-cells are found in the form of casts of the renal tubules, infection of the renal parenchyma is present, whilst in this latter the albumin in the urine is in excess of that due to the pus present. Polyuria, with a diminution of the total solids of the urine in a daily examination, is commonly present in inflammatory lesions of the renal tissue.

Renal Tuberculosis.—The miliary form of tuberculosis occurs in children as part of a general dissemination of tubercle, and causes no urinary symptoms. The kidney is, however, attacked not infrequently by primary tuberculous infection, beginning as a unilateral deposit of small tuberculous nodules. These enlarge and coalesce to form a caseating area, which eventually opens into the renal pelvis by direct ulceration of a calyx to discharge its contents by the urine, when the lining membrane of the renal pelvis and ureter become infected with tubercle and thickened by submucous infiltration. At first, before ulceration into the renal pelvis has occurred, the symptoms of the disease are very slight: there may be aching pain in the loin and slight albuminuria, but as soon as the renal pelvis is involved, more marked symptoms occur—including persistent pyuria, lumbar aching, increased frequency of micturition, and polyuria. The urine is pale, of low specific gravity, and of opalescent turbidity: by careful examination after centrifuging, the tubercle bacillus is usually found. A small amount of blood is generally present. The increased frequency of micturition occurs before any descending vesical infection has occurred, and this symptom, accompanied by pyuria, has frequently given rise to a diagnosis of vesical disease. The occurrence in a young adult patient of persistent pyuria which is not due to gonorrhoea, injury, or stone, should always be looked upon with grave suspicion, and a careful search made for the tubercle bacillus: should this not be found by the microscope, inoculation experiments into guinea-pigs should be conducted. A careful examination of the bladder should also be made by the cystoscope, when early vesical tuberculosis may be seen (*Plate XI, Fig. E*, p. 282), or the characteristic changes in the ureteric orifice may show the presence of renal infection (*Plate XI, Fig. D*). By digital examination per rectum, the lower end of the ureter may be felt to be thickened and rigid in renal tuberculosis.

Renal tuberculosis is often confounded with *renal stone*, and the colic which is usually associated with stone may be present in tuberculosis if a piece of caseous debris be passed down the ureter. A skiagraphic shadow of a calculus shows well-defined margins (*Fig. 133*, p. 279), whereas a tuberculous focus in the kidney may give rise to a faint, blurred, indistinct shadow in the renal area (*Fig. 134*, p. 280). The presence of tubercle bacilli will, however, determine the existence of tuberculosis, whilst tuberculous lesions elsewhere in the body, most frequently in the testes, prostate, or vesiculae seminales, may also serve to confirm the diagnosis.

The symptoms of renal calculus vary with the position of the stone and the changes that have taken place in the kidney in consequence of its presence. It may be situated in the renal parenchyma, and cause no symptoms beyond lumbar aching: or in the renal pelvis, when, if movable, it may cause acute renal colic, due either to the attempted passage of the stone by the pelvic outlet or to the increased intrarenal pressure from blockage of the ureter. So long as the kidney remains aseptic the urine contains only a microscopic trace of blood: but if it becomes infected with micro-organisms, pyelitis, pyelonephritis, or pyonephrosis may result, with their attendant symptoms. Pus only occurs in the urine in a case of renal stone when infection of the kidney has occurred.

Ureteric Calculus.—A small renal calculus may become impacted during its passage along the ureter, and may cause some difficulty in diagnosis. The usual situations of the obstructed calculus are in the upper few inches of the ureter, at the pelvic brim, or at the vesical end of the tube; in most cases the previous history of renal colic and symptoms of renal stone will be sufficient to indicate its partial ureteric descent. A calculus may, however, be present in the upper end of the ureter or at the pelvic brim, and give very few symptoms beyond a fixed pain in the course of the ureter; in the latter situation it has frequently been mistaken for ovarian pain or for chronic appendicitis. If the stone blocks the ureter completely, the kidney of the same side—in the absence of septic infection—becomes functionless and atrophies; but if the calculus only partially occludes the lumen of the tube, renal distention will occur, with resulting uro- or pyo-nephrosis. If, however, the calculus becomes impacted in the vesical segment of the ureter, a train of symptoms occurs simulating vesical stone or vesical tuberculous; namely, increased frequency of micturition, penile pain following micturition, and often a small amount of blood and pus in the urine, in addition to the aching pain in the loin. A ureteric calculus impacted in this situation may often be felt in the ureter upon a rectal or vaginal examination; it may be demonstrated by the *x*-rays (*Fig.* 192, p. 455); whilst the changes seen around the ureteric orifice, and the absence of a vesical lesion on cystoscopic examination, will confirm the diagnosis.

Vesical Diseases.—Pyuria may occur in any lesion of the bladder which is associated with inflammatory changes. The fact that urine is retained in the bladder renders the latter much more liable to septic infection, so that cystitis is common with urethral stricture or prostatic obstruction. Any ulceration of the bladder, tuberculous or malignant, is also accompanied by inflammatory changes, when pus will be present in the urine.

Cystitis may be acute or chronic, and the essential factor of either form is the infection of the bladder by some micro-organism; any agent which produces either congestion of the bladder or retention of urine, acts as a predisposing cause.

With *acute cystitis* the mucous membrane of the bladder becomes œdematous and highly congested, and epithelial desquamation and formation of pus rapidly follow. Hemorrhage may occur from the congested mucosa, or small abscesses develop in it and rupture into the bladder, to leave small areas of ulceration. In severe cases, patches of the mucous membrane may become gangrenous. The symptoms of acute cystitis are usually distinctive: frequent and painful micturition, elevation of temperature, pain in the perineum and suprapubic area, with the presence of pus and blood in the urine, which is commonly of an acid reaction. Usually, some distinct cause for the onset of acute cystitis is apparent, such as some form of acute urethritis or of previous instrumentation, and there is little difficulty in the diagnosis. The same symptoms are, however, produced by an acute inflammation of the prostate which, in nearly all cases, is preceded by acute urethritis; the presence of swelling of the gland, and acute pain on rectal palpation, will determine the presence of prostatic inflammation.

Chronic cystitis may succeed acute. The symptoms are less marked, but increased frequency of micturition is always present. The urine is alkaline, contains pus and mucus, and the disease is commonly associated with some form of urinary obstruction, or with retention or incontinence due to some nervous disease, such as tabes dorsalis or transverse myelitis. The possibility of retroversion of a gravid uterus should not be overlooked. The association of pyuria and increased frequency of micturition, which is present in chronic cystitis, must be distinguished carefully from that due to pyelitis or pyelonephritis, for increased frequency of micturition may be present without any vesical infection. In renal pyelitis, the urine is usually acid in reaction, pale in colour, and shows a general turbidity, with little inclination towards a deposit at the bottom of a specimen. The urine of chronic cystitis is alkaline, and rapidly deposits a greyish sediment of pus. In pyelitis and pyelonephritis, the urine contains more albumin than the pus would account for, and on microscopic examination renal or pus casts are frequently found, whereas in cystitis the albumin is less, and vesical cellular elements are present, without casts unless the kidneys are affected also. Further evidence may be obtained by the use of the *cystoscope*. In cystitis the bladder wall is trabeculated and the mucous membrane thickened; it has lost the normal iridescent appearance, and the vessels of the mucous membrane are obscured. With pyelitis, the bladder wall is normal, but the ureteric orifice of the affected side shows

the thickened or pouting lips and slightly raised area of thickened mucous membrane whilst the urine flowing from the orifice may be seen to be turbid or to contain small particles of mucus-pus.

Chronic cystitis may be simulated by an inflammation of the posterior urethra. In such a case there is almost always a history of urethral infection, and the diagnosis can be made by urethral irrigation. The patient is directed to retain his urine for some three hours, and after irrigating the anterior urethra as far as the compressor muscle with sterile water or boric acid lotion, the urine is passed into two glasses. With posterior urethritis, the urine contained in the first specimen will contain shreds of mucus-pus, whilst that of the second specimen is clear; whereas, with cystitis, the second specimen will be as turbid as, or even more turbid than, the first.

Tuberculous cystitis occurs usually in young adults. The characteristic symptoms are increased frequency of micturition during both day and night, pyuria, with pricking pain in the glans penis at the end of micturition, and the appearance of a few drops of blood in the last drops of urine. The same symptoms are often present with vesical calculus and with vesical epithelioma, when ulceration has taken place. *Vesical calculus* is usually present in older patients, and during the early part of the illness, before cystitis has set in, the calculus only gives rise to penile pain and desire to micturate during movement. When cystitis supervenes, the frequency of micturition will be marked during both day and night. *Vesical epithelioma* also occurs in older patients, and when ulcerated may cause haematuria: frequently the diagnosis may be made by palpation per rectum of an indurated area in the bladder base, or of some enlarged glands in the pelvic lymphatic space. Tuberculous cystitis in the early stages, when the disease is characterized by the deposition of greyish tubercles in the submucous coat of the bladder, may give rise to increased frequency of micturition without other symptoms, but in the progressive advance of the disease the tubercles enlarge, coalesce, and ulcerate on the surface, by which time pus and blood will be present in the urine, and tubercle bacilli should be found. It may be taken as a general rule that in any patient of young adult life with increased frequency of micturition and pyuria, a careful search should be made for tubercle bacilli in the urine, and for other tuberculous lesions, especially in the testes, prostate, or vesiculae seminales.

Tuberculous cystitis is much less often a primary disease than secondary to other lesions in the genito-urinary apparatus—most commonly to tuberculous disease of one kidney, when, after the primary focus has ruptured into the renal pelvis, the lining membranes of the latter, of the ureter and of the bladder become affected successively. The diagnosis between primary renal and primary vesical tuberculous disease is very often difficult, for when the renal focus has ulcerated into the pelvis, and descending infection has commenced, the symptoms of the two affections are very similar. Thus, with renal disease, persistent pyuria, increased frequency of micturition, and penile pain at the termination of urination, may be present before the bladder shows any sign of disease: blood is usually present in small quantity in the urine, but its amount is not so definitely greater in the urine passed at the end of micturition as is the case in vesical disease. In renal tuberculous disease there may be tenderness in the loin, the kidney is usually enlarged, and the lower end of the ureter can be felt distinctly thickened upon rectal or vaginal examination. The two conditions can usually be diagnosed by a careful cystoscopic examination. In vesical tuberculous disease the deposition of submucous tubercles, together with the shallow ulceration in the bladder mucous membrane, may be seen (*Plate XI, Fig. E*, p. 282), whilst in renal tuberculous disease changes may be seen in the ureteric orifice of the affected side (*Plate XI, Fig. D*). At first the orifice becomes thickened, oedematous, and slightly patulous: but later it is rigid and patent, or drawn up by the shortening of the ureter to occupy a position above and outside the normal situation in the trigonal area of the bladder, or drawn up to the apex of a conical retraction of the bladder base. When tuberculous cystitis is secondary to lesions in the testes, prostate, or vesicles, the disease commonly begins in the epididymis of one side, and spreads to the vesicle or prostate, whence a focus may directly ulcerate into the bladder. The patient will first notice increased frequency of micturition and vesical pain, followed by an attack of haematuria when actual ulceration into the bladder base occurs: the formation of a tuberculous ulcer in the bladder leads to pyuria and the other symptoms mentioned above. This sequence is by no means uncommon: the history of testicular disease and the evidence obtained by rectal examination will serve to indicate the nature of the condition.

Vesical calculus may give rise to pyuria when it is accompanied by cystitis, but may present a long time before any inflammatory infection occurs. When cystitis is present, the urine shows no features which will distinguish it from that of patients suffering from some other form of cystitis, except that there may be a constant presence of crystals, or an increased amount of blood after exercise. The constant symptoms of vesical calculus are vesical irritability during the day time, penile pain after micturition, and hæmaturia, especially after any exercise. If a calculus in the bladder is suspected, examination by the x -rays (Fig. 135, p. 282), a sound, or the cystoscope, will reveal it: the cystoscope may detect a stone that is in a diverticulum, partially encysted or lying in the pouch behind an enlarged prostate, where it may easily be overlooked in searching the interior of the bladder with a sound.

Ulceration of the bladder, apart from tuberculous and epithelioma, may occur as a simple ulcer, consecutive to chronic cystitis, or as the result of injury. A single non-tuberculous ulcer, similar to gastric ulcer, has been described as occurring in young adults in the neighbourhood of the ureteric orifices, causing hæmaturia and painful frequent micturition. Later, the surface of the ulcer becomes encrusted with phosphatic material, when the urine contains muco-pus, and often small flakes of phosphatic débris from the surface of the ulcer. This single ulcer is rare, and can only be diagnosed by the use of the cystoscope. Ulceration may also occur in the bladder as a result of severe cystitis, when necrosis has occurred in the mucous membrane. This condition is present occasionally in a case of obstinate cystitis, giving rise to painful and frequent micturition, and may be diagnosed by means of the cystoscope. Both the simple and the consecutive ulcer must be differentiated from tuberculous ulceration of the bladder; in the latter, hæmorrhage is usually slight, and occurs at the termination of micturition; tubercle bacilli may be found in the urine, or other deposits of tubercle found in the epididymis, prostate, or seminal vesicles. The cystoscopic appearance of tuberculous disease, and its more generalized distribution in the vesical wall, will afford the strongest evidence in the diagnosis.

Malignant ulceration of the bladder occurs in two distinct forms: (a) The infiltrating epithelioma; (b) The villus-covered carcinoma.

(a). *The infiltrating variety* occurs as an ulcer, with raised edges and uneven necrotic surface, usually at the base of the bladder. It is usually met with in men over fifty years of age, causing increased frequency in micturition, pain at the glans penis following micturition, with blood and pus in the urine. The bladder-wall in the vicinity of the ulcer is densely infiltrated, and frequently can be felt on digital examination per rectum, whilst at the same time the lymphatic glands in the pelvic space may be felt to be enlarged.

(b). *The villus-covered carcinoma* of the bladder is not uncommon, and gives rise to irregular profuse hæmorrhages. The tumour is attached to the bladder by a broad pedicle, or may be entirely sessile and covered by blunt villi, presenting a coarsely mammillated surface. It occurs in elderly patients, and the tumours are frequently multiple. The surface is often necrotic, giving rise to pyuria. The diagnosis is not difficult, the frequently recurring hæmorrhages in the urine, associated with increased frequency of micturition, pain, and pyuria in an elderly patient, being fairly distinctive. Not uncommonly there is unilateral renal aching from the interference, by the position of the growth, with the flow of urine from one ureteric orifice, so that renal disease may be suspected; but in all cases a careful cystoscopic examination will show the nature of the disease. Difficulty may be experienced in obtaining a satisfactorily clear medium for a cystoscopic view, but in most cases this can be accomplished by gentle manipulations, or by the use of a styptic such as adrenalin 1-1000, or silver nitrate 1 1000. Difficulty may be found in distinguishing cystoscopically between a benign papilloma and villus-covered pedunculated carcinoma; but the broad attachment of the latter to the bladder, the stunted villi covering it, and the multiplicity of the tumours, will be signs of malignant disease (Plate XVI, Fig. F, p. 284). In rare instances a *benign papilloma* may begin to slough on the surface, or may be accompanied by cystitis, when pyuria will be present. A cystoscopic examination will reveal the diagnosis. Microscopical examination of the urinary deposit may show distinctive fragments of new growth.

Bilharzia hæmatobia may cause pus in the urine in advanced cases. When the small nodules in the submucous tissues (Plate XVI, Fig. K, p. 284) of the bladder ulcerate, small

fungating masses are found in the bladder. The typical ova in the urine (*Fig. 26*, p. 79), in addition to pus and blood, will be found on microscopical examination of the urinary sediment.

Urethral Causes.—Any condition which sets up a purulent urethritis will cause pyuria. If the urethritis is recent or profuse, the local condition will be enough to indicate the diagnosis, but it must be remembered that cystitis may complicate a case of urethritis by direct backward infection. If, in addition to urethral discharge, there is increased desire to urinate, suprapubic pain, or hæmaturia, acute cystitis is probably present. The anterior urethra should be irrigated well with sterile water or boric acid lotion, and the patient then directed to pass urine into two glasses. If the first portion passed contains pus and the second is clear, infection is present in the posterior urethra and not in the bladder, but if both specimens are turbid with pus, cystitis is present.

The onset of acute prostatitis complicating urethritis gives rise to increased desire to micturate, and perineal and suprapubic pain, in addition to pyuria, or may cause retention of urine. Digital examination of the prostate, per rectum, will show the prostate to be enlarged, and very painful.

A small amount of pus may be present in the urine in cases of chronic urethritis which is not sufficient to cause any visible discharge from the meatus. The anterior urethra should be irrigated well, and the urine again passed into two separate glasses, when, if the first washings from the urethra contain pus, there is infection in the anterior urethra; if the first specimen of urine contains pus but the second is clear, there is infection in the posterior urethra; whilst if both contain pus, cystitis is present. In any case of urethral discharge, a bacteriological examination should be made for the organism causing the infection, for it is far from uncommon to find that an apparent gonorrhœal urethritis is in reality due to staphylococcal infection.

Pyuria is commonly present in cases of stricture of the urethra, from the co-existing urethritis or cystitis.

PYURIA CAUSED BY DISEASE OUTSIDE THE URINARY ORGANS.

Pus may be present in the urine, apart from any disease in the urinary apparatus, either by accidental contamination of the urine, or by the direct spread of inflammatory or carcinomatous processes from neighbouring organs to the urethra, the bladder, or more rarely the ureter. In the male, the accumulation of pus behind a *phimosi*s may account for pyuria, or in the female a *leucorrhœal discharge* may contaminate the urine. In the latter case the vulva should be cleared well with an antiseptic, and a catheter passed to obtain a specimen for examination.

The spread of inflammatory processes, or the actual rupture of an abscess into any part of the urinary tract, will cause pyuria, and may create considerable difficulty in diagnosis. If symptoms pointing to urinary trouble, such as markedly increased frequency of micturition or slight hæmaturia, be followed by the sudden appearance of a quantity of pus in the urine, there is strong probability of the *rupture of an extra-urinary abscess* into the bladder or urethra, provided that the sudden emptying of a renal abscess or a pyonephrosis can be eliminated. Frequently the history of any case will give some indication of the primary trouble, of which the most frequent are prostatic abscess, appendical abscess, pyosalpinx, psoas, iliac, or pelvic abscess.

Prostatic abscess is most frequently a sequela of an acute urethritis which has infected the posterior urethra and caused an acute prostatitis. It may be due to a gonorrhœal or to a septic venereal infection, or may result from septic instrumentation in the urethra. An acute prostatitis is very prone to result in the formation of an abscess which may rupture into the urethra, bladder, or rectum, unless appropriate surgical measures be undertaken. The onset of acute prostatitis is marked by increasing desire to micturate, pain in the perineum and hypogastric areas, and raised temperature, whilst, per rectum, the prostate is felt to be uniformly enlarged and very tender. If an abscess result, there may be rigors and increased difficulty in micturition, even retention of urine, whilst a soft area may be felt in the prostate from the rectal aspect. A prostatic abscess may occur more rarely in connection with a *prostatic calculus*; or may be present in advanced *genito-urinary tuberculosis*, when a prostatic focus may caseate and ulcerate into the trigonal area of the bladder, a condition which is usually accompanied by a sharp attack of hæmaturia. A tuberculous

focus in the prostate is commonly a comparatively late feature in the disease, and the presence of nodules in the epididymis or seminal vesicles, or the previous knowledge of vesical tuberculosis, will assist very largely in the diagnosis.

Pyuria in Inflammation of the Vermiform Appendix.—In the usual position of the appendix the bladder is commonly not affected; but if the appendix passes downwards across the pelvic brim, it is not uncommon to find that should it become inflamed, the patient complains of frequent and painful micturition. The appendix may be adherent to the bladder, when the latter will show on cystoscopic examination a localized area of acute congestion on the right lateral wall, and both pus and blood may be present in the urine; further, a small abscess may be formed in the adhesions between the appendix and the bladder, ulcerating into the latter and giving rise to pyuria. Two such cases have come under the care of the writer, when the association of frequently recurring attacks of pain low down in the right side of the pelvis, with increased frequency of micturition and pyuria, had given rise to the suspicion of ureteral calculus. In each case a cystoscopic examination showed a normal ureter, and a small ulcer in the right lateral wall of the bladder, surrounded by an area of acute cystitis. The diagnosis of these cases is by no means easy; in the first place the situation of the pain is lower in the pelvis than is usual with appendicitis, whilst the association with urinary symptoms rather points to vesical disease; but the character of the onset of the trouble, with elevation of temperature and pulse-rate, and right-sided abdominal rigidity, will point to an acute intra-abdominal lesion. In other cases, again, an abscess resulting from appendicular suppuration may track down into the pelvis and, if unopened, may rupture into the bladder. In these cases, there will be the usual history of acute appendicitis, followed by a tumour in the right iliac fossa or pelvic space, with a continuance of pyrexia, or even rigors, which subside on the appearance of a large quantity of pus in the urine.

A *pyosalpinx* may rupture into the bladder or cause cystitis from direct spread of the inflammatory process to the bladder. There will usually be a history of leucorrhœa, with constant aching or dragging pains in the lumbo-sacral region, with more severe attacks of pain and malaise at intervals. The periods may be profuse and associated with more pain than usual, and on vaginal examination a distinct fullness or tumour may be felt in one or both fornices.

Psoas or iliac abscess may rupture into the bladder, and a psoas abscess has been known to open into a ureter; but the swelling in the iliac fossa or inguinal region, together with signs of spinal caries, will point to the condition.

Carcinoma of the neighbouring organs in the pelvis frequently attacks the bladder by direct spread of the growth. This is most common in carcinoma of the uterine cervix and of the rectum, but may result from cancer of the pelvic colon, sigmoid, or cæcum. In any case, the spread of the disease to the bladder occurs late in the disease, so that symptoms of the initial trouble are sufficiently manifest to point to the diagnosis. The implication of the bladder is shown first by an increased desire to pass urine, and by pain during the act; later, when the growth has actually infiltrated the vesical mucous membrane, ulceration into the bladder occurs, with the passage of pus and blood in the urine. If the growth has extended from the uterus or vagina, there may be a leakage of urine into the latter; or if from the rectum or colon, some faeces or flatus may be passed per urethram.

Tuberculous or dysenteric ulcers of the small intestine have in some instances become adherent to the bladder wall, and caused cystitis by direct spread, or have even perforated into the bladder.

RAINBOW VISION.—(See VISION, DEFECTS OF, p. 762.)

RASHES.—(See ERYTHEMA, p. 222; PUSTULES, p. 557; VESICLES, p. 753, ETC.)

REACTION OF DEGENERATION.—In testing muscles and nerves electrically, two different kinds of current are employed, namely: *faradic*, in which there is a very rapid alternate making and breaking of the current, and the *galvanic*, in which the current flows continuously until it is voluntarily interrupted by the operator. The faradic current excites the nerve and muscle continuously all the time it flows; the galvanic current only excites when it is made and when it is broken; not whilst it is flowing. In the case of

the faradic current there is no difference between the poles, each being alternately an anode and a kathode many times a minute; in the galvanic current, on the other hand, the pole connected to the zinc of the battery is known as the kathode, and it is by this that the current leaves the body, whilst the other pole is known as the anode, and by it the current enters the body. When testing muscles or nerves, it is usual to have one pole in contact with an indifferent part, such as the spine, and the other over the motor point of the muscle or nerve to be tested. Broadly speaking, the best spot for stimulating a nerve is the place where it is most superficial, and for a muscle, over the site of entry of its motor nerve. It is important to have the skin well wetted, to minimize its resistance to electrical conduction; and the strengths of current required to produce contractions should be measured by a galvanometer, without which the relative excitabilities of the nerves and muscles of the two sides of the body cannot be compared.

Under normal conditions, both faradic and galvanic currents produce brisk contractions of a muscle when applied either to it or to its nerve; and with galvanism it is found that a weaker current will suffice to evoke a contraction on making the circuit when the kathode is on the muscle or nerve than when the anode is similarly employed. This is usually summarized by the formula $K.C.C. > A.C.C.$, which means "the kathodal closure contraction is more easily obtained than is the anodal closure contraction." When the nerve is degenerated, however, there is a change in these electrical reactions, and when there is complete reaction of degeneration—often written and spoken of as R.D.—stimulation of the nerve itself evokes no muscular contractions whether the faradic or the galvanic current is employed, stimulation of the muscle evokes no contraction when the faradic current is used, whilst with galvanism the muscle can still be made to contract, though its method of response differs from the normal in the following respects:—

1. It may be evoked by a strength of current less than the healthy minimum.
2. The twitch of the contraction is slow and sluggish, instead of brisk and quick.
3. It may be evoked at least as readily when the pole upon the muscle is the anode as when it is the kathode; this is expressed by the formula $A.C.C. = K.C.C.$, or $A.C.C. > K.C.C.$, the latter meaning that the anodal closure contraction is obtained from a smaller current than the minimum required for the kathodal closure contraction.

In this connection, however, two considerations require to be understood clearly. In the first place, if a given nerve were cut across with a knife, there would be no immediate R.D.; it takes a week or more for the process of nerve degeneration to reach the stage that produces R.D.; it then depends upon what happens to the nerve how long the R.D. persists; if regeneration occurs, it takes from twelve weeks onwards to complete itself, and R.D. will be found all that time; if the nerve does not regenerate, then R.D. may persist for two or three years or more, provided that the muscle fibres are kept, by massage and electrical treatment, from becoming mere strands of fibrous tissue. Should the latter change ensue, there will be no more electrical response in the fibrous tissue that used to be muscle than there would be in any other fibrous tissue.

In the second place, it happens, as often as not, that when some fibres in a nerve trunk degenerate, others do not, and the same applies to the corresponding muscle fibres. It follows that there will then be a mixed reaction, the normal fibres giving a normal response, the degenerated fibres giving R.D.; the greater the proportion of degenerated fibres, the nearer will the reactions obtained approach to complete R.D., and vice versa. The result is spoken of as *partial R.D.*; some excitability both of the nerves and of the muscles to faradism remains, but it is less than normal; the nerve responds to galvanism, but not so readily as does the muscle when the latter is stimulated directly; the response of the muscle will be less brisk than normal, and yet $K.C.C.$ may still be more easily obtained than $A.C.C.$ It is by no means easy to be sure of the interpretation of a partial R.D., but partial is commoner than complete R.D.

The chief use of R.D. is in distinguishing muscular atrophy due to organic changes in the lower neuron from other cases of atrophy, especially when the latter is due to general wasting from cachexia, or to arthritis, or disuse, or a primary muscular dystrophy. When R.D. is present there is a lesion in the lower neuron, either in the anterior cornual cells, in the anterior nerve roots, or in the peripheral motor nerve fibres. The differential diagnosis of the various affections of these parts is discussed under *ATROPHY, MUSCULAR* (p. 59).

It remains to add that there are a few maladies in which the electrical reactions are peculiar, though they do not present R.D. In tetany, for instance, Erb has shown that A.C.C. is often greater than K.C.C., although in other respects the reactions are normal. In Thomsen's disease there is variability in the polar responses, the original contraction produced on closure lasting a long while, and sometimes developing into a series of wave-like movements during the continuance of the passage of the constant current; but excitability to faradism remains. It is a rare malady, but one so characteristic that it is recognized easily; the chief feature of it is slowness of the relaxation of the muscles when they are first used after a period of rest. When the patient starts to rise from a chair, for example, he does so very slowly and as though he were stiff: the muscles are unduly rigid, and the first few steps he takes are consequently awkward and very slow; after a few seconds the peculiar delay in relaxation passes off and ordinary walking becomes possible. After sitting down again for a while, the same difficulty of rising and starting to walk ensues; and the trouble is generally persistent. There is no pain as a rule, which distinguishes the condition from true stiffness, ankylosis, or rheumatoid arthritis, which might otherwise be diagnosed in error. The legs are nearly always affected more than other parts, and the main complaint is that of difficulty in starting to walk or otherwise use the legs, this difficulty passing off after a few seconds or minutes.

In some cases of Raynaud's disease, and in angio-neurotic oedema and allied vasomotor neuroses, there may be variations from the normal galvanic reactions. In myasthenia gravis (*Figs.* 111, 112, p. 235) it is characteristic that, whereas the affected muscles respond readily to the first few faradic stimuli, the contractions diminish rapidly in size and cease after a few minutes, notwithstanding the continuance of stimulation. After a period of rest this myasthenic reaction is obtainable again, and so on. This type of electrical response corresponds precisely to the rapid fatigue of the voluntary muscle movements, and the diagnosis is not difficult, though the disease is rare. *Herbert French.*

RECTUM, ABNORMALITIES FELT PER.

Method of Examination.—The patient should be placed in a good light on a couch of convenient height. With male subjects the best position is the knee-elbow, with females the right lateral with the knees flexed and the right arm behind the back. The examination should be made with the left hand, leaving the right free for manipulations. Most diseases of the rectum are situated within two inches of the anus. It is advisable, therefore, that to begin with the finger should be inserted as far as the first joint only, and the lower inch of the bowel examined thoroughly. The examination must not be concluded until the finger has been passed up as high as possible and the whole of the rectum within reach explored, as well as the coccyx, sacrum, ischio-rectal fossae, and adjoining viscera. The rectal speculum and the sigmoidoscope may also be needed to complete the examination.

If any abnormality be felt the first thing to ascertain is (1) *Whether it lies free in the lumen or is attached to the wall of the rectum*; (2) *Whether it is some abnormality of an adjoining structure or viscus that can be felt through the rectum.*

I. ABNORMALITIES LYING FREE IN THE LUMEN OR ATTACHED TO THE WALL OF THE RECTUM.

Foreign Bodies.—Though feces can hardly be considered as foreign to the rectum, yet a hard, scybalous mass, enterolith, or hair-ball may amount to an abnormality. True foreign bodies include those that have been introduced through the anus, and those that have been swallowed. Examples of the first class are seldom met with, and then are generally in persons of weak intellect. Thieves sometimes employ the rectum as a hiding-place for stolen goods. The majority of foreign bodies felt per rectum have been swallowed—for instance, fishbones, pins, needles, or splinters of wood. Their importance lies in the fact that they may cause a rectal or ischio-rectal abscess, and in treating such a case their discovery and removal is essential for a complete cure.

Swellings of the Rectum projecting into the Lumen:

Internal Hemorrhoids are rarely palpable to the finger unless chronically inflamed, thrombosed, or gangrenous. If palpable, they will be felt immediately inside the anus, and can be hooked out with the finger and made to protrude through the anal orifice for inspection. The existence of piles having been diagnosed, an effort should be made to see if there is any causative condition, such as a carcinoma in the bowel above.

Abscess (submucous) gives rise to a more or less elongated, smooth, elastic swelling in the rectal wall. It is intensely tender, the slightest pressure causing great pain. The mucous membrane may feel hot, and pit on pressure. If the abscess has burst or bursts during examination, the finger on withdrawal will be covered with pus. An abscess that has already emptied itself feels like a small pea or bean in the submucous tissue.

Polypus is a term used to designate, without reference to its histological characteristics, any benign tumour that is pedunculated. Almost all innocent tumours in this position, even if sessile at the beginning, become pedunculated owing to the downward pressure of the feces. The passage of blood and mucus, combined with the absence of piles and carcinoma, should lead one to suspect the presence of a polypus. It may not be easy to feel, because its consistency is much the same as that of the mucous membrane, and further, its peduncle may allow such free movement that it may easily be mistaken for a small mass of feces. The best way of fixing these growths is to sweep the finger round and round the whole circumference of the rectum up to the highest point attainable. The growth is then arrested by the pedicle, and the finger can be hooked round it, so that the growth is drawn down and, if possible, made to protrude through the anus. If the polypus is large, a rectal speculum may be of service. It is to be remembered that polypi are often multiple.

Ulcers, unless malignant or chronically inflamed, can rarely be felt with the finger; they must be exposed to view with the speculum. They may be tuberculous, gummatous, traumatic, or due to ulcerative colitis or dysentery.

Carcinoma occurs usually in people over forty. Its commonest site is within the four terminal inches of the bowel. It is generally hard, fixed, irregular, and nodular. Its extent varies with its stage; it may involve only part of the circumference of the bowel, or may extend right round so as to occlude the lumen and cause a stricture. The surface is usually ulcerating, so that it is friable and bleeds easily. There is nearly always a belt of normal mucosa between the internal sphincter and the neoplasm. Not only the lateral but the upper limit of the growth may sometimes be ascertained by inserting the finger to its extreme limit, care being taken not to split the mass. Another point to be gauged by a rectal examination is the degree of infiltration as measured by the fixity of the tumour to the neighbouring structures, e.g., sacrum and coccyx. Following the rectal examination, the abdomen is to be palpated for evidence of infection of the inguinal, pelvic, or lumbar glands, and the existence of secondary deposits in the liver.

The clinical symptoms of carcinoma of the rectum are very suggestive. The patient generally complains of diarrhoea, the bowels being open five to twenty times a day, and this may have followed on a period of constipation. Notwithstanding the apparent diarrhoea the total amount of feces passed is very small, and no sense of satisfaction is obtained by the patient after stool. The evacuation may be so rapid as to merit the description 'explosive diarrhoea.' Hemorrhage from the bowel is common, and in the later stages there is a discharge of mucus. Pain is complained of—a dull aching pain in the rectum and at the bottom of the back, which is not made much worse by the passage of a motion, quite unlike the sharp temporary excruciating pain associated with an anal fissure or ulcer. Emaciation is rapid, and a history of wasting and diarrhoea in a middle-aged patient should always lead to a careful examination of the rectum, and if nothing is to be felt with the finger, a sigmoidoscope should be used. A carcinoma is likely to be overlooked from carelessness and from not making an examination. Mistakes may, however, arise between carcinoma and an adenomatous polypus or ulceration, either traumatic or tuberculous, around which much long-standing inflammation has caused thickening. The facts that a carcinoma is hard, the surface often excavated, and the edges nodular and everted, are generally sufficient. If real doubt exists, a piece of the ulcer may be removed for microscopic report.

Intussusception. Occasionally a piece of intussuscepted bowel may come down so far as to be felt per rectum. This condition is associated with the passage of blood and mucus, and therefore might be mistaken for a disease of the rectum proper. The fact that intussusception occurs nearly always in children, especially at the age of nine months or thereabouts, and causes intestinal obstruction, should make such a mistake easily avoidable.

Stricture due to a carcinoma is dealt with above, but a few remarks remain to be made about fibrous stricture. This may be present at the anal orifice, at the level of the upper

border of the internal sphincter, or three to four inches up the rectum. It may be annular or tubular. The finger meets with a firm cord-like constriction, which perhaps will not allow the entrance of more than its tip; there will be no bleeding unless the finger is forced through the stenosis and the mucous membrane torn.

Fistulae, either recto-vaginal or recto-vesical, whether congenital or acquired, may be felt with the finger. The passing of urine or feces by abnormal passages indicates the complaint.

Malformations of the Rectum.—Some children are born without an anus, or without the lower portion of the rectum, or the finger introduced may be stopped by a membrane separating the upper from the lower portion of the bowel. The diagnosis is obvious. The usual types of abnormalities are shown on the accompanying diagrams, *Figs. 249-252*, reproduced from the *Medical Annual*, 1910; the figures are a summary by Dr. A. Keith of a series of 54 cases in male, and 52 cases in female, children.

Fig. 249.—Sagittal section of the pelvis of a male child, showing the rectum opening into the prostatic part of the urethra. A bladder; B rectum; C recto-vesical pouch; D uteri-musculus; E intra-occal anus; F prostate; G proctodaeum; H external and internal sphincters; I Cowper's gland.

Fig. 250.—Diagram illustrating the degrees of imperfection in the male. The rectum is shaded; the various degrees make up a series between the proctodaeum and base of the prostate.

Fig. 251.—Sagittal section of the pelvis of a female infant, showing the rectum opening into the navicular fossa of the vulva. A bladder; B rectum; C recto-uterine fold; D symphy-sis pubis; E vulva-anus; F cervix; G proctodaeum (rarely present if the rectum opens into the vulva); H urethra; I clitoris; K hymen.

Fig. 252.—Diagram illustrating the common varieties of malformation in the female; the various degrees make up a series between the proctodaeum and the recto-uterine fold.

II. ABNORMALITIES OF NEIGHBOURING STRUCTURES FELT PER RECTUM.

It does not lie within the scope of this article to give the differential diagnosis of all the morbid conditions that can be felt through the rectum; it suffices to take the structures

within reach of the finger, and indicate the varying conditions in which a diagnosis may be aided by a rectal examination.

On the Anterior Wall the structures that can normally be felt are the prostate in the male, and the uterus in the female.

Prostate.—Any enlargement is easily felt. An *adenoma* is the commonest form. This is soft, elastic, and has a groove in the middle line. A *carcinoma* or *sarcoma* is hard and fixed, and the outlines are blurred. A *prostatic abscess* causes a marked painful protrusion into the rectum.

The Vesiculae Seminales are not palpable normally. The fact that they can be felt is almost sufficient to declare them diseased. They are most commonly affected in connection with tuberculosis of the testes or from present or past gonococcal vesiculitis.

The Bladder is not felt if healthy. If greatly distended it may form a tense resistance in the anterior wall of the rectum. Rarely, a large stone or a malignant growth of the floor may be felt.

The Uterus is easily palpable. Enlargement or retroversion can be recognized; the pressure of a fetal head may occlude the rectum.

The Vagina cannot be felt unless it is occupied by a foreign body such as a pessary, or is the seat of a growth.

The Ovaries, if enlarged by cystic disease or by new growth, may come within reach of the finger; *pyosalpinx* is often a bilateral affection in which the inflammatory masses can be felt per rectum in Douglas's pouch; they can be detected more readily by vaginal examination, however, when this route is permissible.

Through the Posterior Wall the only structures that can be recognized are the coccyx and sacrum.

The Coccyx may be found bent in and pressing on the rectum. In coccydynia any movement of the coccyx may cause great pain.

The Sacrum may be the seat of either a growth or an abscess, which will cause a bulging into the posterior wall.

On the two Lateral Surfaces no structures are normally recognized. The ischio-rectal fossae are common sites for *abscesses*, and these can be felt as tense swellings pushing in the wall. Rarely an *aneurysm* of the internal iliac artery or a *stone in the lowest portion of the ureter* may be felt.

If anything is felt with the tip of the finger through the upper portion of the rectum, it will usually be something distending Douglas's pouch. This may be blood coming from a ruptured or leaking *ectopic gestation*, or a localized *abscess*, either parametric or arising from a septic Fallopian tube or the vermiform appendix. Some surgeons state that they are able to detect the appendix if it is hanging over the brim of the pelvis, but to do this the finger must be long and the senses very acute.

Sometimes, when there is doubt as to whether symptoms arising in connection with a more distant organ, e.g., the stomach or the gall-bladder, are due to malignant disease or not, rectal examination affords valuable evidence of malignancy even when there are no pelvic symptoms at all. When secondary deposits have arisen, they develop not infrequently in the pelvic peritoneum, presumably as the result of gravitation of malignant particles into Douglas's pouch. These latent secondary deposits can sometimes be felt very definitely as a firm band or shelf—the 'rectal shelf'—if the observer's index finger is a fairly long one. Rectal examination is sometimes of value also in verifying the existence of free fluid in the peritoneal cavity.

George E. Gask.

RECTUM, BLOOD PER.—(See BLOOD PER ANUM, p. 75; and MELÆNA, p. 385.)

REDUPLICATION OF HEART SOUND. It seldom happens that the diagnosis in a particular case is influenced to any marked degree by the presence or absence of reduplication of either heart sound; nevertheless, the reduplication is sometimes so definite that it attracts special attention and needs interpretation. It has to be distinguished from other triple sounds, particularly from the canter-rhythm that occurs most commonly with acute pericarditis, and less often with dilatation of the heart from fatty change, especially in pernicious anaemia and other conditions of oligochromæmia; and from the beginning of a mid-diastolic bruit at the impulse in a case of acute rheumatic endocarditis of the mitral

valves. One can lay down no rules as to how these various sounds are to be distinguished; it can only be done by having heard them in other cases: sometimes, indeed, opinions differ as to whether the sounds heard in a given patient are due to a bruit or to a reduplication.

Reduplication of the first sound is rare, and to all intents and purposes it never occurs except at or near the impulse; it indicates some abnormality, but does not specify exactly what that abnormality may be. If there is no bruit, the commonest cause is great hypertrophy of the left ventricle from granular kidney or arteriosclerosis, indicated by the big heart, high blood-pressure, urinary and retinal changes.

Reduplication of the second sound is common, especially in the pulmonary area (second left intercostal space close to the sternum). It generally indicates great relative increase in the intrapulmonary blood-pressure, so that the pulmonary valves close a fraction sooner than the aortic; the reduplication may alternate with simple accentuation (see p. 1), the commonest cause being mitral disease, especially mitral stenosis. Similar reduplication of the second sound may be heard at the impulse also in these cases, though more often the second sound here is weak or inaudible. The commonest cause for reduplication of the second sound at the impulse is great relative increase in the systemic blood-pressure—especially in cases of arteriosclerosis or granular kidney. The second sound in the aortic area (second right intercostal space close to the sternum) is generally very loud and ringing, or even reduplicated at the same time. There are no other really important causes of reduplication of either of the heart sounds.

Herbert French.

REFLEX, PLANTAR.—(See BABINSKI'S SIGN, p. 68.)

REFLEX, PUPILLARY. (See PUPIL, ABNORMALITIES OF, p. 551.)

REGURGITATION OF FOOD THROUGH THE NOSE may be but a temporary accident, the result of an unsuccessful attempt to stave off a sneeze, a cough, or a burst of laughter when the mouth is full of food or fluid; or it may result from an explosive return of gas from the stomach or œsophagus, particularly after drinking gassy fluid such as soda-water, champagne, ginger-beer, cider, or beer. In such cases the diagnosis is generally obvious. Pathological regurgitation of food through the nose results from two main groups of causes, namely:—

A. Structural Imperfections of the Palate:—

- | | |
|------------------------------|--|
| (a) Congenital: cleft palate | (b) Acquired perforation: (i) traumatic,
(ii) syphilitic, (iii) malignant,
(iv) tuberculous. |
|------------------------------|--|

B. Paresis or Paralysis of the Soft Palate or of the Pharynx:—

- | | |
|-----------------------|---|
| (a) Post-diphtheritic | (d) The result of bulbar paralysis |
| (b) Post-operative | (e) The result of pseudo-bulbar paralysis |
| (c) Syphilitic | (f) Cases of undetermined cause. |

Simple inspection of the roof of the mouth is generally sufficient to decide whether the cause belongs to group A or to group B. The median and symmetrical imperfection of a congenital cleft palate is obvious, and there is the history of the trouble dating from birth. There may be a harelip or other congenital abnormality at the same time. When an ulcerative process is still in progress there may for a time be some doubt as to whether it is syphilitic, malignant, or tuberculous. The history may help, or the healing of the ulcer under the influence of mercury or iodide of potassium or salvarsan may indicate its syphilitic nature. If it is important to arrive at the correct diagnosis as early as possible, a small portion of the pathological tissue may be excised and examined microscopically, or Wassermann's serum test applied, or scrapings from the ulcer examined directly for the *Spirochaeta pallida* or for tubercle bacilli. Tuberculous ulceration of the palate is very rare, and is generally associated either with lupus or with definite phthisis. A new growth of the palate may be either epithelioma, endothelioma, or sarcoma, the distinction between these depending mainly on the microscope.

Diphtheria.—If there is no structural defect of the palate, the regurgitation of food through the nose being due to paralysis, by far the most likely cause is previous diphtheria.

The existence of the latter may have been recognized at the time, but quite often the diphtherial attack has been so slight as either to have caused no definite illness, or else to have been regarded as simple sore throat. The palate alone may be paralyzed, giving rise to a nasal alteration in the character of the voice as well as to the regurgitation; or there may be paresis of the ciliary muscles and the eyes as well, causing difficulty in reading; less commonly, there is further evidence of peripheral neuritis affecting the limbs and heart. The trouble may not come on for three or four weeks after the diphtherial attack, and therefore it may no longer be possible to detect Klebs-Löffler bacilli in swabbings from the tonsils or fauces; but in every such case it is important to look for them, both directly and by means of cultures. Probably not a few cases ascribed to 'influenza,' or to undetermined causes, are really post-diphtheritic. The paresis recovers in time, sometimes quickly, but often not until three months or more have elapsed.

Post-operative Cases.—The history in these cases will point to the diagnosis; the accident is rare, and as a rule the effects are temporary; it may happen during the removal of tonsils and adenoids.

Syphilitic Paralysis of the Palate is not common, and it hardly ever occurs by itself. It is a general rule that luetic affections of cranial nerves are multiple and often asymmetrical; thus there may be strabismus, or a laryngeal paresis, in addition to that of the palate; or there may be a history or other evidence of syphilis.

Bulbar Paralysis. When this affects the palate and causes regurgitation of food through the nose, there have generally been other symptoms for some time. The malady is slowly progressive, and starts with paresis of the lips and tongue; swallowing is difficult, not so much because of the regurgitation as because the tongue is unable to thrust the bolus back between the fauces. The constant dribbling of saliva from the angles of the mouth is characteristic of some cases. The title labio-glosso-pharyngo-laryngeal paralysis indicates the usual sequence of events. Bulbar paralysis may be associated with progressive muscular atrophy (p. 61), and it may be distinguished from pseudo-bulbar paralysis by the atrophy of the tongue, which occurs in the former but not in the latter. Bulbar paralysis is due to a lesion in the medulla oblongata, whereas pseudo-bulbar paralysis has very similar symptoms due to bilateral cortical softening. In either case the patients are generally elderly.

Undetermined Causes.—As regards such cases, it may be repeated that the majority are doubtless post-diphtheritic, so that it is important to examine swabbings from the throat of all such patients for the Klebs-Löffler bacillus. The symptom is very rarely hysterical.

Herbert French.

RETENTION OF URINE. (See MICURITION, ABNORMALITIES OF, p. 393.)

RETRACTION OF THE ABDOMEN. (See RIGIDITY OF THE ABDOMEN, p. 592.)

RETRACTION OF THE GUMS is occasionally a symptom which troubles patients very much, but in itself it seldom indicates more than a local affection. In a mild degree it may be due to excessive use of a hard tooth-brush; in most cases it results from a local infective process, especially tartar, caries of the teeth, or pyorrhoea alveolaris. These conditions are discussed under the heading of BLEEDING GUMS (p. 72), though very often retraction may be present, even in an extreme degree, without actual bleeding.

Herbert French.

RETRACTION OF THE HEAD may be a marked symptom in the following conditions:—

Acute meningitis:	Superior longitudinal sinus thrombosis	Strychnine poisoning
1. Suppurative	Acute encephalitis	Tetanus
2. Tuberculous (basal)	Bronchopneumonia with partial asphyxia	Hydrophobia
3. Meningoocoeal (posterior basal)	Laryngeal obstruction, especially diphtheria in children	Catalepsy
4. Meningoocoeal (epidemic cerebrospinal)		Spasmodic torticollis
Cerebellar or other subin- tential tumour or abscess		Paramyoclonus multiplex
		Hysteria and hystero-epilepsy.

In arriving at a diagnosis in any given case, the probability is that *strychnine poisoning*

tetanus, and *hydrophobia* will either suggest themselves at once on account of other circumstances in the case, or else will not need to be discussed at all. *Hysteria* can only be diagnosed when all other possibilities have been excluded, and probably not until the case has been watched anxiously for a time; there may be other functional symptoms in the case (p. 165); the patient is generally a young adult, more often female than male. *Catalepsy* and *hystero-epilepsy* will be suggested by the mental symptoms, or obvious insanity.

These things being excluded, the first thought that marked and maintained retraction of the head arouses is that the patient has some serious intracranial lesion, probably *meningitis*. Before coming to this conclusion, however, it is important not to forget that extreme dyspnoea in children sometimes produces considerable head retraction, so that the physical signs in the lungs and heart should be noted carefully, *bronchopneumonia* and *capillary bronchitis* being kept specially in mind, and any signs of *laryngeal obstruction* looked for, especially stridor and spasmodic up-and-down movements of the thyroid cartilage, with sucking in of the thorax above and below the clavicles, along the attachments of the diaphragm, and in the intercostal spaces. *Diphtheria*, *foreign body in the larynx*, and *retropharyngeal abscess* have all been mistaken for meningitis.

If there is no evidence of sulcicent throat or lung trouble to account for the symptom, an intracranial lesion is probable; and by far the most likely, especially in a child, is acute meningitis, either tuberculous or posterior basal. Symptoms common to all the intracranial affections are headache, vomiting, and giddiness; pyrexia, generalized convulsions, coma, incontinence of urine and faeces, retraction of the head, and optic neuritis; or even local symptoms, especially twitchings, convulsions, or paralysis of individual limbs or parts of limbs, according as one part of the brain or another is more irritated or softened than the rest. If there is an obvious source of sepsis in connection with the cranium, such as otitis media, mastoid abscess, facial erysipelas, a septic scalp wound, boils, pediculi with sores, suppuration in the orbit, nose, antrum of Highmore, frontal, ethmoidal, or sphenoidal air-cells, or nasopharynx, the probability is that any acute meningitic symptoms are due to staphylococcal or streptococcal *suppurative meningitis*; *pneumococcal meningitis* may occur without local sepsis, either alone or as part of a general pneumococcal septicaemia; suppurative meningitis due to the *Bacillus diphtheriae*, the typhoid bacillus, influenza bacillus, or the *Bacillus coli communis* may occur, but it is decidedly uncommon and clinically indistinguishable from other forms of suppurative meningitis, in all of which marked pyrexia and a fatal ending in two or three days are the rule. *Tuberculous meningitis* is much commoner in childhood than it is at any other age; it is always part of a general tuberculosis, and it is very rare in adult life. At first there may be no pyrexia, though this depends on the caseous glands and tuberculous lesions in the lungs and elsewhere more than upon the meningitis. The early diagnosis is apt to be uncertain, but as the days go by the serious nature of the complaint generally becomes obvious; the effortless vomiting, the irregular pyrexia, severe headache, optic neuritis, retracted head, possibly choroidal tubercles (*Plate XX, Fig. a*, p. 418) or evidence of tuberculous foci elsewhere, serve to clinch the diagnosis. The chief difficulty, after the stage of retraction has been reached, is to decide between tuberculous meningitis on the one hand and *meningococcal (posterior basal) meningitis* on the other. The duration of the disease is often of assistance in this respect—suppurative meningitis kills in two or three days, tuberculous meningitis in two or three weeks, whilst posterior basal meningitis ends in recovery in a variable percentage of cases, even after continuing for two or three months. The tendency to head retraction is greatest with the posterior basal, least with the suppurative forms. Optic neuritis barely has time to develop in suppurative meningitis, but it is present more often than not in both basal and posterior basal meningitis. The way in which the heels touch the occiput in some cases of the latter may by itself decide the diagnosis. Another point in favour of meningococcal meningitis, is the occurrence of periodic spike-like rises of the temperature chart—pyrexial 'crises' lasting twenty-four hours or less (*Fig. 253*), and superposed upon what is otherwise a chart of but moderate type. When doubt remains as to the fact of meningitis or as to its nature, microscopical and bacteriological examinations of the cerebrospinal fluid obtained by lumbar puncture will often serve to establish the diagnosis (p. 304). Bacteriologically, tubercle bacilli are the least easy to find. The Gram-negative meningococci (*Diplococci intracellulares meningitidis Weichselbaumii*) (*Plate XXI, Fig. N*, p. 614) are characterized by their occurrence within

the leucocytes in pairs, like gonococci, but without the reniform shape of the latter. The organisms of suppurative meningitis may be discovered on direct staining, but more often cultural methods are required.

Where posterior basal meningitis ends and epidemic cerebrospinal meningitis begins, it is difficult to say: they are both meningococcal, and probably they are only different types of the same malady, connected together by sporadic cases in which posterior basal meningitis is associated with more or less severe spinal symptoms. The way in which the least touch or movement causes the patient to cry out with pain sometimes indicates how inflamed the coverings of the posterior nerve-roots are, besides which, the erythematous, vesicular, or purpuric skin eruptions that may accompany it often suggest the diagnosis. There is less difficulty during an epidemic; it is the sporadic case that may be missed. The clinching point in the diagnosis is bacteriological investigation after lumbar puncture, assisted perhaps by the beneficial effects of the specific antimeningococcal serum.

Fig. 275.—1-hourly temperature chart in a case of meningococcal cerebrospinal meningitis. The pyrexial crises are even more marked in some cases. The diagnosis was verified at autopsy.

Superior longitudinal sinus thrombosis and acute polio-encephalitis are both nearly always diagnosed as acute meningitis in the first instance. It is when a case that has simulated acute and severe meningitis, with coma and apparently impending death, gets rapidly better after a few days and ends in speedy recovery, with or without some impairment of local or general brain functions, in a child or young person, that one changes one's diagnosis of meningitis to polio-encephalitis, though even then it remains one of opinion chiefly. Almost the same applies to superior longitudinal sinus thrombosis: though, if acute cerebral symptoms in a previously healthy child end in a gradual and but partial recovery, accompanied by permanent spastic paralysis of the legs, without much affection

of the arms, it is very possible that the lesion has been thrombosis of the superior longitudinal sinus, with softening of the leg areas of cortex on either side of it.

Cerebellar or other *subtentorial tumours* or *abscesses* generally cause a much more gradual onset of symptoms than do any of the above. Head retraction is not present until the later stages. The diagnosis of tumour will rest on the slow increase in the signs of raised intracranial pressure, with nystagmus, optic neuritis going on to optic atrophy, and a tendency to fall always in one definite direction—forwards or backwards if the tumour is in the vermis, to the right or to the left according as it is in the right or left hemisphere. There is often marked ataxy, with exaggeration of the tendon reflexes, particularly on the same side as the tumour. If nystagmus is well marked this serves as a point of some value in distinguishing a cerebellar from a cerebral tumour. Abscess is distinguished from tumour chiefly by the existence of some obvious cause for intracranial abscess, especially otitis media on the one hand, bronchiectasis upon the other. Cerebellar abscess may give rise to no pyrexia and no leucocytosis: but whether the temperature is raised or not, the pulse-rate is often absolutely slowed.

Herbert French.

RIGIDITY OF THE ABDOMEN is a sign not to be regarded lightly, and one to find the true significance of which may call for the greatest care and skill. The patient should be examined lying on the back with the whole of the abdomen and lower thorax exposed. The observer, seated on a level with the patient, should watch the abdomen for a minute or so and see whether it moves or not with respiration, and whether one part moves more than another.

It should be remembered that some patients, whether from modesty or timidity, hold their abdomens intensely rigid in a wholly unnecessary way, a tendency which may create a false impression. This can be avoided by engaging them in conversation for a minute or two, by asking them to take a few deep breaths, or by making them draw their knees up and keep their mouths open, when the normal abdominal walls will generally relax.

There are varying degrees of rigidity. The whole abdomen may be rigid, the upper or lower part only, or one side, as in the presence of a localized appendicular abscess. Again, one part or one rectus muscle may be put, as it is termed, 'on guard,' whenever the patient thinks a tender spot is about to be touched. The rigidity over an inflamed gall-bladder, and that over a gastric or duodenal ulcer, are instances of this.

The most important cause of universal rigidity is *septic infection of the peritonæum*, which may follow external wounds, abdominal operations, childbirth, abortion, endometritis, parametritis, extension of inflammation from or perforation of the appendix, ulcer of the stomach, duodenum, or bowels, perforation of the gall-bladder, suppurating Fallopian tube, or abscess of the liver, spleen or kidney; or which may be primary, as in some pneumococcal cases. It is a safe rule to believe there is peritonitis until the contrary is proved. As in the case of other disease, diagnosis must not be based on one clinical sign, and the patient must be examined for the other signs of peritonitis.

The history of the onset is important. In perforative cases, the beginning is marked by intense abdominal pain. This may be general and continuous, or by being referred to the stomach or appendix region give an indication of the primary seat of the mischief. The position taken up is on the back, sometimes with the knees drawn up to relieve abdominal tension, and the patient generally lies still, for any movement causes increase of pain. In colic, on the contrary, whether intestinal, biliary, or renal, the patient rolls about during the spasms. It is painful to use the diaphragm: therefore, respiration is superficial and costal in type. The abdomen gradually becomes distended, tense, and tympanitic; the liver dullness which was previously present may disappear, and in some forms of peritonitis fluid may accumulate in the abdomen and be detected by the signs of shifting dullness in the flanks. The pulse is small and rapid, 100 to 150, and has the tendency to quicken. A friction rub may be heard over the liver or the spleen when the patient breathes. Borborygmi will generally be absent. Vomiting is an early, prominent, and almost constant feature. The contents of the stomach are ejected first, then bile-stained fluid, and later green or brownish fluid with a slight fecal odour. The vomiting is often of a peculiar 'pumping' character. The bowels may be loose at first and then constipation follows, but is not complete as in intestinal obstruction. Micturition may be frequent, or there may be retention when the pelvic peritonæum is acutely inflamed. When the disease is well

developed the appearance of the patient is very characteristic, exhibiting the 'Hippocratic facies.' The pulse is often of great assistance in arriving at a diagnosis of the need to operate urgently in these cases; it should be counted every ten minutes; if its rate falls or does not rise at successive counts, peritonitis is less probably present than when the pulse-rate is found to be rising each time.

In suppurative peritonitis leucocytosis, though it may not occur at all, is often marked (15,000 to 39,000 per c.mm.).

It does not necessarily follow, because the whole abdomen is rigid, that the peritonitis is general. For instance, in cases of perforative appendicitis it has been shown by operation that pus was only to be found around the caecum, and yet there was general rigidity. Without operating, it is often impossible to tell. The best way of finding out whether there is pus in the abdomen, and the method to be employed at once if there is any doubt, is to open the abdomen and see.

OTHER CONDITIONS ASSOCIATED WITH ABDOMINAL RIGIDITY WHICH MAY BE MISTAKEN FOR PERITONITIS.

Pneumonia or Diaphragmatic Pleurisy. In the early stages here, before the onset of dullness in the lungs and other physical signs in the chest, the most prominent features may be abdominal pain and rigidity. Laparotomy has often been performed on the mistaken diagnosis of peritonitis. If, however, the examination is thorough, signs pointing to implication of the lungs will usually be found. Rapidity of respiration, working of the nares, and blueness of the lips should receive particular attention. Examination of the blood may reveal a high leucocytosis (30,000 to 40,000); in suppurative peritonitis the numbers are rarely so high.

Colic. The suddenness of the onset of pain, its intense character, and the abdominal rigidity, may render this condition extremely difficult to differentiate from peritonitis due to perforation of some viscus. Collapse may be marked, and the effect on the pulse is considerable; vomiting is common also. The temperature is raised slightly but rarely exceeds 100° F., and the pulse, though it may be rapid, does not tend to quicken progressively. The pain is spasmodic, not continuous as in peritonitis, and is generally relieved in a few hours. Biliary and renal colic are fairly characteristic, but that due to lead, the crises of tabes dorsalis, or gastro-intestinal disturbances may easily be mistaken. The gums are to be examined for a blue line, the knee-jerks and pupils tested, and a blood-count made. In uncomplicated colic there is no leucocytosis. In cases of extreme difficulty the abdomen may have to be opened. The persistence of horborygni is in favour of colic rather than of general peritonitis.

Intestinal Obstruction. The vomiting and constipation here present may lead one to think of peritonitis, and indeed the two conditions may be present at the same time, as in the case of an ulcerating carcinoma of the bowel. Usually the rigidity is not well marked, and the constipation, which is not absolute in peritonitis, is here complete.

Injuries of the Abdomen.

1. Contusion of the abdominal wall, with laceration of muscle: Particularly in patients who have been run over across the abdomen, rigidity is a marked feature, and there must always be a doubt at first as to whether any of the viscera have been torn and are bleeding, or whether the escape of their contents is setting up peritonitis. In the case of mere contusion, if the patient is put to bed and kept warm, collapse will soon disappear, the abdomen will become less rigid, and the pulse-rate will fall.

2. Contusion of the abdominal wall with injury of viscera: The signs here will be more marked, and instead of tending to diminish rapidly will become worse. If there is internal bleeding the mucous surfaces will be pale, the skin cold and clammy, and the pulse small and frequent. If the contents of a viscus have escaped, the signs of peritonitis will develop rapidly. In all cases of doubt an exploratory laparotomy should not be delayed.

Ruptured Tubal Gestation. This may simulate general peritonitis. The abdominal rigidity here is not well marked, and the signs of bleeding are. A moderate degree of leucocytosis is present (10,000 to 15,000), but the number of red cells is much diminished. If the patient is a woman of the child-bearing age, known to be a week or more overdue as to monthly period, and has begun to lose blood per vaginam synchronously with the onset of acute abdominal pain and pallor, the diagnosis will suggest itself at once.

Acute Hemorrhagic Pancreatitis is usually diagnosed as intestinal obstruction or acute perforative peritonitis. The attack sets in with intense pain, usually in the upper and left part of the abdomen. Vomiting, constipation, and tympanitic distention are present. The condition is so rare, and the signs are so unreliable, that an exploratory laparotomy should be made, and the nature of the case becomes obvious directly the characteristic opaque yellow patches of fat-necrosis are seen in the omentum.

Rupture of an Abdominal Aneurysm, Dissecting Aortic Aneurysm, Embolism of the Superior Mesenteric Artery, may simulate peritonitis, and so also may *Acute Thrombosis of the Inferior Vena Cava*; but all these conditions are rare, and they will be very difficult of diagnosis unless the existence of some cause for them, such as aortic aneurysm or fungating endocarditis, is already known.

Acute Suppurative Nephritis sometimes gives abdominal rigidity, and is associated with fever and vomiting. There is always marked tenderness in the loin on the affected side, and the urine will contain albumin, pus, blood, casts, and bacteria. The milder types of the infection (see BACTERIURIA, p. 69) may be mistaken for acute appendicitis, or for general peritonitis, unless the centrifugalized deposit from the urine is examined microscopically for pus.

George E. Gask.

RIGORS, or CHILLS, are common at the onset of the most various acute febrile disorders, and may occur at regular or irregular intervals in the course of many of the more severe of them. The chief sign of a rigor is shivering, the chief symptom a feeling of cold and general wretchedness. At its beginning, the patient looks chilly, pinched, and blue, and sits or lies huddled up, complaining of the cold; his arteries are contracted, the pulse is rapid, small, and of raised tension; the extremities are chilled superficially, but the internal temperature is above the normal. Very soon the sensation of cold induces involuntary shivering; the patient shakes all over, sometimes so violently that the chair or bed is thrown into noisy vibration; the teeth chatter, and even the muscles of the face twitch involuntarily. This shivering lasts for minutes, or even for an hour, dying away gradually as the patient feels himself to be warmed up. Thus the initial stage of the fever passes into the second stage or fastigium, in which the complaint is of sweating, thirst, and undue heat, and the body temperature rises still further. In children, general convulsions, with partial or complete coma, may occur at the onset of an acute infection, in conditions that would give rise to a rigor in adults. In adults, convulsions are not known to take the place of rigors. Cases may arise, however, particularly when only an imperfect history can be obtained, in which it may be hard to say whether a patient has had a rigor, or an epileptiform, hysterical, or epileptic fit. Should the patient have lost consciousness during the shivering, or have fallen down, bitten his tongue, or passed his water during the attack, or should he give a history of similar attacks on previous occasions, the diagnosis of epilepsy would be more than probable. Epileptiform fits that unskilled observers might confuse with rigors may occur in uræmic or eclamptic patients; the history of the case, and the discovery of albumin in the patient's water, together with other evidences of acute or chronic renal disease, should make the diagnosis clear. Fits indistinguishable from rigors to the untrained eye may occur in hysteria; in these, however, the shivering patient would be red in the face, or at least would not present the slightly livid and shrunken facial appearance characteristic of a rigor, the temperature would not be raised, and the signs or a history of other hysterical phenomena should be obtainable.

For their further consideration it is convenient to classify rigors according as they are single or multiple.

1. **Single Rigors.** The occurrence of a *single rigor* at the outset of an acute infectious disorder is extremely common, and may be taken as evidence of the severity of the infection to some extent; in lobar pneumonia this initial rigor is often particularly long and severe. No exhaustive list of the disorders that may be thus ushered in can be given; but it may be stated generally that an initial rigor is common in:—

Lobar pneumonia	Pneumonic tuberculosis	Malaria
Small-pox	Typhus	Yellow fever
Influenza	Relapsing fever	Weil's disease
Severe feverish colds	Erysipelas	After catheterization.
Septicæmia	Cerebrospinal fever	
Pyæmia	Acute poliomyelitis	

It is less often seen in :

Scarlet fever	Tetanus	Acute gastro-intestinal disorders
Measles	Miliary tuberculosis	Nephritis
Diphtheria	Sapremia	Cholelithiasis
Tonsillitis	Glanders	Renal calculus.
Rheumatic fever	Sick headache	

And is comparatively rare in :

Enteric fever	Anthrax	Dysentery
German measles	Hydrophobia	Malta fever
Mumps	Cholera	Beri-beri.
Gout	Plague	

The diagnosis of all these different morbid conditions must naturally be made from the history of exposure to infection, and from the subsequent signs and symptoms. It is clear that the occurrence or non-occurrence of an initial rigor will rarely be of much practical assistance in determining the nature of the disorder from which any given patient is suffering.

A rigor after catheterization is not rare, whether the kidneys be sound or no, and in some cases is due to septic infection of the urethra or bladder. In others, however, it ensues when no infection has taken place, and is not followed by any evidences of urinary sepsis; in these instances the rigor must be referred vaguely to nervous shock, and need not give rise to alarm.

2. **A Second Rigor** coming on in the course of any of these disorders, or a rigor occurring unexpectedly for the first time when the disease is well established or declining, is often evidence of the spread of the infection, or of the occurrence of some complication. For example, a second rigor occurring in the course of *lobar pneumonia* may coincide with the appearance of signs indicating the spread of the disease to the second and previously sound lung; a second rigor happening after the crisis may indicate an empyema. In *enteric fever* a rigor is rare, though it may be due to such complications as perforation of the intestine, acute peritonitis, pleurisy, pneumonia, middle-ear disease, periostitis, and so forth; but there is an abnormal type of enteric fever in which rigors occur for no apparent reason, followed by heavy sweats; and rigors may be observed in cases with constipation, or during defervescence, or in enteric patients who have been treated with antipyretic drugs.

3. **Recurring Rigors.** The occurrence of a *series of rigors* often gives information of more definite value, for they are seen in but a limited number of local or general infections, most of which have some characteristic or localizing signs. In themselves these rigors are no more than evidence of the severity of the infection, and of the extent to which bacterial toxins have been absorbed into the blood. The following are the chief disorders characterized by a series of rigors:

Malaria tertian, quartan, astivo-antimalar or malignant	Acute blood-infections, including	} Special forms of these may be known as puerperal fever, malignant endocarditis, acute infective osteomyelitis, suppurative pyelophlebitis, etc.
Relapsing fever	Portal pyæmia	
Acute leukaemia	Pyæmia	
	Septico-pyæmia	
	Septicæmia	
Acute inflammations, e.g.:	Abscess formation:—	Pulmonary tuberculosis
Pyelitis	Hepatic (tropical)	Bronchiectasis
Pyelonephritis	Appendicular	Enteric fever
Cystitis	Subphrenic	Erysipelas
Cholecystitis	Perinephric	Rat-bite fever
Empyema	Prostatic	Influenza.
Infective sinus thrombosis	Cerebral	

A very thorough physical examination of any patient presenting multiple rigors should be made; the condition is always serious, and may be due to septic absorption from some deep-seated abscess that produces only the scantiest of physical signs. When no abnormal physical signs can be found bacterial cultures should be made from the circulating blood, care being taken to draw off a sufficient quantity of blood—5 to 10 c.c.—and to repeat the cultivation several times before it is decided that the blood-stream is sterile.

In *malaria* the rigors tend to recur at regular intervals of forty-eight (*Fig. 6*, p. 28) or seventy-two hours (*Fig. 7*, p. 29) in the benign tertian and quartan infections, at shorter intervals if the infection is mixed. In the astivo-autumnal form the rigors and also the course of the fever are much less regular (*Fig. 10*, p. 31). The parasite (*Plate VI*, p. 32) may be found in the circulating blood, and the patient, if not in extremis, is cured by quinine: there is no leucocytosis, but a relative increase in large lymphocytes occurs.

In *relapsing fever* the onset is acute, with a rigor or a series of rigors. A fortnight later, when the patient has been convalescing for a week or ten days, relapse and a second rigor or series of rigors occurs (*Fig. 5*, p. 27). A second relapse may be noted at the end of the third week, and in a very few cases a third relapse. Relapsing fever has practically died out of the United Kingdom, but it is met with in Egypt, India, and other countries. It occurs in epidemics, and Obermeier's spirochete (*Plate XXI*, *Fig. 1*, p. 614) can be found in the patient's blood while he is feverish.

Multiple rigors occur exceptionally in the course of *acute blood-diseases*, such as acute leukaemia, pernicious anaemia, or Hodgkin's disease. Severe and progressive anaemia, wasting, fever, heavy sweats, and haemorrhage from the mucous membranes, are likely to occur in these cases, with characteristic changes in the microscopical appearances presented by the blood (p. 24).

Multiple rigors are commonest in the various forms of *acute blood-infections*: special forms of these have received particular names. Thus *puerperal fever* occurs after delivery, and is due to bacterial infection of the uterus and its spread thence to the blood: the patient will probably have a sanious or offensive vaginal discharge as well as the evidences of septicæmia or pyæmia. In *malignant endocarditis*, attention is directed mainly to the condition of the heart, the presence of valvular murmurs and the signs given on p. 34. In *acute infective osteomyelitis* the first complaint arises from the acute inflammation occurring in the marrow of one of the bones. *Portal pyæmia* or suppurative pylephlebitis is seen in patients with various acute inflammatory intra-abdominal lesions, and is due to the spread of bacterial infection to the portal vein. The commonest precursor is mild appendicitis. The blood in the portal vein clots, the clot is infected with microbes, softens, and breaks up, to be dispersed throughout the liver in the form of infective emboli. Multiple hepatic abscesses result, with pain, swelling, and tenderness in the hepatic region: jaundice is present in less than half the cases, with more or less coloured stools, vomiting and diarrhoea are frequent, and there is hectic fever. *Pyæmia* is characterized by the formation of metastatic abscesses in any of the tissues or organs, oftenest in the lungs, in consequence of the lodgement there of multiple infected emboli. Before the days of antiseptic or aseptic surgery, pyæmia was the common outcome of serious surgical operations or severe wounds. Nowadays it is comparatively infrequent, and when it does occur is secondary to a severe infected wound, to ulcerations of the mucous surfaces, or to deeply-seated abscesses that are not amenable to surgical treatment. Occasionally it seems to be idiopathic, or due to some infective lesion that escapes discovery. Pyæmia oftenest begins suddenly: the main symptoms are hectic fever, rigors, leucocytosis, diarrhoea and vomiting, heavy sweats, prostration, and the formation of secondary abscesses due to the arrest of septic emboli. When the lungs become the seat of multiple abscesses, the breathing becomes rapid, and signs of bronchitis, pleurisy, or pulmonary consolidation appear. Abscesses in the more superficial tissues or joints make their presence known by the local evidences of pain, swelling, redness, and heat: in the deeper parts or organs, by pain and disturbance of function. The development of secondary subcutaneous abscesses is common in the less acute cases: abscess-formation in the heart, and suppurative pericarditis, are prone to occur when the primary lesion is a periostitis or an acute necrosis of bone. Pyæmia may be distinguished from enteric fever only with great difficulty if evidences of abscess-formation or some source of primary infection are not forthcoming, especially as the typhoid state is common in the later stages of both diseases: the occurrence of multiple rigors is rare in enteric fever, common in pyæmia: Widal's reaction should be tested for. From malaria, pyæmia is distinguished by not reacting to quinine: malarial parasites will not be found in the circulating blood. Pain and inflammation in the joints after childbirth or a miscarriage may be diagnosed as rheumatism when the condition is really one of pyæmia or puerperal fever.

The precise diagnosis between pyæmia and septicæmia is often impossible, and is,

indeed, of academic rather than clinical interest. The necessity for it is in part avoided by the use of the term *septicopyemia*, the evidences of which are much the same as those of pyæmia: all three conditions may arise from identical causes, and bacteria (streptococci, staphylococci, gonococci, pneumococci, *B. coli communis*, *B. typhosus*, *B. influenza*, *B. pyocyaneus*, etc.), may be cultivated from the circulating blood in any of them. Multiple rigors are far commoner in pyæmia—where several may occur daily—than they are in *septicæmia*. The latter condition is due to the growth of microbes in the blood without the formation of metastatic abscesses: it originates in lesions very similar to those that underlie pyæmia, or results from infected but apparently trifling cuts or injuries, or even from neglected chronic suppuration about the teeth. Its main symptoms are pyrexia, debility, anæmia; in severe cases rigors occur, and the patient may fall into the typhoid state. The bacteria causing it can be cultivated from the circulating blood; septic rashes are often seen in both pyæmia and *septicæmia*, but they are not seen in enteric fever. It should be noted that, at the best, a deal of looseness attaches to the meaning of the term *septicæmia*: for in lobar pneumonia, enteric fever, Malta fever, and many other acute febrile disorders, the specific microbes can habitually be cultivated from the circulating blood. Technically speaking, therefore, these are all instances of *septicæmia*. Two new terms have recently come into vogue in this connection, namely, *bacillæmia* and *bacteriæmia*.

Multiple rigors may result from *acute localized inflammatory infections* if the inflammation is sufficiently extensive and the infecting micro-organism virulent. It is often impossible to say how far such rigors are evidence of the absorption of toxins, and how far they indicate that living bacteria have gained access to the blood-stream. Situated in the genito-urinary tract, these inflammations are often associated with a history of *gonorrhæa*, *renal calculus*, or *gout*, and produce characteristic pathological changes (hæmaturia, pyuria, albuminuria) in the urine, or difficulties in micturition. If the gall-bladder or bile-ducts are the seat of the inflammation, jaundice, and pain in the hepatic region will probably be observed with the fever and rigors, and a history of gall-stone colic may be given, *suppurative cholecystitis* or *suppurative cholangitis* having supervened: the gall-bladder will be tender and probably enlarged from the former, the whole liver swollen and possibly tender from the latter; Charcot's hepatic intermittent fever is due to *chronic cholangitis*, with intermittent biliary obstruction due to a ball-valve stone often lying in the ampulla of Vater. The occurrence of rigors in a child convalescing from pneumonia, measles, scarlet fever, or pleurisy, may lead to the discovery of an unsuspected *empyema*. *Infective sinus thrombosis* occurs mainly in patients with otorrhœa, and indicates that the bacterial infection has spread from the ear to one of the cranial venous sinuses. Its symptoms are general—those of *septicæmia* or *pyæmia*, often with an initial rigor and vomiting followed by high fever, more rigors (*Fig.* 244, p. 567), and sweating; and local—very severe pain about the ear, excruciating headache, and venous congestion of the optic disc, with others that vary with the site of the thrombosis. If the sigmoid sinus is thrombosed, œdema and tenderness over the mastoid appear, and should the clotting spread downwards a thrombus may be felt in the internal jugular vein. Thrombosis of the cavernous sinus is accompanied by squint, exophthalmos, and œdema of the orbits and eyelids. Thrombosis of the superior longitudinal sinus may set up œdema of the scalp near the sagittal suture. The diagnosis must be made from cerebral or cerebellar abscess, in which repeated vomiting is likely to occur, and the localizing signs and symptoms will suggest brain-disease; and from meningitis, in which rigors are rare. In other patients, some acute inflammatory disorder may result in definite *abscess formation*, when rigors may develop from toxic or septic absorption: here again, the virulence of the particular microbe causing the inflammation will be the chief factor in determining whether rigors occur or not. In many cases the rigors will really be due to a secondary and probably terminal *septicæmia* or *pyæmia*.

Tropical abscess of the liver, usually single, occurs in patients who have been abroad and have had dysentery, whether amoebic or bacterial. The early symptoms of liver abscess are often obscure, malaise, fever, sweating, rigors, and gastro-intestinal disturbances occurring, or a pleural effusion secondary to spread of infection through the diaphragm, while nothing particularly suggests implication of the liver. As a rule, complaint of dull pain in the right hypochondrium, axilla, or shoulder will be made. The diagnosis of this and other forms of suppuration in the liver is discussed on p. 369.

Multiple rigors may occur from septic absorption in various diseases of the lungs, the most important of which are *bronchiectasis*, and advanced *pulmonary tuberculosis* with secondary pyogenic infection of the bronchi or tuberculous cavities. In either case the sputum will be abundant, and will probably contain fragments of elastic tissue: it is sure to be offensive in bronchiectasis.

High or irregular fever with recurring rigors has been recorded in a few unusual cases of *enteric fever* (Fig. 241, p. 565) and of *influenza* free from any complication, and in *crystalis* (Fig. 245, p. 568).

Only about a dozen cases of *rat-bite fever* have been recorded in Great Britain so far, but it is probably commoner than it would appear to be, and habitually unrecognized. It occurs in persons who have been bitten by rats, or by ferrets, cats, or weasels that have killed rats recently: the rat-bite heals slowly, and after an incubation period of from two to four weeks the patient begins to suffer from a series of acute febrile attacks at fairly regular intervals of a few days. These attacks recur for from two to ten months in different instances (Fig. 254). The onset of each is abrupt, with headache, fever up to 102°–106° F.,

Fig. 254.—Temperature chart in a severe case of rat-bite fever: only part of the chart is shown; the recurrent attacks extended over a period of four months.

malaise, pains all over, often a rigor, severe pain and swelling in some of the muscles, recurrence of inflammatory phenomena, rarely suppurative, about the original wound, and urticarial, measy, patchy erythematous rashes on the face, limbs, and trunk. Each attack lasts for a day or two, the patient being fairly well in the intervals: during the attack a varying leucocytosis is common. Rat-bite fever is not fatal; the infecting agent, though often looked for, remains unknown.

A. J. Jee-Blake.

RINGWORM. (See FUNGUS AFFECTIONS OF THE SKIN, p. 246.)

RISUS SARDONICUS is the fixed unmitrful grin that results from spasm of the muscles of both sides of the face. The angles of the mouth are drawn outwards and the eyelids raised by tonic contraction of the same muscles as produce the facial expression of smiling, but the spasm is maintained in a way that at once excludes natural smiling. The chief causes of the condition are tetanus, strychnine poisoning, malingering, hysteria, catalepsy.

Catalepsy. The differential diagnosis is not, as a rule, difficult. A cataleptic case is chronic: the facies is by no means always that of smiling, but if it should be, then the smile is a fixed one: the chief characteristic of the condition is the maintenance for hours at a stretch of some attitude that would rapidly fatigue an ordinary person: the history and the associated mental symptoms of melancholia or dementia point to the diagnosis, and tetanus and strychnine poisoning would be excluded by the absence of tetanic spasms.

Hysteria sometimes takes a form that may for a while raise doubts as to strychnine having been taken, but, as a rule, the uniformity of the contortions points to the correct diagnosis. The features may be kept fixed for a time, but sooner or later they become twisted into all sorts of shapes, and the tonic and clonic spasms of the body and limbs are not in any way regular, as they are apt to be in strychnine poisoning and tetanus. The patient is likely to be a woman, and there may be a history of previous hysteria (p. 465).

PLATE XXIII

INTESTINAL SAND

1. Microscopical appearance of true intestinal sand.
2. Microscopical appearance of false intestinal sand, following the ingestion of pen

By permission from "The Faces of Children and Adults," P. J. Connolly.

During a quiescent interval it may be found possible to stroke or touch the patient without bringing on a convulsion, whereas in strychnine poisoning and in tetanus the slightest touch is apt to evoke a violent and generalized spasm, even opisthotonos.

Malingering may take the form of imitated convulsions, during which the features may be kept fixed in one position or another, sometimes in that of smiling. The fixed voluntary contractions cannot be maintained long, however, on account of fatigue, so that although there may be some doubt at first, this generally disappears soon. The patient is usually a man who has something to gain by malingering: a night's lodging in a hospital, for instance.

Strychnine Poisoning and Tetanus are the two chief causes of typical risus sardonius. The main point to rely on in distinguishing the two is the history, if it is obtainable—the injection of an overdose of strychnine hypodermically, or the taking of a rat-paste, on the one hand, or the occurrence of some small but penetrating wound by a rusty nail or earth-soiled knife or stick during the fortnight preceding the symptoms, on the other. The absence of any known wound, however, does not exclude tetanus. If lock-jaw and stiffness of the neck are prominent features, tetanus is more probable than strychnine poisoning, and vice versa. In strychnine cases, the patient will either die quickly, or the symptoms will subside rapidly, whereas in tetanus they may persist unabated for several days. In a few instances the diagnosis may only be settled by the discovery of strychnine in the gastric contents, or of tetanus bacilli (*Plate XXVIII, Fig. T, p. 614*) in anaerobic cultivations from the infected wound.

It only remains to add that a few cases of *facial sclerodermia* may simulate risus sardonius, though more often there is complete smoothness of the features and lack of expression. There are no spasmodic contractions, the condition comes on gradually, is permanent, and the diagnosis becomes obvious at once when the hard smooth skin is palpated, for one cannot pick it up between one's fingers.

RUMINATION. (See **MLRYCISM**, p. 388.)

RUPIA. (See **SCABS**, below.)

SALIVARY GLANDS. (See **SWELLING OF THE SALIVARY GLANDS**, p. 694.)

SALIVATION, UNDUE. (See **PIVALLISM**, p. 542.)

SAND, INTESTINAL. This is seen in the motions, especially when they are fluid and the patient has membranous colitis. It is like the finest sea-sand; its colour varies owing to varying degrees of imbibition of faecal pigment. Usually it is red, looking something like fine uric acid, and it varies from this to a pale dirty yellow. It is seen best showing up against the white of the bed-pan in which it lies. Analysis shows that it consists of from 30 to 70 per cent of organic matter, doubtless all derived from the faeces. The inorganic matter is invariably nearly all calcium phosphate, with traces of calcium oxalate, magnesium, iron, and perhaps silica. The amount of sand passed in a day may be four teaspoonfuls, but usually it is much less. Many patients pass it for years, but not always constantly even then; it may be passed daily for weeks, and then for weeks none is passed. It is far commoner in those who have membranous colitis than in other patients, but it has been seen with malignant disease of the large intestine; it always indicates some organic disease of the colon. It must be distinguished from false intestinal sand, which looks very like it and may be found in the motions of those who have eaten largely of pears. This is entirely vegetable, and can be distinguished easily from true intestinal sand by microscopical examination (*Plate XXIII*).

W. Hale White.

SCABS.—The scab, or crust, one of the secondary cutaneous lesions, is a more or less irregular, dried-up mass of exudation on the surface of the skin. It may be produced by the desiccation of serum, pus, or blood, or of a mixture of these fluids, and commingling with these substances there may be epithelial debris, or fat, or fungous elements. Scabs form on matured vesicles, bullae, and pustules, on ulcerations, erosions, and on every kind of excoriation, pathological or traumatic. If the exudation is thin, as sometimes in eczema,

they are soft and friable; if it is thick, they may be tougher and more adherent, and successive layers may be formed, as in the rupial crusts of syphilis. Scabs composed largely of fungous elements are more or less friable, and these, like those resulting from the seborrhoeic process, may partake of the character of scales as well as of scabs. Such formations, however, as for example the 'crusts' of favus, are in the nature of scales rather than of scabs, and are noticed elsewhere. (See SCALY ERUPTIONS, p. 601; and FUNGOUS AFFECTIONS OF THE SKIN, p. 246.)

Scabs vary greatly, not only in consistence, thickness, and adhesiveness, but also in colour and in form; and by attention to these differences the diagnosis of the affections in which they occur may be assisted. Some guidance may also be obtained from the condition of the surface from which the scab has been removed; it may be dry when the scab has been long adherent, as in some cases of impetigo, excoriated as in eczema, or ulcerated as in rupia. But the clinician will be guided much more by the primary than by any secondary lesion; and for the decisive diagnostic features of the diseases about to be mentioned, the reader is referred to the articles MACULES (p. 382); VESICLES (p. 753); BULLE (p. 96); PAPULES (p. 487); NODULES (p. 402); and PUSTULES (p. 557.)

In *irritative herpes* the vesicles on the skin shrivel up and form yellowish-brown crusts, which after a few days become detached, as a rule leaving no scar, but only a brownish stain, which slowly fades away. In *herpes zoster* most of the vesicles which do not abort reach the same termination; but others, instead of drying up, may burst and discharge a fluid, which then forms yellowish or brownish crusts. In *zoster* a scar is produced sometimes. In *erythema multiforme* there is often considerable scabbing, as is mentioned under VESICLES (p. 753). In *eczema* the lesions may dry up either into scales or into crusts. Crustation is usually the third stage in the evolution of the disease, the discharge from the vesicles drying into greyish-yellow scabs of varying thickness, which become detached and are succeeded by others until the 'weeping' ceases. When the lips are attacked, they may become so stiffened under layers of crusts superimposed one upon another that the patient can hardly move his lips without fissuring the skin. In the male, the 'bathing-drawers' area may be so covered with crusts that the patient cannot walk or sit down without breaking them. In the same region in the female the inflammation and crustation may be even more severe, and the scabs may be marked by much foulness. One of the characteristic features of what is called *papular eczema* is the appearance of a tiny dome of blood-crust on the papules, due to scratching. In *seborrhoeic eczema* there may either be scaling, or the squames may be massed into fatty crusts (see SCALY ERUPTIONS, p. 601). The scabs in *eczema rubrum* are extremely thin, like goldbeater's skin; when they are torn off, a red, wet, raw, tender surface is laid bare. The crusts of *scabies* may be distinguished from those of *eczema* by their being isolated and distributed irregularly, instead of being grouped, and by the multiformity of the lesions with which they are mixed—vesicles, bullae, pustules, hamorrhagic scabs, etc. In most itching diseases there will be found blood-scabs, resulting from the scratching to which the patient is provoked.

In *cheirapompholyx* the bullae into which the little sago-grain vesicles run dry up into crusts, the removal of which reveals a surface that is red and exquisitely tender. The appearance and sensitiveness of the underlying skin, together with the limitation to the hands and feet, and often to the hands alone, will help the diagnosis. The crusts of *syccosis vulgaris* also have a limited distribution; they may be confined to the upper lip, and in any case they do not extend beyond the hairy parts of the face. They are brown or yellow in colour, thin, and distinctly adherent.

In *impetigo contagiosa* the scabs which are formed from the dried-up fluid discharged by the pustules on rupture are yellowish; in uncleanly persons they are brown, or even black. A characteristic feature is that they have around them no hyperæmic halo, but look as if they might have been stuck on artificially. In the severe form of the disease styled *ecthyma*, however, the flat irregular scab formed from the ruptured vesicles is surrounded by a more or less pronounced areola. At first loosely attached, the scabs in *impetigo contagiosa* afterwards become so firmly adherent that their removal requires some force and gives rise to a little bleeding. In this affection there is what may be called a secondary scab, formed by the drying-up of the thick, purulent discharge—honey-like in consistence and appearance—from the surface left raw by the removal of the earlier crusts. The reddish stain that appears when the lesion heals is not permanent. In

pemphigus vulgaris the crusts into which the bullae shrink are brownish-yellow; and when they fall off spontaneously the surface beneath is not raw, as in impetigo, but is found to be covered with newly-formed epidermis, at first purple, afterwards turning brown, and gradually becoming normal in colour. When the area covered by the scabs is extensive there is an unpleasant sense of tension, and if they are removed prematurely, excoriation may be caused. In the more serious affection known as *pemphigus foliaceus*, the crusts are yellowish, and as the disease proceeds, large scales are formed. In *pemphigus vegetans* the foul-smelling secretion from the patches of affected skin forms a thin crust, which can easily be stripped off, when a papillary excrescence, partly covered with a thin stratum of epidermis, is revealed. The process usually ends in gangrene and death. The excrescences are distinguishable from the condylomata of syphilis by always being surrounded by a zone of bullae, while condylomata have an infiltrated border.

In *nerve leprosy* the bullae, which have the same characters as those of *pemphigus vulgaris*, form, on rupture, a large crust, the removal of which exposes a grey surface consisting of altered rete, the epidermis being cast off by suppuration. In this way a succession of yellow scabs or crusts may be formed and fall off, leaving at last a granulating surface, which ultimately is converted into a white scar. If the bullae abort, they are followed by a parchment-like scale instead of a crust, and this in turn gives place to a hyperæsthetic ulcer. The scabs of nerve leprosy have some resemblance to the *rupial crusts* of secondary syphilis, but there is little danger of confusion between the two. The *rupial crusts*, greenish or blackish, consist of several successive layers, each smaller than the one immediately below it, so that a pyramidal structure is formed, somewhat resembling the shell of a limpet. This very characteristic crust, which can scarcely be mistaken for that of any other condition, and distinguishable from the psoriasis *rupioides* of McCall Anderson by the base being ulcerated, is formed from pustules usually, but may follow also on the drying up of bullae. The scabs in *secondary yaws* form upon the yellow heads of large papules, and beneath them are found reddish raspberry-like granulations which secrete a little pus, and after a time become pale or even white. Healing usually takes place beneath the scabs, which fall off about the end of the second month from the onset of the secondary rash. The raspberry-like granulations, the characteristic lesion of yaws, will obviate confusion between these crusts and those of any other affection. The crusts of *lupus vulgaris* are greenish-black, like *rupial crusts*, but they do not consist of layers superimposed upon each other, and dotted around the ragged edge will be seen the 'apple-jelly' nodules which are the 'note' of lupus.

In *small-pox* the formation of scabs on the pustules begins in the centre and causes a secondary 'umbilication': it is generally attended by intense itching. In from three to four weeks from their appearance the crusts fall off, leaving a reddened surface, made uneven by scars or 'pits.' The true nature of the disease will have been discovered, even in doubtful cases, before the crust stage is reached. (For the differential diagnosis, see under PUSTULES, p. 557). In the diagnosis of *ulcers*, as in that of small-pox, the crust is of little importance. These are dealt with under ULCERATION OF THE FACE (p. 735) and ULCERATION OF THE FOOT (p. 735).

Malcolm Morris.

SCALY ERUPTIONS.—The squame, or scale, one of the secondary cutaneous lesions, is a dry, and as a rule laminated, exfoliation of the epidermis. Disregarding the slight, imperceptible desquamation which is a purely physiological process, scales may be said to result either from inflammation, as in psoriasis and pityriasis rubra pilaris; from an abnormal dryness of the skin, as in dry seborrhœa and keratosis pilaris; or from an earlier acute hyperæmia, as in scarlatina and other erythematous eruptions. The process may consist in an over-multiplication of the epidermic cells or in interference with the normal horny transformation. In colour, scales are ordinarily white or grey, either dull and lustreless, as in seborrhœa, or silvery, as in psoriasis; but they are sometimes a dirty yellow, as in some dry syphilides, or even reddish-brown, as in oily seborrhœa. They may be large and thin, as in pityriasis rubra, or small and branny, as in tinea versicolor; even in the same affection (e.g., pityriasis rubra) they may vary greatly in size in different regions. They may consist of a single layer, as in squamous eczema, or of several adherent strata, as in psoriasis. In quantity they may be inconsiderable, as in tinea versicolor, or most profuse, as in psoriasis and pityriasis rubra. Usually they are dry and friable, but

if mixed with an oily secretion, as in seborrhœa, or with a serous or seropurulent discharge, as in eczema, they may partake of the nature of both scales and crusts.

A brief description of the scales met with in various affections may be given here; but except in a few diseases of which they form a highly characteristic manifestation, such as seborrhœa, psoriasis, and pityriasis rubra, they have little diagnostic value, and, as I have said elsewhere of scabs, diagnosis must usually rest upon primary rather than upon secondary lesions.

Sometimes there is scale-formation in eruptions due to the internal administration of such *drugs* as quinine or belladonna, or to the external application of carbolic acid, iodine, etc.; but it has no significance in diagnosis. In *keratosis pilaris* (xeroderma) and other forms of *ichthyosis*, there is always more or less desquamation of the dry and roughened and sometimes warty skin; but here also it is without diagnostic import. Of the scales of scarlet fever, measles, German measles, and other *infectious fevers*, again, nothing need be said, for the diagnosis ought to have been settled before they appear. Nor need I speak of the scaldiness of *tinca tonsurans*, *tinca versicolor*, and other *fungous affections*, for the differential diagnosis of these diseases has been given under FUNGUS DISEASES (p. 246). The scales of papular syphilides, again, have been described under PAPULES (p. 487), and the diagnosis of the lesions, both primary and secondary, from those of psoriasis will be found in that article. In the unusual instances of *urticaria* in which desquamation is present, it is so slight as to be negligible. In most forms of *erythema*, scales occur; but here again they have little significance for the diagnostician, and it will be sufficient to say that in *erythema simplex* the desquamation is slight, and that in *erythema scarlatiniforme* it is more considerable. In *lupus erythematosus* the central scar-like depression of the primary eruptive lesions may be covered either with thin, papery, greyish scales, or with a firmly adherent scab. In parts furnished with sebaceous glands, the skin will usually be covered with small adherent scales of sebum, which at the margin of the patch plug the dilated orifices of the glands, so that numerous comedones are formed. From other forms of *erythema*, as also from ringworm, *lupus erythematosus* may be distinguished by the slowness and persistence of the process. The lesion itself, atrophic in the centre, with a well-defined red border, and studded with plugs, can scarcely be mistaken when it appears on its site of election, the face. When, however, it occurs on the limbs, it may mimic chilblains so closely that only the lapse of time can make the diagnosis certain, *lupus erythematosus* being much more obdurate to treatment, and not disappearing in the summer. For the diagnosis between *lupus erythematosus* and psoriasis, see below; for that between *lupus erythematosus* and *lupus vulgaris*, see under NODULES (p. 402).

We now come to affections in which scales play a more important part. In *seborrhœa sicca* there is an excess of the solid fatty constituents of the sebum, and the excreted material takes the form of scaly but usually somewhat greasy masses. In *seborrhœa oleosa* there is an abnormal predominance of the oily part of the sebaceous secretion, which dries into yellowish or reddish-brown cakes of greasy scales, often with a hyperæmic base and a fringe of papules about the edge. In the face, oily seborrhœa is more often met with than the dry form; but seborrhœa generally, though it may occur on the trunk and limbs, almost invariably begins on the scalp. When not limited to the scalp, as usually it is, it spreads downwards to the face, round the neck, the chest, the centre of the back, and the limbs. In the light of this preference for the scalp, and the downward extension when the affection is not confined to that part, a typical case of seborrhœa is unmistakable. In cases of seborrhœa which resemble psoriasis, guidance may be found in the scales, which in the latter affection are silvery, and harder. The respective starting-points of the eruptions, however, furnish a safer indication, psoriasis almost always appearing first on the elbows and knees and spreading upwards.

In typical *eczema*, scaling forms the final stage of the pathological process. After the initial erythema comes the exudation, then the crustation (see SCABS, p. 599), next the dry stage, and lastly the desquamation, the epidermis being shed in scales that become progressively thinner and smaller until only a brownish stain is left to mark the site. All the stages are often present at once in a given case. Scaling is frequently a noticeable feature when there is a predominance of erythematous lesions, as it is also in *eczema folliculorum*. But it is in *seborrhœic eczema* that this phenomenon is most prominent, the latent

catarrh with which the affection begins being followed by the agglutination of epidermic scales which are thrown off in the form of large lamelle. In some cases the scales may increase in quantity, in others, as is mentioned under SCABS (p. 599), they may become massed into fatty crusts among the hairs. The differential diagnosis of *eczema* has been set out in the articles on the primary lesions. The secondary lesions in this affection may indeed be rather a hindrance than a help in determining its true nature, and in doubtful cases the first thing to do is to remove both scales and crusts in order that the underlying lesion may be examined carefully. As between *eczema* and *psoriasis*, however, just as between *eczema* and *seborrhoea*, the scales afford guidance in the diagnosis; while in *psoriasis* the lower layers of scales are whitish or silvery and hard, in *eczema* they are yellowish, dull, and friable.

In *psoriasis* the scale has distinct diagnostic value. It enters, indeed, into the definition of the disease as an affection of the skin, characterized by flat, dry patches of varying extent, covered with whitish, silver-grey, or asbestos-like scales. The scalliness may vary from a thin film to a dense, heaped-up mass. If the scales are removed, a smooth, dry, shining hyperemic surface is seen, studded with spots that show various gradations of colour, from a deep to a bright red, the bright-red points being the tops of inflamed papillae. The eruption appears as papules of pin-head size, at first red, but becoming white as the scales form. Spreading centrifugally, the papules form patches, generally roundish or oval when small, and becoming more irregular as they grow larger. They may remain stationary for a long time, and slowly disappear, or, continuing to spread, may become confluent. While the disease is active the individual patch is encircled by a narrow zone of redness, but when it is not spreading this fades away. Sooner or later involution takes place, and the redness which the lesions leave behind them soon disappears, though in protracted cases a brown stain may persist, and in rare instances there may be superficial atrophy. The malady may come and go, recrudescing after nearly disappearing, for the greater part of a patient's life. It is often most abundant when the patient is in the best health, and may almost or quite disappear during serious illness. In distribution, *psoriasis* is almost invariably symmetrical. Like small-pox, it shows a marked predilection for surfaces that are exposed to friction. Almost always it starts on the tips of the elbows and the fronts of the knees. After the extensor aspects of the limbs, its favourite site is the hairy scalp, and then the trunk, especially over the lumbar region. In typical cases the clinical picture—the patches with sharply defined border, covered with hard, shiny scales; the hyperemic surface beneath, dotted with red points; the distribution as just described; the unimpaired health, the natural complexion, the proneness to attack blue-eyed fair-haired persons, and the absence of exudation—scarcely admits of misinterpretation. In all these particulars, except the unimpaired health, *psoriasis* differs from *eczema*, as well as in the less intense and less constant itching by which it is attended. On the scalp, while *psoriasis* usually occurs in patches and ends abruptly at or only just beyond the margin of the hair, *seborrhoeic eczema* almost invariably extends over the whole surface, and often involves the face and the neck. Almost always, too, *psoriasis* spreads upwards from its sites of election, *seborrhoeic eczema* downwards from the head. In very chronic forms of *eczema*, in which there may be no history of 'weeping,' the diagnosis from *psoriasis* may be difficult. In all doubtful instances, gentle scratching on the affected surface will bring out the silvery scales, if the case is one of *psoriasis*.

The papular stage of *lichen planus* may be mistaken for *psoriasis*. In *lichen planus*, however, the eruption shows a preference for the flexor aspects of the wrists and knees; it consists of shining-smooth papules, without scales; the ground-tint is bluish-red or violet; and the patches are formed by the aggregation of a number of papules instead of by centrifugal extension. In doubtful cases the whole body must be searched for the typical lesions of either disease.

Lupus erythematosus differs from *psoriasis* in that, in the former condition, the scales are not abundant, the edge of the patch is more elevated, the cheeks are usually attacked, as they are not in *psoriasis*, and there are the distinctive plugs in the orifices of the sebaceous ducts, as described earlier in this article. Scarring, too, may be found in the patch, and there may be atrophy of the ears.

As between *psoriasis* and *papular syphilides*, the diagnosis is given under PAPULES (p. 187). The heaped-up crusts of the condition which has been styled *psoriasis rupioides*

can be distinguished from the rupial lesions of syphilis by the base being ulcerated in the latter disease; but syphilis mimics everything, and cases sometimes occur in which it can be distinguished even from so distinctive an affection as psoriasis only by attention to the history, and by the discovery of other lesions, the presence of cachexia, the influence of salvarsan, iodides, and mercury, or by the Wassermann serum test.

In *pityriasis rubra* the whole cutaneous surface is always inflamed and reddened, without infiltration or thickening, but accompanied by profuse desquamation (*Plate XXIV*), branny on the head, larger flakes from the trunk, huge scales from the hands and feet. Pityriasis rubra may occur as an independent disease—an extremely rare event—or may follow in the wake of erythema multiforme, eczema, psoriasis, lichen planus, dermatitis herpetiformis, and certain drug eruptions. Its most frequent precursor is psoriasis. The constant and profuse desquamation, the papery scales and sheets in which the epidermis is shed, are important diagnostic signs; others are the vivid redness of the eruption, the rapidity with which it is diffused, its universality, the serious impairment of health—sometimes issuing in death.—and the frequent absence of itching. From eczema it is distinguished by the absence of exudation and of crusts; from psoriasis by its rapid spread and universal diffusion; from pemphigus foliaceus by the absence of loose bullae and of foul-smelling discharge, the less severe general symptoms, and the greater amenability to treatment; from lichen ruber planus by the absence of papules, as well as by its rapid extension and involvement of the whole area of the body.

The essential lesions of *pityriasis rosea* are patches or circles, very slightly raised and thinly covered with small scales. The eruption usually shows itself first on the abdomen, though it may begin on the chest, the face, or the arms. It spreads less rapidly than pityriasis rubra, but in two or three weeks the trunk, the face, and the limbs may be covered, and though occasionally it is universal, it seldom extends below the elbow or the knee. The diagnosis is seldom in doubt, the characteristic 'herald patch' with which the rash begins, the pale-red tint, the slight elevation of the patches, the mingling of maculate and circinate lesions, the slight degree of scalliness, and the spontaneous involution, forming a distinctive *ensemble*. The differences it presents from pityriasis rubra have been indicated above. From psoriasis it is differentiated by its less inflammatory character, the more rapid onset, the slight scalliness, its neglect of the situations most vulnerable to psoriasis attack, and the absence of hyperæmic spots on the surface beneath the scales. From seborrhœa corporis, by the dryness of the scales, its much less chronic character, the lesions disappearing spontaneously in a few weeks. From tinea circinata, by the large number and wide distribution of the lesions, and the absence of the fungus which is the cause of cutaneous ringworm. From the maculo-papular syphilide, by the absence of infiltration, the lighter colour, the fact that the palms of the hands are usually spared, and the lack of concomitant syphilitic signs.

Pityriasis rubra pilaris may appear in the form of scaly patches, resembling psoriasis, on the palms and soles, or as a dry eruption, covered with eczematous-looking crusts; but the papule which soon appears is a more characteristic lesion, and the diagnosis of the condition from psoriasis and other affections will be found under PAPULES (p. 488).

SCLEROTICS, BLUE. (See FRACTURE, SPONTANEOUS, p. 242.)

SCOLIOSIS.—(See CURVATURE, SPINAL, p. 153.)

SCOTOMATA.—(See VISION, DEFECTS OF, p. 737.)

SENSATION, SOME ABNORMALITIES OF. The abnormalities of sensation met with in disease are as numerous as they are important for the purpose of diagnosis. Under PAIN IN THE FACE (p. 416); PAIN IN THE UPPER EXTREMITY (p. 442); and PAIN IN THE LOWER EXTREMITY (p. 438), the question of subjective pain in relationship to diagnosis has been discussed, and reference will be found on p. 414 to another subjective abnormality of sensation to which the term 'acroparæsthesia' is applied.

Wherever sensory loss occurs, it should assist in forming a conclusion as to the site of disease, even if it does not indicate clearly anything with regard to its nature. In order that the sensory loss may give the necessary information, it is absolutely necessary that the

PLATE XXIV

PITYRIASIS RUBRA

*From "Diseases of the Skin,"
by kind permission of Sir Malcolm Murray, K.C.V.O.*

physician should ascertain both the limit and the nature of the loss. He will be able to judge from the shape and locality of the anæsthetic area whether it conforms to a lesion of a peripheral nerve, a spinal root, or some part of the central nervous system. Analysis to show whether the loss is uniform to all forms of sensory stimuli, or whether it is limited to one or two forms only, will provide additional information for diagnosing the situation of the lesion. In order to utilize the information provided by the shape and size of the

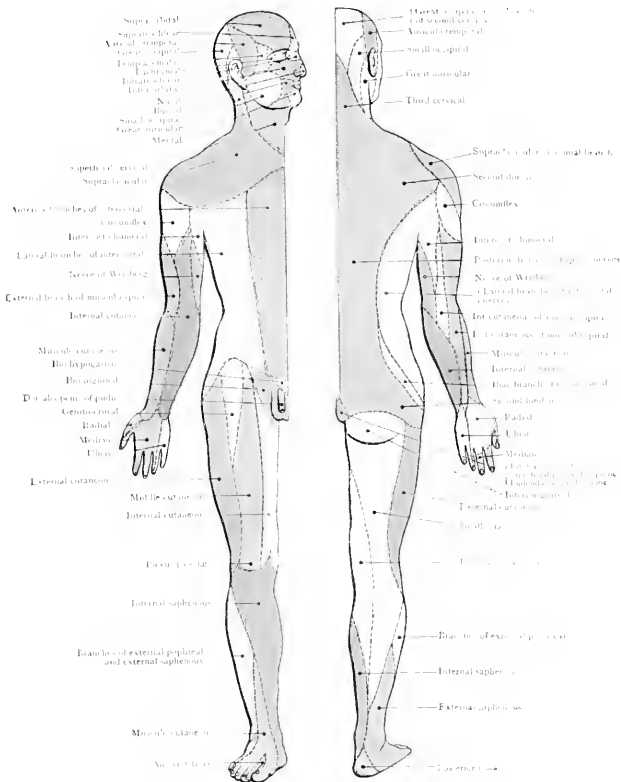

Fig. 255. THE DISTRIBUTION OF SENSORY NERVES IN THE BODY.

area of anæsthesia, it is necessary to know what are the areas on the surface of the body which correspond to the distribution of peripheral nerves on the one hand, and of spinal segments or spinal roots on the other. The accompanying diagrams (*Fig. 255 and Plate XXI, p. 608*) supply this information to some extent, but in order that it may be used to the best advantage, it is necessary to say a few words about various forms of sensory loss due to lesions in different parts of the nervous system. Before entering upon this part of the subject, we may explain the way in which we propose to use the terms anæsthesia, analgesia, and thermo-anæsthesia.

Anæsthesia denotes impairment or loss of the cutaneous sensibility to cotton-wool

touch, and it is important to remember that parts which are hairless should be chosen for accurate examination.

Analgesia refers to impairment or loss of pain-sense, the adjective 'superficial' being applied when the surface pain produced by the prick of a pin is interfered with, and the adjective 'deep' when the pain usually associated with pinching or squeezing the muscles and deeper tissues is no longer appreciated.

Thermo-anæsthesia indicates loss of appreciation of heat and cold; but the inability to distinguish between things which are warm and cool is not always associated with equal loss of sensibility in distinguishing between objects which are ice-cold and really hot.

Disturbances of Sensation in Peripheral Nerve Lesions.—The afferent mechanism of the peripheral nervous system consists of the following three sub-systems:

1. *Deep Sensibility.*—This conveys impulses excited by pressure and by all movements of joints, tendons, and muscles. Painful impulses derived from excessive pressure are also carried by this sub-system. By its means a healthy person is able to recognize not only movements of joints, but also the locality of the stimulus and the direction of the movement. The fibres which conduct these sensory impulses run mainly with the muscular nerves, and are not destroyed by division of the sensory nerves to the skin.

2. *Protopathic Sensibility.*—This sub-system responds to painful cutaneous stimuli (pinpricks) and to the more extreme degrees of heat and cold. The appreciation of these stimuli is vague and inexact as to the locality of the spot stimulated.

sub-system is due the power of perceiving and of discriminating between two points applied simultaneously to the surface, and of recognizing the finer grades of temperature called

3. *Epicritic Sensibility.*—To this locating light touches (cotton-wool), simultaneously to the surface, and of cool and warm.

It has been shown that when a *peripheral cutaneous nerve* is divided the area of epicritic loss is greater than that of protopathic loss; in other words, there is more overlapping of protopathic sensibility than of epicritic sensibility between neighbouring nerve distributions. Thus, if the *ulnar nerve* is divided near the wrist, there is complete loss to touch, superficial pain, heat, and cold, over an area including the little finger and part of the inner edge of the palm of the hand. This is the area of epicritic and protopathic loss. But epicritic loss extends over a wider area which includes half the ring finger and more of the band (Fig. 257). In this area of epicritic loss pain can be recognized but cannot be localized exactly, while light touch is not appreciated, and the discrimination between cool and warm is absent.

Consideration of the above points shows how important it is to define accurately the exact nature of any sensory loss, and to be careful that the appreciation of pressure is not mistaken for the appreciation of light touch. If tactile sensibility is tested by the observer's finger or with the head of a pin, the results will be vitiated, because pressure sensibility is at once brought into action.

Another important diagnostic point depends on the fact that protopathic sensibility returns some months before epicritic sensibility in the process of regeneration after the division of a peripheral nerve. During the stage of protopathic repair there is often a

Fig. 256.—Peripheral neuritis. 'Glove and stocking anæsthesia.' Cotton-wool and pinprick sensibility impaired or lost over the dotted areas. This is associated with hyperæsthesia of the underlying muscles.

Fig. 257. Division of ulnar nerve at the wrist. The dark area represents loss of epicritic and protopathic sensibility. The line indicates the limits of epicritic loss. (After Head and Sherrin.)

considerable degree of hyperalgesia in the affected area; that is to say, the pain produced by a pin-prick or a scratch is out of all proportion to the nature of the stimulus.

So far we have dealt with the disturbance of sensibility produced by the disease or injury of a single nerve. In the disease known as *peripheral neuritis* the sensory disturbances are very characteristic, and consist of pain, tingling, tenderness, and cutaneous anaesthesia. Spontaneous pain in the limbs is often complained of, but more important is the intense suffering produced by movements, and especially by handling the limbs or by squeezing the muscles. At the same time cotton-wool touch is often unperceived on the peripheral parts of the limbs, particularly in what are known as the glove and stocking areas (*Fig. 256*). This combination of deep hyperalgesia and cutaneous anaesthesia constitutes an important differential sign between peripheral neuritis and tabes dorsalis, in which superficial and deep analgesia are nearly always associated.

Disturbances of Sensation in Lesions of the Cord.—The impulses of the three peripheral sub-systems—deep, epicritic, and protopathic—combine in new groups soon after they enter the spinal cord. Some impulses cross to the opposite side immediately, others cross after running a short course on the same side, and others ascend to the upper extremity of the cord entirely on the side of their entry. This rearrangement may be summarized briefly thus:—

1. Impulses of pain, whether excited by cutaneous stimuli or by excessive pressure, run together in the spinal cord, and cross, probably soon, to the opposite side.

2. Impulses of temperature of all degrees cross to the opposite side and are closely associated, but not intermingled, with those of pain; the impulses of heat are also separated from those of cold.

3. Impulses excited by light touch and by pressure, and those which subservise their localization, accompany each other, cross to the opposite side, probably less rapidly than those of pain and temperature, and ascend in a path which is distinct from that of the latter.

4. Impulses subserving the senses of passive position and movement are associated with those of tactile discrimination (compass points) in their ascent of the cord on the same side as their entry. These impulses pass up the posterior columns.

The accompanying diagram represents this rearrangement of impulses and their course in the spinal cord.

The chief points of practical importance in

clinical work to be deduced from the above considerations are as follows: In the first place, analgesia resulting from a cord lesion always includes deep as well as superficial pain, and so differs from the analgesia produced by a peripheral nerve lesion in which, as we have seen, superficial analgesia may be associated with deep hyperalgesia. Secondly, a lesion of the spinal cord may abolish the appreciation of thermal stimuli, but, if it does so, the discrimination between all degrees of heat and cold will be lost. This again differs from the effect of some peripheral lesions. In the third place, a lesion of the posterior columns may produce loss of the sense of passive position and movement without any loss of tactile, painful, or thermal stimuli, a combination which does not obtain as the result of a lesion limited to the peripheral nervous system.

In all diseases or injuries of the spinal cord, the degree of sensory loss depends, of course

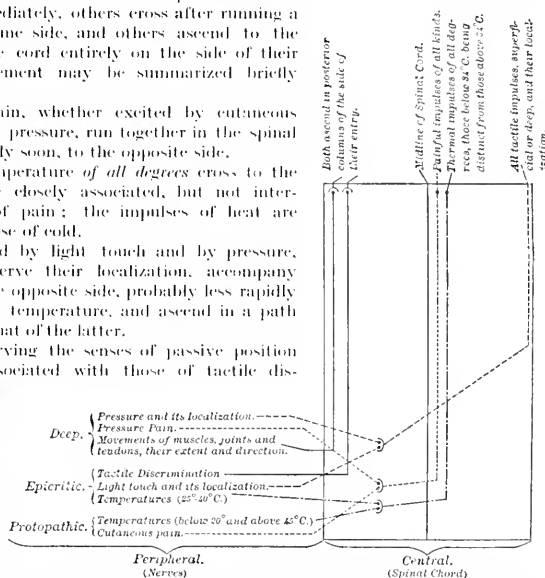

Fig. 258.—Diagram illustrating the course of the sensory impulse passing from the peripheral nerves into the spinal cord. From the authors' article in *Oster's Medical Medicine*, vol. viii.

upon the severity of the lesion. On the other hand, the distribution of the sensory loss is of the greatest importance for the diagnosis of the level of the lesion. The distribution must be mapped out carefully, and then compared with the accompanying diagram (Plate XXI'), which shows the sensory areas corresponding to the different spinal segments.

Fig. 259.—Comminuted fracture of the sacrum, with injury to the 3rd, 4th, and 5th sacral roots. Complete loss of sensibility to touch, superficial pain, heat and cold.

In a case of *myelitis*, for instance, it may be found that sensation is perfect above the level of the umbilicus, and impaired on the trunk and legs below that level (Fig. 260). We shall be justified in concluding that the highest point of the disease corresponds to the 9th dorsal segment of the cord. Take another example: *fracture dislocation of the vertebrae* is common in the cervical region, and may crush the spinal cord at the level of the 7th cervical segment. The resulting sensory loss is represented in the accompanying chart (Fig. 261).

In testing the sensibility of the skin it is always advisable to work from the anæsthetic area towards the normal, and to note not only complete anæsthesia, but all modifications of sensation. For instance, bordering on the region of complete anæsthesia there may be an area in which the patient is able to appreciate a touch or a pin-prick, but in which he describes the sensation produced as differing from the natural sensation elicited by these stimuli. Such modifications should be taken into account in diagnosing the level of the lesion.

As a result of disease or injury of one side of the spinal cord, a symptom-complex called *Brown-Séquard paralysis* is met with. This is discussed on p. 496. Fig. 204 (p. 497), illustrates the sensory loss in a case of this kind.

Syringomyelia and *hamatomyelia* are other conditions in which dissociative anæsthesia is common (Fig. 262). In the former disease thermo-anæsthesia and analgesia are usually found first in the arms and thorax, and they tend to spread all over the body. In rare instances they begin in the legs or on the face. Their distribution is nearly always asymmetrical. The borders of the cutaneous loss are not sharp but shaded off, and correspond to the limits of spinal-root

Fig. 260.—Dorsal myelitis affecting the cord as high as the 9th dorsal segment. The shaded parts are insensitive to touch, deep and superficial pain, and all degrees of temperature.

Fig. 261.—Fracture-dislocation of the cervical spine. The shaded area represents the loss of sensibility to touch, pain, heat and cold.

areas. On the other hand, charts sometimes show regions of dissociative anæsthesia which correspond laterally to one or more root areas, but do not cover their longitudinal extent. For instance, the sensory loss in one hand may be limited above by a line encircling the

PLATE XXI

DIAGRAM SHOWING THE RADICULAR SENSORI AREAS OF THE HUMAN BODY

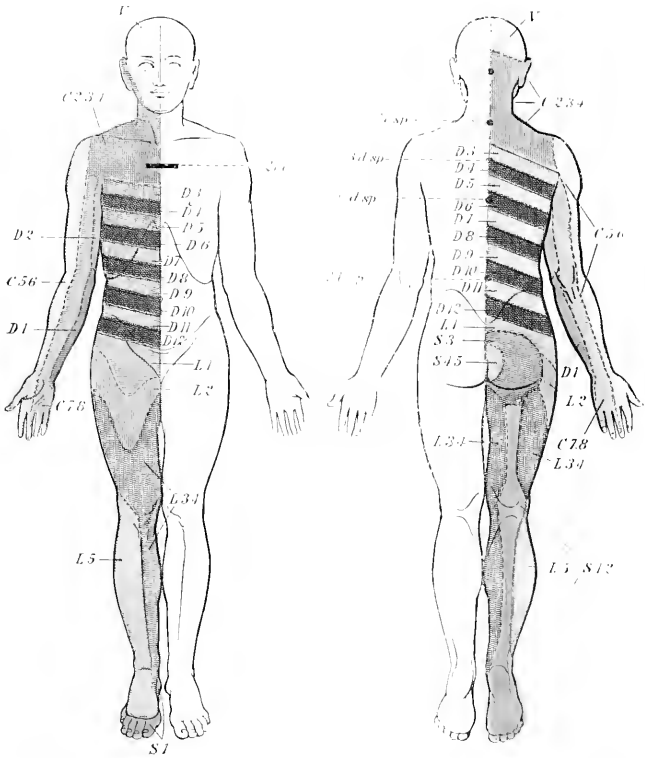

Diagram 1

Diagram 2

This diagram has been compiled from the data furnished by the following sources: (1) the author's personal observations and studies in accordance with the sensory areas of the body.

Although the sensory areas of the body are generally fixed, they are not constant and may vary considerably from all the areas shown. The author has observed many cases of sensory areas which do not correspond to the areas shown in this diagram. It is for this reason that the areas shown in this diagram are only approximate and should not be taken as absolute. The areas shown in this diagram are only approximate and should not be taken as absolute.

The present diagram is a composite of the sensory areas of the body as shown in the following sources: (1) the author's personal observations and studies in accordance with the sensory areas of the body. It is for this reason that the areas shown in this diagram are only approximate and should not be taken as absolute.

forearm, so as to give it the appearance of a glove distribution. Similarly, on the face a central area, including the nose, mouth, and eyes, may preserve its sensibility intact, while the surrounding regions are completely insensitive to painful and thermal stimuli. Thermo-anæsthesia and analgesia are sometimes, but not always, co-extensive. Tactile loss also occurs, but usually supervenes in the later stages of the disease. Subjective sensations may form the initial evidence of the disease, and may be thermal, painful, or tactile. Lancinating pains and cramps are described. More curious are the subjective sensations of drenching sweat in a part which is dry, or of cold in a part which is quite normal in temperature.

In *tabes dorsalis* the disturbances of sensation are numerous and characteristic. Lightning and dull boring pains, tingling, numbness, girdle sensations, and various painful crises are among the subjective abnormalities. Impairment or loss of deep and superficial pain sensibility in various parts of the body is one of the earliest and most important physical signs for the purpose of diagnosis. The cutaneous analgesia is generally found on the legs, and often also in the root areas on the arms and thorax corresponding to the C 8 to D 5 segments (Fig. 263). Deep analgesia is nearly always present in the calf muscles.

Fig. 262.—Syringomyelia. The shaded parts show the areas of dissociative anæsthesia, i.e., of thermo-anæsthesia and analgesia. This was associated with atrophic palsy of the upper extremities.

Fig. 263.—Early tabes dorsalis. The dotted area represents a characteristic distribution of sensory disturbance. The loss is chiefly to painful stimuli, and the superficial analgesia is almost always associated with deep analgesia.

Superficial nerves such as the ulnar may often be found insensitive to rolling or pinching. Delayed sensibility is another phenomenon very characteristic of some cases of tabes dorsalis. Hyperæsthesia may be present, especially in bands around the abdomen, when gastric or intestinal crises form part of the clinical picture. Intolerance of hot or cold water on any part of the skin is described by some patients suffering from severe forms of the disease. Allocheiria, or reference of a sensory stimulus to the opposite side of the body, has also been observed. The sense of position and movement is nearly always disturbed in locomotor ataxy, and this results in varying degrees of inco-ordination and in the production of Romberg's sign. Astereognosis, or the inability to gauge approximately the size and shape of objects placed in the patient's hand, is another common sensory defect.

In *disseminated sclerosis*, sensory troubles do not as a rule constitute so prominent a feature as do the motor disabilities, but subjective and objective changes are by no means uncommon. Numbness of one limb lasting a few weeks or months, girdle sensations, and even pains of a neuralgic type, are sometimes complained of. I have known transient hemianæsthesia to be an initial symptom in one case, and astereognosis with loss of sense of position on one side, to be the earliest signs of disease in two or three cases. From the diagnostic standpoint these are important facts, because it is very tempting to assume, erroneously, that such sensory phenomena, occurring alone without any reflex or motor

signs of organic disease, are hysterical in origin. They are doubtless due to patches of disease near the internal capsule.

This brings us to the consideration of the **Abnormalities of Sensation resulting from Disease of the Higher Parts of the Nervous System.** Hemianæsthesia is a common result of the various vascular accidents responsible for *apoplexy* and hemiplegia. It may be present with or without motor paralysis and with or without hemianopia; sometimes all three phenomena are associated in the case of severe lesions of the internal capsule and optic radiations. In most cases of apoplexy hemianæsthesia is slight and transient. Tactile and pain sensibility may be impaired, usually more so on the limbs than on the trunk, and more especially in the distal portions of the arm and leg. Even when touches are perceived they are localized badly by the patient. In *lesions of the optic thalamus* the opposite side of the body may be the site of a curious sensory disturbance which consists in part of a lowered sensibility to painful stimuli and in part of a great exaggeration of the disagreeable effects produced by such stimuli when they are perceived. For instance, the patient may fail to recognize a light pin-prick so well on the affected as on the sound side, but a scratch may produce an intensely painful sensation referred to a very wide area and not localized to the spot stimulated. In such cases the patient often complains also of paroxysms of severe pain in the affected limbs.

The *hemianæsthesia of hysteria* is usually far more complete to all forms of stimulation than any hemianæsthesia due to organic disease of the brain. The hysterical patient is found to have lost taste, smell, and sometimes even hearing, on the anæsthetic side. The visual defect, instead of being hemianopic as in the organic cases, is generally a marked contraction of the visual fields, sometimes amounting to blindness, especially in the eye corresponding to the other sensory defects.

Lesions of the brain-stem may also be responsible for extensive loss of sensation. For instance, thrombosis of the posterior inferior cerebellar artery gives rise to a localized softening on one side of the medulla, which produces thermo-anæsthesia and analgesia on the same side of the face, and on the trunk and limbs of the opposite side (Fig. 264). This sensory disturbance is sometimes complicated by homolateral cerebellar ataxy and cranial nerve palsies.

Fig. 264.—Thrombosis of left posterior inferior cerebellar artery. The dotted areas show the regions of dissociative anæsthesia, i.e., loss of sensibility to pain and temperature of all degrees.

So far we have dealt chiefly with the various forms of lowered sensibility, and have given little attention to perversions of sensation, such as are indicated by the terms *hyperæsthesia* and *paræsthesia*.

Hyperæsthesia is observed in cases of tabes dorsalis and peripheral nerve lesions as described above, but it is also met with in other conditions of organic as well as functional disease. It is found, for instance, in root areas in cases of vertebral and intravertebral disease. In *spinal caries* and in *tumours of the spinal meninges*, a zone of hyperæsthesia may be detected just above the area of anæsthesia produced by the compression of the cord, or it may precede the appearance of compression signs. The increased sensibility is probably caused by pressure on, or irritation of, the posterior root fibres. A similar phenomenon is a frequent accompaniment and sequel of an attack of *herpes zoster*. The shape and situation of such hyperæsthetic zones afford a clue to the site of the lesion. Hyperæsthesia as well as paræsthesia are among the earliest signs of *subacute combined degeneration of the cord*, and are referred by the patient to peripheral parts of his four extremities. They may precede by many weeks or months the appearance of ataxic or spastic paraplegia and definite areas of sensory loss. Similar symptoms are also complained of in not a few cases of pernicious anemia and other severe blood diseases, probably on account of scattered degenerations in the nervous system as the result of the ANÆMIA (p. 20).

Neurasthenic and *hysterical states* are responsible for hyperæsthetic areas which have

no relation to central or peripheral innervation. In neurasthenia, especially the traumatic variety, the patches are usually found on and around the spine and over the scalp. In hysterical conditions similar patches may be detected in the mammary and ovarian regions.

Hyperæsthesia in connection with *visceral disease* has been referred to in other articles, such as those on **PAIN IN THE FACE** (p. 446); **PAIN IN THE UPPER EXTREMITY** (p. 442); etc.

A very special peculiarity of sensation, known as Magnan's sign, is met with in sufferers from the cocaine habit; it consists in a subjective feeling as of multiple small worms creeping about under the skin, though in some cases the patient compares his sensation to that of fine sand under his skin.

E. Farquhar Buzzard.

SKIN, PIGMENTATION OF.—(See **PIGMENTATION OF THE SKIN**, p. 527.)

SKODAIIC RESONANCE.—When there is a basal and unilateral pleuritic effusion of medium degree, the pitch of the percussion note over the upper part of the thorax in front is often higher on that side of the chest on which the effusion is than on the other. It is not a question either of impairment of resonance or of hyper-resonance, but merely of pitch. This higher pitch of the percussion note over the upper lobe, when the lower lobe is compressed by an effusion, is named 'Skodaic resonance,' after the observer who first drew attention to it. Its importance is mainly twofold: in the first place it does not indicate disease of that part of the lung which affords the sign—for instance, the fact that, in a case of right-sided effusion, the right upper lobe gives a higher-pitched percussion note than does the left cannot be taken as evidence that there is a lesion, perhaps tuberculous, at the right apex; in the second place, it is erroneous to suppose that skodaic resonance is obtained only in cases of effusion; its occurrence cannot be taken as proof that dullness at the base is due to fluid there. It is true that *pleural effusion* gives it not only in most marked degree, but also most commonly; nevertheless it may also be observed in some cases of *basal pneumonia* without effusion, or as the result of compression of a lower lobe by such causes as *subdiaphragmatic* or *hepatic abscess*, *hepatic masses* such as *carcinoma*, *gumma* or *hydatid cyst*, *great enlargements of the spleen* such as occur in leukemia, a *big heart*, a *pericardial effusion*, or a *mediastinal or pulmonary new growth*.

The cause of skodaic resonance has never been quite decided, and many theories have been propounded about it; clinically, the most serviceable view is that anything that lessens the degree to which the upper lobe is stretched, yet without actually compressing it, may produce a rise in the pitch of its percussion note. Bilateral compression of the bases of the lungs by such lesions as ascites, presumably causes bilateral skodaic resonance, but this is difficult to determine, because the latter is recognizable only when there is a difference of pitch between the two sides.

Skodaic resonance over an upper lobe when there is some lesion affecting the lower lobe on the same side, should not be confused with the tympanic note that may sometimes be heard over the other parts of the thorax. Stomach tympany is heard normally external to and below the precordial region over an area known as Traube's space, which is bounded above by the precordial dullness, behind by the splenic dullness, and below by the rib margin. When the stomach is dilated there may be an abnormal extent of this gastric tympany in the thorax. When the transverse colon is distended with gas, or when it is pushed upwards by something intra-abdominal, it may produce abnormal areas of thoracic tympany, particularly in the lower sternal region or on either side of this. Such conditions can scarcely be mistaken for skodaic resonance, for the latter concerns the upper lobe, and is not a definite tympany, but rather a moderate rise in the pitch of the ordinary percussion note, not as a rule obvious till the two sides are contrasted.

Herbert French.

SLEEPLESSNESS.—(See **INSOMNIA**, p. 320.)

SMELL, ABNORMALITIES OF.—Abnormalities of the sense of smell fall into three main categories, namely:—(1) *Too great sensitiveness to smells which actually exist;*

(2) *Deficient sensitiveness to smells which actually exist*; (3) *Subjective sensations of smells which do not exist*.

Too great sensitiveness to existing smells is sometimes a nuisance to the individual, but is seldom a sign of disease. There are great differences in the powers of perception of different sensations in different persons, and just as some can appreciate very slight differences in sounds more than others, so can some detect smells that are indiscernible by others. This is natural idiosyncrasy.

Deficient sensitiveness to actual smells is often but the obverse of the above, and no sign of disease, although it may be a detriment to the individual, especially in certain commercial pursuits in which the varying qualities of products are judged partly by smell. When the power of smell, having been normal, becomes deficient or totally absent, the change may affect one nostril only, or both. The condition may be transient or persistent. The commonest cause of transient anosmia is *acute nasal catarrh*, whether the result of an ordinary cold, or of other affections such as *hay fever* (coryza e feno), oncoming measles, or the effects of drugs such as *iodide of potassium* or *arsenic*.

Persistent anosmia may be due to :—

(a). *Inability to get air freely, or at all, through the nostril*, as the result of :—

Adenoids	Hypertrophic rhinitis
Polypi	Syphilis
Dislocated nasal septum	Necrosis of bones in the nares
Nasal septal spur	Occluded anterior or posterior nares.

(b). *Alteration in the olfactory mucous membrane*, so that it no longer transmits impulses to the endings of the olfactory nerve, although the airway is free :—

Atrophic rhinitis	Paralysis of the fifth nerve, leading to undue dryness of the mucosa.
-------------------	---

(c). *Abnormalities of the olfactory nerves* :—

Congenital absence	noxious vapours, ammonia, or snuff ;
Hydrocephalus	or part of a general peripheral neuritis
Olfactory neuritis, either the result of overstimulation locally by strong	Post-influenzal changes.

(d). *Cranial lesions*, especially hemorrhage, thrombosis, embolism, softening, injury, or tumour of the uncinate gyrus, which is the centre for smell.

(e). *General nerve diseases*, especially :—

General paralysis of the insane	Tabes dorsalis
---------------------------------	----------------

(f). *Hysteria*.

There is little need to discuss the above table in detail, for each heading speaks for itself. When a case is being investigated, the history is very important : it is next necessary to examine the nose carefully through a speculum, and to test the air-way through each nostril : if there is any local lesion it will generally be obvious, and only after local affections have been excluded should conditions in groups *c*, *d*, *e*, and *f* be discussed. Anosmia will seldom if ever be a prominent symptom, except in connection with local affections of the nose : when due to any other cause there will nearly always be some other symptoms which will attract attention more than the anosmia itself.

Subjective sensations of smells which do not exist externally may be due to :—

- Offensive or purulent inflammations of the nose or of the air-cells communicating with it, especially empyema of the antrum of Highmore, or of a frontal sinus.
- Local thickening of the meninges, tumour of the brain, or interference with the vascular supply, causing irritation of the hippocampal region.
- An aura preceding an epileptic seizure.
- Hysteria.
- Insanity.

In arriving at a diagnosis, it is chiefly important to exclude purulent affections discharging into the nose : if it is possible to state with certainty that the abnormal sensations have no such organic basis, it is not difficult as a rule to decide between the

other causes. It is a curious fact that subjective abnormalities of smell are apt to be associated with delusional insanity concerning the genital organs, in which the prognosis is not free from acute dangers. *Herbert French.*

SNORING may be a very troublesome symptom in some patients, particularly to those who have to sleep in the same room with them; but it is often less an indication of disease than merely a bad habit. Most snorers sleep with their mouths open, and breathe partly through the nose and partly through the mouth; but it is possible for snoring to occur with the mouth completely shut, and nothing the matter with the nasal passages. The tendency is increased, however, by any obstruction of the nasal airway, so that particular examination should be made for such lesions as undue smallness of the nares or a tendency for the soft parts of the nostrils to collapse on inspiration, deflected septum, hypertrophic rhinitis, polypi, adenoids, acute or chronic nasal catarrh, inflammation of the accessory sinuses or of the pharyngeal tonsils, or even a fibrosarcoma or other neoplasm of the nasopharynx. *Herbert French.*

SORE THROAT may be due to one or other of many different causes:—

1. Affections of the Tonsils:—

Quinsy.

Acute Tonsillitis.

(a). With reddening and swelling only:

Acute inflammation due to various micro-organisms, especially to streptococci; staphylococci; pneumococci; pneumobacilli; diphtheria bacilli; Hofmann's bacilli; Vincent's spirilla and fusiform bacilli; spirochaeta (*treponema*) pallida; micrococci catarrhales; bacilli influenza; tubercle bacilli. The sore throats of scarlet fever, rheumatic fever, German measles, and measles are probably not due to specific micro-organisms, but to streptococci, or others of the bacteria just enumerated.

(b). With redness, swelling, and exudation:

Follicular tonsillitis due to streptococci, etc., as above

Diphtheria

Vincent's angina

Syphilis

Kirkland's disease, or epidemic cervical adenitis.

(c). With ulceration:

Phlegmonous tonsillitis due to streptococci, etc., as above

Syphilis

Vincent's angina.

Chronic Affections of the Tonsils:—

Recurrent inflammation often associated with adenoids, or tonsillar hypertrophy, especially in children

Primary or secondary syphilis

Vincent's angina

Squamous-celled carcinoma (epithelioma)

Sarcoma

Gumma. Tubercle.

2. Inflammation of the Soft Palate, Uvula, and Fauces:—

Catarrh, occurring either by itself or associated with any of the varieties of tonsillitis enumerated above

Gumma

Squamous-celled carcinoma

Tubercle.

3. Affections of the Pharynx:—

Acute catarrhal pharyngitis due to any of the micro-organisms mentioned under the heading of acute tonsillitis

Chronic granular pharyngitis due to smoking in excess; or to over-use, as in clergyman's, costermonger's, or stockbroker's sore throat

Squamous-celled carcinoma of the pharynx

Post-pharyngeal abscess

Variella

Variola.

4. Laryngeal Conditions, especially:—

Acute catarrhal laryngitis due to any of the organisms mentioned above

Tuberculous laryngitis

Syphilitic laryngitis

Carcinoma laryngitis

Acute perichondritis of the arytenoid thyroid, or cricoid cartilages.

5. Sore Throats the result of the Swallowing or Inhalation of Irritants:

Corrosives, such as alkalis or strong acids

Ammonia vapour, chlorine fumes

Hot steam.

6. Mumps.

7. Acute and Subacute Adenitis of the lymphatic glands in the neck

Notwithstanding the length of the above list the differential diagnosis of a sore throat in practice is not difficult as a rule. Inquiry into the history and inspection of the parts locally in a good light will generally serve to give one a shrewd notion of the nature of the complaint. The chief point in practice is to determine as soon as possible whether the Klebs-Löffler bacilli of diphtheria are present or not, for it has been established that there is no kind of sore throat which can be recognized clinically as non-diphtheritic. It is important that swabbings should be taken from the inflamed parts and examined by a bacteriologist both directly in films stained by Neisser's method or one of its modifications, and by means of cultures. Similar bacteriological investigations will serve to determine which of the organisms mentioned above is responsible for an acute or follicular or ulcerative sore throat other than diphtheritic, it being borne in mind, however, that the organism should be found in fairly pure cultures if it is to be regarded as causative and not merely as a secondary or even casual infection.

Affections of the Tonsils.

Quinsy is practically always asymmetrical, one tonsil being very much more bulged than the other; the surface is reddened, generally without follicular suppuration, and the diagnosis is ultimately confirmed by the bursting of the abscess.

The presence of Klebs-Löffler bacilli in association with a sore throat may be regarded as conclusive proof that the lesion is *diphtheria*, even though there may be no typical diphtheritic exudate. Diphtheria having been excluded, the diagnosis of one of the other varieties of acute tonsillitis is rendered possible. The frequency with which *acute rheumatism* is associated with recurrent tonsillitis, especially in young people between the ages of five and twenty, should always be borne in mind; the patient may or may not have suffered from other effects of acute rheumatism, such as joint pains, endocarditis (evidenced by the bruits), pericarditis, pleurisy, erythema nodosum, chorea; or a history of such rheumatic affections may be obtained in other members of the same family. The tonsillitis is benefited by sodium salicylate, but by no means to the same extent as are the joint pains, so that the effect of treatment is not by itself conclusive evidence of the nature of the complaint.

When acute rheumatism gives rise simultaneously to generalized erythema and to tonsillitis, there will be very considerable difficulty in excluding *scarlet fever*, especially if there has been considerable nausea or actual vomiting; in some such cases the diagnosis will be one of opinion only; that which was regarded at first as acute rheumatic tonsillitis and erythema may prove to have been scarlatina after all, should the patient presently develop acute nephritis, or if other members of the family develop typical scarlatina; the occurrence of extensive peeling of the skin is not conclusive evidence of scarlatinal erythema and sore throat. If the patient is known to have had scarlet fever formerly, the rheumatic nature of the case is more likely.

Follicular tonsillitis is not a final diagnosis, for it may be due to various different micro-organisms, and there is no doubt that the diphtheria bacillus may produce that which to inspection presents multiple foci of pus in the different tonsillar crypts formerly regarded as characteristic of follicular as distinct from diphtheritic tonsillitis. The only conclusive proof that a comparatively simple follicular tonsillitis is not diphtheritic is bacteriological examination. If clinical points alone have to be relied on, one would say that the higher the temperature, the greater the constitutional disturbances, and the more sudden the onset, the more likely is it not to be diphtheria.

Vincent's angina has been differentiated bacteriologically, cases of this kind having formerly been regarded either as diphtheria or as follicular tonsillitis. The characteristic micro-organisms present are elongated fusiform bacilli symbiotic with spirilla (*Plate XXI, Fig. M*). The disease is, as a rule, more resistant to treatment than are other forms of acute sore throat, so that what has originally been a tonsillitis with exudation presently becomes an ulceration associated with remarkable fetor of the breath, but without that tendency to fatal termination presented by most other varieties of acute ulcerative or phlegmonous sore throat. The disease cannot be recognized without the aid of the bacteriologist.

Syphilis may cause acute soreness of the throat in its secondary stages, and unless that possibility is borne in mind, one may diagnose as acute simple or acute follicular tonsillitis that which is really syphilitic. There is more or less pyrexia, and in most cases

A, Malaria, early ring form; B, Malaria, ordinary ring form; C, Malaria, mature form; D, Malaria, tetanous body to sporozoite; E, Malaria, crescent; F, Leishmania; G, Trypanosoma; H, Leishman-Donovan bodies, abundant in splenic parasite; I, Spirochetes; J, Spirochetes; K, Tubercle bacilli; L, Tubercle bacilli; M, Vincent's bacillus; N, Metastreptococci and pus cells; O, Pneumococci and pus cells; P, Staphylococci and pus cells; Q, Streptococci and pus cells; R, Gonococci, in and outside of pus cells; S, Antinomycetes; T, Tetanus bacilli.

(The nonspiral ones of F and S are much less than that of the remainder; the others are approximately as indicated by the relative size of the white copesules.)

there will be tenderness of the scalp and of the bones, together with the well-known roseolous eruption upon the skin and the 'snail-track' ulcers upon the pharynx. The diagnosis may be more difficult in women than in men, for in the latter the remains of the chancre may still be obvious. Wassermann's serum test may assist materially in the diagnosis of doubtful cases.

Chronic affections of the tonsils in children are nearly always the result of recurrent acute attacks of non-diphtheritic tonsillitis, generally in association with adenoids, both affections arising from the habit of mouth breathing. Inspection of the bulging hypertrophied tonsils, with or without digital examination of the posterior nasal fossae, will indicate the diagnosis. In an older person, simple hypertrophy from recurrent tonsillitis becomes progressively less common. Chronic tonsillitis in a young adult may be diphtheritic, syphilitic, or due to Vincent's angina, the diagnosis between these being arrived at in the way described above. It may be mentioned that in very rare instances an actual chancre appears upon one tonsil, giving rise, unless secondary symptoms are present, to much difficulty in diagnosis until the case has been watched. *Malignant disease of the tonsils*, whether *squamous-celled carcinoma*, or *sarcoma*, is fortunately not very common; when it does develop, its comparatively non-acute course and its unilateral distribution with progressive ulceration of the central parts and overgrowth of the edges of the neoplasm will point to the diagnosis. A *gumma* of the tonsil is rare, but may at first simulate squamous-celled carcinoma; in case of doubt a small portion of the suspicious mass might be excised, and examined microscopically; or if operative measures were not to be adopted at once, potassium iodide or salvarsan might be administered, and the lesion would be shown to be gummatous if it were thereby relieved or cured. *Tuberculous ulceration of the tonsils* is uncommon, practically never primary, but nearly always preceded by both phthisis and tuberculosis of the larynx. The diagnosis will be indicated by the discovery of tubercle bacilli in the sputum, though it should not be forgotten that carcinoma or gumma might affect the tonsil in a person who has phthisis.

Inflammation of the Soft Palate, Uvula, and Fauces.

This may be seen in many cases of common cold; in association with acute rheumatism; in persons who have recently returned to town from a holiday; in patients who have been subjected to the influence of motor-car dust stirred up from the roads after the latter have been dry for about three days—a longer period of dryness seems to lead to relative disinfection of the dust, whilst rain keeps the dust from rising, so that either continuance of fine weather or a return to wet leads to a disappearance of the sore throats; or in those who are subjected to the influence of relatively concentrated microbes, as in the air of old-fashioned hospital wards, of ill-ventilated much-inhabited rooms, of sewers, and the like. Often a rim of acute reddening is to be seen all along the edge of the anterior pillars of the fauces, and affecting much of the uvula and of the soft palate, producing, as a rule, but little pyrexia, though much discomfort in swallowing, and a raspy feeling at the back of the mouth on first waking in the morning. This inflammation of the palate and fauces may or may not be associated with tonsillitis, pharyngitis, or laryngitis; it is clearly microbial; and doubtless more than one of the varieties of bacteria mentioned above may produce the lesion. The diagnosis of the fact of inflammation is obvious on inspection; that of the nature of the micro-organism requires skilled bacteriological assistance.

During the last few years a new and common disease, epidemic in character, and with acute sore throat, fever, and enlargement of the upper cervical glands as its main

Fig. 25. Temperature chart in a severe case of Kirikubo's disease in which the sore throat and constitutional symptoms were more pronounced than in the cervical adenitis. In an average case the temperature lasts less than a week.

symptoms, has been described by Kirkland, of Cheltenham; it is spoken of variously as *Kirkland's disease*, the *Cheltenham disease*, or *epidemic cervical adenitis*. In some respects it resembles diphtheria, in some rheumatic fever, and in some atypical scarlatina without rash, but it differs from all these according to most observers, and it is now regarded as a specific malady. It affects young and old alike, is very infectious, generally occurs in epidemic form, may be mild, medium, or very severe, but generally ends in recovery. Starting with sore throat and a rise of temperature to 102° F. or higher, the patient soon complains mainly of extreme tenderness of the neck, and on palpation acute tender swelling of the parotid, submaxillary, and jugulo-facial glands is found; the swelling may be very considerable, but it generally resolves without suppuration. Fever may last only a day or two, but in severe cases it may persist for a fortnight, especially if the malady relapses after a period of improvement as it is apt to do (*Fig. 265*). The tonsils, uvula, fauces, and pharynx may be merely red and injected; or on the other hand there may be an exudation simulating diphtheria. On cultivation of swabbings from the throat no Klebs-Löffler bacilli can be found, but as a rule streptococci in abundance. What is very remarkable is that in most of the cases the heart is affected during the illness, but without producing permanent valvular changes like those of rheumatic fever; the impulse becomes diffuse, the heart dilates, there is often a local systolic mitral or aortic bruit, or both, and the pulse may be both feeble and intermittent. There is seldom albuminuria, but the general toxæmia in severe cases may be enough to cause delirium and temporary coma. There are no definite joint pains, though the patient aches all over. Convalescence is generally slow at first, two or three weeks elapsing before the patient begins to feel anything like well; but complete recovery soon takes place after this.

Gumma, squamous-celled carcinoma, and tuberculous affections of the fauces, soft palate, and uvula are relatively uncommon; they are differentiated in the same way as has been described in connection with tonsillitis.

Affections of the Pharynx.

Acute pharyngitis may occur by itself, or in association with acute tonsillitis or acute laryngitis, and in either case it may be due to any of the micro-organisms mentioned above. The differential diagnosis of the micro-organisms is carried out in the bacteriological laboratory. The fact of acute pharyngitis is determined by careful inspection of the structures at the back of the mouth.

Chronic pharyngitis is generally the result of excessive smoking, or of the undue use of the voice, in which latter case it may be associated with hoarseness or ready tiring of the voice, as in those who have to declaim loud and long—clergymen, stockbrokers, costermongers, public orators, and others. The history will generally point to the nature of such a case, but one should examine the sputum and the lungs for evidence of tuberculosis, and also look for signs of syphilis or new growth, in order to exclude these possible alternatives.

Post-pharyngeal abscess is a cause of acute dyspnoea rather than of soreness of the throat; it is almost confined to infancy; after three or four years of age the disease becomes almost unknown. It might be simulated by spinal caries, in which, long before there is soreness of the throat, there is severe pain in the cervical region of the spine, especially on movement.

Chicken-pox and *small-pox* may each produce its characteristic eruption in the mouth, pharynx, and œsophagus, and thus give rise to sore throat; but the latter symptom will never be present by itself, and the presence of the cutaneous papules, vesicles, or pustules, will indicate the diagnosis, especially if there have been other similar cases in the neighbourhood.

Laryngeal Conditions.

Acute laryngitis may be due to the same micro-organisms as acute tonsillitis; soreness of the throat is generally less complained of than is huskiness, or weakness, or loss of voice. The nature of the inflammation is determined bacteriologically. One variety of acute non-diphtheritic laryngitis that merits special mention is that due to pyogenic cocci—pneumococci, streptococci, staphylococci—which in a few cases, in addition to producing acute superficial inflammation, also lead to rapid and extreme œdema of the larynx, with death from asphyxia unless tracheotomy be performed speedily. These cases have been spoken of as *acute suffocative œdema* of the larynx.

Tuberculous, syphilitic, and carcinomatous lesions of the larynx are less acute, though

they may have relatively acute exacerbations or become secondarily infected with pyogenic cocci; their diagnosis depends partly upon laryngoscopic inspection—tuberculosis and syphilis being bilateral, whilst new growth is generally unilateral; upon examination of the sputum for tubercle bacilli, and of the lungs for apical physical signs of phthisis; upon the beneficial influence of potassium iodide, mercury, or salvarsan; upon Wassermann's syphilitic serum test; upon microscopic examination of small excised portions; or upon the course of the disease.

Sore Throats the Result of the Swallowing or Inhalation of Irritants and Corrosives are diagnosed as a rule by the history; inquiry will generally suffice to indicate that some irritant has been taken, or there may be direct evidence of it in the form of eschars on the lips or the buccal mucosa; there may be vomiting and hæmatemesis; analysis of the gastric contents may indicate the nature of the poison taken; ammonia may be detected by the smell.

Mumps and Acute Adenitis of the Cervical Lymphatic Glands may each produce marked soreness of the throat in addition to dysphagia, stiffness, discomfort, and pain. Mumps is not difficult to diagnose unless its possibility is forgotten, in which case it might be mistaken for acute œdema of the neck or other similar lesions. The way in which the swelling is located in the salivary glands, starting on one side and spreading to both, is often pathognomonic. Cervical adenitis might simulate mumps, but careful palpation will generally enable one to determine that the swelling is not in the salivary but in the lymphatic glands, and it will only remain to decide what has been the source of the infection. This will probably have been from some inflammatory, ulcerative, or malignant focus in connection with the shoulders, neck, head, face, lips, cheeks, gums, teeth, tongue, fauces, uvula, palate, tonsils, pharynx, or nares; the differential diagnosis will be based upon inspection and palpation of the parts, together with bacteriological examination.

It only remains to add that *scarlet fever* is at the present time so atypical that acute cervical adenitis may really be of scarlatinal origin without any scarlatiniform rash having been observed upon the skin. One would naturally look for evidence of desquamation, sore throat, bad tongue, albuminuria, nephritis, perhaps otitis media; but there is no doubt that some cases of acute cervical adenitis are really scarlatinal, without there having been any other sign of this disease except pyrexia and sore throat. A few such cases prove rapidly fatal, and they have recently been recorded as examples of acute and fatal sore throat corresponding to one form of the *angina maligna* of the eighteenth century.

Herbert French.

SORES, PENILE.—Sores on the penis may be present on the thin mucous covering of the glans or prepuce, or on the cutaneous surface of the body of the penis; they are more common in the former situation.

Ulceration in the neighbourhood of the glans penis may be due to:—

- | | | |
|------------------------|-------------------------|----------------------------|
| 1. Balanitis | 4. Chancre | 7. Tuberculous ulceration. |
| 2. Herpes progenitalis | 5. Epithelioma | |
| 3. Soft sore | 6. Gummatous ulceration | |

Balanitis. If inflammatory processes have been allowed to continue beneath the prepuce, ulceration and excoriation of the mucous membrane covering the glans penis or lining the prepuce will occur. The surface of the glans will be denuded of epithelium, and the process will be accompanied by a stinking, purulent discharge. Multiple shallow ulcers are formed, rapidly coalescing and causing considerable discomfort. The prepuce often becomes swollen and œdematous, preventing retraction, so that a condition of phimosis occurs; care must then be exercised in diagnosing a simple balanitis from one accompanying acute gonorrhœal urethritis or an underlying syphilitic or soft chancre. With an acute urethritis, there will be a history of infection, pain along the course of the urethra during micturition, and perhaps chordee; further, the intracellular gonococcus may be identified in a stained smear of the discharge (*Plate XXVIII, Fig. K, p. 614*).

If a chancre exist under the swollen phimosed prepuce, there is often a tender spot about the corona or at the frenum. With a soft sore, consecutive sores may appear about the orifice of the prepuce, whilst the inguinal glands are much more likely to be inflamed or to suppurate than with simple balanitis. A syphilitic chancre obscured by a phimosis can usually be felt distinctly under the skin, and causes a comparatively small amount

of discharge, whilst the inguinal glands become enlarged but do not suppurate. The history of the date of infection, Wassermann's reaction, or the subsequent appearance of secondary symptoms, will help materially in the diagnosis. Spirochaetes may be found in the discharge.

A form of balanitis which is frequently very obstinate to treatment may occur in patients the subjects of gout or diabetes mellitus.

Herpes Progenitalis.—Herpes may attack the genital organs as part of a herpes zoster in which the cutaneous eruption depends upon some lesion of the central nervous system, or as a local affection, the so-called catarrhal herpes. The disease begins as a patch of erythema on the inner surface of the prepuce or on the glans penis, followed by the appearance of vesicles and pustules; the latter become rubbed by the clothes, and form small ulcers. Herpes of the genital organs tends to recur, so that a previous history of a similar attack is often forthcoming. If seen during the vesicular stage, no difficulty will be met with in the diagnosis; but if suppuration has followed, it must be diagnosed from a venereal sore. Soft chancres are usually deeper, with marked edges; their base is sloughing, and they are usually accompanied by a bubo, which is exceptional with herpes. A syphilitic chancre is usually single, indurated and raised, and is accompanied by the typical, multiple, discrete, amygdaloid glands in the inguinal region. It should be remembered that syphilis may become inoculated upon a herpetic patch, or that herpes may appear in an area previously inoculated with the syphilitic virus.

Soft Sores or **Chancroids** of the penis occur almost invariably from infection during sexual connection. The incubation period is short, a vesicle occurs in two days, and this breaks down rapidly to form a rounded or oval ulcer with sharply defined edges, and a yellowish sloughing base. The ulcers appear usually on the mucous surface of the glans, frenum, or corona, and are most often multiple, direct inoculation occurring from an ulcer to the contiguous part. They may cause rapid destruction of tissue, perforating the frenum or spreading over the surface of the glans. The soft sore must be differentiated from others occurring on the glans, and above all from a syphilitic chancre. At the same time it must be remembered that besides the infection with chancroid, a simultaneous infection with syphilis may have taken place, so that a soft sore may ultimately become indurated and assume the character of a primary syphilitic lesion. The chancroids are multiple, are accompanied by a good deal of thin, purulent discharge, and by a painful swelling of the inguinal glands, usually of one side, which have a marked tendency to suppurate. On the other hand, a syphilitic chancre is nearly always single, is raised and indurated, has little discharge, and is accompanied by enlarged, but firm and indolent, glands in both inguinal regions; the incubation period of a syphilitic chancre is from twenty-one to twenty-eight days.

The multiple ulcerations caused by herpes are more superficial, and rarely cause a bubo.

Chancre—the initial lesion of syphilis—generally appears on the penis, and is most common in the neighbourhood of the frenum or coronary sulcus. A chancre appears about twenty-five days after infection, as a reddened patch, which becomes raised above the surface of the mucous membrane, with distinctly indurated margins. The central part breaks down into an ulcer, discharging a thin, purulent fluid, and at the same time the inguinal glands of both sides become palpable, slightly enlarged, but discrete, and with no tendency to suppurate. The chancre increases but slowly in size, or may occasionally become smaller without any treatment, and after a further lapse of from four to six weeks the typical secondary symptoms make their appearance; namely, a roseolar rash on the chest, abdomen, face, and thighs, general adenitis, and mucous patches about the faucial pillars and tonsils. The diagnosis of the primary lesion of syphilis frequently presents no difficulties, the indurated character of the sore, the date of its appearance after infection, and the presence of firm, indurated glands in the inguinal region, being distinctive. In other cases the character of the sore is by no means distinctive, and it is necessary to differentiate it from other lesions of the penis. If the sore be syphilitic, the secondary manifestations of the disease will follow, provided that the doubtful ulcer is not treated as a chancre. Thus, in any case in which syphilis is suspected, but not wholly certain, it is advisable to withhold any specific treatment for syphilis until such time as secondary symptoms appear, so that a patient may not be condemned to the lengthy process of

treatment for syphilis until the diagnosis is absolutely certain. The *Spirochæta pallida* should be looked for in scrapings from the affected parts, but too much reliance should not be placed upon a negative Wassermann blood-reaction in the early stages of the disease.

A chancre may be simulated by an inflamed soft sore, especially if the latter has undergone cauterization. Soft sores are, however, frequently multiple, appear within a few days of infection, and are accompanied by painful enlargement of the inguinal lymphatic glands, which are particularly prone to suppurate. It must not be forgotten that a double infection may have occurred, so that a soft sore may show little inclination to heal or, becoming indurated, may present the features of a chancre after about three weeks, and later, the symptoms of constitutional syphilis.

Epithelioma of the penis in the early stage may be confused with syphilitic chancre. In epithelioma there is no history of infection: it occurs only in elderly patients, and there is frequently a greater destruction of tissue than in syphilis. The inguinal glands are not enlarged until the sore has been present for some weeks, and there are no secondary lesions such as the faucial ulceration and cutaneous rash. If any doubt exists, a small piece may be removed from the edge of the ulcer for microscopical examination.

Perhaps the greatest difficulty in the diagnosis of a chancre is experienced when the latter is hidden beneath an inflamed and phimosed prepuce. There is a purulent and foul discharge from beneath the œdematous and swollen prepuce: the inguinal glands are enlarged from the associated sepsis. If a chancre is present, it can frequently be felt as an indurated area under the prepuce, whilst if it has been present for some time, the secondary lesions of syphilis may be present. If any doubt exists in an elderly patient as to whether an indurated subpreputial area be an early epithelioma or a syphilitic sore, the prepuce should be split up along the dorsal aspect under anaesthesia, the ulceration inspected, and a small piece submitted to microscopical examination if necessary.

Epithelioma (squamous-celled carcinoma) is the most common form of malignant growth of the penis. It arises most frequently from the inner aspect of the prepuce, or from the mucous membrane of the glans, as a small, raised ulcer, with friable, irregular edges. It is rarely present before the age of forty, and frequently occurs on the site of previous ulceration or long-standing irritation. An epitheliomatous ulcer increases gradually in size, in spite of various forms of treatment, and with it is frequently associated glandular enlargement in the inguinal area. At first the glands may be enlarged from septic infection, but later from malignant infiltration. An epitheliomatous ulcer may in some cases be confused with a chancre: but the friable, irregular edges of the former, the liability to bleed, and the gradual progressive increase in size in spite of treatment in an elderly patient, should give rise to grave suspicion of malignant disease. Microscopical examination of a small piece removed from the edge of the ulcer will give direct evidence of epithelioma.

Gummatous Ulceration of the penis occurs occasionally, resulting from the disintegration of a small gumma of the glans or prepuce, frequently in the position of an old scar. A gumma commences as a small, elevated nodule, which, if left untreated, softens and discharges its contents, leaving an ulcer bounded by thin edges and with a yellowish, sloughy base. A gummatous ulcer has been mistaken for a primary lesion of syphilis: but the absence of induration, the history of the onset and of a previous infection with syphilis, would be points against a chancre. A second infection with syphilis is by no means unknown, especially in those who have had salvarsan alone in the treatment of the first attack, but it is rare. Occasionally the base of a gummatous ulcer proliferates into a papillary tumour and has given rise to a suspicion of carcinoma: the diagnosis will be confirmed by the behaviour of the lesion under potassium iodide, when a tertiary syphilitic affection will clear up rapidly.

Tuberculous or Lupoid Ulceration of the penis is rare, and is generally associated with advanced tuberculous infiltration elsewhere. Tuberculous ulcers are usually shallow, with thin overhanging edges, painful and multiple. The infection has resulted from the rite of infantile circumcision by the Jewish method.

R. H. Jocelyn Sican

SORES, PERINEAL.—Ulceration may be present in the perineum as the result of:—

- | | | |
|--------------------------------------|--|-----------------|
| 1. Cutaneous inflammations or injury | | 1. Syphilis |
| 2. Urethral fistula or suppuration | | 5. Epithelioma. |
| 3. Prostatic suppuration | | |

Cutaneous Inflammation or Injury.—An ulcer in the perineum may result from *direct injury* to the area, or from *inflammatory infection of the sebaceous or hair follicles* of the cutaneous covering. An ulcer from these causes may be placed at the centre or to one side of the perineum, is movable on the deeper parts, and shows no track into which a probe can be passed. In women, ulceration of the perineal area may be associated with *gonorrhœal or septic vaginal discharge*.

Urethral Suppurations or Fistulæ.—During the progress of an acute urethritis, a glandular follicle frequently becomes infected. The suppurative process leading from this in the bulbous urethra may extend towards the perineum and open externally, leaving a small fistula which may or may not discharge urine during the act of micturition. In a similar manner, urinary fistulæ may result from inflammatory processes behind a urethral stricture, and in an old-standing case it is not uncommon to find a urinary calculus in the dilated portion of the urethra behind the stricture. When the urethral suppuration is acute and an abscess bursts in the perineum, the diagnosis will be quite obvious, and the ordinary treatment for an abscess, in addition to that of the acute urethritis, will usually suffice to cure the condition.

If, however, the perineal wound discharges urine, it will be found that this occurs as a rule only during the act of micturition, as there is no interference with the vesical sphincter. In nearly all cases, however, a stricture of the urethra will be found, though not necessarily one of sufficient degree to cause severe interference with micturition. Endoscopic examination will show the presence of a urethral stricture, whilst behind it can be seen frequently the sloughy granulations denoting the position of the urethral opening of the fistula. Occasionally urine drains from a perineal fistula continuously, and not only during the act of micturition. In these cases there is constant soaking of the perineal skin, and frequently excoriation. That urine should leak constantly from the fistula denotes interference with the vesical sphincter, either by dilatation behind a tight urethral stricture, by the presence of a calculus in the prostatic or membranous urethra, or by actual division of the vesical sphincter following some operation, such as perineal prostatectomy or perineal lithotomy.

Diseases of the Prostate.—An abscess or tuberculous focus in the prostate may occasionally discharge in the perineum, and remain as a sinus. An abscess in the prostate arises practically always from some infection in the posterior urethra, from venereal causes, or after septic instrumentation. It is accompanied by urethral discharge, or there is a history of a recent infection, whilst per rectum the prostate may be felt to be inflamed, or scarred from the shrinkage of the abscess cavity.

When a tuberculous cavity in the prostate opens in the perineum there is advanced tuberculous disease, so that little difficulty will be found in arriving at a diagnosis. A tuberculous prostate is very rarely a primary condition, but in most cases is secondary to disease in the testis or bladder, so that examination of these organs will in nearly all cases give evidence of tuberculous disease and indicate the nature of the perineal fistula. Palpation of the prostate per rectum may reveal the rounded nodular deposit of tubercle in the gland.

Syphilis may cause ulceration on the perineum either as a chancre or as mucous tubercles. A *chancre* on the perineum is rare. It forms a small ulcer with slightly indurated borders, indolent in character, and accompanied by slight enlargement of the inguinal lymphatic glands. A chancre of the skin does not possess the usual features of a genital chancre, and is not usually diagnosed with certainty until the secondary lesions of syphilis become apparent; but an ulcer with raised, infiltrated edges, which shows no tendency to heal under aseptic precautions, should always give rise to a suspicion of syphilis. The *Spirochæta pallida* may be looked for, and Wassermann's serum test tried.

Conglyomata may be present about the perineum in association with active syphilis. They may extend from the anal or vulval orifice, and form oval or rounded, flat-topped, sessile masses, covered by macerated, greyish epithelium, or they may be ulcerated on the surface. The accompanying signs of syphilis will indicate the diagnosis.

Epitheliomatous Ulceration of the perineum is practically only seen as a direct spread of a growth of the anus or vulval area, when the diagnosis presents no difficulty. An epithelioma may develop in the scar of some former cutaneous affection, in which case an ulceration may exist, showing the usual characteristics of a cutaneous epithelioma.

namely, gradual progressive increase in size, raised, friable edges, and tendency to slight hæmorrhages. The inguinal glands may be enlarged early from inflammatory absorption, or later by infection with malignant disease. In case of doubt a fragment may be removed for microscopical examination.

R. H. Jocelyn Swan.

SORES, SCROTAL.—Ulceration of the scrotum occurs in association with:—

- | | | |
|----------------|------------------------|-----------------------|
| 1. New growth: | 3. Syphilis, | Syphilitic. |
| Epithelioma | 4. Testicular disease: | 5. Suppurating cysts, |
| Papilloma. | Inflammatory | |
| 2. Fistule. | Tuberculous | |

Epithelioma of the Scrotum, commonly known as 'chimney-sweep's cancer,' is by no means limited to this avocation, but is certainly more common in men engaged in work in which they are exposed to much irritation from solid particles or from noxious fumes. Hence the disease is most commonly seen amongst chimney-sweeps, employes in gas-works, paraffin and chemical works, and coal-mines. It often begins as a small subcutaneous nodule, over which the skin is thinned and adherent; the nodule enlarges slowly, and the thinned covering gives way, to form an ulcer with thickened, irregular edges and a tendency to bleed on slight injury. The ulcerated area extends both radially and into the tissues of the scrotum, later involving the testes. The inguinal lymphatic glands become enlarged soon after active ulceration commences, at first from inflammatory causes, later from malignant infiltration. In other cases a scrotal epithelioma begins in a *wart* or *papilloma*, which may have been present for years with only slight increase in growth. These soft papillomata are not unusually the starting-point of malignant change, when they become more vascular, whilst the surface epithelium becomes thinned and easily excoriated. A small amount of foul discharge is present, often encrusted into a scab, which on removal leaves an ulcer with indurated, everted edges, with the gradual progress of a cutaneous epithelioma. Any ulcer on the scrotum, especially if indurated or readily caused to bleed, must be looked upon with extreme suspicion, and when it does not improve with ordinary antiseptic medication, should be widely removed without waiting for glandular enlargement.

Epithelioma may occur in the scrotal area as a localized recurrence after removal of a malignant growth of the penis or testicle. Knowledge of the previous condition for which operation has been performed would give the diagnosis.

Fistule may occur in the scrotum and cause ulceration. They are most common in association with tuberculous or syphilitic disease of the testes (see below), but occasionally they occur from urethral extravasation, or burrowing from rectal suppuration. An abscess may form and open through the scrotal skin from a peri-urethral abscess accompanying an acute urethritis or formed by septic infection behind a urethral stricture. In either case a small amount of urine may leak through the opening during micturition, whilst the history of urethral discharge, or of difficulty in micturition and other symptoms of stricture, will point to the diagnosis.

Syphilis of the Scrotum may be present either as a primary chancre or as a mucous tubercle. A *primary chancre* in this situation is by no means easy to recognize unless other signs of syphilis are present; but the presence of a cutaneous sore which does not show much inclination to heal under non-mercurial antiseptic dressings should always give a suspicion of syphilis. There is often only slight induration of the ulcer compared with that of a penile chancre, but the edge is raised and of a rolled appearance. The inguinal lymphatic glands are enlarged and discrete, and some five to six weeks after the commencement of the ulcer the usual secondary symptoms of syphilis become manifest.

Mucous tubercles may be present on the scrotum, usually on the femoral aspect. They may extend directly from the anal area. No difficulty will be met with in the diagnosis, as other signs of syphilis are obvious.

Testicular Disease.—In some cases extension of disease in the testicle may involve the coverings of the scrotum, and may even perforate them to form a scrotal sore. This sequence occasionally occurs with: (1) A testicular abscess; (2) Tuberculosis of the testis; (3) Gumma of the testis.

A *testicular abscess* is somewhat uncommon, but may arise from direct extension from the urethra via the vesicule seminales and vasa deferentia or by a hæmatogenous infection

during the course of a specific fever, such as scarlet fever, mumps, or enterica. It may also follow chronic torsio testis. With urethral disease, the primary trouble may be due to gonorrhoea, or more frequently to a septic urethritis from the introduction of infected instruments, and is thus not infrequent in cases of prostatic enlargement in which the patient is passing his own catheter. In cases in which the infective process extends from the urethra, the epididymis is affected first, whilst in the metastatic cases the body of the testis usually shows the first sign of enlargement. These acute inflammations of the testis occasionally suppurate, when the serotal tunics become inflamed and adherent, whilst softening occurs later, and unless surgically relieved the abscess opens through the skin, leaving an ulcer, and a sinus discharging pus.

Tuberculosis of the testicle may occur as a primary disease or as a secondary deposit in association with tuberculosis elsewhere in the genito-urinary tract. Testicular tubercle almost always begins as a nodule in the epididymis, but in the later progress of the disease may extend into the testicle proper. If the tuberculous nodule progresses rather than undergoes cure, the serotal skin becomes adherent, thinned, and finally perforated, leaving a shallow ulcer with thin, undermined edges, and discharging thin pus. Occasionally the necrotic tubules of the epididymis fungate through the opening in the serotum, appearing as a greyish, sloughy projection from the cutaneous opening—the so-called ‘hernia testis.’

A *gumma of the testis* causes a swelling in the body of the testis rather than in the epididymis. A gumma which remains unrecognized or untreated may soften and ulcerate through the serotal skin in a manner similar to tuberculous disease, leaving a clearly-defined ulcerated area with sharply-cut margins, and a wash-leather-like sloughy base. The gummatous granulation tissue may fungate through the serotal aperture, forming a yellowish necrotic mass.

The diagnosis of these three conditions may produce some difficulty in the earlier stages (see SWELLING, SCROTAL, p. 696), but in the advanced stage now under consideration, when an open serotal sore is present, the diagnosis is easier. The *opening of a testicular abscess* on the serotum leaves a small sinus discharging pus and accompanied by a general enlargement of the organ. Preceding the rupture of the abscess there is acute pain in the testicle, with rise of temperature, rigors, and general signs of suppuration, which are much diminished as soon as the abscess is allowed to burst. There is often a urethral discharge, which, however, is often much lessened with the onset of the acute epididymitis, with distinct thickening of the cord and aching pain in the neighbourhood of the external abdominal ring, or in metastatic cases the abscess occurs during the progress of an acute fever. The general history is one of acute pain commencing in the testicle, with rapid and extremely tender swelling of the organ, followed by abscess-formation.

In *tuberculosis of the testis* the progress is much more gradual. A nodule may have been present in the epididymis for some time, gradually enlarging, but causing very little pain; in some cases a nodule may have been present for months without any apparent change, and then it may enlarge suddenly, involve the serotal tunics, and discharge its contents. By the time the disease has reached this stage, it is probable that evidence of tuberculous trouble will be found in other organs, particularly the other testis, prostate, seminal vesicles, or bladder. The affected testicle usually presents several nodules in the epididymis, tender on pressure, whilst small nodules may also be felt in the vas deferens.

The opening remaining from the discharge of a *gummatous orchitis* is usually a rounded ulcer with sharply-cut edges and yellowish base. The whole testis is enlarged, practically painless, and feels heavy. The cord is not thickened, and there is no evidence of disease in the other testicle, prostate, or seminal vesicles. There is probably a history of syphilis, and other tertiary syphilitic lesions may be present elsewhere, such as gummatous periostitis. Strong evidence of the syphilitic nature of the disease is often obtained by the result of treatment with large doses of potassium iodide, alone or in combination with mercury or with salvarsan, when a gumma diminishes in size with marked rapidity. It should be remarked, however, that, as in two cases under the writer's care, testes which are subsequently removed and found to contain large gummata, may show no improvement before operation, even under large doses of iodides, though the Wassermann test may be positive.

A *hernial protrusion of necrotic testicular tissue* may be present either with tuberculous disease or from a gumma. In tuberculosis the mass is greyish and necrotic, discharging thin pus, and there will be sufficient evidence of tuberculous disease in the underlying testis and other genital organs. Tubercle bacilli may be found in the discharge. A distinctive feature of the gummatous hernia testis is found in the appearance of the cutaneous opening: if the fungating mass be pushed aside, the opening in the serotal skin will be seen to be cleanly cut and to encircle the protruding tissue tightly. The fungating hernia testis of tubercle or syphilis must also be diagnosed from other conditions producing a raised tumour on the serotum. An epithelioma of the serotum has raised borders, but the centre is excavated, and there is rarely any enlargement of the testis. A sloughing papilloma of the serotum may more nearly reproduce the appearance, but the tumour and the skin are freely movable on the underlying testis, whilst in hernia testis the mass is connected with the testicle, and the tubular structure of the latter is often apparent on picking up a small fragment of the fungating tumour.

Cysts of the Serotum.—As an exceptional occurrence, a sebaceous cyst may develop in the serotal skin, suppurate, and leave an open sore. The areas remaining present raised borders, and are easily mistaken for an early epithelioma. An accurate history of the previous swelling in the skin is of little assistance in these cases, but microscopical examination of a piece removed from the margin of the ulcer will exclude malignancy. A suppurating cyst in the serotum is more uncommon than epithelioma.

R. H. Jocelyn Scan.

SPASTICITY. (See GAFF, ABNORMALITIES OF, p. 251.)

SPEECH, ABNORMALITIES OF.—Abnormalities of speech are numerous, varying from complete mutism to slight defects in articulation, and dependent on disturbances, functional or organic, in some part of the complex mechanism which is responsible for the production of intelligible language. This article is intended to expose the broad principles by which various abnormalities of speech can be detected and used for the purposes of diagnosis: it does not embrace a discussion of the controversial views which are held concerning their exact production.

The amount of investigation required for making a diagnosis in cases of speech abnormality varies within wide limits. Great care is called for in examining cases of aphasia which result from disturbance in the function of the cerebral speech centres or their dependent paths of communication: the defective articulation of a patient suffering from cleft palate needs only a comparatively superficial examination in order to arrive at a correct diagnosis.

It will be convenient to consider the various abnormalities of speech under the following heads: (1) *Mental defects*; (2) *Aphasia*; (3) *Deaf mutism*; (4) *Dysarthria*; (5) *Functional disorders*—*stammering, lalling, idioglossia*.

Mental Defects.—The acquirement of the power of speech may be delayed in children who are mentally defective, and in some forms of idiocy may be suspended altogether. Before making a diagnosis of mental deficiency in a child who appears to be dilatory in talking, it is well to remember that the age at which speech is acquired is very variable, and that the delay may be considerable where no mental impairment is present. In such cases the diagnosis must depend on a consideration of other points in the child's development. Inquiry should be made as to whether he is clean in his habits, whether he is destructive, whether he plays with toys or with other children in a natural manner, and whether he displays abnormally bad temper or irritability. In some cases the delay in speaking may be due to a defect in hearing which has been unsuspected by the parents. This point is especially apt to arise in respect to children who have begun to talk at the normal age, and who have lost what little they had learned of the art in the sequel of some acute illness.

In adults, loss of speech may be due to many forms of mental deficiency of a temporary or permanent nature. A familiar example of temporary loss of speech is that degree of alcoholic intoxication to which the term 'speechless' is vulgarly applied. Similarly, the intoxication of the higher mental faculties associated with organic poisons, such as those of pneumonia or typhoid fever, may be responsible for temporary loss of speech. Complete mutism due to disease of the higher intellectual centres is common in various forms of

dementia, and is proved to be no aphasic defect by the sudden and complete restoration of speech which may take place after months or even years of silence. The speechlessness of a melancholic patient or of one who is suffering from paralytic dementia is further differentiated from true aphasia by the fact that the latter is associated with attempts at communication, while the former is not. On the other hand, general paralysis of the insane is a disease in which temporary aphasia is by no means uncommon, especially in connection with the transient hemiplegia following 'congestive' attacks.

Aphasia.—A definition of aphasia is difficult to supply in a few words. The term is used to denote that loss of speech which does not depend on mental deficiency, nor upon paralysis of the motor mechanism of articulation. Such a negative description requires, however, some modification, because aphasia is frequently associated with some impairment of intelligence resulting from disturbance of internal language, which plays an important part in all intellectual processes, and any lesion of the cerebral centres connected with it must necessarily interfere with the higher mental activities. This is particularly the case in what is called sensory aphasia, that variety which depends upon a lesion of the auditory and visual word centres situated in the cortex near the posterior part of the left Sylvian fissure of the brain.

In right-handed persons the chief speech centres are placed in the left cerebral hemisphere (*Fig. 266*), and it is customary to consider them as being three in number. The

Fig. 266.—Left cerebral hemisphere, with speech centres.

posterior part of the first temporal convolution is regarded as the area in which the auditory memories of spoken words are stored and recalled. It plays an important part in the development of speech, because it is largely through the sense of hearing that the child first learns to associate objects with their names and expressions with their meaning. The cortex in the angular gyrus has a similar special function in regard to the storage of visual word memories, a function which bears the same relationship to written language as the auditory word centre has to spoken language. These two portions of the cortex constitute the sensory speech centres. A third important centre is called the motor, or, better, the higher kinasthetic centre, and this is located in Broca's area, or the posterior part of the third frontal convolution. In this situation are stored the memories of afferent impulses excited by the motor activities employed in speech. Unless this centre is intact, the conversion of internal into external language is imperfect or impossible. In the opinion of some authorities, there is a similar kinasthetic centre in the posterior part of the left second frontal convolution, which plays a part in connection with written language comparable to the part played by Broca's area in relation to spoken language.

With these physiological and anatomical data as a basis, we can proceed to consider the chief varieties of aphasia and the points in their differential diagnosis. Before doing so, it is well to sound a note of warning with regard to the complications which are constantly being met with by the clinician in attempting to analyse cases of aphasia. In the first place, a diagrammatic anatomical definition of the cerebral centres is liable to give

a wrong impression. These centres are more diffuse in their function than they appear to be on a map of the brain, and they are much more interdependent than their topography would suggest. Communicating nervous tracts bind them together in such a way that a destructive lesion of one must necessarily upset the function of another, and so modify profoundly the clinical picture of any particular case. In the second place, aphasia is, in most instances, the result of a vascular lesion, and all the centres referred to lie in the area supplied by one artery—the middle cerebral. Consequently even when the main brunt of a vascular disturbance falls on one of the special speech centres, the others may also suffer more or less, temporarily or permanently, from disturbances of nutrition. In any case of aphasia, therefore, we may have to be satisfied if we can arrive at a conclusion as to the site of the chief defect, without being able to define the exact limits of the loss or impairment of cerebral function. In the third place, due allowance must be made for the fact that the right cerebral hemisphere may gradually acquire some degree of speech activity, especially in cases of aphasia occurring during the earlier years of life, and may tend to replace the loss caused by the defective action of the left.

Word-deafness is the result either of a lesion of the auditory word centre in the temporal cortex, or of one which isolates that centre from the periphery: that is to say, of a sub-cortical lesion cutting off the centre from auditory impulses. In either case the patient who is word-deaf is unable to recognize the meaning of spoken language, although he may hear perfectly the sounds by which it is conveyed. He fails to understand anything which is said to him, and does not obey simple commands so long as they are not accompanied by gestures suggestive of their meaning. If the visual word centre has not been affected at the same time, he will still be able to read and to understand what is written. He will depend upon writing and reading for his means of communication with others. The amount of interference with spontaneous speech will depend upon whether the lesion is cortical or sub-cortical. If the latter the integrity of the auditory word centre preserves internal speech, and so permits the patient to speak spontaneously with fluency and probably with accuracy, and his power of writing will be equally unimpaired. When the cortical centre is itself destroyed, internal language is thoroughly disorganized, and although some spontaneous speech may be possible, it is certain to be more or less unintelligible. According to the extent of the lesion, it will vary between a speech containing inaccuracies of minor importance, and one which is a jargon incapable of interpretation. Characteristic of this defect is the fact that the patient himself does not appreciate the mistakes he makes. His written language is likely to be more accurate and more intelligible than his spoken language, but it will probably not reach a very high standard. He may copy with accuracy, but is quite unable to write from dictation. Such are the usual chief attributes of word-deafness in its pure form. Clinically, word-deafness is usually accompanied by word-blindness, to a greater or less extent.

Word-blindness, or *Alexia*, is produced by a lesion of the left angular gyrus, and may or may not be accompanied by defective vision. As in the case of word-deafness, it may result from a cortical or from a sub-cortical lesion, and it is in association with the latter class of case that *HEMIANOPIA* (p. 300) is most common. In cortical word-blindness the patient is unable to read, although he sees the letters clearly and may even be able to copy them in the same way as a child copies letters when learning the alphabet. Writing conveys no meaning to his mind, although in the less severe cases the patient may still recognize familiar words, such as his name. There are, in fact, varying degrees of word-blindness, some of which are difficult to understand and to analyze. The word-blind patient suffers in his spontaneous speech to a greater or less extent according to whether he uses his visual or his auditory memories chiefly in the process of internal language. Should he be a 'visual' his spontaneous speech will suffer much more than if he is an 'auditive.' The terms 'visual' and 'auditive' are used to distinguish two classes of persons, the first depending more on their visual memories of words, and the second more on their auditory memories of words in the course of reviving them for the purposes of internal thought and speech. Spontaneous writing is likely to be lost completely, but writing from dictation may be carried out with more or less accuracy. In word-blindness due to a sub-cortical lesion, although hemianopia is almost certain to be present, spontaneous speech and spontaneous writing are preserved perfectly, although the power of reading and of copying hand-written sentences into printed capitals is entirely in abeyance.

When word-blindness and word-deafness coexist, the condition is called *sensory aphasia*, and is one to which some authorities believe that the term aphasia should be limited. It is, however, usual to describe a motor aphasia which may be dependent upon a cortical or sub-cortical lesion.

Cortical motor aphasia results from a destructive lesion of Broca's area, the part of the cortex which stores memories of the afferent impulses excited by speech, and in which such memories must be revived if spontaneous speech is to be carried out perfectly. This form of motor aphasia may be present without any paralysis, but it is usually accompanied by some disturbances of internal speech, and perhaps even by some defective understanding of spoken and written language, which, however, never amounts to true sensory aphasia.

Much more common is the *sub-cortical motor aphasia*, which is due to a lesion cutting off Broca's cortical area from the motor mechanism connected with articulation. In this form intellectual processes and internal language may be perfectly intact, but in most cases the inability to speak is associated with right hemiplegia in right-handed persons, or with left hemiplegia in left-handed individuals. The imperfect speech of the patient who is partly aphasic from a sub-cortical motor lesion may resemble to some extent that of the patient who is word-deaf; but the former is conscious of his mistakes and the latter is not. Sub-cortical motor aphasia may perhaps be described better as an articulatory rather than a speech defect; as an anarthria rather than an aphasia. All the attributes for speech are preserved, but its emission is impossible.

Agraphia results usually from a lesion of the visual word-centre, or perhaps in some cases from a lesion of the posterior part of the left second frontal convolution. In the former case the power of writing may be lost, although there is no paralysis of the arm or hand. In the latter case the agraphia is usually associated with right hemiplegia, and in order to test whether the power of communicating thoughts by written language is preserved, the patient must be asked to use the left hand for the purpose. There is some doubt as to whether pure motor agraphia occurs, and some doubt as to the lesion upon which it may depend. I have had experience of the clinical occurrence of pure motor agraphia without being able to correlate the phenomenon with its anatomical basis.

We have now considered the various forms of aphasia and have indicated their points of distinction. This will serve as a basis for diagnosing the site of the lesion responsible for the speech defect, but the nature of the lesion must be determined from other considerations. Vascular lesions, for instance, are usually acute in their onset, sudden in the case of *embolism*, less precipitate as a rule in cases of *haemorrhage* or *thrombosis*. In *cerebral tumour* or *abscess* the onset of symptoms is more gradual, and local troubles such as that of aphasia are generally accompanied or preceded by the symptoms of increased intracranial pressure in the form of headache, vomiting, and optic neuritis. But aphasia is not always the result of a gross and permanent lesion. Transitory aphasia may be observed in the sequel of epileptiform convulsions, or may be in itself an *epileptic equivalent*—a form of *petit mal* in an epileptic subject. Temporary aphasia occurs also in connection with *migraine*, and I have known it to occur at intervals during a period of thirty years in a woman who was perfectly healthy in every respect, and who showed no other symptoms suggestive of either epilepsy or migraine.

Dysarthria, or in its extreme form '*anarthria*,' is the term used to describe defective articulation as opposed to defective speech. Articulation is carried on by certain muscles of the larynx, pharynx, palate, tongue, and lips which are innervated by the bulbar nuclei, and the latter are set into action by voluntary impulses coming from the motor cortex of both cerebral hemispheres via the pyramidal tracts. The articulatory movements, therefore, are represented bilaterally in the brain, and, like other bilaterally represented movements of the body, are not disorganized by unilateral lesions of the pyramidal system. Thus, in cases of hemiplegia without aphasia, there is little or no defect in articulation, and the examination of such a patient shows that both vocal cords, both sides of the palate, and the tongue, retain their power of voluntary movement almost, if not quite, to perfection.

Suprabulbar dysarthria is induced, however, in cases of *double hemiplegia*, when the fibres from both hemispheres to the bulbar nuclei are interfered with by destructive lesions. When a right-sided stroke is followed by a left-sided stroke, or when double hemiplegia results from a lesion in the pons, dysarthria results. In such cases the power of speech may be perfect, but the ability to articulate naturally and clearly is disturbed. The patient

is not aphasic but dysarthric. Articulation is usually slow, spastic, and indistinct, if it is not altogether unintelligible. These cases are differentiated from cases of dysarthria due to lesions of the bulbar nuclei or of the cranial nerves, not only by the presence of other hemiplegic signs in the limbs and trunk, but by the fact that the tongue retains its shape, nutrition, and normal electrical reactions, and the palate its natural reflex. This condition of *pseudo-bulbar palsy*, as it is sometimes called, is further distinguished by facial starchiness or spasticity, and by the patient's inability to control the expression of his emotions.

Dysarthria of similar origin, but generally of less degree, may be observed in cases of *general paralysis of the insane*, in *cerebral diplegia*, and in *disseminated sclerosis*. In the latter disease the terms 'staccato' or 'scanning' are applied to describe the articulatory defect. Some cases of *Friedreich's ataxia* exhibit a form of articulation which is slow and jerky, not unlike that of disseminated sclerosis. Probably some degree of inco-ordination enters into the production of this peculiar utterance. In all these diseases the diagnosis of the condition depends upon the presence of other symptoms and physical signs, and can rarely be deduced from the articulation alone.

Dysarthria also arises from disease of the bulbar nuclei, or of the nerves arising from the latter which supply the muscles of the larynx, pharynx, tongue, and lips. In true *bulbar palsy*, which is a disease depending on a slowly progressive degeneration of these motor nuclei, articulatory defects are often among the earliest symptoms. The diagnosis of these cases is based on the fact that the symptoms begin insidiously and progress gradually, that the paresis affects the muscles of both sides more or less symmetrically, and that it is an atrophic form of paralysis. The atrophy is seen best in the tongue muscles, and is usually associated with a certain amount of fibrillation, and with diminution of their electrical excitability. The palatal reflex is also impaired, and examination of the vocal cords shows that they too are the seat of a progressive palsy. The dysarthria is always accompanied, sooner or later, by some degree of dysphagia, and also by some weakness and atrophy of the muscles of mastication. Atrophic palsy may also be observed in the small muscles of the hands, and there is a tendency to exaggeration of all the tendon reflexes in the limbs. A similar clinical picture may develop in cases of gross disease of the bulb, due either to local softening or hæmorrhage, or in rarer cases to the gradual growth of a tumour in that region. Such cases can be differentiated from true bulbar palsy, partly by the more acute onset of symptoms in the case of the *vascular lesions*, and partly by the asymmetrical distribution of the muscular atrophy and paresis when a *tumour* forms the basis of the disease. *Gummatous meningitis* at the base of the brain may involve the cranial nerves close to their exit from the bulb, and so produce a dysarthria of a somewhat similar character. When tumour or meningitis is the cause of dysarthria, symptoms of increased intracranial pressure are likely to be observed.

Another form of bulbar palsy is seen in cases of *myasthenia gravis*. In this condition there is little or no atrophy of the articulatory muscles, although some thinning of the tongue is observed sometimes. The distinguishing characteristics of this dysarthria are first of all its marked variability, and secondly the effect produced by fatigue. A myasthenic patient may begin a conversation, or may begin to read aloud from a book, without showing much difficulty in his utterance, but, as he progresses, his articulation becomes more and more defective and more difficult to understand. Usually the palate fails quickly, and a nasal quality is given to the voice. If he is asked to repeat the word 'rub' many times, the terminal 'b' becomes an 'm,' and he ends by saying 'rum' instead of 'rub.' Most cases of myasthenia gravis exhibit similar fatigue phenomena in relation to other parts of the musculature (see *Fig. 111*, p. 235), and in particular show varying degrees of ocular palsy, which, like the dysarthria, is at one time more marked than at another, and is much influenced by rest and exercise.

Some articulatory defect is produced by bilateral peripheral palsy of the palate, which most often results from the effects of the *diphtheria poison*. The voice is nasal, and the pronunciation of certain consonants becomes impossible, 'B' becomes 'm,' 'd' becomes 'n,' and 'k' sounds like 'ng.'

Bilateral facial palsy interferes with that part of articulation which depends upon the labial muscles, and so renders speech indistinct, although not unintelligible. Facial palsy of this kind (*Fig. 201*, p. 493) is met with in some cases of peripheral neuritis and

also in some cases of myopathy, especially that form to which the name Landouzy-Dejerine is applied.

Unilateral bulbar palsy may exist without much interference with articulation or phonation. There may be considerable palsy of one vocal cord due to a lesion of one recurrent laryngeal nerve, without a recognizable alteration in the character of the voice. A bilateral laryngeal palsy, when complete, leads to aphonia. Similarly, unilateral palsy of the palate or of one-half of the tongue may exist without articulatory defect, especially after the patient has become accustomed to the altered conditions.

Functional Disorders of Speech.—In cases of hysteria, a *functional aphonia* is by no means uncommon, and in many cases can be distinguished from aphonia due to organic disease only by an examination of the larynx. Hysterical aphonia may be complete; in other cases the voice is reduced to a whisper, and yet the patient is able to adduct the cords properly in coughing. This is sometimes a recurrent malady, and the suddenness of its onset, as well as the suddenness with which it is often cured, are characteristic.

Stammering is another type of functional dysarthria and presents a large variety of forms. There is little difficulty in their recognition, because in all cases when once the articulatory flow is established the utterance is perfectly normal. The difficulty generally arises either in commencing a word or a sentence, or in connection with certain consonants. Some of the cases depend on an initial spasm of the articulatory muscles, and others upon an inco-ordination between the action of the respiratory muscles and those which have to do with phonation and articulation. The complete absence of physical signs of disease, and the history of the case, make the diagnosis easy. On the other hand, stammering is occasionally an early symptom of progressive degenerative conditions of the central nervous system, especially of general paralysis of the insane.

The term '*lalling*' is applied to a defective form of articulation met with chiefly in persons who are more or less mentally feeble. It is characterized by what appears to be an imperfect pronunciation of certain consonants. In more severe cases one consonant is consistently replaced by another, such as 'r' by 'w.' These mistakes in pronunciation are common enough in normal children when learning to speak, but the endurance of the defect after the learning age is passed generally indicates some permanent mental deficiency. A temporary perversion of speech is seen occasionally in children before they learn the proper use of language. They may talk glibly and fluently in a language which they appear to understand themselves but which is unintelligible to their neighbours. In this condition, to which the term '*idioglossia*' is generally given, the prognosis may be regarded as favourable.

E. Farquhar Buzzard.

SPINAL CURVATURE. (See CURVATURE, SPINAL, p. 153.)

SPLEEN, ENLARGEMENT OF THE.

The Physical Signs of Enlargement of the Spleen.—If the organ is only slightly or moderately enlarged, there is no alteration in the size or shape of the abdomen; if it is considerably or enormously enlarged, the abdomen may be much distended, and at a first glance this distention may appear to be uniform, as though due to ascites. Closer inspection may show that it is by no means uniform, there being distinct bulging of the left side, especially in the left hypochondrium, the left lumbar, and the left half of the umbilical regions. The inner border of the spleen may be tilted forward in some cases, so that a distinct edge or ridge may be seen pushing the abdominal wall forward, this ridge running downwards and inwards from the left costal margin near the anterior axillary line towards the umbilicus; in a few cases a distinct notch can be seen in this edge or ridge. When the patient takes a deep breath, the prominence may be seen to move distinctly downwards, though occasionally the spleen may be so enormously enlarged that its lower end becomes impacted in the pelvis, when no downward movement is possible.

Palpation is the best means of detecting splenic enlargement. If the organ is but little enlarged, it may not be felt until the observer, standing upon the left-hand side of the recumbent patient, and supporting the lower left ribs posteriorly with his right hand, steadily but firmly presses the fingers of his left hand under the left costal margin just in front of the anterior axillary line; when the patient now takes a deep breath, a definite sense of increased resistance may reveal splenic enlargement when the organ is comparatively

soft, as in many cases of typhoid fever for example, or a hard mass with a distinct edge may be felt in more obvious cases. When the enlargement is moderate or considerable, the splenic tumour will be felt coming down from beneath the left ribs close behind the abdominal wall; and unless there is a very large liver at the same time, or some other cause preventing the viscus from following its natural direction as it enlarges, it tends to reach and ultimately cross the middle line at or just below the level of the umbilicus. It is generally smooth and firm, and the characteristic notch or notches can be felt in its anterior border. Except in those rare cases in which the whole spleen is dislocated, it will not be possible to insert a hand between it and the left costal margin, or to define its upper limit by palpation. The lower pole can be felt to move decidedly downwards on inspiration, unless the enlargement is very great. On bimanual palpation, the loin is not filled out as it would be by a renal tumour, and the mass cannot be pushed back into the loin so as to be felt by the posterior hand as readily as it is by the hand on the anterior abdominal wall.

Percussion yields a dull note over the mass, the dullness being directly continuous with an increased area of dullness in the thorax extending upwards as high as the seventh rib in the mid-axillary line, the sixth rib in the nipple line, or even higher, and including the ordinary area of splenic impairment of resonance behind. Percussion of the left loin may elicit resonance here, indicating that the colon is not displaced as it would have been by a renal tumour; no intestines can be felt or percussed over the front of the spleen.

Auscultation seldom affords much evidence of value in these cases, but sometimes when the splenic enlargement is associated with local peritonitis, as in cases of infarction for example, a loud rub may be heard over the mass when the patient takes a particularly deep breath; and sometimes, especially if the enlargement is associated with venous engorgement, a well-marked continuous humming bruit may be heard.

Distinction between an Enlarged Spleen and other Tumours which may simulate it.—An enlarged spleen has to be distinguished from other tumours which may arise in the left hypochondriac region, especially from: (1) Kidney tumours or perinephric inflammation or abscess; (2) Suprarenal tumours; (3) Carcinoma of the splenic flexure of the colon; (4) Pancreatic tumours, especially cyst or carcinoma; (5) Malignant growth of the stomach; (6) Ovarian tumour; (7) Tuberculous peritonitis; (8) Faecal accumulation in the colon.

Distinction from a Renal Tumour. It may be difficult to distinguish an enlarged spleen from a kidney in some cases. Both conditions may cause local prominence or bulging of the left side of the abdomen; in the case of splenic enlargement the bulging is more forward and inward, whereas in a kidney enlargement the loin is more likely to be bulged. No distinct edge or notch can be seen or felt in the case of most renal enlargements, a point the significance of which cannot be over-estimated. Either tumour may move downwards when the patient takes a deep breath; but the spleen, being in closer contact with the under surface of the diaphragm, moves the more markedly of the two. A renal tumour being more deeply situated in the abdomen seldom approximates closely to the anterior abdominal wall unless the enlargement is very great, in which case the loin will be filled out and feel very firm and resistant on bimanual examination. A renal tumour generally slopes away as it approaches the ribs, so that it is less difficult to get one's hand between its upper pole and the costal margin than is the case with the undislocated spleen. The colon may be seen or felt over the anterior surface of a renal tumour, which is never the case with splenic enlargement; and percussion may yield a resonant note in front, or in typical cases a vertical band of colonic resonance down the centre of an otherwise dull mass, the loin posteriorly being dull; whereas with a splenic tumour the loin may be resonant, and the anterior aspect of the mass quite dull. The presence of a local bruit or rub would make renal tumour unlikely. The occurrence of HEMATURIA (p. 275), PYURIA (p. 574), or ALBUMINURIA (p. 4), would suggest renal enlargement, whilst the conditions of the blood might be such as to suggest splenic.

Notwithstanding all these points, to distinguish between splenic and renal masses is sometimes by no means easy; and it is only by paying careful attention to the history and the patient's own sensations, as well as to the physical signs and the changes in the blood and urine, that a correct diagnosis can be made.

Malignant Disease of the Left Suprarenal Gland may cause a large mass which is

sometimes particularly difficult to distinguish, either from a splenic or from a renal enlargement. Owing to the close proximity of the suprarenal capsule to the kidney, and the liability for the capsule of the latter to become infiltrated by growth of the former, the physical signs of a suprarenal are practically the same as those of a renal tumour, except that it may be more difficult to pass the hand between the mass and the costal margin. Haematuria and other urinary changes may result from spread of the disease to the kidney; affection of one suprarenal gland alone does not produce Addison's disease, and it may be impossible to arrive at a correct diagnosis without laparotomy. A peculiar affection of children deserves special mention: at a comparatively early age there may be an abnormal development of the pubic and axillary hair and of the genital organs (see *Figs.* 174, 175, p. 408), with premature puberty, associated with overgrowth of suprarenal rests in the kidney, the resultant tumour being spoken of as a hypernephroma.

Carcinoma of the Splenic Flexure of the colon is usually annular, giving rise to no definite tumour, but rather to symptoms of chronic, followed by acute, intestinal obstruction. Occasionally, however, the growth may be more voluminous, or it may have caused leakage and inflammatory matting from local perforation through or above the growth, with the result that a fairly large tumour may be felt in and below the left hypochondrium. This mass is generally resonant to percussion, has no well-defined edge or notch, and may vary somewhat in position from day to day; it will usually be associated with intestinal symptoms, especially constipation alternating with diarrhoea, and the passage of mucus, and occasionally blood, per rectum. Sometimes there are obvious secondary deposits in the liver or in the left supraclavicular glands.

Pancreatic Tumours are usually situated more in the median line of the abdomen than is a spleen, between the ensiform cartilage and the umbilicus; sometimes, however, a very large cyst, such as may nearly fill the abdominal cavity, may cause considerable difficulty in the diagnosis. One very important point is that no definite edge and no notch can be felt. The stomach generally lies in front of a pancreatic cyst; or, if the latter pushes its way forward so as to displace the stomach upwards and the transverse colon downwards, it may be possible to define its relationship to the stomach by inflating the latter with gas. A splenic tumour rarely extends to the right of the middle line unless the enlargement is great, and then it crosses at or below the umbilicus, whereas a pancreatic cyst reaches across to the right of the middle line above the navel. Pancreatic new growth has a similar position; but the outline of the mass, if any can be felt at all, is more nodular; there will generally be jaundice and a palpable gall-bladder, and the urine may yield Canmidge's pancreatic reaction (p. 100).

Malignant Growth of the Stomach may be mistaken for enlargement of the spleen, especially gastric sarcoma, which, though very much rarer than carcinoma, is more likely to involve the whole of the stomach and give rise to a very large tumour occupying chiefly the upper part of the left side of the abdomen. The following changes will serve to distinguish a gastric new growth from enlargement of the spleen: the mass is apt to shift its position during the course of an examination or from day to day; it does not present a well-defined edge with definite notch or notches; it may extend a considerable distance to the right of the middle line, although its lower limit may not be below the level of the umbilicus; it is likely to be resonant in front, though the percussion note over it may be impaired; there may be anaemia and leucocytosis, but the blood-changes would not be characteristic of any positive blood disease; the taking of food may cause an increase in the gastric pain; vomiting will generally be a prominent symptom; the vomit may contain blood, obviou or occult; free hydrochloric acid may be deficient or absent; sarcine ventriculi may be found (*Fig.* 121, p. 241); and there may be secondary deposits, especially in the liver or in the left supra-clavicular glands. Examination of the stomach with the *x*-rays after a bismuth or barium meal may also assist the diagnosis (*Fig.* 131, p. 270).

Ovarian Tumours have been mistaken for enlargement of the spleen, and vice versa, the differential diagnosis being particularly difficult in cases in which the spleen has become dislocated, or is so large as to reach down as far as the uterus. The organ has sometimes been found so dislocated as to lie wholly within the pelvis. The differential diagnosis depends in most cases on the following points: an ovarian tumour rarely extends upwards to such an extent that its upper limit comes into actual contact with the left costal margin

so that the hand cannot be placed between it and the ribs; it does not move much downwards during deep inspiration; it extends upwards from the pelvis, whence it may be felt definitely to arise, the lower part of the abdomen being more prominent than the upper; it is usually more globular than a splenic tumour, and has no sharp, well-defined edge with notches in it, even when covered with projecting bosses of simple or malignant new growth; it usually extends more to the right of the middle line than an enlarged spleen; and it is more apt to transmit aortic pulsations; a vaginal examination may determine that the mass is attached to one or other of the broad ligaments, and that the cervix and the body of the uterus are drawn upwards; there will probably be no distinctive blood-changes, but very likely amenorrhœa.

Tuberculous Peritonitis may cause various abdominal tumours (see p. 48), and sometimes gives rise to a mass occupying the left hypochondriac region, the result of matting together of the intestines, thickening of the omentum, or thickening and infiltration of the peritoneum attached to the abdominal wall here. The tumour does not generally extend close up under the ribs, so that the hand may be placed between it and the costal margin, and although it may feel somewhat rounded, with a more or less well-defined edge, there is no definite notch to be felt; sometimes, however, when there are two, three, or more separate masses united together, a notch may be simulated to some extent. The mass itself may be dull, but there is generally resonance between it and the normal splenic dullness. Ascites is often present, and there may be palpable lumps in other parts of the abdomen, or perhaps redness and œdema of the abdominal wall, or a purulent or fecal discharge from the umbilicus. Indeed, tuberculous peritonitis is the commonest cause of acquired umbilical fistula, the next commonest cause of the latter being pneumocœcal peritonitis which has recovered slowly, either without or with operation. There may be signs of tuberculosis elsewhere, for instance in joints, or lymphatic glands. Guénet's or von Pirquet's tuberculin reactions may be positive. The patient will generally be young, and have consumed unsterilized cow's milk. Pyrexia may be present or absent, either with tuberculous peritonitis or with splenic affections, so that its occurrence does not assist the diagnosis much, except perhaps that if the chart exhibits marked evening pyrexia in a young subject, with a sub-normal temperature in the morning, it is an additional argument in favour of tubercle. The reverse type of pyrexia—morning rise and evening fall—has been spoken of as characteristic of tubercle, but it is seldom met with.

Fæcal Accumulation in the Splenic Flexure or adjacent parts of the transverse or descending colon may be mistaken for an enlarged spleen upon a first examination; but this source of error is usually removed when the patient is re-examined after an action of the bowels has taken place. The condition is found most frequently in women if the age is not great, or in elderly people of either sex. There is generally a history of severe obstipation, and possibly attacks of temporary obstruction. The mass is generally irregular, more or less cylindrical, and in thin persons it may be possible actually to alter its shape by manipulation with the hand. The best test of the condition, however, is the effect of copious enemata upon the mass.

Hæmatoma due to Leakage from an Abdominal Aneurysm is by no means always easily recognized, and it may be mistaken for an enlargement either of the spleen or of the kidney, unless the aneurysm itself can be felt pulsating; or unless there is a history or an acute exacerbation of intra-abdominal pain, accompanied by blanching due to the amount of blood lost.

CAUSES OF SPLENIC ENLARGEMENT.

Having concluded that the spleen is enlarged, the next step is to decide the cause of the enlargement. There are various ways in which the different causes may be classified, but from a diagnostic point of view the following is serviceable:—

I. Chronic Enlargement of the Spleen.

(a). *Very great enlargement:*

Splenomedullary leukaemia	Splenic anaemia
Lymphatic leukaemia	Pseudo-leukaemia infantum
Mixed leukaemia	Gaucher's disease
Chronic malaria	Still's disease
Kala-azar	Familial acholuric jaundice.
Splenomegalic polycythæmia	Egyptian splenomegaly
Splenomegalic cirrhosis	

(b). *Moderate enlargement.*—All conditions mentioned in group (a) will at some stage exhibit a spleen that has not yet become enormous; and besides these, chronic and moderate enlargement of the spleen may be exhibited in cases of:—

Pernicious anæmia	Thrombosis of the portal vein
Rickets	Pressure on the portal vein by enlarged lymphatic glands or by adjacent tumour of the gall-bladder, liver, pancreas, stomach, etc.
Congenital syphilis	
Hodgkin's disease	
Cirrhosis of the liver	
Lardaceous disease	

II. Acute Enlargement of the Spleen, the enlargement as a rule being slight.

(a). *Acute infective fevers:*

Especially—

Typhoid fever	Malaria
Paratyphoid fever	Malta fever
Relapsing fever	Erysipelas
Typhus fever	Septicæmia.

Less often in—

Pneumonia	Rheumatic fever
Diphtheria	Influenza
Scarlet fever	General tuberculosis.
Small-pox	

(b). *Embolism*, especially in cases of fungating endocarditis.

(c). *Injury*.

(d). *Strangulation* by twisting of the pedicle.

It will be noted that no mention is made of abscess, gumma, carcinoma (whether primary or secondary), sarcoma (primary or secondary), or hydatid cyst of the spleen, for these are all so exceedingly rare they are very unlikely to be met with. It will also be noted that no mention is made of backward pressure, whether due to chronic valvular disease of the heart with failing compensation, or to obstruction to the inferior vena cava above the hepatic veins, such as may result from thrombosis or from pressure upon the veins by mediastinal fibrosis or new growth; these conditions are omitted purposely, for it is quite exceptional for ordinary backward pressure to produce enlargement of the spleen. So true is this that in a case of chronic valvular heart-disease with failing compensation the existence of a definitely palpable spleen is evidence of there being more than mere mechanical heart-failure—probably superposed fungating endocarditis. The chief exceptions to this occur in childhood, where the spleen becomes palpable more easily than in adults, so that with heart-failure in a child enlargement of the spleen is less good evidence of fungating endocarditis than it is in a grown-up person.

I. CHRONIC ENLARGEMENT OF THE SPLEEN.

Chronic and very great Enlargement of the Spleen.—When the spleen is so large as to occupy half the abdomen or more, the diagnosis is generally easy. The largest of all spleens are those due to *spleno-medullary leukaemia*. The first step is to make a full examination of the blood, including particularly total and differential leucocyte counts. If there is an extreme degree of leucocytosis, up to anything between 50,000 and 1,500,000 per c.mm. for example, the diagnosis is almost certainly leukaemia, and if in the differential leucocyte count there are from 20 per cent to 50 per cent of myelocytes, it is of the spleno-medullary type, whilst if the lymphocytes amount to 90 per cent or more, the disease is of the *lymphatic* form, in which the lymphatic glands are almost certain to be enlarged as well as the spleen; in some cases of lymphatic leukaemia the latter may be scarcely enlarged at all, but in others it may be almost if not quite as large as in the spleno-medullary type of the disease. For mixed leukaemia, see ANÆMIA (p. 25). In the absence of any marked leucocytosis, or of characteristic differential leucocyte counts (see also ANÆMIA), the diagnosis of the nature of a very large spleen will depend in the first place upon whether there has or has not been residence in a *malarial* region—the fen districts of Great Britain, the tropics, or certain parts of Europe, particularly Italy. The *ague-cake* spleen of the fens is now very rare; it is more often found in chronic cases of tropical malaria, when the history may indicate its nature, and if the patient is having febrile attacks, the parasites

(Plate XXVIII, Figs. A, B, C, D, E, p. 614) may be found in the blood. Recent investigations have shown that some, at least, of the enlarged spleens formerly attributed to malaria, are due to other infections. One of these has been differentiated clearly from the rest, namely *Kala-azar*, which occurs in India, particularly in Assam, in Africa, and in Sicily, and is diagnosed chiefly by the discovery of the Leishman-Donovan bodies in the fluid obtained by splenic puncture (Plate XXVIII, Fig. H, p. 614).

Splenomegalic polycythaemia is a rare affection of adults, characterized by more or less cyanosis (Plate XXIX, p. 634) and symptoms which might suggest a cardiac lesion, together with more or less enlargement of the spleen, and polycythaemia amounting perhaps to six, seven, ten, or even twelve million red corpuscles per c.mm. The malady is generally chronic, extending over years: with an insidious onset and slow progress. The first symptoms are vague, with progressive loss of working power, and some shortness of breath on exertion. Haemorrhages may occur early, or at any stage of the malady: especially bleeding from the mouth, epistaxis, haemoptysis, haematemesis, haematuria, or melena. Purpura is not common. The patient's heart is generally hypertrophied and dilated to some extent with or without a systolic apical bruit: and the blood-pressure is above the normal—it may be anything between 150 and 250 mm. Hg. The patient does not usually waste. He may develop effusion into any of the serous cavities. The diagnosis is arrived at when polycythaemia and enlargement of the spleen occur in the absence of any definite cause.

Splenomegalic cirrhosis is an affection of children and young adults, in whom there are likely to be more or less jaundice, anaemia, lack of development, and ultimately ascites, as well as considerable enlargement of the spleen. There is a tendency for this malady to affect more than one member of a family, and this sometimes gives the clue to the diagnosis. When death ultimately ensues, in addition to the great enlargement of the spleen these cases exhibit more or less fibrosis or cirrhosis of the liver, and sometimes the liver is indistinguishable from that of ordinary alcoholic cirrhosis. What relationship this malady has to ordinary alcoholic cirrhosis of the liver on the one hand, and to splenic anaemia or Banti's disease upon the other, is not clear; but owing to the enlargement of the spleen, it is differentiated as splenomegalic cirrhosis. Haemorrhages, particularly haematemesis, are not infrequent in this as in other forms of cirrhosis of the liver. The blood-changes are merely those of a simple chlorotic anaemia. The diagnosis is afforded chiefly by the age of the patient, by the size of the spleen, and by the absence of any positive blood-changes, particularly if more than one member of the family is affected in the same way. The patient often lives for a number of years, and is able to work in spite of the complaint, until ascites supervenes. The fingers may be clubbed.

FIG. 267. Splenic anaemia; photograph showing the outline of the spleen. There was severe chlorotic anaemia without leucocytosis; the patient died, and at the autopsy there was no cirrhosis of the liver.

Splenic anaemia has been discussed under ANAEMIA (p. 37). The spleen is not as a rule very greatly enlarged, though sometimes it may be enormous (Fig. 267). The blood changes are simply those of progressive and severe anaemia of a chlorotic type: even though there may really be a disease meriting the distinctive term, 'splenic anaemia,' not a few cases diagnosed as such on account of the co-existence of splenic enlargement with simple anaemia, ultimately turn out to be cirrhosis of the liver. When that which is really cirrhosis of the liver is diagnosed in its early stages as splenic anaemia, the condition is termed *Banti's disease*. One particular variety of familial splenic anaemia of young persons has been distinguished from the rest as *Gaucher's disease*. It runs a course very

similar to that of familial acholuric jaundice (see below), but is distinguished during life by the occurrence of a peculiar fat-like deposit under the exposed part of the conjunctiva external to the cornea; and after death by the presence of special Gaucher cells in the spleen and liver. It is rare.

Pseudo-leukæmia infantum (VON JAKSCH'S DISEASE) was until recently regarded as, apart from true leukæmia, almost the only cause of very great enlargement of the spleen in young children (*Fig. 13, p. 37*). It is diagnosed by the severity of the anæmia, which is of the indeterminate chlorotic type without great leucoeytosis, but with all the changes that are to be expected in any severe anæmia (pp. 21, 22) developing in an infant of a year old or less, running a chronic course, but sometimes resulting in complete recovery. It is probable that von Jaksch's disease (splenomegaly and anæmia in a child) is not a disease but a syndrome, and that it includes cases in which these symptoms are due to different causes; in some this is congenital syphilis, as proved by Wassermann's test; others with a negative Wassermann reaction are probably related to the splenic anæmia of adults; others are familial acholuric jaundice; others, Gaucher's disease; while some are due to obscure causes not yet elucidated.

One clinical point of interest which may assist some day in separating these cases into more definite groups is that some show undue fragility of the red corpuscles and others do not; this fragility is tested by putting a drop or two of the patient's blood into successively weaker solutions of salt until the point at which laking occurs is found; the nearer to normal saline this point is, the greater the fragility of the cells. In one group, with normal fragility undue destruction by some toxic agent in the patient is taking place; in another, the fragility of the corpuscles is a main cause of the anæmia.

Still's Disease is really subacute generalized rheumatoid arthritis of children (*Fig. 169, p. 377*) associated with wasting, moderate enlargement of most of the superficial lymphatic glands, and in some cases considerable enlargement of the spleen. The latter is not essential, however, and in any case it is the affection of the joints that attracts chief attention. The patient may be completely crippled.

Familial Acholuric Jaundice is in many respects similar to splenomegalic cirrhosis of children, described above; without laparotomy, or post-mortem examination, it may be impossible to be certain whether the enlarged spleen is accompanied by cirrhosis or not. The disease affects several children in the same family as a rule, runs a chronic course, beginning soon after birth but permitting of survival for many years. The patient might be described as delicate rather than ill, with more or less anæmia of chlorotic type, a facies reminiscent of that of pernicious anæmia, no great wasting, a distinctly icteric tinge of the skin and conjunctive, without any bile-staining of the urine, which remains of a normal colour; considerable enlargement of the spleen and often of the liver also; some of these cases give a positive Wassermann reaction, others do not; the congenital syphilitic type is held by some to be quite distinct from true familial acholuric jaundice. Splenectomy has cured a certain number of these cases (*Plate XVIII, p. 332*).

Egyptian Splenomegaly is a disease affecting natives in Egypt, clinically very similar to splenic anæmia, but thought to be due to infection by a protozoon not yet discovered, though perhaps related to either malaria on the one hand or to trypanosomiasis upon the other. It runs a chronic course for some years, but ends like cirrhosis of the liver with ascites, pyrexia, and cachexia. The spleen may be enormous.

Chronic Enlargement of the Spleen, the enlargement being of moderate size.

It is clear that conditions which may sometimes produce great enlargement of the spleen must go through a phase in which the spleen is not yet enormous, and at this stage all those diseases that have just been discussed will come into the present group. The remarks already made need not be repeated here, however, for the diagnosis at the stage in which the spleen is yet only moderately big is arrived at in the way already described. A blood-count is essential in order to exclude or diagnose leukæmia; parasites may be discovered to account for malaria or kala-azar; and so on. The spleen is palpable in a considerable proportion of cases of *pernicious anæmia*, but it is seldom greatly enlarged, and the diagnosis is arrived at by finding the blood-changes described under ANÆMIA (p. 24). In none of the other diseases mentioned in the list above are the blood-changes themselves pathognomonic.

The spleen of a small child is often just palpable without there being any disease at

PLATE XXIX

SPLENOMEGALIC POLYCYTHÆMIA

The characteristic face of splenomegalic polycythemia

all: if it is more decidedly enlarged, the first suspicion will be that it is due to *ricketts* or *congenital syphilis*. The bony changes, quadrate head, beaded ribs, large epiphyses, exaggerated curves of the long bones, particularly of the legs, delay in the closure of the fontanelles, and the pot-belly, will suggest ricketts; it should be added, however, that owing to the eversion of the lower ribs along a line corresponding with the attachment of the diaphragm, and known as Harrison's sulcus, the spleen often becomes unduly palpable in rickety children without being necessarily enlarged. Congenital syphilis may be suggested by a knowledge of the family history, by the occurrence of snuffles, of specific skin eruptions, and so forth; but in many cases the diagnosis will be one of surmise only, unless it can be confirmed by the specific serum reaction of Wassermann. *Pseudo-leucæmia infantum* has been discussed above; by some it has been regarded as in some way associated either or with ricketts, with congenital syphilis, or both; but the most recent view is that it is due to some cause other than these, of a nature not yet known.

Hodgkin's Disease, when it is typical, is associated with considerable and progressive LYMPHATIC GLAND ENLARGEMENT (p. 376), especially those of the neck, and later those of the axillæ and groins, thorax and abdomen, together with moderate but seldom very great enlargement of the spleen; without any anæmia to begin with, but later with a progressive and ultimately severe anæmia of the chlorotic type, with all the changes mentioned on pp. 21, 22; without leucocytosis, and with nothing characteristic about the differential leucocyte count, except that an occasional basophile cell or myelocyte may be seen. Hodgkin himself laid particular stress upon the changes in the spleen in this disease, but there can be little doubt that there are cases of a precisely similar nature in which there is much lymphatic glandular enlargement without enlargement of the spleen. An attempt is sometimes made to distinguish this type from that with splenic enlargement, by styling it lymphadenoma; but where lymphadenoma ends and Hodgkin's disease begins, and vice versa, is by no means settled. It would seem much more likely that there is every degree of acuteness and severity between extremes that are wide apart, those cases which have lymphatic glandular enlargement and a rapidly fatal ending without leucocytosis as their most prominent feature being styled lymphosarcoma; similar cases with the addition of enlargement of the spleen, but a fairly rapid fatal ending, being termed acute Hodgkin's disease; others again, with enlargement of the glands without enlargement of the spleen and with rather greater duration, being termed lymphadenoma; whilst precisely similar cases with enlargement of both spleen and glands, and a duration of anything between several months and several years, are termed ordinary Hodgkin's disease. One very important point to be realized about this disease is that the blood-changes in it are not pathognomonic even when they are severe.

Cirrhosis of the Liver, by the time it has ended fatally, is nearly always associated with a spleen that is bigger than normal as judged by post-mortem weights. Clinically, however, this enlargement can be made out only in a small proportion of the cases, and even in these the enlargement is seldom great. When, however, there is doubt as to the diagnosis, and cirrhosis of the liver seems to be a possible cause for other symptoms, such as HÆMATEMESIS (p. 265), ASCITES (p. 43), JAUNDICE (p. 324), the presence of chronic but not very great enlargement of the spleen, without affection of the lymphatic glands and without pathognomonic blood-changes, is an additional argument in favour of the diagnosis. On the other hand, splenic enlargement is a very prominent and relatively early feature in a few cases, as in the splenomegalic cirrhosis of children (p. 372) and young adults; whilst in some older patients, long before the hepatic changes themselves attract attention, the case may come under observation for anæmia, with or without hæmorrhage, such as purpura, epistaxis, hæmatemesis, or the passage of blood per rectum; and a considerable enlargement of the spleen may be found. The blood-changes may be merely chlorotic, and in the absence of other definite signs or symptoms the diagnosis of splenic anæmia, that is to say of simple anæmia associated with an enlarged spleen, may be made; many such cases ultimately turn out to be examples of cirrhosis of the liver. Banti's disease.

Lardaceous Disease.—A lardaceous spleen is not always large, but is frequently big enough to be palpable, and the liver is generally enlarged at the same time. The condition results from long-continued suppuration, discharging sinuses from empyema or spinal caries, purulent cavities in phthisis or bronchiectasis, or from tertiary syphilis. If considerable enlargement of the spleen is associated with any of these it is probably due

to lardaceous disease. There is generally diarrhoea on account of affection of the intestines: and polyuria and albuminuria owing to renal changes. The patient is weak, frail-looking, and bloodless. Blood-counts exclude leukaemia, and indicate more or less anaemia of the chlorotic type. The disease is very much less common than formerly, because modern surgical methods have done away with much of the persistent suppuration that was formerly common; for the most part it is diagnosed by reason of there being obvious cause for it, especially prolonged sepsis or tertiary syphilis.

Thrombosis of the Portal Vein as a cause for splenic enlargement can seldom be more than guessed at (see ASCITES, p. 51).

Pressure on the Portal Vein by enlarged lymphatic glands or by adjacent tumours, will almost certainly be associated with obstruction to the bile-duct at the same time, so that there will be jaundice, and probably also ascites, in addition to any splenic enlargement: the latter will be slight.

II. ACUTE ENLARGEMENT OF THE SPLEEN.

Acute Infectious Fevers.

Typhoid Fever is the best-known febrile disease in which moderate enlargement of the spleen occurs. The organ is usually soft, so that in many cases only an increased sense of resistance is noticed on palpating close under the left ribs. The enlargement may be so slight that the organ may be felt only when the patient takes a deep breath, so as to push it down from under the ribs: or it may be so big that its lower border reaches to the level of the umbilicus. If, in a case of obscure fever in which a continued pyrexia (Fig. 241, p. 565) is associated with a relatively slow pulse-rate, the spleen is found to be enlarged, the diagnosis of typhoid fever is very likely: especially if there is a history of gradual onset with anorexia and lassitude, accompanied by headache and sometimes epistaxis, a gradual rise of temperature which, if it has been observed from the first, is seen to go up about two degrees every night, with a fall of one degree the following morning, until step by step it reaches 103° F., or 104° F., or even higher: and perhaps no definite abnormal physical signs whatever except as regards the spleen, or a few rhonchi in the chest. The characteristic rash does not appear until the sixth day or later, when it comes out on the abdomen, sometimes also upon the chest and back, in the form of small, rosy-red, flattened papules which fade on pressure, come out in successive crops, and are seldom present to the extent of more than half a dozen or a dozen at a time. Widal's agglutinating serum reaction should ultimately be positive in a dilution of 1 in 200 in half an hour, but it is generally the second week before this test is positive. Earlier confirmation of the nature of the fever may be obtained by the blood-count, there being no leucocytosis—indeed, sometimes LEUCOPENIA (p. 361)—whilst, unlike many febrile illnesses, typhoid fever produces a relative increase, not in the polymorphonuclear cells, but in the small lymphocytes. Such blood-changes are in themselves almost pathognomonic, and they are obtainable before Widal's reaction is to be expected, though the latter is the ultimate test of the fever. Typhoid bacilli may be recovered from the blood on special cultivation quite early in the attack, but this method of diagnosis is not resorted to often. When neither blood-count nor serum-test is possible, the diagnosis may not be cleared up until the third week or later, when sloughs from Peyer's patches can be discovered in the stools. The ratio of the pulse-rate and temperature is of considerable value in the diagnosis, for in most cases the pulse-ratio is very low; for instance, with a temperature of 104° F., the pulse-rate may be only 90 or 100 per minute, when the physiological ratio for this temperature is 120. Pneumonia in its earlier stages may also produce a low pulse-ratio: but the respiration-ratio is here increased, which is not the case in typhoid fever. The following figures illustrate these points:—

				T		P		R.
Physiological ratio	104° F.	..	125	..	32
Typhoid fever	104° F.	..	90	..	30
Pneumonia	104° F.	..	100	..	40

General tuberculosis may simulate typhoid fever in this respect also, and sometimes it is not possible to decide between the two until the case has been watched for some time.

Paratyphoid Fever is closely related to typhoid fever, and the clinical symptoms are very similar: the importance of distinguishing between the two lies chiefly in the carrying

out of Widal's agglutinating serum reaction. It sometimes happens that in a case which, from a clinical point of view, is almost certainly typhoid fever, the serum will not cause clumping of Eberth's typhoid bacilli; and so far as the bacteriological test goes, the diagnosis might remain altogether obscure unless the serum were tested also against the *Bacillus paratyphosus A* and the *B. paratyphosus B*. In a certain proportion of cases clumping will be obtained with one or other of these, the diagnosis of paratyphoid fever being based upon bacteriological rather than upon clinical conditions. The spleen is enlarged in paratyphoid fever to about the same extent as in typhoid.

Relapsing Fever is associated with considerable enlargement of the spleen. The disease is contagious, but nowadays rare, developing only under conditions of filth and famine. It is characterized by an acute onset, with chills, pains in the back, and a sudden rise of temperature. The latter remains high for six or seven days, and then falls by crisis. For about a week the temperature remains normal, and then it rises again as before, several such remissions and relapses succeeding each other and being pathognomonic of the disease (Fig. 5, p. 27). The pulse is rapid, and there is profuse sweating. Enlargement of the spleen is detected early. It is most conclusively distinguished from other diseases by examination of blood-films in which the *Spirochæta obermeieri* (Plate XXVIII, Fig. 1, p. 614) will be found.

Malaria is discussed on p. 565: the splenic enlargement is similar to that of typhoid fever.

Malaria.—Apart from the chronic enlargement of the spleen due to recurrent attacks of malaria, the spleen becomes enlarged and soft as the result of active hyperæmia during acute attacks. Even when no splenic enlargement can be detected in the intervals, during the paroxysms the viscus can usually be felt projecting below the costal margin, presenting a soft and indefinite lower border. When the patient has more or less chronic enlargement of the spleen as the result of preceding attacks, each acute febrile paroxysm is associated as a rule with an additional swelling which passes off after the attack. For the characters of the fever, see pp. 29-32. The nature of the malady will be suggested by geographical considerations, or by the influence of quinine; but the only conclusive proof is the discovery in stained blood-films of the malaria parasites (Plate XXVIII, Figs. A, B, C, D, p. 614). There is often marked anæmia, especially in cases of recurrent malaria, the red corpuscles and hæmoglobin becoming reduced as in chlorosis; the leucocytes are also diminished, and the differential leucocyte count shows a relative increase in the large hyaline lymphocytes up to even 15 or 20 per cent.

Erysipelas is often associated with moderate enlargement of the spleen; but the fever, rigors (Fig. 245, p. 568), and slightly-raised red spreading infection of the skin are sufficiently characteristic to indicate the diagnosis.

Septicæmia may be less easy to diagnose unless there is some obvious source of sepsis in the first instance, such as infection of the uterus after childbirth, sepsis in connection with the general peritoneal cavity, joints, wounds, and so forth. The chief difficulty arises in those cases in which the source of the sepsis is not obvious, being due to absorption from such lesions as pyorrhæa alveolaris, whitlows, æcne, or other comparatively small superficial affections: or to deep-seated suppuration, such as a hidden empyema, infective pylephlebitis, infective cholangitis, pyosalpinx, and so forth. In some cases of chronic or subacute septicæmia, enlargement of the spleen may be considerable, and the diagnosis of infective endocarditis will very likely suggest itself. Whether or not the heart valves are affected in these cases, the ultimate diagnosis will depend upon discovery of infective organisms in cultures obtained by venepuncture.

Diphtheria, *Pneumonia*, *Scarlet Fever*, and *Small-pox* seldom give rise to very prominent splenic enlargement, and the only importance of it is that in the early stages of the malady detection of a spleen that is just palpable may temporarily arouse a suspicion that the patient may be suffering from typhoid fever. The course of the disease, bacteriological examination of swabbings from the throat, the physical signs in the lungs, and characters of the sputum and the skin rash, will serve to point to the correct diagnosis.

Typhus Fever is fortunately very rare now, although there are small outbreaks of it in the poorer parts of large cities from time to time: the spleen becomes soft and moderately enlarged, but less constantly so than in typhoid fever. The disease sets in more acutely than enteric, with chills, early prostration, and a high temperature which ends by less

SPLEEN, ENLARGEMENT OF THE

marked lysis (*Fig. 268*) than does that of typhoid fever (*Fig. 241*, p. 565); and sometimes almost by crisis at the end of the second week (*Fig. 269*). The rash differs from that of typhoid fever, in that it appears on the fifth day, and consists of petechiæ and of dark-red groups of subcutaneous macules in addition to rosy-red papules on the surface. Nervous symptoms become very marked, especially at the end of the first week, the so-called typhoid

Fig. 268. Temperature-chart from a typical case of typhoid fever ending by lysis rather than by crisis. (Chart kindly supplied by Dr. Torner, Med. Dept., of the South Eastern Fever Hosp., London.)

state being an expression used to denote, not the condition that occurs in typhoid fever, but that which develops in typhus. There may be severe vomiting, and retention of urine, important symptoms that are rare in typhoid fever. There should be no positive Widal's reaction, and no sloughs in the stools.

Influenza is a diagnosis which should never be made except with very good cause, for many febrile illnesses in which the real cause escapes recognition receive the label influenza.

It is easiest to diagnose correctly in times of severe epidemic, and then slight enlargement of the spleen may occur in a few cases. This in itself is not important if influenza can be diagnosed with certainty on other grounds; but until the nature of the fever becomes obvious, it is important in that it may suggest typhoid when none exists. The sudden

Fig. 269. — Case of typhus fever, showing termination by crisis at the end of the second week. The majority of the cases exhibit a less abrupt ending to the pyrexia perhaps, but the above type is characteristic in some epidemics. (Chart kindly supplied by Dr. Turner, Med. Sup't, of the South Eastern Fever Hospital, London.)

onset, extreme prostration, high pulse-rate as well as temperature, initial chill, profuse sweating which comes on when the patient begins to improve, and the fall of the temperature after an illness lasting from twenty-four hours to three or four days or a week, would all point to influenza. It may, however, be impossible to distinguish influenza from

typhoid fever until the course of the pyrexia has been watched, or unless typical *Bacilli influenzae* are recovered in nearly pure culture from some secretion, such as the sputum. It is worthy of note that in influenza as well as typhoid there is no leucocytosis.

General Tuberculosis may also simulate typhoid fever in certain cases, and enlargement of the spleen may result from the development of tubercles in it. When cerebral symptoms predominate, the diagnosis is relatively easy; the headache may be equally severe in both, but with tuberculous meningitis there is more vomiting and more retraction of the head, whilst it is probable that optic neuritis, and perhaps choroidal tubercles, can be detected. Widal's test will remain persistently negative; there will be no rosy rash, probably no leucocytosis, and no sloughs will be found in the stools. In some cases, however, general tuberculosis produces a clinical picture that may be very difficult to distinguish from typhoid fever. Lumbar puncture may decide the diagnosis.

Embolism.—Fungating endocarditis is nearly always associated with palpable enlargement of the spleen, and sometimes the organ attains a considerable size (Fig. 270). As stated

Fig. 270. Photograph showing great enlargement of both the spleen and liver in a case of fungating endocarditis (the same patient as in Fig. 236, p. 555, illustrating purpura). Note also clubbing of the thumb and fingers, first discernible in the left hand. The diagnosis was verified at autopsy.

above, ordinary heart-disease with failure of compensation does not give rise to splenic enlargement that can be recognized clinically, except perhaps in children, notwithstanding the fact that one might have expected the backward pressure to cause the spleen to be big by being dilated with blood. Except in children, enlargement of the spleen in a heart case should always arouse serious suspicion of infective endocarditis. The enlargement may be due to embolism and infarction, in which case there may have been a history of acute pain low down on the left side of the chest, accompanied by a definite rub due to perisplenitis over the infarct. The splenic enlargement in some cases, however, is due less to actual infarction than to the general toxæmia; even when there has been an infarct it is not always easy to be sure of it. Fungating endocarditis sometimes develops without there being any bruit at all; the diagnosis is then exceedingly difficult unless the patient suffers from multiple emboli cerebral, renal, intestinal, splenic, peripheral. Sometimes such an embolus may be followed by the development of an acute aneurysm—femoral, popliteal, cerebral and so forth. A cerebral embolism of this kind has sometimes resulted in sudden transient coma and hemiplegia; the patient has seemed to be recovering;

then in a day or two has relapsed into coma again, and died, the cause of the relapse and fatal ending being the development of an acute cerebral aneurysm at the site of the embolus, rupture of this aneurysm, and death from the resultant hæmorrhage. Progressive anæmia of the chlorotic type, without much leucocytosis, is another feature of these cases. The diagnosis must always be difficult when there is no cardiac bruit; when there is a bruit, the difficulty is to determine whether the patient is suffering merely from mechanical heart-failure, or from fungating endocarditis superposed upon the chronic heart lesions (p. 34).

Thrombotic infarction may cause acute splenic enlargement in almost any of the blood diseases, particularly in lymphadenoma and leucæmia.

Neither *Injury* nor *Strangulation of the spleen by its becoming twisted upon its own hilum* is a very common event, and the latter is nearly always the result of injury. A blow in the splenic region may cause a rupture in the pulp of the spleen without bursting its capsule, and without obviously injuring the chest wall or abdomen. The bleeding that occurs within the capsule of the spleen itself causes great pain in the part and enlargement of the organ: the diagnosis can seldom be more than guessed at unless laparotomy is performed. Strangulation of the spleen seldom occurs if the organ is in its natural position: but when there has been previous dislocation, an abdominal injury, or sometimes a sudden spontaneous effort, has led to its becoming twisted on its own hilum, the symptoms being such as to suggest an acute intra-abdominal condition requiring immediate laparotomy, but seldom pointing to the actual diagnosis until the laparotomy has been performed.

Herbert French.

SPONGY GUMS.—(See BLEEDING GUMS, p. 72.)

SPUTA vary enormously as to their amount, consistence, colour, and so forth: but by far the most important point about them in diagnosis is the determination of whether they contain tubercle bacilli or not. There is no particular variety of sputum which can be said to be characteristic of pulmonary tuberculosis, although stress is generally laid upon the fact that phthisis with cavitation produces a nummular sputum—that is to say, sputum of which the individual portions expectorated tend, not to coalesce but to flatten out as separate round portions, if they are spat out on a flat, dry surface: if expectorated into antiseptic fluid, they remain as more or less globular, separate masses. As a matter of fact, however, ordinary bronchitis may produce sputum possessing a typical appearance of nummularity, and it is most unwise to rely on the naked-eye appearances of sputum for any diagnosis except that of lobar pneumonia, when it may be typically viscid and rusty. It is in almost all cases essential to make films of the sputum, and to stain these for tubercle bacilli by the Ziehl-Neelsen method with carbol-fuchsin.

The carbol-fuchsin solution is made up of 1 gm. of fuchsin, 10 c.c. of absolute alcohol, and 100 c.c. of 5 per cent solution of carbolic acid in distilled water. The slide is covered by the stain in a suitable receiver, and held over a small Bunsen burner or spirit flame until the fluid steams briskly but does not actually boil. After immersion in this for five minutes at least, and it does not much matter if for longer, the excess of stain is poured off, the film washed in water, the excess of the latter drained off, and the slide immersed in 25 per cent sulphuric acid for about half a minute: it is then transferred to water again, and recovers more or less of the red tint of the fuchsin: if too little of this has been discharged, the slide is returned to the sulphuric acid for another period, and so on: when well decolorized, only the thickest parts of the film retain obvious red: it is then counter-stained by five minutes' immersion in carbol-methylene blue, the excess of this stain being washed off with water, the film dried in the air, and either mounted in Canada balsam or else examined directly through cedar-wood oil: the tubercle bacilli (*Plate XVI. Fig. K*, p. 614) show up as bright-red rods in a blue field under the oil-immersion lens.

The presence of acid-fast bacilli in an ordinary sputum film is very nearly proof positive of tuberculosis of the lung, the only source of fallacy being the possibility of non-pathogenic acid-fast bacilli being derived from the mouth. It is very unlikely that this source of fallacy will persist from day to day, especially if care be taken to make the films from the interior of the sputum pellets. It should be remembered, of course, that the absence of tubercle bacilli, or rather their non-detection, is no proof of the absence of pulmonary phthisis, and if there is doubt, successive sputa should be tested in the same way. It should also be remembered that a lesion which may have been tuberculous originally, may in time lose its tuberculous character, the tubercle bacilli may die out, though the cavities produced by them still persist and become occupied by pyogenic organisms and their products. Many of the symptoms of phthisis itself are not due to tubercle bacilli directly, but rather to secondary infection by streptococci, staphylococci, pneumococci, micrococci catarrhales, and so forth: and the degree of this secondary infection may be gauged from the films at the same time as one looks for tubercle bacilli.

It is also important to realize that a person may expectorate sputum containing tubercle bacilli in abundance every day for months, and yet may have precisely as much lung tissue left by the end of that time as at the beginning: this is due to the fact that when cavities have been produced they are lined by granulation tissue, and it is possible for the discharge from the surface of these granulations to produce a continuous supply of sputum without the erosion of the lung tissue progressing. One sees a precisely similar state of

affairs in cases of some skin ulcers, which may discharge abundantly and yet remain much the same size for months. The best evidence of lung destruction is afforded by the discovery of elastic fibres (*Fig. 271*) in the sputum; if these are present there must be something which is eroding the lung tissue, and if tubercle bacilli are present at the same time, the two together indicate advancing phthisis. The elastic fibres may be obvious when ordinary sputum is examined fresh after it has been pressed out between cover-slip and slide, but oftener they are more easily detected when a quantity of sputum has been boiled with strong caustic soda to destroy pus cells, mucus, and so forth, leaving the very resistant elastic fibres unaffected. Tubercle bacilli are also very resistant to the effect of strong alkali, and when they are suspected to be present but cannot be found without in some way concentrating them, it is a useful plan to boil the sputum with an equal amount of 5 per cent caustic potash, or with antiformin, to dilute the result with water, to centrifugalize it well, and make films from the deposit. There are various other methods of obtaining concentrated bacilli from the sputum, but this is one of the simplest. It should be borne in mind that tubercle bacilli may be found even when the sputum is exceedingly small in amount and apparently insignificant and mucoid.

Fig. 271.—Elastic fibres from sputum. The lower figure is less magnified than the upper, and shows alveolar arrangement of the fibres. (From French's *Medical Laboratory Methods*.)

For sputa containing blood, see HEMOPTYSIS (p. 285).

Viscid, Rusty Sputum is almost pathognomonic of pneumonia. As a rule the diagnosis of lobar pneumonia is fairly clear owing to the sudden onset of an acute pulmonary complaint associated with fine crepitations confined to one or more lobes, followed by dullness, with bronchial breathing, bronchophony, and pectoriloquy without râles; these being succeeded by *redux* crepitations, with a diminution in the bronchophony, pectoriloquy, and bronchial breathing until normal voice and breath sounds are restored. Herpes labialis is common. The patient's temperature, after maintaining a high level such as 103° F. or 104° F. for from five to ten or more days—usually about seven—falls by crisis (*Fig. 272*). The respiration rate is very rapid—for example, 40 per minute—during the height of the fever, and the skin is flushed dry, pungent before the crisis, moist from profuse perspiration after it. The diagnosis is much more difficult in

Fig. 272.—Temperature chart of an ordinary case of lobar pneumonia, showing a crisis on the seventh day of the illness, and a slight post-crisis rise on the following day.

some cases, however; there are not a few patients in whom the consolidation is deep-seated, so that it does not come to the surface at all, and lobar pneumonia has to be diagnosed when there are no abnormal physical signs to be detected in either side of the chest. In such cases the general symptoms may suggest the diagnosis, and the sticky, viscid sputum, the colour of which is generally that of iron rust—but which may be any of the colours that a bruise may have, from bright-red or brown to greenish-brown, greenish,

yellowish, or even bluish-yellow confirms it even when the lung signs remain normal. The viscosity of the sputum in these cases is of as much importance as the colour. Films of it usually contain numbers of pneumococci (*Plate XXI/III, Fig. O* p. 614); in exceptional instances pneumo-bacilli. When lobar pneumonia is due to the influenza bacillus, the sputum has not the viscid, rusty character as a rule, but is more like that of ordinary mucopurulent bronchitis. The presence of large numbers of pneumococci, however, or of any other micro-organism than the tubercle bacillus, is by itself no proof that these are the cause of the lung lesion, for even in the sputum of perfectly normal persons pneumococci and other bacteria are frequently abundant. It is quite possible for a patient who is dying of general miliary tuberculosis of the lung to have no tubercle bacilli in the sputum, but an abundance of capsulated pneumococci which may readily, when they are discovered, lead to an erroneous diagnosis.

Influenza bacilli are exceedingly small; but it is important that they should be looked for, both directly and by cultural methods, in all cases thought to be influenzal, before this diagnosis is regarded as established; even when influenza bacilli are found there is still the possibility that they may be an intercurrent infection in some other malady; but it is so tempting to think of influenza when no other obvious cause for a febrile illness can be discovered, that it should not be diagnosed until influenza bacilli have been shown to be present.

Abundance of Foul Sputum, especially when expectorated much at a time at comparatively long intervals, is sometimes by itself a striking symptom, and it suggests that the patient is suffering from one or other of the following:

Bronchiectasis Phthisis with cavitation Fetid bronchitis	}	An empyema ruptured into the lung Gangrene of the lung.
--	---	--

It is sometimes very easy to distinguish between these: with *fibroid lung and bronchiectasis* the patient is likely to have had symptoms periodically for a long while; there will generally be CLARKE'S FIGURES (p. 111); the abnormal physical signs are confined to one lung as a rule, and especially to the lower lobe, with displacement of the heart towards that side; there will be deficiency of movement, resonance, and vesicular murmur in the affected lower lobe, together with either absence of voice sounds and of râles, or scattered foci of crackling râles, especially when the patient coughs, with bronchophony, pectoriloquy, and bronchial breathing. If, on the other hand, the abundant and foul sputum is associated with abnormal physical signs in both lungs, and if the upper lobes are obviously more affected than the lower, if the patient has a strong tuberculous family history, and if tubercle bacilli are either now present in the sputum, or are known to have been present formerly, the diagnosis of *chronic phthisis with extensive cavitation and secondary infection* of the cavities with pyogenic organisms is obvious.

Fetid bronchitis is always a dangerous diagnosis to make, and the probability is that many cases so diagnosed have been examples either of deep-seated bronchiectasis, of phthisis with cavitation and secondary pyococcal infection, or of *empyema ruptured into the lung*. The latter is generally associated with hardly any abnormal physical signs, because if the original empyema had given rise to the ordinary signs it would have been diagnosed and relieved by operation: an empyema may develop either between the lobes, or between the pericardium and the lung, or between the diaphragm and the lung, in such a way as to leave normal lung tissue all round the surface next the chest wall, so that the usual evidence of pus in the chest is entirely wanting. Even if abnormal physical signs are produced when the pus is kept in an abnormal position in this way, the needle may have to pass through so much tissue before the empyema cavity is entered, that the pus cannot be located; in either of these cases the empyema will, in the course of time, tend to ulcerate its way through the pleura and lead to the expectoration of large quantities of foul sputum at intervals as the empyema cavity re-fills. The diagnosis depends largely upon the exclusion of other causes of abundant foul expectoration, and perhaps upon the history of a preceding illness predisposing to empyema, for example lobar pneumonia.

Gangrene of the lung may be simulated to some extent by bronchiectasis or by empyema rupturing into the lung: but generally speaking nothing but gangrene will produce so much stench. Foul though the sputum in bad bronchiectasis may become,

it seldom approaches the awful fetor of pulmonary gangrene. The history, moreover, is acute; there may be some obvious cause for gangrene, particularly lobar pneumonia in a patient debilitated from some other cause, such as diabetes, or inhalation of foul particles after immersion in a dirty river, or as the result of disease of the mouth, throat, or oesophagus, or septic embolism of the lung from lateral sinus thrombosis. If any doubt remains as to whether lung tissue is being destroyed or not, elastic fibres can be sought for, their presence at once distinguishing between bronchiectasis or deep-seated empyema on the one hand and gangrene on the other.

When a large quantity of pus is expectorated through the lung in a person who, having been in the tropics and having possibly suffered from dysentery, has since had symptoms pointing to hepatic trouble, the possibility that an amebic abscess of the liver may have opened its way through the diaphragm into the lung will immediately occur to one, especially if the expectorated pus is tinged the colour of anchovy sauce. It might be thought that the *Amaba coli* would be found in it; but this is not the case, for this protozoon is not present in the pus of a hepatic abscess as a rule, but only in the granulations of the abscess wall. The sputum in these cases is not generally foul.

The other abnormal features that may be exhibited by sputum are relatively uncommon, and are of diagnostic significance only in exceptional cases. The serous, mucoid, muco-purulent, or purulent sputum of the various stages of acute and chronic *bronchitis* may arouse a doubt as to whether the patient has not a tuberculous focus; repeated examination will fail to reveal either tubercle bacilli or elastic fibres, but it is to be remembered that a considerable minority of phthisical subjects seem not to expectorate the bacilli. *Black sputum* is common in those who live in smoky atmospheres, particularly in towns, colliery districts, and manufacturing centres. Other changes in colour may be due to hæmoptysis, pneumonia, or hepatic abscess, which are all discussed above; sometimes infection by the *Bacillus pyocyaneus* may produce greenish or bluish sputa which may alarm the patient, but which need not have any serious import, and red sputum simulating the hæmoptysis of phthisis may be due to infection by pigment-producing bacilli such as the *Bacillus prodigiosus*; phthisis may be diagnosed wrongly in such a case unless the most careful investigations of the sputa are made by cultural methods.

Cursemann's spirals (p. 153) and *Charcot-Leyden crystals* (p. 102) have been discussed elsewhere.

Casts of the bronchial tubes are met with in very exceptional cases, and they are of two main types—namely, diphtheritic, and non-diphtheritic. The distinction depends on bacteriological examination; histologically they consist of ill-defined exudate containing cells irregularly embedded in it. Non-diphtheritic casts are due to plastic or fibrinous bronchitis, a very rare disease of which the sputum is the diagnostic point. Two other rare causes for the expectoration of casts of the bronchi are lobar pneumonia, and the inhalation of blood from some other part of the lung in a case of hæmoptysis, and its subsequent expectoration after it has clotted.

Now and again a cretaceous pellet (*Fig. 273*) or a small caseous mass may be found in the sputum of a patient who either has pulmonary phthisis, as evidenced by the abnormal apical physical signs, and by the detection of elastic fibres as well as tubercle bacilli in the sputum, or in children as the result of the ulceration of a caseous bronchial gland into the trachea or a main bronchus, and then expectoration of its caseous or cretaceous contents.

Another rarity which has occasionally been found in the sputum is a recognizable particle of new growth, the detection of which may be of material assistance in diagnosis.

Chemical analyses are relied on by some observers in distinguishing tuberculous from non-tuberculous sputum, it being stated that expectoration containing coagulable proteid is more likely to be the result of tuberculous infection than is sputum which does not coagulate with heat. This distinction, however, is not universally accepted, and microscopical examination for tubercle bacilli is certainly a more reliable test in the great majority of cases.

Fig. 273.—Caseous concretions from phthisical sputum.

The rarer bacteria and moulds that may be detected in the sputum by special bacteriological methods generally require very special investigation, including cultural tests by skilled bacteriologists: one need not, therefore, enter into details here, though it may be well to enumerate certain micro-organisms which may be pathogenic in the lung in comparatively rare instances - *B. mallei*, generally amongst workers in stables or otherwise in connection with horses; *Aspergillus flavus*, *A. niger*, *A. fumigatus*, generally amongst those who have to do with the artificial feeding of pigeons and other birds; *Actinomyces* or the ray fungus, in those who have had to do with barley in some way or another, or, as has recently been demonstrated, in those who are in the habit of holding cotton in their mouths, such as tailors and seamstresses. Besides these pathogenic micro-organisms, not a few others which are not actually pathogenic are to be recognized in the sputum when it has become secondarily infected in chronic cases. *Penicillium glaucum*, for instance, or *Oidium albicans*; yeast and other moulds; *Micrococcus tetragenus*; or *Oidium tropicale*, a micro-organism similar to but culturally different from *Oidium albicans*, which has recently been reported to be a cause of lung lesions both in Europeans and natives in Ceylon, the symptoms suggesting phthisis, but the latter being excluded by the persistent absence of tubercle bacilli from the sputum and by the absence of reaction to tuberculin.

Whooping-cough is sometimes difficult to distinguish from other colds and from bronchitis, and if the recent statements to the effect that it is due to the minute Bordet-Gengou bacillus prove true, bacteriological examination of the sputum may be of use in diagnosing this condition in doubtful cases: the patient's blood-serum may also give a positive clumping reaction with cultures of this organism.

The lung fluke, *Paragonimus Westerni*, which causes hæmoptysis in Korea, Japan, and parts of China, is to be diagnosed by the discovery of its oval, capsulated eggs in the sputum.

Herbert French.

SQUINT. (See STRABISMUS, p. 649; and DIPLOPIA, p. 174.)

STAMMERING. (See SPEECH, ABNORMALITIES OF, p. 623.)

STERILITY. The differential diagnosis of the causes of sterility is often difficult, and although there are many well-defined conditions which give rise to it, there are numbers of cases in which no definite cause can be found. Further, we must not overlook the fact that the husband is responsible for a sterile marriage in one-fourth to one-third of the cases. This is a fact shown by many observers, and too often forgotten when investigating cases. Therefore, we must not consider a case to be complete unless the husband *and his semen* have been investigated. Many a woman has her married life made miserable, and is taken from doctor to doctor on account of sterility, when the husband really is to blame.

The causes of sterility are shown in the table on the next page. From a study of it, it is clear that some of the causes of sterility are primary, whilst others are secondary. Thus absence of the uterus or infantile uterus means primary sterility, whilst hyperinvolution, carcinoma of the cervix, etc., may occur in women who have had children, and only secondarily become sterile on account of these lesions. Further, some of these causes are common, or may be remedied; others, on the other hand, are rare or absolutely incurable. Diagnosis is therefore of great importance, for it is far better to discover and remedy a defect early in married life, than to wait until the best years are soured and embittered by the longing for a child. Unfortunately, many patients, from various motives, put off the investigation too long.

Congenital lesions. Some of the congenital lesions are diagnosed easily, such as *closure of the hymen*, *absence of the vagina*, or *closure of the cervix*, whilst absence of the essential organs often requires an anæsthetic in order that a binannual examination may be made satisfactorily. The *infantile uterus* and *small adult type* are very difficult to differentiate; but in the former the body forms only one-third of the total length of the organ, whilst in the latter it forms two-thirds, both types of uterus being small in the antero-posterior and lateral dimensions, and only slightly shortened in the vertical. Of all the congenital lesions, the '*cochleate*' uterus of Pozzi is the commonest cause of sterility, and is the most hopeful as regards treatment. The uterus is felt to be unusually curved anteriorly, has a long conical cervix, and a small external os. In such an externally unformed

uterus as this it is possible that the internal structure is abnormal: the endometrium, perhaps, is unduly thin and fibrous, the muscle layers badly developed. The hypothetical *change in the endometrium* may be the essential cause of sterility: hence curettage for its complete removal forms an essential part of the treatment. The peculiar shape and curvature have long been considered a possible cause, preventing the entrance of spermatozoa into the cavity. *Pseudo-hermaphroditism* usually shows itself by shortness of the vagina, elongation of the clitoris, and the presence of glandular masses in the groins, which are almost always testes, proving that the subjects of it are really undeveloped males.

LESIONS OF THE GENERATIVE ORGANS.

GENERAL CONDITIONS.

Congenital Lesions—
Absence of uterus, tubes,
ovaries
Closure of hymen, vagina,
cervix
Pseudo-hermaphroditism
Infantile uterus
Small adult type of uterus
'Cochleate' uterus
Displacements
Hypothetical changes in the
endometrium.

Acquired Lesions—
Dysparemia
Vaginismus
Salpingo-oöphoritis
Uterine fibroids
Endometritis
Cervical catarrh
Polypi
Carcinoma of cervix
Carcinoma of fundus
Ovarian tumours
Acquired atresia of vagina
" " cervix
Genital fistule
Hyperinvolution
Astringent douches
Deficient ovarian activity.

In the male.

Azoospermia
Oligospermia
Necrospermia.

Old age
Obesity
Anæmia
Nutritional disturbances
Incompatibility
Absence of sexual feeling.

Acquired Lesions. The differential diagnosis of the acquired lesions can only be made by complete examination of the patient by inspection, bimanual examination, and the use of the microscope to elucidate doubtful growths. *Dysparemia* as a cause is dealt with in the article under this head (p. 193). *Hyperinvolution* is diagnosed easily: it occurs always after a labour, and strictly means a continuance and progressive increase of the normal lactation atrophy of the uterus: the latter is felt to be very small bimanually, and the sound may pass only $1\frac{1}{2}$ inches in a marked case: it is always associated with incurable amenorrhœa.

Deficient ovarian activity, whereby the Graafian follicles do not ripen or rupture, is not to be diagnosed by any of the ordinary methods we can employ, and it is doubtful whether a microscopic examination of the ovaries themselves would reveal the true condition. It is supposed to be associated with scanty menstruation or amenorrhœa for which no other definite cause can be found. Absence of ovarian activity must be the true cause in the general conditions which are outwardly shown by *obesity, anæmia, and disturbances of nutrition*: and it is a fact that some women have not conceived as long as they remain too fat, whilst loss of weight has in some cases been followed by conception. *Incompatibility* between husband and wife sexually is an ill-defined condition, which, however, is fully believed to be a cause of sterility. It is almost incapable of proof, for in the case of a sterile widow who remarries and conceives for the first time we have no proof that the former husband was capable of procreation. *Absence of sexual feeling* or the sexual orgasm, too, is not always a cause of sterility, for conception has occurred in women who are absolutely devoid of these feelings. On the other hand, most authors quote the case of a woman who conceived as a result of the only coitus at which an orgasm was experienced. The influence of *age* on child-bearing must not be forgotten, the liability to conceive falling rapidly every year over thirty.

Sterility of the Male. Finally, the examination of the husband and his seminal fluid should never be omitted unless there is some quite well-defined cause to be found in the wife. Assuming that the penis and testes are present, and that erections render the

sexual act possible, the seminal fluid must be examined carefully. The fluid should be collected in a condom by means of a normal coitus, and should be examined within twelve hours. It must be spread on a slide and examined with a high power of the microscope. There may be no spermatozoa present at all, the condition known as *azospermia*, in which case the husband is incapable of procreation. There may be but few spermatozoa, and those exhibiting only feeble powers of movement: *oligospermia*. There may be plenty of spermatozoa present, but quite devoid of motility: *acrospermia*. It is unnecessary in this article to enter into the causes of these conditions. They are usually incurable, and consequently further investigation is unnecessary. *Thos. G. Stevens.*

STERTOR is really another word for snoring: but it is commonly restricted to the heavy, snoring sound accompanying inspiration, produced not in the nose but by vibrations of the soft palate, generally when the patient is in a state of profound unconsciousness. It differs from stridor in that the latter is produced in the larynx. If, as is generally the case, the patient is comatose, the presence or absence of stertor helps little in the diagnosis, which is discussed under the heading COMA (p. 117). Sometimes, however, without being comatose, the patient may have stertor during sleep, when he is suffering from the effects of drink or from any of the following:—

Adenoids Hypertrophied tonsils Quinsy	Paralysis of the soft palate Post-pharyngeal abscess.
---	--

The stertor in these cases is closely akin to snoring. The differential diagnosis generally becomes manifest when the interior of the mouth and the pharynx are examined. Possibly the condition most likely to be overlooked is post-pharyngeal abscess, but this should not be mistaken for anything else if a digital examination of the back of the mouth is made: moreover, except when due to tuberculous caries of the cervical vertebrae, it is commonest in infants and quite small children, becoming rarer with each year of life. *Herbert French.*

STIFF NECK. This occurs in a number of diseases entirely different in character, and its significance may be either grave or trivial. It is rarely that stiffness is the only symptom, but it may be the first thing complained of, or it may be a complication arising in the course of a disease. It is not right to assume that the trouble is trivial, or vaguely to designate it as 'rheumatic,' without a thorough investigation. It is necessary first to inquire into the history, when it may become obvious that it follows, say, an injury, or has arisen during the course of some disease, and is not primary. Next examine the patient with the head and shoulders bared, and see whether there is any swelling or abnormality present, also the extent of possible movement, and whether or not it is the movement that causes pain: if possible, locate the seat of the pain. Many further investigations may be necessary, e.g., examination of the throat for tonsillitis, the ear for suppurative otitis media, etc., according to the circumstances of the case.

Exposure to Cold or Sleeping in a Cramped Position may give rise to a transient stiff neck associated with no other symptoms. There is generally a distinct history of the patient waking up in the morning with a stiff neck, and the diagnosis is made by exclusion.

Inflammation of the Lymphatic Glands and the cellular tissues of the neck may cause local stiffness, whether the infecting focus be a boil or carbuncle, or a carious tooth, an inflamed tonsil, pediculosis capitis, or other similar cause. There is no spasm or rigidity of the muscles here, the neck can be moved quite well: but it hurts to do so, and therefore it is held stiffly. The diagnosis is easy as a rule.

Torticollis or *Wry-neck* is due to contraction of the sternomastoid muscle on one side, usually the result of an injury to the muscle caused by pulling on the aftercoming head in breech presentations. The muscle stands out as a tight band in the neck, and its contraction leads to a characteristic deformity. The head is pulled down towards the affected side, and the face and chin are tilted towards the opposite shoulder. The movements of the head are necessarily restricted owing to the shortening of the one muscle, and in long-standing cases this leads to a marked asymmetry of the face. The consequences are not limited to the head and neck, for the spine shares in the general obliquity, and shows marked lateral curvature in old cases.

Spasmodic Torticollis is an unusual form due to spasms of the sternomastoid and other muscles of the neck. The spasms are intermittent, coming on suddenly with great pain, the affected muscles relaxing after a variable time.

Cervical Caries.—The greatest care must be taken not to confound muscular rigidity with tuberculous disease of the cervical vertebræ. In the latter, pain and rigidity are among the earliest signs; the pain is increased by the least movement, and the child—for it is generally a child that is affected—takes the greatest precaution to avoid any movement, even holding the head between the two hands. The position of the head varies: it is most often held very stiff and straight, the natural backward curve of the neck being lost. In the late stages there may be an angular or lateral curve. The distaste for movement is very well brought out when the patient is asked to look round—the eyes only are moved, or the whole body is rotated. Bearing the possibility of this condition in mind, there is not much difficulty in diagnosis, but in doubtful cases a skiagram should be taken.

New Growth in one of the cervical vertebræ may cause progressive stiff neck, and generally much local pain on movement; the diagnosis may suggest itself when the patient is known to have had a new growth elsewhere, especially a carcinoma of the breast or of the thyroid gland: cases of primary new growth of the vertebræ are fortunately rare, but myeloid sarcoma does occur: it can generally be diagnosed only after the patient has been observed for a long time. The symptoms simulate those of caries.

Infective Arthritis of the Cervical Vertebræ.—Following infective diseases such as scarlet fever, diphtheria, and tonsillitis, especially in children, there may ensue a very chronic form of suppurative arthritis affecting one or several of the cervical vertebræ, and going on sometimes to complete bony ankylosis. Similar stiffness of the back of the neck, especially its lower part, with pain on movement, is apt to occur in sufferers from rheumatoid arthritis (p. 341): it is due to infective peri-arthritis of the vertebral joints, secondary to toxic absorption from such sources of chronic infection as pyorrhæa alveolaris.

Spondylitis Deformans causes fixation of the neck (Fig. 274), though the movements of nodding 'yes' and 'no' remain: the nature of the case is at once indicated, however, by the fixation of the other regions of the spinal column also.

Injuries to the Neck. A stiff neck may arise from some slight injury, such as a blow or a sudden twist. This will be clear from the history. Severe injuries involving fracture or dislocation are almost always fatal: if not immediately, then in a few days. A rare injury that may not be fatal is unilateral dislocation of one of the cervical vertebræ. This may result from a fall on to the head. From the start there are great pain and stiffness in the neck, the head being fixed immovably and turned to the opposite side to that of the displacement.

Burns.—A self-evident cause of stiffness is the cicatricial contraction following a burn on the neck.

Fig. 274.—Spondylitis deformans. The patient was unable to raise the head, though he could just nod and shake it slightly. Except for the atlas and axis, the whole vertebral column was fixed. There was no affection of other joints in the body, and the general health was good.

Stiffness and retraction of the head are important indications of *meningitis*, but they are by no means constant : when present they are generally accompanied by other well-marked signs of meningitis.

Stiffness of the neck is one of the earliest signs of *tetanus* ; it is rarely the only one, however. The trouble soon spreads to the jaw, causing trismus and other characteristic symptoms (p. 730). *Gen. E. Gask.*

STOMACH, DILATATION OF. (See DILATATION OF THE STOMACH, p. 173.)

STRABISMUS Squints may be classified, according to their *direction*, into convergent, divergent, or attitudinal ; according to their *cause*, into paralytic and non-paralytic (concomitant). The diagnosis between paralytic and non-paralytic strabismus is, as a rule, easy. In a paralytic strabismus the convergence or divergence of the two eyes is not constant in amount in all directions, as the farther the eyes are moved over in the direction of the action of the paralyzed muscle the greater will be the deviation from parallelism. In a concomitant squint the eyes always bear the same relative position to each other in whatever direction they are turned.

The diagnosis of the cause of a paralytic strabismus, which is associated with *DIPLOPIA*, is discussed under that heading (p. 174). The causes of concomitant strabismus are usually — *Error of refraction ; Failure of binocular vision ; Defective vision in one eye ;* or the association of one or more of these conditions. The cause cannot be determined accurately without a careful examination of the ocular refraction under a mydriatic. In general terms it may be stated that convergent squints are, as a rule, due to hypermetropia, and divergent squints to myopia. *Herbert L. Eason.*

STRANGURY differs somewhat from mere pain on micturition, in that, in addition to severe pain before, during, or after the act, the patient is troubled constantly by urgent and repeated necessity to discharge his urine, sometimes as often as every few minutes, yet without any satisfactory relief to his discomfort. The condition is also spoken of as vesical tenesmus. Very little urine is passed each time ; sometimes the desire and the necessity are urgent when there is no urine in the bladder at all. The causes resolve themselves into five groups, as follows : —

1. **Nervous Conditions, especially :**

Hysteria	Irritable bladder	Tubes dorsalis
Neurasthenia		(vesical crises).

2. **Obstruction to the Urine Outflow, leading to Retention with Overflow :** —

Urethral stricture Enlarged prostate Carcinoma of the prostate Retroverted gravid uterus Uterine fibroid Ovarian cyst Ovarian carcinoma) Impacted in the pelvis	Extreme prolapse of the uterus and bladder Calculus impacted in the urethra Inflamed urethral caruncle Gonorrhoea Urethritis other than gonococcal Periprostatic abscess Periproctal abscess.
---	--------------------------------	---

3. **Local Affections of the Bladder Wall :**

Injury	Tuberculous cystitis	Infiltration by —
Acute cystitis	Papilloma vesicæ	Carcinoma of the uterus
Chronic cystitis	Carcinoma vesicæ	Carcinoma of the rectum.

4. **Reflex Conditions :**

Inflamed hemorrhoids Injury to the back Tuberculous kidney, before the bladder is involved) Acute myelitis Cili bacilluria	Without infection of the bladder wall.
--	--	--

5. **The effects of certain Drugs, especially : —**

Cantharides	Crotonine	Cystopurin
Oxalic acid	Helmitol	Hexamethylenetetramine.
Turpentine		

Most of the conditions mentioned above, and the methods of distinguishing between them, are discussed in the article on MICTURITION, ABNORMALITIES OF (p. 393). Irritable bladder is discussed under the heading of OXALURIA (p. 423). Two points of importance

deserve stress, however, and chief amongst these are the vesical crises of *tabes dorsalis*. The patient's sole complaint may be that he can never be far from a lavatory because of acute and painful calls to empty his bladder at frequent intervals; sometimes he has no sooner passed what is in his bladder than he has to run back and again do it, though there is no urine whatever to pass; and his vesical pains may be extreme. From loss of sleep his general health suffers, and he becomes anæmic and wasted to such an extent that carcinoma of the bladder or genito-urinary tuberculosis are simulated closely, and in some cases acute cystitis is diagnosed erroneously upon the symptoms alone. The true diagnosis will be suggested when it is discovered that the knee-jerks are absent and the pupils give the Argyll Robertson reaction; in some cases, however, the nature of the malady may be difficult to decide for a time, because crises of all kinds, like the lightning pains, are apt to develop in the earlier stages of tabes, when the knee-jerks are not yet absent. Both jerks should be tested, for there are a good many cases in which one knee-jerk is still present when the other has disappeared. A thorough examination of the urine and bladder should be carried out even if the patient is known to have tabes dorsalis, for he may have a gross lesion of the bladder in addition to his nerve disease; but this is unusual. The actual cystitis resulting from retention of urine with overflow is generally a late symptom, and not a relatively early one like the vesical crises, which are quite distinct phenomena. As time goes on the bladder crises may cease spontaneously just as the lightning pains, the rectal crises, and the other painful phenomena of tabes are apt to do.

The other point that merits attention is the strangury that certain drugs produce. *Cantharides* is familiar in this respect, but more from its prominence in text-books upon forensic medicine than from its occurrence in actual practice. The same applies to *oxalic acid* and to *turpentine*. It is less recognized that certain drugs in common use may be responsible for very similar symptoms, in which respect *urotropicine*, *helmitol*, *cystopurin*, and *hexamethylenetetramine* are important. These are all employed in the treatment of pyuria, as well as for gall-stones and other conditions. If given for pyuria, when there may have been frequent and painful micturition already, before any treatment is begun, the increased frequency and pain that sometimes ensue when any of the above drugs are administered are very apt to be attributed to an increase in the cystitis or other genito-urinary lesion, and the dose of the drug is increased instead of diminished. It may be only after the patient deliberately ceases to take the medicine that the fact of the increase in the symptom being due to the drug becomes obvious; some cases develop strangury every time they take urotropicine, and lose the symptoms a day or two after they have stopped the medicine. In some instances transient hæmaturia accompanies the strangury, and the danger always is lest these symptoms be attributed to the disease and not to the drug. Speaking generally, it is in cases in which the urine is concentrated, or at least in small amount, that urotropicine and its allies are most liable to cause strangury and hæmaturia. If the patient drinks excess of water, so as to dilute his urine, these symptoms often disappear. Sometimes the patient can take helmitol with ease when he cannot bear urotropicine, and vice versa. The important point is that urotropicine and other drugs of like nature may be responsible for such strangury as may simulate local disease of the bladder, and unless this is borne in mind an erroneous diagnosis is liable to be made. *Herbert French.*

STRIDOR is a term used to denote a harsh, vibrating noise produced as the air passes in or out of a partially obstructed larynx or trachea. It may be due to many different causes, which may be classified as follows:—

1. Partial Obstruction Inside the Larynx or Trachea:—

Mucus or muco-pus Foreign body		Caseous gland bulging or rupturing into the trachea.
-----------------------------------	--	---

2. Affections of the Wall of the Larynx or Trachea:

Diphtheria	Secondary infection in cases of tuberculous, syphilitic, malignant, traumatic, or post- typhoidal ulceration
Acute œdema due to— Bright's disease Potassium iodide	Stenosis after tracheotomy or cut throat
Irritant vapours such as ammonia or chlorine	Epithelioma of a vocal cord Fibroma of the vocal cords
Acute laryngitis streptococcal, pneu- mococcal, staphylococcal	Epithelioma of the trachea Syphilitic stenosis.

3. **Swellings Outside Compressing the Larynx or Trachea :** —

Enlargement of the thyroid gland	Epithelioma of the œsophagus invading the trachea
Enlargement of the thymus gland	Malignant glands in the neck
Thoracic aneurysm	Cellulitis of the neck
Mediastinal new growth	Erysipelas of the throat
Post-pharyngeal abscess	Angina Ludovici.

4. **Bilateral Abductor Paralysis of the Vocal Cords**, generally due to syphilitic degeneration of the vagal-nuclear nerve cells.

5. **Unilateral Vocal Cord Paralysis** in a few cases ; generally if one cord remains normal there is no stridor. The diagnosis of the causes is given on p. 491.

Distinction is sometimes drawn between inspiratory and expiratory stridor, and stridor which is both inspiratory and expiratory ; but in practice such a distinction is not helpful. The main value of stridor as a symptom is that it indicates stenosis of the main air-passages by one or other of the above causes, except in those rare cases in which it is functional ; *hysterical stridor* ceases during sleep, is nearly always confined to the female sex, as a rule between the ages of fifteen and thirty, and is often associated with other functional nervous symptoms, such as globus hystericus and functional aphonia (p. 494). Stridor should never be diagnosed as functional, however, until every possible organic cause has been excluded. The differential diagnosis of the causes of obstruction to the main air-passages will be found discussed on page 448. Herbert French.

STUPOR. (See COMA, p. 117.)

STUTTERING. (See SPEECH ABNORMALITIES OF, p. 628.)

SUCCUSSION SOUNDS may be heard when a part that contains any considerable bulk of both fluid and gas is shaken whilst the ear or the stethoscope is applied over the part. Sometimes the sounds are so loud that they can be heard at a considerable distance from the patient. A very good example of succussion sound is often afforded by the normal stomach after a quantity of fluid has just been swallowed. It is a mistake to suppose that gastric succussion sounds are evidence of abnormality ; they merely prove that the viscus contains fluid and gas at the same time ; the gas may be due to fermentation, but it is often nothing but air that has been swallowed during drinking. The chief value of gastric succussion sounds is that, according to the position in the abdomen at which they can be heard, they afford some clue as to the position, and perhaps as to the size, of the stomach. They should not be heard lower than the umbilicus ; if they are, the stomach is either displaced downwards, or dilated, or both.

Another variety of succussion sounds may sometimes be heard in the chest, especially in cases of *hydro-pneumothorax* ; when the patient deliberately oscillates his trunk to and fro, and then stops, the fluid and air can be heard making noises like those produced when a partly-filled barrel is moved about. Sometimes the fluid splashes up on to the collapsed lung and then drips off again into the pool at the bottom of the pleural cavity, each drop echoing in the cavity and producing a metallic clink like a *bruit d'airain* or coin sound. Similar succussion sounds may be produced by a *pyopneumothorax* or a *hæmopneumothorax*, the difference between these being decided, as a rule, by exploratory needling.

Succussion sounds other than those due to the stomach, or to gas and fluid in the pleural cavity, are uncommon, but the following is a list of the chief possible causes :

1. **Causes of Succussion Sounds in the Thorax** —

Hydro-pneumothorax	with the <i>Bacillus coli communis</i> , and containing gas and pus
Pyopneumothorax	Hydro-pneumopericardium
Hæmopneumothorax	Pyopneumopericardium
Diaphragmatic hernia	A huge phthisical cavity beneath a thin chest wall.
Subdiaphragmatic abscess communicating with stomach or duodenum, and so containing air and pus ; or else infected	

2. Causes of Succussion Sounds in the Abdomen:—

The normal stomach
 Dilatation of the stomach
 Enormous dilatation of the cæcum
 Enormous dilatation of the sigmoid colon
 Enormous dilatation of some other part of the colon
 Pneumoperitonæum, due to: (i) Perforated gastric ulcer; (ii) Perforated duodenal ulcer; (iii) Perforated typhoid ulcer of the intestine; (iv) Perforated tuberculous ulcer of the intestine; (v) Perforated malignant ulcer of the colon;

(vi) Production of gas by the *Bacillus coli communis*, either in a local abscess (e.g. appendicular or subdiaphragmatic) or in the general peritonæum
 Subdiaphragmatic abscess communicating with the interior of stomach
 Air and urine in the bladder (see PNEUMATURIA, p. 529)
 Infection of an ovarian cyst or other collection of fluid by a gas-producing micro-organism.

Succussion Sounds in the Chest.—The diagnosis is not as a rule difficult. It is very rare indeed for a *phthisical cavity* to give succussion sounds; but should it do so, the phenomenon would be apical rather than basal, and thus distinguishable from most cases of hydro- or pyo-pneumothorax. It is possible for the latter to be apical, however, if old adhesions prevent the parietal and visceral layers of pleura from separating in the lower part of the chest, and then, if tubercle bacilli were found in the sputum, it would become a matter of opinion as to whether the sounds were produced in the pleural cavity or in a huge *vomica*. *Hydro-* and *pyo-pneumo-pericardium* are very rare, and they are at once distinguished by the extraordinary churning sounds made by the heart beating within the mixture of air and fluid. Survival is improbable. The cause is generally either an epithelioma of the œsophagus opening the pericardium from behind, a foreign body, such as a tooth-plate, ulcerating through from the œsophagus, or the opening of an air-containing subdiaphragmatic abscess through the diaphragm into the pericardium, or infection of the pericardial sac by a gas-producing organism such as the *Bacillus coli communis*.

A *subdiaphragmatic abscess* containing air owing to communication with a hole in a gastric or duodenal ulcer, sometimes pushes the diaphragm up so high that the condition may be mistaken for hydro- or pyo-pneumothorax; it may be possible to distinguish the two by knowing that the trouble began with gastric ulceration; on the other hand, it may be impossible to tell which it is until the position of the diaphragm is ascertained, either by the use of the *x*-rays, or by operation. When the trouble is subdiaphragmatic, the tendency is to displace the heart upwards rather than towards the opposite side of the chest, whereas the contrary is true of pneumothorax.

Diaphragmatic hernia is very rare; it may be congenital, or it may be the result of severe injury to the abdomen and chest. In neither case are the patient's prospects of survival good. The exact diagnosis may not be arrived at without operation or post-mortem examination; if the stomach is herniated into the thorax, however, the effects of eating and drinking upon the physical signs may point to the diagnosis, or the *x*-rays may be used to demonstrate the gastric shadow after the administration of bismuth or barium salts by the mouth.

In most cases of *hydropneumothorax* there is little difficulty as to the diagnosis of the condition itself; it may be less easy to decide what the hydropneumothorax is due to. If the onset has been sudden, with acute pain in the affected side of the chest, cyanosis, and dyspnoea, the commonest cause is *phthisis*. The sputum should be examined for tubercle bacilli. In some instances an injury may have been the immediate cause, but injury will very seldom produce hydropneumothorax unless there was already a tuberculous or other lesion in the lung at the time of the accident. Hydropneumothorax may result temporarily after *paracentesis thoracis*. If there has been bleeding at the same time, *hæmopneumothorax* may be found, and it is common after bullet wounds of the chest. Either a hydro- or a hæmo-pneumothorax may become infected with pyogenic organisms and converted into a *pyopneumothorax*. The diagnosis will be confirmed by needling the chest. Pyopneumothorax is apt to escape detection, however, because it arises when the patient is too ill to be shaken—in cases of gangrene of the lung for instance, resulting perhaps from lobar pneumonia, obstruction of a bronchus by a foreign body or a new growth, or the breaking down of an infective bronchopneumonia or pulmonary infarct. Generally speaking one may say that the existence of well-marked succussion sounds in

the pleural cavity of a patient who has sufficient vigour to shake his own body to and fro indicates hydropneumothorax of phthisical origin.

Succussion Sounds in the Abdomen. The first point in the differential diagnosis of succussion sounds in the abdomen is to decide whether the sounds are *gastric* or not. Generally this is obvious; if there is doubt, the effect of putting more gas or more fluid into the stomach by taking a scidlitz powder in two halves, or by drinking a quantity of water, will usually so change the character and distribution of the sounds if they are gastric, that little doubt will remain; or the *x*-rays and bismuth method of demarcating the stomach may be employed. As has been mentioned, the existence of gastric succussion is no proof of gastrectasis; if, however, the succussion sounds are audible over a larger area than the normal stomach should occupy, they afford valuable evidence of *gastrectasis*, and the next step will be to determine the cause of the latter. Dilatation of the stomach has three main causes, namely, atony, non-malignant pyloric obstruction, especially by a healed simple ulcer, and malignant pyloric obstruction by primary gastric carcinoma.

The presence of visible peristaltic waves, or the occurrence of vomiting, will exclude simple atony, which can never be diagnosed with certainty until it is known that there is no pyloric obstruction. The latter will be indicated by the periodicity of the vomiting; by the abundance of the fluid vomited being greater than the amount taken at the last meal; by the presence in it of particles of food eaten a day or more previously—ham, for instance, vomited on Tuesday when last partaken of on Sunday;—by the visible peristaltic waves corresponding with the stomach; and by the presence of sarcine in the vomit (see *Fig. 121*, p. 241). The most certain method of detecting pyloric stenosis, however, is by means of bismuth or barium and the *x*-rays, especially in those cases, not infrequent, in which vomiting does not take place in spite of great gastrectasis.

There may also be evidence of delay in the absorption of substances that are not dissolved until they reach the pancreatic juice in the duodenum, tested for instance by giving methylene blue in keratin-coated capsules, and observing when the urine first begins to be blue. Keratin is not dissolved by gastric juice, but is by pancreatic; if there is no evidence of pancreatic disease, delay of more than one to two hours in the first sign of blueness of the urine, after giving the capsules, indicates marked delay in their transit from stomach to duodenum.

It is often a matter of extreme difficulty to decide whether pyloric stenosis is simple or malignant, though upon the whole the shorter the history, the older the patient, and the more definite the pyloric thickening or lump the more likely is the lesion to be carcinomatous. The latter may occur in quite young subjects, however, even between 20 and 30; and a long history does not exclude carcinoma, since some cases of simple ulcer ultimately become malignant. Even when laparotomy is performed for the relief of the condition, its nature may not be obvious; sometimes, indeed, post-mortem examination has failed to decide whether the stenosed pylorus was carcinomatous or not, until microscopical examinations have been made. It has been stated that if the gastric juice after a test meal contains a normal amount of HCl, the diagnosis is unlikely to be carcinoma, and vice versa; but even this general rule has many exceptions (p. 270).

The diagnosis of pyloric stenosis due to other causes than adhesions, a healed ulcer, or a carcinoma is seldom possible without a laparotomy; occasionally such out-of-the-way things as a calcified retroperitoneal cyst adherent to the pylorus and thought to have been a carcinoma pylori may be found.

If there are well-marked abdominal succussion sounds that can be shown to be definitely not gastric, there are generally other well-marked signs and symptoms which materially assist the diagnosis.

Succussion sounds in the general peritoneal cavity are excessively rare, for even though this cavity should contain both gas and fluid, for instance after perforation of a typhoid ulcer, the coils of bowel prevent the sounds from being produced readily. The list of causes given above indicates the conditions that may be present. It would clearly be next to impossible to diagnose most of them unless the previous state of the patient was known accurately, or unless exploratory laparotomy were resorted to. It is important to remember that the *Bacillus coli communis* produces gas, so that intra-abdominal abscesses, appendicular and otherwise, are not infrequently resonant. The occurrence, however, of marked non-gastric succussion sounds in the abdomen of a patient who is not acutely

ill will generally arouse a suspicion that there is distention with gas and fluid of some part of the large bowel, especially the caecum or the sigmoid colon. This distention will generally be the result either of chronic constipation (see p. 121) or of some cause of intestinal stenosis.

In some cases that were formerly described as idiopathic dilatation of the colon, but which are now regarded as chronic volvulus of the sigmoid colon, the result of persistent constipation, the sigmoid dilatation may be so extreme that this part of the intestine bulges up as far as the diaphragm (Hirschsprung's disease, see *Fig. 55*, p. 127, and *Fig. 171*, p. 389); the occurrence of succussion sounds in such a dilated colon might readily lead to the erroneous diagnosis of gastrectasis: the pear-shaped outline of the dilated viscus, and the fact that it is known to have come upwards from the pelvis, may indicate the true nature of the case, but sometimes the fact that succussion sounds are colonic and not gastric can only be determined by giving large doses of bismuth by the mouth and then outlining the stomach by the dark shadow cast by the bismuth under the *x*-rays. *Herbert French*,

SUGAR IN THE URINE.—(See GLYCOSURIA, p. 260.)

SUPPRESSION OF URINE.—(See ANURIA, p. 39.)

SWEATING, ABNORMALITIES OF.—The functional disorders of the sweat-glands, *sudamen (miliaria)* and *hidrocystoma*, are dealt with from the diagnostic point of view in the article on VESICLES (p. 753). The other abnormalities require but the briefest notice in a work on diagnosis, for it is hardly possible to confuse them with each other or with any other conditions. In *hyperidrosis* the secretion of sweat is excessive, either over the whole skin or in some particular region, e.g., the palms and soles, and especially covered parts furnished with large sweat-glands, such as the axillæ and genital regions. Occasionally hyperidrosis is limited to the area of distribution of a particular nerve—the fifth, for example. In some cases a peculiar pink tint of the inner side of the palm and the ball of the little finger and thumb has been noticed. In rare instances hyperidrosis in delicate children is associated with *granulosis rubra nasi*, a condition in which the skin of the nose becomes intensely red, and is dotted over with minute deep-red specks and papules, the papules gradually developing into pustules which soon dry up. The cells around the sweat-ducts are infiltrated, and both ducts and coils, and also the blood-vessels and the lymphatic spaces of the corium, are dilated. This complication is distinguishable from rosacea by the age of the patient and the absence of telangiectases and of change in the sebaceous glands: from eczema, by the absence of vesiculation and weeping, and its obduracy to local treatment; from lupus erythematosus, by the absence of scales: and from lupus vulgaris, by the absence of apple-jelly nodules. The night sweats of *phthisis*, and those associated with *rickets* and with *infantile scurvy* (Barlow's disease, p. 556), are not, as a rule, difficult to attribute to their cause.

In *anidrosis* the secretion may be merely diminished or totally suppressed, and either the whole skin, or only some particular area, may be affected. The abnormality is rarely idiopathic, but is usually associated with ichthyosis, psoriasis, eczema, sclerodermia, belladonna poisoning, with malnutrition or with disordered innervation; under the latter heading one may mention in particular the unilateral sweating of the face and head that accompanies irritation of the cervical sympathetic by an aneurysm, thoracic cyst, or new growth: the outbursts of local perspirations, such as a band of sweating round the body, that constitute a rare symptom of *tuberculosis dorsalis*—a sweating crisis: and the sweating of half the body—*hemidrosis*—that may be a purely functional or hysterical phenomenon.

Bromidrosis, or foul-smelling sweat, sometimes associated with hyperidrosis, may occur in connection with such general affections as acute rheumatism, uræmia, and scurvy, or following a serious illness like pneumonia, or may be idiopathic. Occasionally generalized, it is much more frequently limited to particular parts, such as the feet, the axillæ, and the perineum. The foul smell is due to the growth of the *Bacillus fœtidus* upon the sweat after exudation.

In *chromidrosis* both sweat and sebum may be coloured, generally some shade of blue, but occasionally red, green, yellow, violet, and even black. The pigmentation is usually localized, the most frequent situations being the eyelids, cheeks, forehead, and side of the

nose; but occasionally the whole of the face and large parts of the trunk and limbs, and especially the axillæ and groins, are affected. The condition is often a neurosis, but it may be due to the ingestion of copper (green sweat), or of iron (blue sweat), or to the action of cocci or the *Bacillus pyocyaneus* upon the sweat after secretion. The chief point in diagnosis is the exclusion of imposture.

Hæmatidrosis, or bloody sweat, generally limited to particular parts, the face, hands, feet, navel, etc., may be a form of so-called vicarious menstruation, or an expression of emotional stress in highly-strung persons; it is sometimes simulated by the presence in the sweat of bacteria producing a red pigment, such as the *Bacillus prodigiosus*. *Uridrosis*, in which urinary constituents are present in the sweat in abnormal quantity, is not an idiopathic affection, but an accompaniment of such grave conditions as cholera and uræmia. It is quite unmistakable; the sweat has a urinous odour, and white crystals will be seen on the skin.

It is worthy of note that the sweat may have peculiar effects when the patient is taking certain drugs; for example, persons whose occupation it is to make polished steel implements, may be discharged from their employment if they are taking mercury and iodide of potassium, because the articles they have polished go dull and spotty almost at once, in a way which does not result from ordinary perspiration. *Malcolm Morris.*

SWELLING, ABDOMINAL. This may be acute or chronic, general or local, and caused by abdominal accumulations that are mainly either gaseous, fluid, or solid. The *position*, *physical consistency*, and *duration* of abdominal swellings are their three outstanding clinical features for purposes of diagnosis.

CLASSIFICATION.

I.—Swellings in the Abdominal Wall.

II.—General Abdominal Swellings:—

A. Mainly Gaseous—

Surgical emphysema		Meteorism (p. 388)
--------------------	--	--------------------

B. Mainly Fluid—

Ascites (p. 43)		Distention of hollow viscera
Large cystic tumours		Hydatid disease

C. Mainly Solid—

Obesity (p. 408)		Inflammatory deposits
Constipation (p. 121)		New growths

III.—Local Abdominal Swellings:—

A. Due to General Causes—

Encysted ascites		Subphrenic abscess
Tuberculous peritonitis		Phantom tumours
Hydatid disease		Enteroptosis

B. Due to Enlargement of Particular Organs.

I. SWELLINGS IN THE ABDOMINAL WALL.

Swellings situated in the abdominal wall itself can be recognized by their superficial position; by their adherence to the skin, muscles, or fascia; or by their not following the movements of the viscera immediately underlying the wall of the abdomen, to which they must therefore be superficial. But it may be impossible to distinguish between a fatty tumour in the deeper part of the wall, for example, and a fatty omental mass that has become adherent to the parietal peritoneum and so has practically incorporated itself with the abdominal wall.

Inflammatory swelling of the wall may occur by infection from without or, less often, from within. Thus a liver abscess may cause extensive redness and swelling in the right hypochondriac region; infiltration of the abdominal wall is often met with in operations for appendicular abscess; in acute cases of *Hodgkin's disease* and *lymphosarcoma*, tumours suggesting a subacute inflammatory process may occur in the abdominal wall, but they are

really localized lymphadenomatous or sarcomatous deposits, not due to infection, and are associated with gland enlargement in other parts of the body. *Inflammatory scelling about the umbilicus* is not rare in newly-born infants, due to the entrance of infection by way of the cord: in stout uncleanly adults the umbilical fossa may be the seat of intertrigo, which becomes painful, swells, and suppurates: but a far more serious umbilical inflammation may occur in patients, usually children, with *tuberculous peritonitis*: a tuberculous mass in connection with the round ligament may break down, perforate at the umbilicus, set up a chronic discharge there, and ultimately establish a fecal umbilical fistula: in rare cases a *subdiaphragmatic* or *perigastric abscess* may cause inflammatory thickening of the round ligament and umbilicus.

Edema of the abdominal wall may be either local or general (see ŒDEMA, p. 410).

Tumours of the abdominal wall, excluding those due to inflammation, are rare except in certain situations. *Lipomata* and *fibro-lipomata* may occur in any part of it, and in the inguinal or femoral rings closely imitate omental hernias. *Hernia* are commoner, particularly at the umbilicus and in the groins: there is little likelihood that a definite hernial protrusion in any part of the abdominal wall will be overlooked, but minute hernias into the abdominal wall, such as may occur along the linea alba, especially above the umbilicus, at the femoral or inguinal rings, or along the lineæ semilunares, may suffice to produce complete intestinal obstruction and yet be small enough to demand very careful palpation for their discovery.

In *malignant disease* of the stomach, pylorus, or region of the portal fissure generally, small secondary nodules may appear quite early at the umbilicus or in the round ligament just above it: and this may occur before the primary tumour has given rise to any definite signs or symptoms.

II. GENERAL ABDOMINAL SWELLING.

A. Mainly Gaseous.—In certain cases of extensive *surgical emphysema* the fascia planes of the abdominal wall are invaded and dissected out by gas, which imparts to them a highly characteristic feathery, crepitant, and crackling feeling on palpation. The gas may have entered from wounds in the neck, thorax, or trachea, or it may have been generated by gas-producing microbes in any abscess or focus of inflammation in the trunk or viscera, and have made its way thence into the abdominal wall.

Distention of the intestines with gas is an event so common as to be familiar to all: its diagnosis is discussed under METEORISM (p. 388). In this condition the whole of the abdomen, or in special cases some part of it only, is distended, and on percussion gives a highly resonant or tympanitic note. It often happens that the outlines of the gas-distended viscera can be seen on the abdominal wall, particularly when it is looked at in an oblique illumination. The increased size of the inflated intestine is apt to produce displacement of the other viscera: the dome of the diaphragm is pushed up into the chest, carrying the heart with it and shifting the apex-beat upwards: the liver is similarly pushed up, and in addition it is often caused to rotate round a transverse axis, its lower anterior edge ascending and its lower posterior edge descending, with the result that the area of liver-dullness in front is much reduced, or even lost altogether: but it is reduced only a little in the mid-axillary line so long as the gas remains in the intestine: and if the liver-dullness in the mid-axillary line disappears, the diagnosis of free gas in the peritoneal cavity is to be made.

B. Mainly Fluid.—The diagnosis of the various causes producing accumulations of fluid in the peritoneal cavity is given under the heading ASCITES (p. 43).

C. Mainly Solid.—In OBESITY (p. 408) the abdomen may swell either in consequence of the deposit of fat in the abdominal wall itself, or as the result of fatty deposits behind the peritoneum generally, in the mesentery, in the omentum and appendices epiploicæ. In very fat patients it is rarely possible to diagnose the exact nature of an intra-abdominal mass by the usual methods of palpation and percussion, and without having recourse to exploratory laparotomy, because the abdominal walls are so thick. The frequency with which inconveniently large fatty accumulations occur in the abdomens of such persons must not be forgotten when the diagnosis of some vaguely-felt tumour within the abdomen has to be considered.

In severe chronic cases of CONSTIPATION (p. 121), abdominal distention may result from accumulation of feces in the large intestine, particularly when dilatation of the colon,

idiopathic or secondary, is present. The scybala can usually be felt, perhaps soft and plastic in the region of the ascending colon, usually hard and nodular in the descending sigmoid and colon. *Idiopathic dilatation of the colon (Hirschsprung's disease)* seems to be congenital, and is associated with much hypertrophy of the colon (*Fig. 171, p. 389*). A description of it will be found on p. 126. In older patients a very similar *dilatation and hypertrophy of the colon* may come on as the result of chronic obstruction about the lower end of the large intestine. As much as 47 lb. of faeces may accumulate in the intestines of such patients.

In rare cases of chronic, particularly tuberculous, peritonitis, semi-solid *inflammatory masses* may bring about a general swelling of the abdomen; the diagnosis is discussed under ASCITES (p. 17). General swelling of the abdomen may occur in *malignant disease* of the peritoneum, due in part to the growth of numerous secondary malignant nodules, in part to a concomitant ascites. The symptoms are often vague at first—loss of weight, strength, appetite, with indefinite abdominal disorders. The abdomen enlarges, and if there is not much ascites the secondary deposits can be felt obscurely through the abdominal wall. Occasionally they can be palpated in the abdominal wall itself near the umbilicus, or in the round ligament above it, or the urachus below. As the case progresses, emaciation becomes marked, the skin loses its elasticity and often develops a diffuse brownish pigmentation; bedsores are not rare. The primary growth may be in any of the thoracic, abdominal, or pelvic organs, or in the mamma or testis. If any primary growth can be made out, the diagnosis will not be difficult, especially if glandular enlargements are found in the groins or axillae, if the ascitic fluid is hæmorrhagic, and if it is found to contain multinuclear endothelial cells, and cells with atypical mitotic figures. Tuberculous peritonitis can be excluded by means of the tuberculin test and by the result of injecting several c.c. of the ascitic fluid into guinea-pigs.

Hydatid disease of the peritoneum is discussed on p. 49.

III. LOCAL ABDOMINAL SWELLING.

A. Due to General Causes. It often happens that the causes which produce general swelling of the abdomen fail to do so in particular cases, and give rise only to a local swelling. Thus in *encysted ascites*, left behind after an acute diffuse peritonitis, or accompanying a chronic peritonitis, an accumulation of fluid bounded by fibrinous or fibrous adhesions between the adjacent viscera may be found in any part of the peritoneal cavity, but most often in the flanks and about the pelvis. If a good history of the case can be obtained, the diagnosis of the nature of such a cyst will at least be suggested; the physical signs will be those of a fixed cystic or semi-solid tumour, and the diagnosis will often be obscure until laparotomy has been performed.

Abdominal swellings of the most various size and position may occur in *tuberculous peritonitis* (p. 17, under ASCITES). Many of them are composed of the infiltrated and rolled-up omentum, others of enlarged and tuberculous mesenteric glands, others of doughy masses of adherent intestine and fibrin. The amount of ascitic fluid varies widely in different cases. When there is much, and the patient is an adult, the diagnosis of cirrhosis of the liver is likely to be made; when the peritonitis is dry (the obliterative form), the abdominal cavity may be smaller than normal, and occupied by a doughy, rather tender mass that presents areas of alternating resonance and dullness. The physical signs vary from day to day according to the amount and position of flatus in the intestine. The symptoms of tuberculous peritonitis are very variable; as a rule the patient is thin, anæmic, seriously ill, with a drawn aspect; abdominal pain and tenderness are usual, nausea and constipation with chronic intestinal obstruction are frequent; in acute cases there is high fever, in chronic the temperature is not high, but irregular, or may even be subnormal. If there is ulceration of the large intestine, diarrhoea may occur, and blood may be passed in the motions. The discovery of tuberculosis in some other part of the body, or of a family history of tuberculosis, is strong argument for regarding a case with such signs as tuberculous. A general or patchy brown pigmentation of the skin is not uncommon.

Single or multiple *hydatid cysts* may occur in any part of the abdominal cavity. Usually they are single, the large majority occurring in the liver; more rarely they affect the spleen, omentum, mesentery, or peritoneum. The cyst grows slowly, and is spherical

except in so far as it is moulded by the pressure of adjacent structures. It contains a clear saline fluid, in which may be found hooklets (*Fig.* 18, p. 49), and secondary cysts completely detached from the walls of the parent cyst. Until it has become large enough to cause mechanical obstruction and pressure-symptoms, the single hydatid cyst gives rise to little pain or complaint. It then produces a bulging of the overlying abdominal wall, smooth, rounded, more or less tense, dull on percussion; if it is of a certain degree of tenseness it may yield the hydatid thrill—just as any other cyst may. Hydatid cysts in the mesentery, omentum, or peritoneum are often multiple, and may be felt as scattered, rounded tumours generally accompanied by ascites; the disease runs a slower course than malignant peritonitis, and echinococcal cysts may be found in the ascitic fluid if it is tapped. As a rule, these are secondary after rupture (accidental or by paracentesis) of a primary cyst in the liver. They cause a slowly progressive enlargement of the abdomen, which appears to be filled with a solid or semi-solid mass; if the individual cysts are large, they can be seen outlined on the abdominal surface, and can be felt. They are freely movable, and not connected with any particular viscera; they do not, as a rule, give the hydatid thrill on percussion. Peritoneal hydatid disease is rare except in countries (Iceland, Australia, or South America) where the inhabitants live in close company with dogs that are the hosts of *Tania chinococcus*. Eosinophilia may be found, and when the cysts are living and active the patient's blood-serum may give a specific hydatid precipitin reaction, though the absence of both this and eosinophilia does not exclude hydatid disease; exploratory laparotomy may be necessary before the diagnosis can be established.

Any part of the abdomen may swell from the formation of an *abscess*; several forms of which are more or less localized, and are considered below (see *B*); others present more generalized abdominal signs and symptoms, and will for that reason be considered here. A *subphrenic abscess* is any abscess in contact with the under surface of the diaphragm except those situated in the liver or in the spleen. It is intraperitoneal in more than half the instances; it contains gas in about half the cases. The *simple* or *non-gaseous abscesses* are generally the result of appendicitis or of suppuration in the liver, and so are usually on the right side of the body; less often they are secondary to gastric or duodenal ulcer, or to suppuration spreading from the pancreas, kidney, Fallopian tubes, spleen, or thorax. They are deep-seated, and tend to produce abdominal swelling with signs and symptoms that are indefinite. The onset is insidious, often consisting in nothing more than failure to recover from the primary disorder—appendicitis, hepatic abscess—after it has been treated surgically; the patient remains seriously ill, with fever and quick pulse, leucocytosis, and often a septic aspect. If the abscess is at the back the signs may point to pleurisy or pleural effusion, with the appropriate pain and friction sounds. If it pushes forwards, the hypochondrium and epigastrium may bulge in front and become tender. The diagnosis of subphrenic abscess may be very difficult when there is no obvious antecedent to suggest its occurrence, especially if the abscess is behind and below the liver, and is complicated by pleurisy or empyema. If it is above the liver, it may be very difficult to say whether the pus is inside the liver or outside it, or both; enlargement of the liver downwards is in favour of intrahepatic abscess. Examination with the *x*-rays is often of great assistance; but often it is necessary to give the patient a general anaesthetic and insert a long exploring needle successively into the intercostal spaces (tenth to sixth) in the scapular and mid-axillary lines. It must be thrust in deeply. As viewed by the *x*-rays the diaphragm is depressed by empyema or pleural effusion, elevated by subphrenic abscess, and immobilized by either.

The gas-containing abscess or *subphrenic pyopneumothorax* is commoner in females than in males, and is usually due to the perforation of a gastric, or less often a duodenal, ulcer, or to appendicitis; in rare instances it is secondary to an ulcer of the colon or even to a suppurating hydatid cyst. It is usually on the left side. When a gastric ulcer perforates, the onset is generally sudden, with acute abdominal pain and collapse; but both the ulcer and its perforation may be latent, and nothing more than a history of chronic dyspepsia may be obtainable. The abdomen soon becomes distended; hectic fever, with rigors, rapid pulse, leucocytosis, and shortness of breath, are the symptoms likely to appear. The physical signs, on the whole, resemble those of PNEUMOTHORAX (p. 530); the diaphragm is pushed up into the thorax, and the gas in the abscess-cavity below it causes the signs of pneumothorax to develop in the upper part of the abdominal cavity and the

lower part of the thorax. The picture is complicated by the fact that the inflammatory process habitually spreads through the diaphragm, so that the signs due to pleurisy, with or without effusion, are added. The diagnosis has to be made between this condition and true pneumothorax. The points that serve to distinguish the two are, that in pneumothorax the gas seems to occupy the whole of one side of the thorax, the heart is pushed or pulled over to the sound side, and the physical signs are limited to the thorax; whereas in subphrenic pyopneumothorax the signs occur at the base of one or both lungs but not at the apex, the heart is displaced upwards but not to either side, and the upper part of the abdominal cavity is involved as well as the thorax. Examination with the *x*-rays is of the greatest service, for it shows that the gas-containing cavity is below the diaphragm and not above it; the readiness with which the level of the fluid in the abscess changes as the patient alters his position can also be noted, and proves that the abscess-cavity contains gas as well as fluid.

The abdomen is not infrequently the seat of *phantom tumours*. These are felt as fixed and more or less rounded smooth swellings, either in or immediately underneath the abdominal wall; they are dull on percussion, and may be tender on palpation. They are caused by involuntary contractions of the muscles in the area in which they occur; they persist when the patient's attention is distracted, and also during sleep, but disappear under a general anaesthetic. Phantom tumours are commoner in women than in men, and in the neurotic than in the stolid. They often persist for long periods, but may vanish when the patient believes that they have been cured. A phantom tumour in the region of the liver may simulate cholecystitis, hepatic abscess, or gumma; in the left hypochondrium, gastric carcinoma; in the appendix region, an appendicular abscess; above the pubes, pregnancy (*pseudogestis*).

In *enteroptosis* (Gilchrist's disease), or downward displacement of abdominal viscera, any or all of the organs may slip away from their normal position and attachments (*Fig. 56*, p. 127). The diagnosis must be made by the discovery that one or more of the viscera is out of place, and is also abnormally mobile.

B. The Regional Diagnosis of Local Abdominal Swellings. For clinical purposes the abdomen may be subdivided into nine regions, by two vertical lines drawn through the middle of Poupart's ligaments, and by two horizontal lines, one passing through the lowest points of the tenth ribs (the subcostal line), the other drawn at the level of the highest points of the iliac crests (*Fig. 275*). The viscera, or portions of viscera, commonly contained in the areas thus demarcated, are given in the table on page 660.

The abdominal swellings that may be felt in and about these nine regions will now be considered seriatim, excluding the tumours situated in the abdominal wall itself that have been described under heading **A.** (p. 655).

1. Right Hypochondriac Region.

Most tumours in this area are connected with the liver or gall-bladder, and their diagnosis is discussed under LIVER, ENLARGEMENT OF THE (p. 366), and GALL-BLADDER ENLARGEMENT (p. 252).

To regard the firm and rounded swelling produced by the upper segment of the right rectus abdominis muscle as evidence of tumour, enlargement, or induration of the liver or gall-bladder, is a mistake easily and frequently made.

Tumours in connection with the *hepatic flexure of the colon*, excluding scybala, are rare. Scybala may be recognized by their general shape, by the ease with which they can be moulded or indented by the pressure of the fingers, and by their being dispersed by a purgative. Carcinoma or tuberculosis of the colon may produce a palpable tumour here; and so may an intussusception. The diagnosis must rest upon the previous history and the course of the disease.

Fig. 275.—The regions of the abdomen for the *scythic* use of the numerals; see the table on page 660.

THE NORMAL CONTENTS OF THE ABDOMINAL REGIONS.

1. Right Hypochondriac	2. Epigastric	3. Left Hypochondriac
Liver Gall-bladder Hepatic flexure of colon Right kidney	Liver Stomach and pylorus Transverse colon Omentum Pancreas Duodenum Kidneys Suprarenal capsules Aorta Lymphatic glands	Liver Stomach Spleen Splenic flexure of colon Spleen Tail of pancreas Left kidney
4. Right Lumbar	5. Umbilical	6. Left Lumbar
Riedel's lobe of the liver Ascending colon Small intestine Right kidney	Stomach Duodenum Transverse colon Omentum Crachus Small intestine Kidneys Aorta Lymphatic glands	Descending colon Small intestine Left kidney
7. Right Inguinal	8. Hypogastric	9. Left Inguinal
Cecum Vermiform appendix Lymphatic glands	Small intestine Sigmoid flexure Distended bladder Crachus Enlarged uterus and adnexa	Sigmoid flexure of colon Lymphatic glands

Tumours of the *kidney* or *suprarenal gland* rarely present themselves in this region of the abdomen.

2. Epigastric Region.

Abnormal lobes in the liver, tumours in either of its lobes or in its falciform or round ligament, may be felt here.

In thin people and children the curvatures of the normal *stomach* when it is full may often be seen dimly outlined in the epigastrium, the lower curvature habitually, the upper less often, and the gastric succussion-splash can often be elicited here in healthy persons as well as in those with dilatation of the stomach. An epigastric splash is usually gastric, but may be colonic. In *dilatation of the stomach* due to obstruction at the pylorus (caused in infants by spasm or hypertrophy of the pylorus, in adults by malignant or cicatricial stenosis), waves of peristalsis (travelling from left to right) may be seen in the epigastrium. Similar waves, but travelling from right to left, occur in the colon of patients with obstruction in the rectum or sigmoid (see below). *Tumours of the stomach*, usually carcinomatous, rarely sarcomatous, or due to inflammatory deposits round a gastric ulcer, may sometimes be felt here, particularly when the patient takes a deep breath and drives the abdominal viscera down and out of the cover of the diaphragmatic dome: it must not be forgotten that the normal pylorus can sometimes be felt in an infant, child, or thin adult, as a rounded finger-like mass deep in the right side of the epigastrium. The connection of a gastric tumour with the stomach can often be made out more clearly if that organ is inflated with gas: or by the method, little used in this country, of gastrodiaphany. Examination with the *x-rays* after the administration of a bismuth or a barium sulphate meal is often of great assistance in obscure gastric cases, and should always be employed.

The *transverse colon* goes across the lower part of the epigastrium in some cases, more usually across the upper part of the umbilical area. Its sacculations and peristalsis are often outlined on the abdominal walls of pot-bellied rickety children or of thin adults.

particularly when they are flatulent or constipated. In acute or chronic obstruction the peristalsis becomes much more marked. Tumours of the transverse colon are very rare, except the common occurrence of scybala in it; a few cases of chronic hyperplastic tuberculosis of this part of the colon have been recorded, with great diffuse thickening of its wall and stenosis of its lumen.

Swellings in connection with the *omentum* lie below the colon and in immediate relation with the anterior abdominal wall, in front of the mass of small intestine. In *tuberculous peritonitis* it often forms an irregular rope or mass composed of inflammatory tissue, cheesy tubercle, or encysted exudate, that may lie in the epigastrium, or extend into any of the regions of the abdomen—when the diagnosis of malignant disease of the intestine or some other viscus may possibly be made. Similar nodular enlargement and deformity of the omentum is common in *chronic peritonitis* of any sort; and it may become the seat of an abscess in cases of perforated gastric ulcer. *Cysts of the omentum*, single or multiple, are not very rare, and are often inflammatory in origin. Tuberculous or inflammatory masses of omentum often adhere freely to the anterior abdominal wall as well as to the neighbouring viscera.

Swellings derived from the *pancreas* push forwards from the depths of the abdominal cavity towards the epigastric and the upper part of the umbilical areas, and present themselves as deeply-seated vaguely-felt masses on palpation. They have the stomach, or the stomach and colon, in front of them, and are fixed to the posterior abdominal wall; they are usually made out best by examination under an anæsthetic; they move little on respiration, and often transmit from the adjacent aorta a non-expansive pulsation. They are separated from the liver and from the spleen by areas of resonance. These swellings may be carcinomatous, in which case wasting, anæmia, and jaundice are likely to be observed, with death in a few months' time; or due to chronic pancreatitis, when the course of the disease will be slower and there will be more epigastric tenderness and pain, with clayey stools and perhaps intermittent jaundice, a positive Cammidge's reaction (p. 100), or glycosuria. In acute pancreatitis the swollen pancreas has only exceptionally been palpated before laparotomy; the main symptoms are acute epigastric pain, vomiting, constipation, fever, and proneness to collapse, simulating in part acute intestinal obstruction and in part acute peritonitis, so that immediate laparotomy is usually resorted to and the diagnosis established by the discovery of opaque yellow patches of acute fat necrosis in the omentum and elsewhere within the abdomen.

Pancreatic cysts, so-called, are often cysts not in the pancreas but in its neighbourhood, and therefore better called peripancreatic cysts. Pancreatic cysts proper are single or multiple retention-cysts, usually the result of chronic pancreatitis; they form deeply-seated, smooth, rounded tumours, possibly giving a feeling of fluctuation. At first they occupy the lower epigastric or hypochondriac regions; but if they enlarge much they may fill the whole upper part of the abdomen, or extend down to the pubic symphysis or flanks. The symptoms of chronic pancreatic disease should be present—chronic indigestion, the passage of pale and bulky stools, glycosuria, perhaps jaundice from time to time if pancreatic calculus is present. *Peripancreatic or retroperitoneal cysts*, due to accumulations in the lesser sac of the peritoneum, or to growths originating in residues of the Wolffian body behind the peritoneum, may produce apparently identical cysts; the evidences of chronic pancreatic disease should be absent in these cases, but the diagnosis may be impossible until laparotomy has been performed. Cammidge's urinary reaction (p. 100) is said to be of assistance in diagnosing these cases.

Swellings in connection with the *duodenum* are felt in the right side of the epigastric and umbilical areas, and are usually due to primary malignant disease. In many cases they escape palpation because they are so deeply placed, and they usually have to be diagnosed from such conditions as cancer of the stomach, pylorus, pancreas, bile-ducts, and portal fissure generally, not by their physical signs but by the general symptoms and progress of the disease. A growth in the first part of the duodenum produces symptoms like those of cancer of the pylorus—wasting, anæmia, progressive dilatation of the stomach with visible peristalsis, attacks of copious vomiting, and occasional hæmatemesis perhaps; the motions contain bile, but the vomit does not; jaundice is absent unless there are secondary growths in the portal fissure. Malignant disease of the second part of the duodenum, in or involving the biliary papilla, soon produces obstructive jaundice and

distention of the gall-bladder, and often leads to suppurative cholangitis, whereas cancer in the head of the pancreas or bile-duets produces steady jaundice and is not followed by suppuration in the bile-passages. Cancer in the third part of the duodenum or below the bile papilla produces duodenal stenosis, with dilatation of the duodenum and stomach and frequent vomiting; but in this case the vomit is habitually bilious and contains the pancreatic ferments. If there is no stenosis, the bilious vomiting will be less, and the case may be indistinguishable from one of cancer of the stomach. In most of these cases the exact diagnosis is more often made post mortem than ante mortem.

Swellings in connection with the *kidneys* and *suprarenal* capsules occur in the epigastrium only after they have reached a considerable size. They rise up out of the loin and flanks, and their diagnosis is considered below.

Enlargement of the *spleen* may bring its blunt anterior end or its notched upper edge into the epigastric area. The splenic swelling always lies in contact with the anterior wall of the abdomen, with the stomach above and behind it (see SPLEEN, ENLARGEMENT OF THE, p. 628).

In every region of the abdomen *lymphatic glands* abound, and any of these may become palpable in cases of Hodgkin's disease, tuberculous peritonitis, or malignant disease. The enlarged glands are felt as nodulated chains or masses, usually hard and rounded, but softer and even cystic if their contents cascade or break down into pus; they may also calcify, when they become hard and stony. The enlarged glands that will be felt in the epigastric area are those connected with the stomach, liver, and mesentery; the diagnosis must be made on general and anatomical lines (see LYMPHATIC GLAND ENLARGEMENT, p. 376).

3. Left Hypochondriac Region.

An abnormally lobulated *liver* may make a superficial tumour in this area continuous with the main mass of the liver in the epigastric region. In the same way, a tumour in the left lobe of the liver may project superficially into the left hypochondrium.

Part of the *stomach* lies in this region normally; the diagnosis of gastric swellings has been considered above. A gastric tumour may often be differentiated from a tumour of the adjoining spleen by the fact that while the spleen is anchored at its hilum, and so is capable of but little movement, the stomach is highly mobile, changing its position with the position of the patient, and also in accordance with its fullness and distention.

The diagnosis of a tumour of the splenic flexure of the *colon*—scybalous, tuberculous, or malignant—is considered above (see 1 and 2).

The diagnosis of the various causes of enlargement of the *spleen* is discussed under SPLEEN, ENLARGEMENT OF THE (p. 631). The tumour is usually to be recognized by the fact that it comes down from under the left costal margin in direct contact with the anterior abdominal wall, descends on inspiration, has a smooth surface, and a notched upper and inner margin. In exceptional cases, however, the enlarged spleen seems to adopt a more compact and cubical form in place of its usual elongated prismatic shape, and also to lie back in the loin and left lumbar region instead of occupying the anterior and upper part of the abdominal cavity; it then simulates a tumour of the left kidney or suprarenal body, and unless the blood and leucocyte count give a definite lead the diagnosis may be settled only by a laparotomy. Conversely, a spleen-shaped hypernephroma or suprarenal tumour, or a calculous and cystic kidney, may easily be mistaken in an anemic patient for an enlarged spleen, unless the possibility of the error be kept in mind.

Tumours of the *pancreas* and *retroperitoneal cysts* may project into the left hypochondrium (see 2 above).

Tumours of the left *kidney* and *suprarenal body* rarely appear in the left hypochondrium unless they are very large (see 6 below). Unless very large, they have the stomach or the stomach and colon in front of them, and so are variably resonant on percussion—according to the amount of gas in those viscera—and are also less distinctly palpable than tumours arising from the spleen, stomach, colon, or omentum, that may be felt in the same situation.

4. Right Lumbar Region.

When the *liver* is abnormally lobulated, either congenitally or as the result of tight lacing, a thin flange of liver-tissue, known as *Riedel's lobe*, may be met with as a superficial

tumour, continuous with the liver above it, in this region. Sometimes it is freely movable, and then may be mistaken for a movable kidney or for a dilated gall-bladder.

The *ascending colon* can usually be palpated and rolled under the fingers as a tube-like structure at the confines of this and the umbilical region; when empty and contracted it may feel almost rod-like. Its contents are usually fluid, but it may contain semi-solid or solid fecal masses that can be moulded by pressure, in constipated patients. In patients with obstruction lower down, it may be greatly distended, and show sacculation and visible peristalsis. It may become much thickened with inflammatory tissue, or even come to lie in an abscess of its own production, in pericolicitis, perityphlitis, typhlitis, appendicitis, and hyperplastic tuberculous of the colon, forming a thickened and tender mass immediately under the abdominal wall; the patient will be more or less acutely ill, with local pain and tenderness, constipation, often vomiting. In the more chronic of these cases, the diagnosis of malignant disease of the colon will often be suggested.

General thickening of the ascending colon, with tenderness and characteristic mucous or blood-streaked stools, is common in mucous-membranous colitis, in dysentery, and in ulcerative colitis. The first of these is met with in nervous constipated women; dysentery, amoebic or bacterial, is caught abroad, and is commoner in men than women; while ulcerative colitis, whether it be dysenteric or no, is a severe and progressive painful diarrhoea, often associated with vomiting and irregular fever, that commonly leads to emaciation and death from exhaustion or intestinal hæmorrhage in a few weeks or months.

The ascending colon can be felt as a sausage-shaped tumour in acute, subacute, and chronic ileocecal and ileocolic *intussusception*; at first in the right flank, then extending across the abdomen above the umbilicus, and finally down the left flank and into the pelvis. The chief symptoms are spasmodic abdominal pain, vomiting, the passage of blood and mucus by the rectum, and tenesmus; the palpability and consistency of the elongated tumour vary according to the degree of muscular spasm in it.

The *small intestine* is but rarely the cause of abdominal swelling in this region, excepting when it becomes the seat of enteric *intussusception*.

Tumours in connection with the *right kidney* and *suprarenal body* usually make their first appearance deep down in this region, having the ascending colon and small intestine in front of them. They can be lifted forwards *en masse* from behind by a hand placed at the back of the loin. For their diagnosis see KIDNEY, ENLARGEMENT OF (p. 352.) The lower pole of the right kidney can be felt in normal persons on deep abdominal palpation; but when the kidney is abnormally mobile, the whole of it may be felt, and in rare cases it may be found in any of the adjoining abdominal areas. The shape and consistency of the movable kidney are characteristic, and the patient complains of a peculiar sickening sensation when it is grasped bimanually; in the lesser degrees of mobility it disappears readily into its normal position under cover of the diaphragm, and ceases to be palpable until the patient drives it down again by a deep inspiration. As regards its diagnosis, the movable right kidney will hardly be mistaken for anything else in this region; on the other hand, Riedel's lobe of the liver, the enlarged gall-bladder, fecal accumulations or a cancer of the ascending colon, and omental masses, have all been mistaken for it, although they are all superficial to the kidney, and lie in contact with the anterior abdominal wall. Other wandering tumours, e.g., of the ovary, Fallopian tube, mesentery, hydatid disease, may give rise to the same error if reniform.

5. The Umbilical Region.

Examination with the *x-rays* after a bismuth-meal has shown that the normal *stomach* is a far more mobile organ than was formerly supposed, and that in health its lower margin often descends even below the level of the umbilicus; but if much of it habitually occupies the umbilical region, it is probably dilated to a pathological degree, either from atony or from pyloric obstruction (*Fig.* 276).

Tumours in connection with the *transverse colon* have been considered under the headings I and F above.

Tumours in connection with the *omentum* are common in this region; those arising from the *small intestine* are rare. Both are superficial, and their diagnosis has been given above (see 2).

Abdominal swellings in connection with the *urachus*, which runs from the umbilicus to the bladder, are considered below (see 8).

Swellings arising from the *duodenum, kidneys, suprarenals, pancreas, and mesentery*, may all present themselves in the deeper parts of the umbilical region, usually as more or less fixed masses arising from or connected with some definite part of the posterior wall of the abdomen. Their diagnosis will depend mainly upon the success with which the origin and connections of the tumour can be made out; if the patient is fat, or if relaxation of the abdomen cannot be obtained, palpation under a general anæsthetic may be desirable. Consideration must also be given to any general symptoms such as may point to renal calculus, hydronephrosis, pancreatitis, for example.

The *aorta* bifurcates half an inch below and just to the left of the umbilicus. In thin, nervous, and excited patients, particularly young women, great pulsation of the aorta can often be felt in the umbilical and lower epigastric areas, and may lead to the wrong diagnosis of abdominal aneurysm. Careful examination will almost always show that

this pulsation is no more than a throbbing, an up-and-down movement as the patient lies, without lateral expansile pulsation. Aneurysm of the abdominal aorta is very rare; it is seen in patients who have had syphilis, and is commoner in men than in women. The aneurysmal sac is distinctly larger than the normal aorta, and presents diagnostic expansile lateral pulsation met with in no other condition. These abdominal aneurysms often leak into the retro-peritoneal tissues: large irregular clots of blood, weighing several pounds and of the most varied extent and distribution, may form gradually in the flanks, pelvis, and back of the abdomen generally, causing the patient great pain by their situation and rendering him anæmic and breathless. The abdominal aneurysm also causes pain and stiffness in the back by eroding the bodies of the vertebrae upon which it presses.

6. Left Lumbar Region.

The enlarged *spleen* (see 3) may intrude into this area: it forms a firm mass, dull on percussion, and is in contact with the abdominal wall, driving the splenic flexure of the colon inwards or downwards before it. The spleen, when enlarged, comes down into the abdomen in front of all the other structures in the left side, and its abdominal dullness is continuous with its thoracic dullness, which extends back and up into the axilla along the line of the ninth or tenth ribs.

Tumours of the stomach, omentum, suprarenal, kidney, or descending colon, may all be in contact with the anterior abdominal wall, and though usually nodular and irregular, may present a smooth and spleen-like surface on palpation. They may be distinguished from the enlarged spleen by the fact that they produce no such typical area of thoracic dullness in continuity with the dullness of abdominal tumour: while the renal and suprarenal tumours may in addition be shown to occupy the back of the loin, so that they can be tilted forwards by the fingers placed behind just outside the edge of the erector spinae muscles, and so pushed against the other hand, which is placed on the anterior surface of the loin. A suprarenal tumour may be associated with sexual precocity (see *Figs. 174, 175, p. 408*).

The diagnosis of tumours of the *small intestine, kidney, and suprarenal gland* in this region has been given already.

7. Right Inguinal Region and Right Iliac Fossa.

Abdominal swellings in the right inguinal region are rarely confined to it, and usually extend into the outer part of the hypogastric region, occupying what may be described somewhat indefinitely as the right iliac fossa.

Fig. 270. Idiopathic dilatation of the stomach. The organ post-mortem almost fills the abdominal cavity.—*Introduction to Surgery* (Rutherford Morrison).

New growths, inflammatory thickenings, and abscesses in connection with the *cæcum* and *appendix* may all extend into this region of the abdomen, giving rise to more or less acute and severe abdominal symptoms—pain, fever, vomiting, constipation, with a tumour in the right iliac fossa. The physical signs are very variable, depending on the extent and acuteness of the process, the degree to which the abdominal wall can be relaxed, the exact position of the tumour—an abscess to the inner side of and behind the *cæcum* and *appendix* may lie too deeply to be felt per abdomen. The rare condition of sarcoma or lymphosarcoma of the *cæcum* may be associated with fever; the tumour is soft, and the diagnosis of some chronic inflammatory condition will probably be made. A *cæcal carcinoma* is usually a harder mass and of slower growth; it tends to constrict the bowel, with the result that fecal accumulation occurs behind it, and so the new growth may be overlooked when the hard mass of impacted feces is discovered. The diagnosis of appendicular abscess has been made in patients with movable right kidney during a Dietl's crisis; fever is usually absent in the latter; careful examination will generally show that the tumour in the right iliac fossa is an enlarged and movable kidney, and a history pointing to intermittent hydronephrosis, with polyuria after the acute attacks, should be obtainable. Inflammation of the right ovary or tube, or ovarian neuralgia occurring with the catamenia, may all give rise to symptoms in nervous patients that closely simulate those of appendicitis; and if scybala are present in the *cæcum*, vaguely felt as a tumour through the rigid abdominal wall, the mistaken diagnosis of appendicitis may easily be made; but as a rule pelvic symptoms and signs will be found, and pain be felt in the pelvic region and the lower part of the back; the diagnosis will be cleared up by a vaginal or rectal examination which, indeed, should never be omitted when there is any doubt as to the exact causation of an inflammatory swelling in the iliac fossa—and by the previous history of the case.

Inflammatory swellings and abscesses in the right iliac fossa may arise in connection with *psoas abscess*, *abscess* originating in the *sacro-iliac joint*, *hip-joint*, or *ilium*, and from the swelling or breaking down of *lymphatic glands* (the external iliac) infected from some perhaps trivial wound in the leg or perineum. The symptoms of bony disease about the hip or the pelvic girdle will be present; the leg will be held more or less stilly in some abnormal attitude of flexion and inversion to relieve the pain, and movement of the leg will be painful. Unless local peritonitis is present, there will be none of the special symptoms that point to appendicular or *cæcal* disease.

8. Hypogastric Region.

In rare instances, tumours arising in the *small intestine*, and more often the sausage-like swelling of an enteric intussusception, may be felt in the hypogastric area (see 4). Tumours extending into it from the iliac fossae are described under headings 7 above and 9 below.

In infants, the *bladder* reaches half way to the umbilicus when moderately full, and does not fall below the pubic symphysis when empty. In the adult, the distended bladder is a common hypogastric swelling, particularly in females with *retroverted gravid uterus*, or in males of about sixty with *enlargement of the prostate*; it may reach up as an ovoid elastic mass arising from the front of the pelvis almost to the umbilicus under conditions that are in no way pathological, as well as when the retention is due to some pathological cause. Such a distended bladder (*Fig. 277*) has been tapped as ascites, operated upon as ovarian or urachal cyst, and diagnosed as the pregnant uterus; mistakes that are not likely to occur if these possibilities be remembered, and are put out of court by micturition or the use of a catheter before the diagnosis is made.

The *urachus* is a fibrous cord running in front of the peritoneum from the top of the

Fig. 277. Abnormal distension of the bladder. The physical signs were those of a large tumour occupying the lower part of the abdomen. (*See also p. 665.*) See a similar case of *Bladder*.

bladder to the umbilicus, in the middle line : it sometimes becomes the seat of cyst-formation, more often in women than in men. The urachal cyst is a rounded tumour lying between the umbilicus and pubes, soft or firm according to the tension of its contents ; it may produce hypogastric pain. It must be distinguished from encysted tuberculous peritonitis, from ovarian cystadenoma, and from the distended bladder.

Abdominal swellings arising from the *uterus, ovaries, tubes, and uterine ligaments* may all rise up out of the pelvis and present themselves as swellings in this region, and, as they grow larger, may spread into the whole or any part of the abdomen. While they are comparatively small and manifestly connected with some intrapelvic organ, their origin is not difficult to determine ; their diagnosis is considered under SWELLING, PELVIC (p. 688). But when they have grown up into the abdomen, or have acquired a long pedicle, or have become fixed by adhesions to some distant part of the abdominal wall or to some other viscus, perhaps causing it to become inflamed and impairing its functional activity, these pelvic tumours may give rise to signs and symptoms suggesting any disease rather than one that is pelvic, and the true diagnosis may be very difficult to make. The possibility of pregnancy in the female should always be remembered.

9. *Left Inguinal Region and Left Iliac Fossa* (see 7 above).

The *sigmoid flexure of the colon* can be felt normally as a tube-like cord passing from the left lumbar region down into the pelvis, and rolled under the fingers. It very frequently contains hard ovoid scybalous masses. In rare instances it may be uniformly thickened and tender in consequence of chronic inflammation, tuberculous or otherwise. It is occasionally the seat of cancerous new growth, when the patient will complain of chronic intestinal obstruction, with cachexia, tenesmus, and the passage of blood-stained stools, phenomena that may also be met with in hyperplastic or stenotic tuberculosis of the sigmoid.

The left iliac fossa may be the seat of abscess or inflammations similar to those described under 7 above. In addition, suppuration around an exaggerated colonic diverticulum, with symptoms not unlike those of appendicitis on the wrong side, has been known to occur ; such a condition has been spoken of as *acute diverticulitis of the colon*.

A. J. Jex Blake

SWELLING, AXILLARY. Swelling in the axilla is due in the great majority of cases to enlargement, from one cause or other, of the lymphatic glands ; a subsequent abscess, either acute or chronic, is frequent. Any other form of tumour is distinctly rare. In examining a case, therefore, these two causes should be uppermost in the mind, and indeed, on inspection only, the diagnosis may be obvious, e.g. :—

Acute Abscess may be recognized at once by the well-marked signs of local inflammation and the general febrile disturbance. There is one form of acute abscess that may not be obvious, namely, one situated in the upper part of the axilla and covered by the pectoral muscles. On account of its distance from the surface the local signs of inflammation may not be great, though the general signs are marked. There will be great disinclination to move the arm on account of pain, and there is usually some cause, such as a whitlow on the finger, to account for the trouble. It must be remembered, however, that the abscess may be 'residual' ; that is to say, the original source of infection, such as the whitlow, may have healed completely two, three, or even more weeks before the axillary abscess declares itself. Occasionally an empyema points in the axilla ; there are generally, but not always, abnormal lung signs to suggest the diagnosis.

Chronic or Tuberculous Abscess forms a single fluctuating swelling which, if large, may extend upwards under the pectoralis major. Owing to the fact that few, if any, of the local signs of inflammation may be present, difficulty arises in distinguishing this form of abscess from a soft lipoma. The duration and the rapidity of growth of the swelling are a good guide, for though the duration of a chronic abscess may run into months, it does not exist for years, as does a lipoma.

Enlargement of the Lymphatic Glands. Next, supposing that examination proves that the swelling is not an abscess, attention should be directed to ascertain whether it is glandular, and it is therefore necessary to recall the anatomical position of the glands. The axillary lymphatic glands are ten to twelve in number, and are arranged in three sets. One chain surrounds the axillary vessels and receives the lymphatics from the arm ; a small chain runs along the lower border of the pectoralis major as far as the mammary

gland, receiving the lymphatics from the front of the chest and the breast; the third chain is placed along the lower margin of the posterior wall, to receive lymphatics from the integuments of the back. If the glands are affected in any way, all need not necessarily be enlarged, but it would be extremely unusual if only one were picked out, and commonly two or three, or one entire group, are affected. Therefore axillary swellings due to glandular enlargement are almost always multiple, and are situated in the part of the axilla where glands are normally present. This may not be quite accurate when much inflammation has occurred around the glands and they are matted together, as happens with tuberculous infection; but even then the mass may be felt to be made up of many glands. For the differential diagnosis of glandular swellings, see LYMPHATIC GLAND ENLARGEMENT (p. 376).

Primary Tumours of the Axilla are distinctly rare.

Lipoma is the most common. It may attain a large size and extend up under the pectoral muscles. It should be diagnosed by its long history, slow growth, definite outline, and free mobility. When very soft, the tumour may give the feeling of fluctuation, and so be mistaken for a chronic tuberculous abscess. The skin wrinkles when one attempts to raise it away from the tumour.

Cystic Hygroma of the axilla is very rare. It is usually congenital. It forms a soft, fluctuating, painless swelling, which sometimes grows rapidly. It may easily be mistaken for a lipoma.

Primary Malignant Tumours may arise, but are of extreme rarity.

Aneurysm of the Axillary Artery does occur, but is uncommon. It is easily recognized, because it is comparatively superficial and it gives an expansile pulsation, synchronous with the heart's beat; the veins of the forearm may be distended on account of pressure on the axillary vein, and the radial pulse on the affected side is diminished in size and delayed. There may be a definite history of local injury, or in cases of apparently spontaneous aneurysm there may be signs or symptoms of fungating endocarditis (p. 34).

George E. Gask.

SWELLING ON A BONE.—It is presumed that the swelling has been ascertained to be of the bone, immovable apart from it, and that it is not merely some tumour lying close to it.

The following method of examination should be adopted: (1) Inquiry into the clinical history, mode of onset, duration; (2) Search for the signs of inflammation; (3) Evidence as to whether the swelling is a localized projection or involves the whole circumference of the bone; (4) Investigation for involvement of other bones or further signs of disease, e.g., tuberculosis, syphilis, rickets, etc.; (5) A skiagram should always be taken if possible; (6) If a discharge is present, a bacteriological examination should be made.

The various swellings may be classified under the following headings:—

(I.) *Injury*; (II.) *Infective Diseases*; (III.) *General Diseases*, not limited to one bone; (IV.) *Tumours*; (V.) *Cysts*.

I. INJURY.

A blow or kick may give rise to a swelling due to *extravasation of blood* or serous fluid under the periosteum. This disappears rapidly, but may leave a small permanent thickening or node. Such a node is found not infrequently on the shins of football players. A fracture of bone is followed by the formation of *callus*, which forms a large swelling if the broken ends do not lie in accurate apposition, or if there is too much movement between them. After four to six weeks the callus begins to be absorbed, and it may disappear entirely; in most cases a small permanent swelling indicates the site of fracture. A green-stick fracture may not show any swelling at first, and may be overlooked on this account, being discovered only when the formation of callus draws attention to it.

II. INFECTIVE DISEASES.

These give rise to inflammatory changes in bone, the signs of which are more or less obvious, according to the nature and virulence of the infection. These changes have usually been named according to the chief starting-point (periostitis, osteomyelitis, etc.), though they seldom remain confined to one particular part of the bone. In this article the classification will be made according to the nature of the infecting organism, viz., pyogenic (staphylococci and streptococci), tubercle, syphilis, etc.

A. With Pyogenic Organisms.

Acute infection may occur through wounds or injuries, or via the blood-stream. The resulting swelling is due to the formation of pus between the periosteum and the bone; this may be a localized abscess, or the whole of the periosteum may be stripped off and the bone lie bare in a bag of pus. The disease usually occurs in young people, and the intimate attachment of the periosteum at the epiphyseal lines limits the spread of suppuration; in long-standing cases the pus may burrow farther and even burst into the joint. Suppuration is rarely limited to the surface of the bone, but spreads into the marrow, causing osteomyelitis; lymphatic absorption and septic embolism are liable to give rise to a general blood-infection and pyæmia.

The signs of inflammation are abundant: the swelling is acutely painful and tender, the skin over it red and œdematous, and the constitutional signs of fever are marked. If the blood is examined, a high leucocytosis will be found.

It is important not to mistake *erythema nodosum* for this affection; in erythema nodosum the red swellings are generally multiple, bilateral, and confined to the shins; it is rare for acute osteomyelitis to be bilateral and symmetrical, and confined to the parts between the knees and the ankles.

Chronic infection.—Such a condition as detailed above may often become chronic and cause a swelling which may last for months, years, or through life. If the pus formed under the periosteum escapes, either by bursting or through an incision, sinuses form, and the periosteum, in the process of repair, becomes thickened. If during the height of the inflammation, a portion of the bone has died—necrosis—this acts as a foreign body, keeps up inflammation and suppuration, and great thickening of all the constituent parts of the bone results (Fig. 278). Usually the diagnosis can be arrived at without difficulty. Occasionally, if the inflammatory changes have not been great, and the amount of necrosis is small and deeply-seated (central necrosis), a condition resembling a slow-growing sarcoma may result. If a skiagram is taken it will be observed that the chronic inflammatory periosteal thickening is added on to or 'applied' to the original compact layer of bone, whereas in the case of sarcoma, though there may be thickening and formation of bony or calcareous spicules in the growth, the compact layer is eaten away (Figs. 283, 286, 287, pp. 671, 673). However, this may be somewhat slender evidence on which to base the diagnosis between so important a condition as sarcoma and inflammation, and if doubt arises an incision should be made into the tumour, so that a portion may be removed for pathological investigation.

Fig. 278. Skiagram from a case of chronic periostitis of the ulna, due to pyogenic infection. (Skiagram by Dr. Hugh Walshaw.)

B. Tuberculous Disease usually starts in the cancellous tissue of the small bones of the carpus, tarsus, and phalanges, and at the ends of long bones. The inflammatory changes, which are slight, give rise to caries of the affected bone; the external signs of inflammation are little marked, and it is comparatively rare for any swelling of the bone to result, though the soft parts around the bone may be swollen considerably.

Tuberculous dactylitis (Fig. 279) furnishes an instance in which the disease forms a periosteal swelling. It is found most often in quite young children, and the bones commonly affected are the metacarpal bones and phalanges of the hand. The affected digit exhibits a fusiform enlargement, slightly tender, which on rest tends to diminish. Tuberculous periostitis may develop in any long bone, on the ribs and the humerus most commonly, and it then has to be differentiated from syphilis.

Chronic tuberculous abscess of bone occurs most frequently in the young adult, and nearly always in the articular extremity of a long bone, by preference in the upper end of the tibia. Enlargement of the bone is found only when the abscess approaches the surface and involves the periosteum. The skin then becomes a little red and edematous, and there is generally a small spot that is exquisitely tender on firm pressure. It is to be noted that when secondary infection with pyogenic organisms occurs—a not infrequent event—all the swellings described under "acute infection" may result. A skiagram will generally reveal the true condition; if not, a diagnostic injection of Koch's old tuberculin may be made, or von Pirquet's skin reaction tested.

C. Syphilis in the acquired form may lead to periosteal thickenings in the secondary stage and

Fig. 271. Skiagram showing tuberculous thickening of the first phalanx of the index finger of a child. (Skiagram by Dr. Hugh Walshaw.)

Fig. 280. Skiagram showing typical syphilitic thickening of the radius; the appearance is diagnostic of this condition. The ulna is normal. (Skiagram by Dr. C. Thurston Holland.)

to gummata in the tertiary. The former give rise to excessively tender swellings on the surface of the tibiae, clavicles, sternum, ribs, or skull. They are generally multiple, two or three often being found on the same bone. The patient complains of pain, particularly in bed, when the extra warmth causes further dilatation of already inflamed vessels. Relief is given almost at once by potassium iodide. Sometimes one of these swellings is followed by the formation of compact periosteal bone, giving rise to a node which fades gradually into the surrounding parts, like a hill rising gently from a plain.

Gummata may form localized swellings, or may invade the whole substance of the bone, causing osteomyelitis and general thickening (Fig. 280). The condition has to be distinguished from tuberculosis, chronic pyogenic infection, and sarcoma; such recognition is arrived at by means of the Wassermann test, and the fact that anti-syphilitic remedies cause a marked and rapid improvement. Diagnosis by incision has rarely to be resorted to.

In *congenital syphilis* two forms of bony swelling are common: (a) Periosteal thickenings of the bones of the vault of the skull, called Parrot's nodes—the hot-cross bun or natiform skull; (b) In new-born infants, epiphysitis and separation of the

epiphyses. So painful is a limb thus affected that it is kept motionless, and may be thought to be paralyzed.

D. Typhoid Fever.—In the course of this disease a periosteal node or abscess may form. From the fluid a pure culture of typhoid bacilli may be obtained perhaps for a long time after the fever. The nodes by no means always break down into pus.

III. GENERAL DISEASES NOT LIMITED TO ONE BONE.

Rickets.—The ordinary form is well known, and can hardly be confused with any other disease.

Scurvy-rickets is quite distinct from rickets. It arises generally in infants under twelve months old, who have been fed too exclusively on artificial foods or preserved milk. The disease therefore is more common among the children of the rich than the poor. The child is often brought to the doctor on account of the sudden appearance of an exceedingly painful swelling of a long bone, such as the femur. The swelling may fluctuate, and yield on aspiration blood-stained fluid. Spontaneous fracture is liable to occur. The diagnosis is indicated by the fact that the child is anemic, and has spongy gums and hemorrhages from the mucous membranes. The condition is most likely to be confused with acute suppurative periostitis and traumatic fracture.

Fig. 281.—Skiergram of a common variety of cancellous exostosis of the femur.
(Skiergram by Dr. Hugh Walsham.)

Leontias Ossis.—In this disease there is general overgrowth of the cranial and facial bones, and one of the chief symptoms may be the fact that the patient has to get progressively increasing sizes of hats.

Swellings of bones associated with diseases of joints may be found in *gout*, *osteo-arthritis*, and *pulmonary hypertrophic osteo-arthropathy*. (See JOINTS, AFFECTIONS OF, p. 351.)

IV. TUMOURS.

These are innocent and malignant. Innocent tumours as a whole are characterized by their long history, slow growth, localized projection, and the absence of all signs of inflammation.

Varieties of Innocent Tumours.

Osteoma or *exostosis* is the commonest form (Fig. 281). The usual site is in the neighbourhood of the epiphyseal line of a long bone, particularly the lower end of the femur; the tumour is capped with cartilage, and often surmounted by an adventitious bursa containing fluid.

Osteitis Deformans (see Figs. 63, 64, p. 155) is a senile disease, very chronic, and characterized by thickening, lengthening, and bending of the bones. The whole osseous system may be affected, but attention is first drawn to the disease by thickening of the tibiae and forward bending of the knees, and by enlargement of the head. In the rare event of one bone only being affected, it may be confused with syphilitic osteitis, and only be recognized on the failure of antisiphilitic remedies and by the subsequent involvement of other bones. The patient suffers from neuralgic pains, and in the later stages from dyspnoea. In such cases death sometimes occurs from the development of multiple sarcomata of the bones.

Acromegaly (Fig. 116, p. 237) is described on p. 237.

The ungual phalanx of the great toe is another common site for a similar tumour, which pushes up the nail and may be very painful if ordinary boots are worn. Multiple exostoses are not uncommon, and they may be hereditary. Diagnosis can be made at once by means of a skiagram, and with this aid it can be seen that the swelling is composed of cancellous tissue continuous with that of the bone. A spurious osteoma may arise by ossification of a tendon or by an extension of the ridge into which the tendon is inserted, the condition being generally consequent on some injury or repeated strain, as in the case of horse riders, who are apt to develop one on the inner aspect of the knee; another example is the spur that is apt to form on the under surface of the os calcis at the posterior end of the long plantar ligament, giving rise to much discomfort and even acute pain below the heel in walking. A skiagram may be required in establishing the diagnosis with certainty (*Fig. 185, p. 440*).

Ivory exostoses may be found on the flat bones of the skull, or in the auditory meatus growing from the petrous bone, or causing unilateral exophthalmos if springing from the orbital plate of the frontal bone or the walls of the frontal sinus.

Chondromata may grow from any bone. They are most commonly multiple, affecting the phalanges and metacarpal bones of the hand (*Fig. 282*). The result is increasing deformity, with pain and ulceration of the skin.

Fibromata grow from the fibrous tissue of the

Fig. 282.—Skiagram of an enchondroma of the fifth metacarpal bone. Compare with *Figs. 284, 286, 287.* Enchondroma and osteoma do not appear unlike in skiagrams. (*Skiogram by Dr. Hugh Walsham.*)

periosteum, but are rare except in the form of an epulis of the jaw. (See SWELLING OF THE JAW, LOWER, p. 683.)

Lipomata are extremely rare. They grow from the outer layer of the periosteum.

Malignant Tumours may occur either primarily (sarcoma), or secondarily by metastasis or by invasion (sarcoma and carcinoma).

Periosteal sarcomata are of so many types, and of such varying degrees of malignancy, that it is a difficult task to lay down any rule as to their characteristics. The softer their consistency and the nearer they approach to the embryonic type of the tissue, the more malignant they are; the nearer they reach the fully-formed tissues and contain cartilage, bone, or fibrous tissue, the slower growing and less malignant they are. A typical case may be represented as a rapidly growing tumour, generally about the end of a long bone (*Fig. 283*). It is not usually painful, and the signs of local inflammation and general fever are little marked, or absent. The patient is commonly a young adult, who often gives a history of injury to the part, and may lose weight and strength before actual cachexia sets in. The veins over the swelling become prominent, the lymphatic glands enlarged, and metastases by the bloodstream occur early, especially in the lungs. It

Fig. 284.—Skiagram of a periosteal sarcoma of the tibia. (*Skiogram by Dr. Hugh Walsham.*)

has to be distinguished from chronic and syphilitic periostitis. If a skiagram is insufficient, a piece of the tumour may have to be excised, decalcified, and a microscopic section from it prepared. This form of sarcoma is the worst possible, and seeing that amputation does not cure, and often does not prolong life, this extreme resource may be delayed where either gumma or chronic periostitis is still a possible diagnosis.

Fig. 284.—Skiagram of an early myeloid sarcoma of the lower end of the radius. This figure and Figs. 286, 287 should be compared with Fig. 282, which shows that enchondroma and sarcoma are not distinguishable by x-rays alone.

(Skiagram by Dr. Hugh Walsham.)

swelling appears. This is at first bony hard, and only as the shell of bone yields does softening occur, or crackling on pressure. The lymphatic glands are not enlarged, and metastases do not occur. In the early stages, diagnosis has to be made from rheumatism and chronic abscess, and later from chronic osteomyelitis and periosteal sarcoma; it is easily made by the aid of x-rays as a rule, but it is most important not to mistake the callus that is produced after fracture for a sarcoma; this mistake is not always obviated even by the use of the x-rays, unless the latter reveal the line of fracture as well as the callus around it.

Sarcoma may also invade the bones from outside, having started in the subcutaneous or deeper soft tissues outside the bone (Fig. 285).

Carcinoma is always secondary (Fig. 62, p. 152). Squamous-celled carcinoma may spread to the tibia from an epitheliomatous ulcer of the leg, or to the jaw from the lip or floor of the mouth. It is mostly spheroidal-celled carcinoma which infects bone by metastatic growths, particularly from the breast or from the thyroid gland. A swelling of bone may be found, but this is rarely discovered until attention is called to it by a spontaneous fracture.

Fig. 285.—Skiagram of a sarcoma of radius and ulna; the growth surrounds the bones and is eating into them; it was not primarily a bone growth. Male, age 28. (Skiagram by Dr. C. Thurston Holland.)

V. CYSTS.

Blood cysts are found in degenerating sarcomata.

Hydatid cysts are uncommon in this country. They affect the diaphyses of the long bones, converting the shaft into a thin-walled tube, which undergoes spontaneous fracture.

Fig. 286. Skiazgram giving the antero-posterior view of a myeloid sarcoma of the lower end of the radius. The tumor is at a later stage than that depicted in *Tr.*, 284.

Fig. 287 shows the same growth as Fig. 286 but seen from the lateral aspect. (Skiazgrams by Dr. Hugh Walsbaum.)

They would hardly be suspected unless there were known hydatid disease elsewhere, especially in the liver (p. 375).

Cysts of the jaw or *dentigerous cysts*, are considered in the article on SWELLING OF THE LOWER JAW (p. 683).

George E. Gask.

SWELLING OF THE FACE. In this article are included only swellings of the skin and subcutaneous tissues. Malignant and other diseases of the facial bones, etc., are considered under SWELLING OF THE JAW (p. 683), and SWELLING ON A BONE (p. 667). SWELLING OF THE SALIVARY GLANDS is discussed on p. 694. Contusions and injuries to the face are so obvious that they need no mention. The remaining swellings will be classified as (1) *Non-inflammatory*; and (2) *Inflammatory*.

Non-Inflammatory Swellings.

Renal and Cardiac Edema.—If the whole face is puffy and the eyelids are oedematous, the urinary and cardiac systems are to be examined for disease. For swelling due to obstruction of the superior vena cava by mediastinal fibrosis, aneurysm, or new growth, see OEDEMA (p. 411), and VEINS, VARICOSE THORACIC (p. 750).

Angioneurotic Edema is a disease characterized by the occurrence, sometimes periodical, of local oedematous swellings, more or less limited in extent and of transient duration. It is not confined to the face, but the eyelid is a common situation (Fig. 178, p. 412), and also the lips and cheek. It may be simulated closely by *urticaria* following the taking of fish or pork; or a somewhat similar effect produced by some drugs, notably by aspirin in certain patients.

Tumours are not common. They may be fibroma, lipoma, epithelioma, or sebaceous cyst.

Inflammatory Swellings.—Often the cause is obvious: for instance, a *boil*, *carbuncle*, or *suppurating wound*; or the ‘blubber-lips’ that result from chronic *lymphangitis*.

Erysipelas is prone to occur on the face. It is marked by a vivid red oedematous swelling, associated with fever. The redness tends to spread, the edges being raised and well defined from the healthy skin. The oedema may be continuous, or it may disappear in one place and re-appear in another. In the very severe cases the fever is high, rigors occur (*Fig. 245*, p. 568), the cuticle may be raised in blebs, and sloughing may ensue.

Alveolar Abscess and *Dental Caries* are fertile sources of facial swelling, also abscess in the nasal sinuses. (See SWELLING OF THE JAW, p. 683.)

Anthrax chiefly affects operatives in wool and horse-hair factories and workers of raw hides. The disease is characterized by the formation of a vesicle, which bursts, forms a scab, and then becomes surrounded by a ring of vesicles, and around this is an area of oedema. The diagnosis is made by the microscope. A drop of fluid from one of the vesicles contains large, square-ended, Gram-staining bacilli, which have a characteristic growth on culture media.

Vaccinia.—An accidental infection about the face may be mistaken for an anthrax pustule. If inquiry into the attendant circumstances is not sufficient to exclude the graver disorder, a bacteriological examination should be made.

Primary Syphilitic Sore, if found on the face (*Fig. 23*, p. 73), is generally situated on the upper lip. It is not so indurated as when on the glans penis, but the surrounding oedema is more marked, and the neighbouring lymphatic glands are considerably enlarged. The condition is often missed because it is not expected. An absolute diagnosis can be made by finding the spirochæta in the serum discharged from the ulcer (*Plate XXVIII*, *Fig. J*, p. 614), and by Wassermann’s test.

Insect Bites—from mosquitoes, gnats, bees, etc.—often cause large, lumpy, irritating swellings. The only difficulty in diagnosis is when they become infected with pyogenic organisms.

The various skin diseases which may be associated with swelling of the face are considered under PUSTULES (p. 557); VESICLES (p. 753); WHEELS (p. 771); ETC.

George E. Gask.

SWELLING, FEMORAL.—By the femoral region is meant Scarpa’s triangle. It is very easy to define on paper what is a femoral swelling, but in a fat patient it may be very difficult. The two great landmarks which, with care, can always be made out, however fat the patient, are the spine of the pubes and the anterior superior spine of the ilium; a line joining these two points and curving slightly downwards separates the inguinal from the femoral region, and indicates Poupart’s ligament. Mistakes are often made, especially in fat people, because a horizontal crease in the thigh which lies below—sometimes as much as two inches below—is mistaken for the ligament. The first point in making the diagnosis is to decide definitely that the swelling is femoral, and then to decide its nature.

It may be obvious at once what the swelling is: for instance, a well-marked acute abscess, with redness and oedema of the skin and an undoubted source of infection, such as a sore toe; or, a rare occurrence, an aneurysm of the femoral artery, showing expansile pulsation. Supposing, however, the signs are not so clear, the various conditions may be classed broadly under two heads: (1) *Swellings that are reducible and give an impulse on coughing*; (2) *Swellings that are irreducible and do not give an impulse on coughing*.

Reducible Swellings with an Impulse are: (a) Femoral hernia reducible; (b) Saphena varix; (c) Psoas abscess. All these give an impulse on coughing; are, or may be, reducible on pressure; may disappear on lying down and reappear on standing. How then is one to distinguish between them?

(a). *Femoral Hernia (reducible).*—The sex of the patient is no real guide, for though it is more common to find a femoral hernia in a woman than in a man, this is not sufficient to base the diagnosis on. Before puberty it is rare in either sex. A femoral hernia leaves the abdomen through the femoral canal and turns directly forward, forming a tumour in the upper and inner part of the femoral region; then, following the line of least resistance, it turns upwards, extending often above Poupart’s ligament, thus simulating an inguinal hernia. More rarely, the hernia extends downwards along the femoral vessels. Its course must be remembered in attempting to discover whether the swelling is reducible. If it is large and contains intestine it will be resonant, and a gurgling may be heard or felt on

reduction, distinguishing it at once from all other femoral swellings. If it is reduced and the finger held over the femoral aperture, the hernia will be felt projected forcibly against the finger when the patient is asked to cough. If a swelling is complained of, and none is found even on standing and straining, it is suggestive of femoral hernia with only occasional descent, and the patient should be examined at another time after exercise.

(b). *Saphena Varix* is a localized dilatation of the saphenous vein at the saphenous opening, immediately before it joins the femoral vein. It may easily be confounded with a femoral hernia, for it forms a swelling in the ordinary position of a femoral hernia, it disappears on lying down, reappears on standing, and gives an impulse on coughing. A little care, however, should suffice to distinguish the two. The impulse is quite different—in a saphena varix it is more in the nature of a thrill, such as may be felt in a varicocele or in big varicose veins in the leg. If, while the patient is standing, a finger is pressed on the swelling, it collapses gradually, and as the finger is withdrawn the swelling follows, regaining its shape like an air-ball, whereas a hernia comes out with a pop. A saphena varix is almost always associated with varicose veins in the leg, though, owing to the persistence of valves, none may show between the knee and Scarpa's triangle.

(c). *Psoas Abscess*.—The need to differentiate between this and the two conditions mentioned above exists only when the abscess has extended from the iliac region, has passed under Poupart's ligament and the femoral vessels, and is pointing in the inner part of Scarpa's triangle. There is an impulse on coughing and the swelling is reducible; but another swelling is to be found above Poupart's ligament, and fluctuation is to be obtained between the two. Conclusive proof can be found by an examination of the back. This should be made with the patient standing and the whole length of the back and the hips exposed. An undoubted angular kyphotic curve may be seen at once, or, if that is not present, there may be rigidity and impaired movement denoting some disease on the anterior surfaces of the bodies of the vertebrae.

Irreducible Swellings without Impulse: (a) Femoral hernia—irreducible; (b) Lymphatic glands—inflammatory or malignant; (c) Primary tumours—lipoma, fibroma, sarcoma; (d) Ectopic testis.

(a). *Femoral Hernia*. The irreducibility may be accounted for in four ways: (i) Strangulation; (ii) A piece of omentum adherent to and plugging the neck; (iii) An empty sac, but a mass of extraperitoneal fat round it; (iv) A hydrocele of the sac.

If strangulation has occurred there will be the signs of intestinal obstruction, viz., vomiting and constipation. It must be remembered that the swelling may be but a small one, and when the patient is very fat it may be missed.

It is usual to find around the sac of a femoral hernia a quantity of extraperitoneal fat, even in a thin person, and it is quite impossible to say without dissection whether the swelling is due to a plug of omentum inside the sac or to a collection of fat outside it.

A hydrocele may be formed as a result of a long-standing hernia into which there has been no descent of bowel or omentum, and in which the communication with the general peritoneal cavity has become constricted or closed. The sac may then become cystic and filled with fluid. The feeling of fluctuation may be obtained in the swelling, though it is often only on dissection that the exact nature of the condition is revealed. It is to be noted that in all cases of hernia the swelling is single, and that though it may be movable in some directions, it is always tied down by its neck to the aperture of the femoral canal.

(b). *Enlarged Glands* may be: (i) Inflammatory; (ii) Malignant (see p. 381).

Chronically inflamed glands may be hard to differentiate from a small irreducible femoral hernia. The whole limb is to be examined to see whether there is any possible source of infection, and the whole patient to see whether there is a general enlargement of the glands, as in lymphadenoma. The chief distinguishing feature between the two conditions is that femoral hernia forms only one swelling, whilst it is very rare for only one gland in its group to be picked out by an infecting agent, and not the others. Therefore, if there is more than one swelling the chances are that these are glands. Perchance both conditions are present, a femoral hernia and enlarged glands; a very difficult combination unless the femoral hernia happens to be reducible or gives an impulse on coughing. In such a case an attempt should be made to feel the neck of the sac running up to the femoral canal.

(c). *Primary Nec Growths* are rare in this situation. They may be lipoma, fibroma,

or sarcoma. The innocent tumours are noted for their free mobility in all directions. A primary sarcoma is diagnosed rather by exclusion and by its malignant characteristics.

(d), *Ectopic Testis*.—One of the places into which a testis may be drawn abnormally is Scarpa's triangle, which it reaches by passing over Poupart's ligament. The facts that the swelling has the shape of the testis, though generally smaller than normal, and that the corresponding half of the serotum is empty, make the diagnosis easy.

Mention may be made here of those swellings which are neither truly femoral nor truly inguinal, but betwixt and between, and bulge Poupart's ligament forwards. They are generally deep, and on that account obscure. They may be due to:—

1. Distention of the hip-joint, as in tuberculous disease of the hip.
2. Distention of the bursa between the tendon of the ilio-psoas muscle and the capsule of the hip-joint. If large, the swelling may be quadrilateral in shape, and owing to its sensitiveness to pressure the leg is kept in the position of greatest ease, i.e., slightly flexed, abducted, and externally rotated. It is often difficult to distinguish from psoas abscess or from distention of the hip-joint, with which, indeed, it often communicates. Diagnosis may be aided by puncturing the swelling with an aspirating needle.
3. Osteophytic outgrowths from the acetabulum in osteo-arthritis of the hip-joint.
4. A parametric abscess.

George E. Gask.

SWELLING IN THE ILIAC FOSSA (LEFT).—For the general method of examination, compare SWELLING IN THE ILIAC FOSSA (RIGHT).

Swellings connected with Structures normally present in the Left Iliac Fossa.

The Sigmoid Flexure cannot be felt normally. It becomes palpable as a cylindrical swelling if distended with feces; or if it is thickened, as it may be in chronic ulcerative colitis or congenital dilatation of the colon.

Carcinoma of the Sigmoid.—Next to the rectum the sigmoid colon is the most common seat of cancer in the bowel. If of the scirrhus or ring type no lump may be felt, and the condition may not be discovered until intestinal obstruction has supervened. When infiltrating the bowel widely, and especially when the tumour is undergoing colloid degeneration, a swelling forms which is most evident on bimanual examination after the bowels have been well cleared by enemata. If a lump can be felt in the sigmoid flexure of a middle-aged patient, the strong probability is that it is a carcinoma, and whether there are other clinical signs or not, the diagnosis should be made sure by actual inspection of the swelling by means of the sigmoidoscope, or even through an abdominal incision. It may be simulated by subacute inflammatory changes around an acquired pouch or diverticulum of the colon—*diverticulitis*; this sometimes subsides by itself, and the course of the case serves to exclude carcinoma; more often the symptoms call for operation, and the diagnosis is made by laparotomy.

Enlarged Lymphatic Glands.—The glands forming a chain round the external iliac vessels may be swollen as the result of pyogenic infection, which has spread up through the femoral lymphatics or from secondary deposit of some malignant growth starting either in the leg, the external genitals, or the pelvis. The enlargement is seldom very great; the source of infection is usually obvious.

Aneurysm of the External Iliac Artery is very rare. It is recognized at once by its expansile pulsations.

Swellings connected with Structures not normally present in the Left Iliac Fossa.—These may be: Swellings coming down from above, extending upwards from the pelvis, or pushing forward from behind.

Swellings coming down from above.—The *Spleen*, if much enlarged, may reach even as far as the left iliac fossa. It is recognized by its rounded margin, and the notch on the inner edge. (See SPLEEN, ENLARGEMENT OF THE, p. 628.) A *kidney*, if freely movable, may be displaced as far as the pelvis; on rare occasions it becomes fixed there by inflammation.

For swellings extending up from the pelvis and those pushing up from behind, see the article on SWELLING IN THE ILIAC FOSSA (RIGHT).

George E. Gask.

SWELLING IN THE ILIAC FOSSA (RIGHT).—It is not always easy to say whether there is or is not a definite swelling in the right iliac fossa, for it may be only small and

deep, or be masked by abdominal rigidity or fat. In all cases a careful inspection of the abdomen is first to be made, the patient lying on the back with the whole of the abdomen and the lower thorax exposed. Most mistakes result from want of a complete examination, which cannot be made through a tiny gap in the clothes. Before even touching the abdomen, much may be made out by the use of the eyes, and the points to observe are: (1) The presence or absence of an obvious tumour; (2) Whether the abdominal muscles move freely; (3) The conformation, etc., of the tumour, should one be present, and whether it moves on respiration.

Palpation is then to be employed, and this method will go a long way to elucidate the complaint, for it will be recognized at once whether there is a well-defined swelling, such as a carcinoma of the cæcum; or an indefinite swelling, such as is common in appendicitis. Distention with wind or an accumulation of feces may cause a considerable swelling, but any doubt as to these may be cleared up by administering an enema. If the swelling persists, the questions that arise are: is it connected with one of the structures normally present in the right iliac fossa, especially the cæcum or the appendix; is it springing from the bone; is it arising from some organ invading this space, for instance the uterus or its appendages, the right ovary, or the bladder; or from some structure displaced downwards such as the gall-bladder, stomach, or right kidney?

A.—SWELLINGS CONNECTED WITH STRUCTURES NORMALLY PRESENT IN THE RIGHT ILIAC FOSSA.

The Appendix.—*Appendicitis* is so common that it is put first. Most well-marked attacks of appendicitis are associated at some period with a swelling, though in the acutest and gravest forms the latter may be absent. The appendix itself, even if swollen and thickened, can rarely be felt by palpating the abdomen, and the swelling is due to paralytic distention of the cæcum, local œdema, or the formation of an abscess. The chief indications of appendicitis are: pain, tenderness, local rigidity, and swelling in the right iliac fossa, associated with a furred tongue, vomiting, constipation, an increase of the pulse-rate, and a rise of temperature. Usually there is also diminished muscular movement in the lower part, or it may be over the whole, of the abdomen. Any movement is painful, and in order to relax the tension the patient lies with the right leg drawn up. A rectal examination should be made, for a bulging abscess may be felt by this route. Micturition is frequently abnormal, with a tendency to be either painful or unduly frequent. A leucocyte count is of great service, for in almost every case of acute appendicitis the number of white cells is increased.

Tuberculosis of the Cæcum or of the Lymphatic Glands in the neighbourhood of the Cæcum.—This is not nearly so common as appendicitis, but is not so rare as is often imagined, and when it does occur it is frequently mistaken for appendicitis; it may be only after the abdomen has been opened that the mistake is discovered. The glands become enlarged and painful, and there may be some local peritonitis over them which makes the diagnosis very difficult. Usually there is some other tuberculous focus about the patient, especially in the lungs, which should be examined with particular care, the x-rays and sputum analysis not being omitted. If doubt exists recourse may be had to a diagnostic injection of Koch's old tuberculin, and the opsonic index may be taken both before and after abdominal massage. Von Pirquet's test is not very trustworthy.

Actinomycosis starting in the cæcum and appendix is another inflammatory condition which may cause a swelling and give the signs of a chronic abscess. The diagnosis can only be made with certainty by an incision and the finding in the pus of the characteristic yellowish granules (occasionally black—the gunpowder variety), and the recognition under the microscope that these granules are formed of a Gram-staining streptothrix (*Plate XXVIII*, p. 614).

Carcinoma of the Cæcum gives rise to a swelling which occasions few symptoms, unless the passage of feces is affected and intestinal obstruction results. It is important, however, from the point of view of treatment that an early diagnosis be made. The presence of a non-inflammatory swelling of long standing in the right iliac fossa, with a history of wasting, is very suggestive of a carcinoma, and early recourse should be had to the only sure diagnostic method, namely, laparotomy. Very rarely is there passage of blood or mucus by the bowel to help one.

Intussusception usually occurs in children, especially during the latter half of the first year of life, and its presence is indicated by the signs of intestinal obstruction, namely, vomiting and constipation, and by the passage of blood and mucus by the rectum. The intussuscepted portion may be palpable, and in some cases it lies in the right iliac fossa, though more frequently in the right hypochondrium. Chronic intussusception may also cause a swelling which generally baffles diagnosis, and is commonly mistaken for an enlarged kidney.

Aneurysm of the Iliac Arteries is very rare, but it is generally easy of diagnosis by reason of the expansile pulsation of the tumour.

**B.—SWELLINGS CONNECTED WITH STRUCTURES NOT NORMALLY PRESENT
IN THE RIGHT ILIAC FOSSA.**

These may be: Swellings coming down from above, swellings extending upwards from the pelvis, or swellings pushing forward from behind.

Swellings coming down from above.

The liver, or an enlarged or abnormal lobe of the liver—Riedel's lobe (p. 366)—is sometimes very deceptive. The facts that there are few symptoms, that the mass moves on respiration and is continuous with the liver, and that there is no intervening area of resonance between it and the liver, should assist the diagnosis; but cases are not infrequently mistaken for enlargement of the gall-bladder. A *suppurating gall-bladder* has been opened in the right iliac fossa under the mistaken diagnosis of appendix abscess, for there is often no jaundice in these cases. Laparotomy may be the only means of certain diagnosis.

The kidney, if unduly movable, may be displaced and come to lie in the right iliac fossa. It is recognized by its shape and free mobility. A tumour of the kidney or a large hydro- or pyo-nephrosis may also invade the upper part of this fossa.

Carcinoma of the Stomach—with extreme distention of the stomach. It is a surprising fact that the stomach may be so distended as to enable the pylorus to lie in the right iliac fossa. The history of copious vomiting, the wasting, the distention of the stomach, and examination with the x-rays after the administration of bismuth make the diagnosis easy.

Swellings extending upwards from the Pelvis, and attached to the uterus and its appendages, can usually be felt dipping into the pelvis; vaginal and rectal examinations will assist the diagnosis; and there are symptoms, such as disturbances of menstruation, indicating their nature. Such swellings might be a large *fibroid of the uterus*, a laterally-placed *ovarian cyst*, *pregnancy*, an *abscess* extending from the broad ligament, or a *pouch of a bladder* distended from obstruction to the urethra.

It happens not infrequently that there may be difficulty in determining between an inflamed appendix and an enlarged and tender ovary, particularly when the attacks of pain are coincident with the menstrual periods. These generally turn out to be due to the appendix, though both may be implicated, the appendix having become adherent to the ovary or tube.

Pyosalpinx is easily confused with appendix abscess; the fact that it is associated with vaginal discharge, or is subsequent to parturition, puts one on the right track. Vaginal examination is essential in these cases.

Swellings pushing forward from behind.

These may be solid, such as *sarcoma* or *chondroma* of the pelvic bones. Here the tumour will be immovable apart from the pelvis, and a skiagram makes the condition clear. If the swelling is fluid it may depend on *suppurative osteomyelitis* of the ilium; or on a *tuberculous* affection of the ilium, either primary, or secondary to hip or sacro-iliac joint disease; or on *tuberculosis*, *necrosis*, or *suppuration of the lumbar vertebrae*.

If the swelling cannot be attributed to any of the causes mentioned above, it is to be remembered that a wandering organ, such as a spleen or kidney, may find its way into the right iliac fossa. Rarities such as hydatid cysts of the peritoneal cavity are met with so seldom that they merit no more than mention.

George E. Gask.

SWELLING, INGUINAL.—A variety of swellings may appear in the groin, and be very difficult to differentiate. The following are some of the most important:—
(1) *Enlarged glands*: (a) inguinal; (b) femoral; (c) iliac. (2) *Abscess, acute or chronic.*

- (3) *Hernia*: (a) inguinal; (b) femoral; (c) obturator. (4) *Retained testicle*. (5) *Hydrocele*. (6) *Tumours of the cord or round ligament*. (7) *Aneurysm and other vascular swellings*. (8) *New growths*. (9) *Distended psoas bursa and other cysts*.

1. Enlarged Glands.—There are two chief groups of glands in the groin. The most commonly affected are the *inguinal*, which lie in the subcutaneous tissues about Poupart's ligament, and drain the external genitals, the anus, the umbilicus, the lower parts of the abdomen and back, the buttock and the upper third of the thigh. The *femoral* glands rest below the saphenous opening and drain the lower limb below the upper third of the thigh. It must be remembered, however, that the lymphatic drainage is somewhat erratic, so that a sore toe may sometimes induce enlargement of an inguinal gland only. The *iliac* glands drain the inguinal and femoral set, and consequently often enlarge secondarily to these; but they also communicate freely with the abdominal lymphatics and may become infected from them.

Enlarged glands in the groin are nearly always multiple, and usually subcutaneous, so that they are easy to recognize as glands; but a solitary one adherent to the saphenous opening may be almost impossible to distinguish from an irreducible omental femoral hernia or a hydrocele of a hernia sac.

The iliac glands just above Poupart's ligament are more difficult to palpate, because they lie deep to the abdominal muscles, but their enlargement is generally secondary to disease of the superficial glands, and this often gives the key to the diagnosis of an obscure swelling in this region.

Some Causes of Enlargement of the Groin Glands.—(a) Mechanical or chemical irritation; (b) Septic infection, for instance from genital sores or from sores on the toes or legs; (c) Tubercle; (d) Syphilis; (e) Other specific diseases, such as rubella and bubonic plague; (f) Lymphadenoma; (g) Lymphatic leukaemia; (h) Malignant diseases; secondary carcinoma; secondary or primary sarcoma.

(a). The glands become slightly enlarged and tender as a result of the *mechanical irritation* of a truss, and more frequently the *bites of parasites* such as the *Pediculus pubis*. The glands generally remain movable, and they rarely suppurate.

(b). *Septic infection* may follow insect bites; but more commonly a septic sore or recent scar can be discovered upon examination of the area drained by the glands. Septic glands either soon subside or cease to be tender after the removal of the source of infection, or they enlarge rapidly, become adherent, and suppurate within three or four weeks of their first enlargement.

(c). This, and the amount of inflammation of the skin over them, distinguishes septic from *tuberculous* glands which do not suppurate for some months, and then with but little inflammatory reaction. Epitheliomatous glands may suppurate towards the end.

(d). The true *syphilitic gland* is hard, movable, and only moderately enlarged, and the existence of the indurated chancre usually makes the diagnosis easy. The *Spirochæta pallida* may be detected, or Wassermann's serum test may be positive; but a negative reaction is not conclusive. It must not be forgotten that, as an apparently soft sore (septic) may later become hard and definitely syphilitic; therefore suppuration of a bubo does not disprove syphilitic infection. Instances of mixed infection by sepsis and syphilis are fairly common.

(f). In *lymphadenoma* the groin glands are rarely affected alone, and the smooth, soft enlargement of many glands without signs of inflammation, associated with increasing anaemia and intermittent pyrexia (Fig. 247, p. 570), makes the diagnosis fairly easy. The spleen may be affected at the same time.

(g). Blood examination will give pathognomonic results in cases of lymphatic leukaemia (p. 25).

(h). *Malignant disease* of the groin glands is nearly always epitheliomatous, and secondary to a primary epithelioma of the skin or mucous membrane in the area drained by the glands. The primary growth, especially at the anus, may be very small, and the patient may be unaware of its existence. The other main points in distinguishing epitheliomatous glands are their exceeding hardness; their progressive but slow growth; their early adhesion to the deep fascia and skin; and the amount of pain to which they give rise without signs of inflammation. Late in the disease they may suppurate or slough, with severe hæmorrhage. Intra-abdominal carcinoma, especially of the ovary or colon, sometimes causes enlargement of the inguinal glands.

Sarcoma of the groin glands is rare; it may be primary or secondary. Usually these are not the only glands affected. They grow with great rapidity and remain smooth and fairly soft until they attain a great size, when they may fungate through the skin. They are distinguished from lymphadenoma by their very rapid growth and the absence of pallor until late in the disease. Melanotic growths of the skin give rise to rapidly growing smooth glands, whose pigment may be visible through the skin. The primary growth or ulceration in connection with the skin, particularly of a toe, may not show pigmentation, and its serious import may thus be overlooked.

2. Abscess.—(a). *Acute.* The only common cause of acute abscess in the groin is suppuration of the glands, and a search must always be made for a primary source of infection, especially about the genitals. A hernia may occasionally suppurate, and an appendicular abscess may point just above Poupart's ligament; but there is then a history of the characteristic symptoms of appendicitis, and the pus when released has the suggestive smell of the products of the *Bacillus coli communis*. Both tuberculous and epitheliomatous glands may become acutely inflamed and suppurate.

(b). *Chronic abscess* here may be due to caries of the sacro-iliac joint or to hip disease, or it may arise from tuberculosis of the superficial or deep glands. Psoas abscess, due to caries of the spine, is distinguished by fluctuation from the loin to the groin, and often bimanually, above and below Poupart's ligament, external to the femoral vessels. There are also some tenderness and rigidity, and often deformity of the lumbar or lumbo-dorsal spine. Iliac abscess does not extend up into the loin, and is placed farther out than psoas abscess. Moreover, there may be pain and tenderness over the sacro-iliac joint, and a limping gait. In hip disease, especially in children, the floor of the acetabulum may give way, and an abscess may thus enter the true pelvis, whence it often ascends and becomes palpable above Poupart's ligament. The diagnosis of the cause is easy from the well-marked signs of hip disease.

3. Hernia.—In examining swellings in the groin, hernia must always be considered. Three chief varieties occur here: inguinal, femoral, and very rarely obturator hernia. A hernia gives an impulse on coughing, but so do psoas abscess, psoas bursa, and a saphena varix. All these may also be reducible like a hernia. A psoas abscess presenting below Poupart's ligament has been mistaken for a femoral hernia; but it is distinguished by its position—external instead of internal to the femoral vessels. Moreover, it is dull on percussion, whereas a hernia is resonant except when it contains omentum alone. Psoas bursa is also placed outside the vessels. A saphena varix has often been mistaken for femoral hernia; but it can be distinguished from the latter easily because it returns after complete reduction, even though the finger is kept pressed against the femoral canal. It is not always easy to distinguish the three hernia which occur in the groin, but close attention to the following points usually leads to a correct diagnosis. An inguinal hernia is both seen and felt to be *above* the fold of the groin and *above* Poupart's ligament; whereas a femoral hernia is seen and felt to be *below* the fold of the groin and *below* Poupart's ligament. It is to be remembered that when a femoral hernia becomes very large and loculated, it generally extends upwards and inwards over Poupart's ligament. Still, the bulk of it remains below the fold of the groin in the upper and inner part of the thigh. An inguinal hernia often extends into the scrotum or labium; a femoral hernia never does this. The neck of an inguino-scrotal hernia is above and internal to the spine of the pubis, whereas the neck of a femoral hernia is below and external to this bony prominence. Inguinal hernia is most easily reduced by pressure directed upwards, backwards, and outwards, whereas a large femoral hernia is most easily reduced by pressure directed at first backwards and downwards, and then directly upwards. In difficult cases it is a good plan to reduce the hernia, then to get the patient to stand up, while the surgeon makes firm pressure over the internal ring and asks the patient to cough. A femoral hernia may then come down, but not an inguinal. Similarly, pressure can be made on the femoral canal; this prevents the descent of a femoral hernia, so that if the swelling now returns it is inguinal. In this connection it may be well to remember that femoral hernia is rare in males, and also in all females under maturity. The prevalent belief that femoral hernia is more common than inguinal in grown-up women is wrong, inguinal being more common at all ages and in both sexes. It is excessively difficult to differentiate between an irreducible femoral hernia containing omentum and an enlarged gland at the

saphenous opening or in the femoral canal. A hydrocele of a hernial sac gives rise to the same difficulty, and sometimes an exploration becomes necessary on account of the danger of overlooking femoral hernia, and the risk of strangulation.

The diagnosis between femoral and obturator hernia is not very difficult; it is far more common to overlook an obturator hernia altogether. When an external swelling is caused by an obturator hernia, it is placed farther inwards, and it is more vague than a femoral hernia. Moreover, there is pain shooting along the inner side of the thigh, and generally the signs and symptoms of strangulation. Further, a tender swelling can be felt at the obturator foramen upon vaginal or rectal examination.

The two chief varieties of inguinal hernia, the oblique and the direct, are usually distinguished quite easily. Direct hernia is rare, and is more globular in shape than the indirect or oblique hernia; the spermatic cord is antero-external to it, and postero-internal to the ordinary oblique hernia. Direct hernia is placed a little farther in and higher up than the oblique. It is generally much more easily reduced, but returns again with striking abruptness when the patient coughs. It rarely travels into the scrotum, and it is uncommon before the age of thirty. There is often a history of sudden onset after some violent straining effort.

4. **Retained Testicle.**—The most important points in the diagnosis of this condition are the absence of the organ from its proper place, and the presence of a swelling about the inguinal canal. Occasionally, the testicle may be maldescended, or after leaving the external ring may have found its way into the upper and inner part of the thigh, where it simulates a femoral hernia, or into the perineum. The swelling in the groin may give the characteristic testicular sensation, or the condition may be associated with attacks of pain which have been mistaken for appendicitis or intestinal colic. It is practically always accompanied by actual or potential hernia into the tunica vaginalis, which is in direct communication with the abdominal cavity.

5. **Hydrocele.**—The neck of the sac of either a femoral or an inguinal hernia may become obstructed, and a hydrocele of the sac may then develop. This may become inflamed and give rise to considerable difficulty in diagnosis. Strangulated or irreducible omental hernia may be simulated, and sometimes an exploration is the only way of settling the diagnosis. It is more easily distinguished from strangulated hernia containing bowel, because it is dull on percussion, and the bowels are not obstructed. An encysted hydrocele of the cord occupying the inguinal canal is sometimes difficult to distinguish from inguinal hernia; but it is not completely reducible, and it is dull on percussion. It is not granular like an omental hernia, and it can even be shown, with some difficulty, to be translucent. Like a hernia, it gives an impulse on coughing.

6. **Tumours of the Cord or Round Ligament.**—The only common tumours of these structures are (a) Lipoma and (b) Fibromyoma of the round ligament. The former is so soft and displaceable that it gives an impulse on coughing, and is often mistaken for an omental hernia, especially in stout patients. The latter is hard and smooth, somewhat simulating the ovary or a thick-walled hydrocele of the canal of Nuck, for either of which it may be mistaken, a certain diagnosis only being possible by exploration.

7. **Aneurysm and other Vascular Swellings.**—Aneurysm of the external iliac artery may be mistaken for a vascular sarcoma arising from the pelvis. It can generally be recognized by the classical signs of aneurysm, such as expansile pulsation, bruit, weakening and delay of the corresponding femoral pulse, and marked reduction of the size of the swelling as a result of pressure on the common iliac artery. Saphenous varix has been referred to above.

8. **New Growths.**—Sarcoma of the pelvic bones or of the soft parts in this neighbourhood is hardly altered in size by pressure upon the common iliac artery, nor does it give such a loud bruit or the *expansile* pulsation, which are characteristic of aneurysm. The x-rays may give evidence which is valuable in distinguishing aneurysm from sarcoma.

9. **Distended Psoas Bursa** may give rise to pulsation communicated from the external iliac artery. On careful examination it can be distinguished by the absence of the classical signs of aneurysm already mentioned, by its translucency and irreducibility. There may also be signs of osteo-arthritis of the hip-joint.

R. P. Rowlands.

SWELLING, INGUINO-SCROTAL.—The most important swellings which occupy both the inguinal and scrotal regions are:—(1) *Hernia*; (2) *Varicocele*; (3) *New growth*; (4) *Hydrocele*; (5) *Lymphangioma*.

Hernia is by far the most common, and when it is reducible there is very little difficulty in the diagnosis. It gives the characteristic impulse on coughing, is resonant on percussion, and when it contains bowel it gurgles on reduction. When it contains omentum only, the diagnosis is more difficult. To distinguish it from a *varicocele* it is only necessary to reduce the swelling and then to place the finger firmly upon the inguinal canal; a varicocele returns in a few seconds, but a hernia does not. Moreover, an omental hernia has a granular feel which distinguishes it from varicocele. An irreducible omental hernia is distinguished from varicocele by its irreducibility; but it may be confused with a very rare condition, lymphangioma of the cord. An irreducible hernia may be confused with encysted hydrocele of the cord. When a hernia contains bowel its resonance distinguishes it; but when it contains omentum there is more difficulty. An *encysted hydrocele* or a *hydrocele of a hernial sac* is more even and elastic than an omental hernia, which is usually nodular. Moreover, it may be possible to show that a hydrocele is translucent. This help is not available when the cyst is deep or contains blood, which it occasionally does as the result of injury or strangulation of the omentum at the neck of the hernial sac. A *strangulated hernia* is distinguished from an inflamed hydrocele by the greater severity of the vomiting and other constitutional symptoms, and the completeness of constipation. Moreover, as stated above, a strangulated hernia containing bowel is resonant on percussion. Strangulated omentum may be very difficult to distinguish from an inflamed hydrocele or a hydrocele of a hernial sac, especially as either of these may complicate it. In such cases an exploration is the final appeal. It should not be forgotten that two or more varieties of inguino-scrotal swellings may co-exist. For instance, it is common to overlook a hernia which may complicate a varicocele, and this is especially true when the hernia contains only omentum. Again, it is quite common for a hydrocele of the tunica vaginalis or of the lower part of the cord to complicate an ordinary omental hernia. In such a case, a part of the swelling may be reducible, and, unless the patient is examined in the upright position, the upper part of the hernia may fail to appear during the examination. Again, the bowel may be reducible, while the omentum, being adherent, is not reducible, and may be mistaken for an encysted hydrocele of the cord. It is very important in all these cases to examine for translucency.

Growths of the testicle involving the inguinal region are, as a rule, easily diagnosed, because of the history and the observed course of the disease, and the general condition of the patient at the later stages. *Growth of the retained testis* may give rise to more difficulty: it may be confounded at first with hydrocele of the tunica vaginalis, hydrocele of the hernial sac, or omental hernia, unless care be taken to ascertain if both the testicles are present in the scrotum. *Torsion of a retained testicle* with strangulation of its vessels has sometimes given rise to inguinal or inguino-scrotal swelling which has closely simulated strangulated hernia; but although there may be much abdominal pain and local tenderness, vomiting is rarely so severe as in strangulated hernia, and the bowels are not really obstructed. Retained testicle is dull on percussion, and thus is distinguished from strangulated hernia containing bowel, and can only be confused with strangulation of the omentum.

The oblique hernia is the only common one to reach the scrotum. It may be acquired or congenital. In about one-tenth of the congenital herniæ the bowel and the testicle are in the same peritoneal sac; in the great majority of congenital herniæ the two sacs are distinct, the testicle lying below the hernia. The same is true of acquired inguinal hernia. It is important to remember that nearly all inguinal herniæ descend into congenital or pre-formed sacs, and this is especially true of herniæ appearing apparently for the first time in young adults. In such cases, on careful inquiry, it may be found that a hernia existed and was apparently cured by a truss, in infancy. Again, it may be learned that the hernia reached the scrotum on its first descent, whereas acquired inguinal hernia very gradually develops as the result of straining in men past middle age. The swelling at first appears only in the inguinal region, and there the swelling increases in size, and extends into the scrotum only after some months or years. Very rarely, a direct hernia may reach the scrotum; it is distinguished from oblique hernia by the fact that

the cord is antero-external to it, instead of postero-internal, as in an oblique hernia. It may be possible in some cases to identify the contents of a hernia. Attention has been drawn above to the method of distinguishing the bowel from the omentum. Sometimes the appendix can be felt distinctly, especially in right-sided hernia. Occasionally the bladder may be identified, as in Astley Cooper's classical case. When the patient has apparently emptied the bladder, the surgeon reduces the hernia, and the patient is immediately able to pass more water.

R. P. Roachlands.

SWELLING OF THE JAW, LOWER.—Swelling of the lower jaw may sometimes be mistaken for, or masked by, swelling of the cellular tissues in front of it. The real site of the swelling is first to be ascertained by opening the mouth and running the finger along the outer and inner borders of the mandible and comparing the two sides.

There are many causes for enlargement, and they may be subdivided under the following headings:—

1. *Injury.*
2. *Inflammatory affections.*
3. *Tumours* (Innocent—Fibroma, osteoma, and odontoma.
 (Malignant—Sarcoma and epithelioma.
4. *Acromegaly.*
5. *Leontiasis ossea.*

Injury.—A *hematoma* or traumatic *periostitis* may follow on a blow. If the injury has been sufficient to cause a *fracture*, the abnormal mobility of the fragments, the irregularity of the line of the teeth and arch of the jaw, and the laceration of the gums, are sufficient to indicate the injury. The nearer the line of fracture is to the symphysis, the more marked is the mobility, and diagnosis is only difficult when the fracture is of the ascending ramus and underneath the masseter muscle. A skiagram may then be needed. Fracture of the mandible is commonly compound, and therefore is often complicated by septic infection. Later, *callus* will form a tumour which might be mistaken for one of some other kind until the course of the case has been watched.

Inflammatory Affections.

Alveolar Abscess.—This is a very common swelling, associated with toothache. An ordinary gum-boil forms at the edge of the gum, and is quite superficial. A more troublesome form of abscess is that which develops at the root of a tooth, which, generally carious, may yet appear healthy on the surface. Pus usually points between the gum and the cheek, but it may travel a long way between the bone and the mucous membrane, and point on the cheek, in the submaxillary region, or on the chin. As in the case of injury, *periostitis* extending up under the muscle may be difficult to diagnose, and it is sometimes mistaken for parotitis. In the early stages the only sign is toothache, but as suppuration becomes established there are also pain, swelling of the gums, furred tongue, trismus, enlargement of the lymphatic glands, raised temperature. The presence of a septic tooth indicates the diagnosis.

Necrosis of the Jaw, often preceded by an acute periosteal abscess, may follow injury, alveolar abscess, syphilis, or mercurial or phosphorus poisoning, and in rare cases acute exanthemata or typhoid fever. In many cases it may be impossible to say whether the bone is necrosed or not, for the signs are much the same as in suppuration in connection with alveolar abscess. It can only be diagnosed for certain if a piece of loose bone can be felt with a probe or seen by the aid of a skiagram. Its presence may be inferred by the long continuance and profuseness of the discharge.

Syphilitic disease of the lower jaw is rare, and if present will not usually be confined to the jaw. If there is doubt, a Wassermann's reaction will be of service.

Actinomycosis.—A long-standing and obstinate suppuration about the lower jaw, with cellulitis of the neck and formation of sinuses in the skin, should lead to the suspicion of the nature of the trouble. In the beginning it gives rise to inflammatory changes which simulate alveolar abscess, and the similarity is increased by the presence of carious teeth, through which the fungus is believed to gain access to the jaw. In the pus, the small yellow granules are to be sought for, and the Gram-staining mycelium on microscopical examination (*Plate XXVIII*, p. 614).

Tumours.—In many cases there will be no difficulty in deciding whether a swelling is inflammatory or a new growth. In the early stages, however—and it is never to be forgotten that an early diagnosis in the case of malignant disease is of extreme importance—there may be grave doubt. Therefore, all possibility of inflammatory mischief should be excluded by a careful, thorough examination of the mouth and teeth for any source of infection, and for this purpose it is frequently advisable to invite the co-operation of a dentist.

Innocent tumours are osteoma and fibroma (more commonly called a fibrous epulis). *Osteoma* is rare, very slow growing, well defined, bony hard, and it does not usually attain a very large size. A not uncommon place to find it is at the angle of the jaw, projecting into the mouth. It may be bilateral. *Fibrous epulis* is common, soft, composed of fibrous tissue, and covered by the mucous membrane of the gum. It arises in connection with the root of a decayed tooth, and if not treated may attain a sufficient size to cause displacement of the teeth or even distortion of the arch of the jaw. Sarcomata may start in this manner; therefore all such tumours should be submitted to microscopical examination before a definite diagnosis or prognosis is given.

Malignant tumours are *primary*, sarcomata, and *secondary*, epitheliomata, which start in the gum or on the floor of the mouth and invade the jaw by direct extension.

The diagnosis of *sarcomata* may be quite easy, or attended by the greatest difficulty. They occur at any age, even in young infants. They may be of rapid growth, associated with constitutional changes which simulate inflammatory conditions before a large size has been attained, or they may be of such slow development as to be confounded with innocent growths. The necessity of early diagnosis cannot be urged too strongly, for it is on this that successful treatment depends. Seeing that a growth may be mistaken for a swelling due to suppuration, examination should first be directed towards seeing if any of the ordinary signs of inflammation are present, and whether there is an obvious source of infection. The history of the duration of the illness may be of great service, and also the nature of the swelling itself. Is it hard or soft, is the bone expanded, are tissues round the bone infiltrated, are the glands enlarged? Exercising the greatest care, diagnosis may still be difficult, and much service is rendered by a skiagram, with the aid of which one may determine whether the swelling is really bony, or in the case of periosteal sarcoma if the bone has been eaten into. If the diagnosis can be settled by no other means, the growth should be cut into and a piece removed for microscopical examination, even if the tumour is bony and a chisel and mallet be required.

Epithelioma—better termed squamous-celled carcinoma—is a very insidious and dangerous form of growth, and in its early stages very apt to be overlooked. It may start as a small ulceration of the gum about a decayed tooth, and so be mistaken for a simple ulcer, and it may not be until a large tumour has formed that the condition is recognized, when most valuable time will have been lost from the point of view of treatment. The diagnosis will be made by careful examination, and noting that the ulcerated gum is hard and indurated and does not heal when the decayed tooth is removed. The name ‘*boring epithelioma*’ has been well applied to this condition. To make the diagnosis sure, a piece from the edge of the ulcer should be removed for histological examination at the earliest moment that suspicion is aroused as to its malignancy. An epithelioma may also spread from the tongue or floor of the mouth and cause a swelling involving the jaw. The diagnosis here is obvious.

Tumours of the Teeth, Odontomata, may arise from any portion of the dental tissue, either from the tooth germ or from the fully-formed tooth. Clinically they are innocent, and commoner in young people. The method of diagnosis is to examine the teeth and find out if any of them are missing or abnormally arranged. It is easy to distinguish them from a periosteal sarcoma, but confusion may arise between them and a very slow-growing endosteal or myeloid sarcoma. A skiagram will generally reveal the true state of affairs, for any abnormality or misplacement of the teeth is clearly shown. It is well to remember the existence of these tumours, for unnecessarily severe operations have often been performed in ignorance.

Two diseases in which the mandible becomes enlarged, but in which the swelling is not confined to the one bone, and is only one of the manifestations of the complaint, remain to be mentioned:—

Acromegaly.—The lower jaw is often enlarged conspicuously in this disease, becoming prominent and massive (*Fig. 116*, p. 237). There is hypertrophy of the whole bone rather than a swelling in it. The other bones of the face are enlarged, the superciliary ridges are exaggerated, and the general effect of the disease is to give the patient the appearance of a dull, coarse-featured person. In addition, the hands and feet become much enlarged; also, in the late stages of this very chronic illness, headache and muscular debility become prominent symptoms, and owing to swelling of the pituitary body, bilateral temporal hemianopia is to be expected (see *Fig. 139*, p. 300).

Leontiasis Ossea is the name given to a rare disease in which hyperostoses of the facial and cranial bones are the distinguishing features. It is not likely to be confounded with any of the above-mentioned swellings, except perhaps acromegaly, from which it is distinguished by the absence of changes in the hands and feet. *George E. Gusk.*

SWELLING OF THE JAW, UPPER. The remarks made in the article on SWELLING OF THE JAW, LOWER (p. 683), apply equally to swellings in the upper jaw. Tumours arising in the antrum of Highmore merit special mention, however, for many cause no pain or discomfort until the late stages. Though innocent tumours may start in the antrum, the commonest are sarcoma and endothelioma. Rapid growth, bulging into and invasion of surrounding fossae, pain, discharge of blood and pus from one nostril, and invasion of the overlying skin, are momentous indications of malignant disease. In the case, though, of slow-growing tumours and in the early stages, differentiation between innocent growths or suppuration is extremely difficult. Transillumination (see PAIN IN THE JAW, UPPER, p. 462) is to be employed (*Fig. 84*, p. 180), also puncture of the antrum, and if necessary exploration and histological examination of the parts removed.

George E. Gusk.

SWELLING OF THE LEGS.—(See ŒDEMA, p. 414.)

SWELLING, MAMMARY.—*Method of Examination.*—The clothes should be removed to the waist, so that a clear view of both breasts, the thorax, axillæ, and supraclavicular fossæ may be obtained. Both breasts should then be looked at to see whether there is any obvious enlargement or abnormality such as redness of the skin, dilatation of veins, tumour, or ulcer. Next, palpation is to be employed, using the flat of the hand and not the tips of the fingers: the surgeon should place himself in a convenient position behind the patient, using the right hand to examine the right breast and the left hand the left. The axillary fossæ should also be palpated carefully, it being remembered that the lymphatic glands affected in diseases of the breast lie on the surface of the thorax and not round the axillary vessels. (See SWELLING, AXILLARY, p. 666.) In cases of suspected cancer the examination must not be concluded without investigation of the supraclavicular fossæ for fullness or enlargement of glands, and of the thorax and liver for signs of secondary growths.

Swelling in Pregnancy and Lactation is normal and physiological. Both breasts are enlarged equally, and feel tense and nodular. The superficial veins are usually prominent, and on gentle squeezing a few drops of milk are discharged from the nipple.

True Hypertrophy of one breast is rare. It may be found in nursemaids who have put children to the breast. The enlargement in the majority of so-called cases of hypertrophy is really due to the presence of one or more fibro-adenomata.

Acute Mastitis occurs usually during lactation, occasionally during pregnancy, and is most often due to infection with pyogenic organisms which have gained entrance through cracks in the nipple. At the beginning of the illness there is shivering, followed by fever and a feeling of weight and pain in the breast; the pain soon becomes very acute. In the early stages the swelling is limited to one part of the breast, which feels more resistant than normal; the skin is not reddened at first, nor are the lymphatic glands enlarged. Pressure over the swelling may cause extrusion of a drop of pus from the nipple, and this is distinguished from milk by its viscosity and yellow colour. Later, fluctuation may become evident, and, as the inflammation approaches the skin, this becomes red and œdematous, and ultimately an abscess may point and burst through it; at the same time other foci of suppuration form, until the breast may be nothing but a bag of pus. The presence of fever and the intense tenderness of one portion of the breast are sufficient to distinguish acute mastitis from the physiological engorgement.

It is not uncommon to find a small *alveolar abscess*, the size of a hazel-nut, in virgins.

Soon after birth and at puberty, a diffuse enlargement may occur in both sexes, and a small quantity of milk may be secreted. If the breasts are handled or squeezed, this congestive condition may pass into true inflammation and suppuration.

Chronic Mastitis may attack numerous lobes of the breast, so that the whole organ has a granular feel (chronic lobular mastitis), or the inflammation may be confined to one segment and form an inflammatory swelling of considerable size. The attention of the patient is usually first called to the breast by the presence of vague pains and tenderness. If the lump is picked up with the fingers it is easily palpable, but if pressed back against the chest wall the induration is much less distinct than is carcinoma or fibro-adenoma. The swelling is elastic, and its outline quite diffuse, more so than in the case of carcinoma. The axillary glands may or may not be enlarged; if they are, they are generally numerous, not so hard as in cancer, and are met with at an earlier period in the disease. The opposite breast is very liable to be diseased in a similar manner. The diagnosis is often very difficult, ordinary carcinoma of the breast being confounded with it. The two tumours resemble each other in that in both their outlines are badly defined and the axillary glands are enlarged. In cancer, however, the tumour is densely hard, and at an early period adhesions form so that the skin puckers on attempting to move it over the swelling. A further difficulty arises from the fact that a cyst may form in connection with chronic mastitis. If this is lax, fluctuation may be detected, but it is usually so tense that it feels hard and solid. This again may be mistaken for a carcinoma or a fibro-adenoma. Where there is the least doubt as to the nature of the swelling and any possibility of the presence of a carcinoma, the right course is to make an exploratory incision and cut microscopic sections from the suspected area.

Multiple Cystic Disease of the Breast.—This condition may follow on chronic lobular mastitis. One breast—sometimes both—becomes filled with cysts, some microscopic and others as large as walnuts, so that the organ has a bossy appearance. The whole organ is often very painful, the pain radiating from the breast and shooting down the arm. There are epithelial changes in the lining membrane of the cysts, and some authorities think that these are precursory stages in the formation of a cancer.

Cysts, unless in connection with chronic mastitis or fibro-adenomata, are rare. A simple serous cyst is described, due to lymphatic obstruction. *Galactocoele*, a cyst containing milk, is formed by dilatation of one of the larger lacteals owing to obstruction; galactocoeles occur only during lactation; they form movable, fluctuating swellings, and on pressure milk can be squeezed out of the nipple.

Tuberculosis of the Breast is not so uncommon as was formerly supposed, and a certain number of cases of chronic mastitis and chronic abscess are really tuberculous. The disease is insidious, starting as a painless irregular swelling, the periphery of which is hard and the centre soft. Later, the skin becomes reddened, and an abscess forms which may burst and leave a sinus. It differs from an acute abscess in that the duration is much longer, there is little or no pain or fever, and the pus, if examined, reveals no organisms. The facts that its history is a long one, that the swelling or the edges of it are hard, and that the axillary glands are enlarged, render this condition liable to be confounded with carcinoma, of the ordinary form, or one in which suppuration has occurred. The various clinical pathological tests for tuberculous disease may be applied, but the best method is to cut into the swelling and remove a portion of the wall for histological examination.

Chronic Submammary Abscess causes a projection forward of the whole breast; it is due to tuberculosis of the underlying ribs, or in rare instances to post-typhoidal periostitis which may have remained latent. The diagnosis is made by opening the abscess and examining the pus from it bacteriologically.

Innocent Tumours.—*Pure fibromata*, *lipomata*, and *enchondromata* are of rare occurrence, and merely call for mention here. *Fibro-adenoma* is the only common innocent tumour, and though there are many pathological varieties, and some contain cysts and some intracystic growths, for the purposes of this article all may be classed under one heading. A *fibro-adenoma* is an encapsulated tumour, generally single, sometimes multiple varying from the size of a nut to that of an orange. Because it is encapsulated, the surrounding tissues are not infiltrated; therefore, if superficial, the outline is clearly defined and the mass is freely movable both under the skin, over the pectoral muscle, and most

important of all, in the breast substance. The axillary glands are not enlarged. The tumours cause no pain, and are usually discovered accidentally. Generally they occur in women between the ages of twenty and thirty. After attaining a certain size they remain more or less stationary, unless they are cystic, when they may go on growing as the result of dilatation of the cyst by fluid. The diagnosis is generally quite easy, but if the breast is fat and the tumour deep-seated, it may not always be quite easy to distinguish a fibro-adenoma from an early carcinoma, without operation and microscopical examination. A fibro-adenoma is elastic in consistency rather than hard like a carcinoma. From chronic mastitis it is distinguished by being less intimately associated with the breast than is the case with the inflammatory nodules, and by its sharper definition. On account of the well-known possibility of error, however, no definite diagnosis or prognosis should be given until the tumour has been removed and a pathological report on its character received.

Malignant Tumours of the breast are nearly always primary; sarcoma is rare, carcinoma common; and the latter is the most important tumour that affects the breast. It is essentially a disease of the female, only about one per cent of the cases occurring in males; most patients have been married, and are between the ages of thirty-five and sixty. In advanced cases the disease is obvious; the tumour is large and hard, fixed to and often fungating through the skin; the axillary glands are enlarged and hard, and the patient is often cachectic. What is wanted is a diagnosis in the early stages, while the patient still looks and feels in perfect health, before secondary deposits are found in the axillary glands and while successful treatment is still possible. Too much insistence cannot be laid on this. Usually the patient feels no pain, but discovers a lump in the breast accidentally during ablutions; therefore its duration must generally be a matter of doubt. Clinically, it is felt as a small tumour which, unless the patient is very fat, can be palpated easily with the flat of the hand. Its chief characteristic is that its outline is not sharply defined, and that it is hard—stony hard. In the very early stage the tumour is freely movable over the pectoral muscles and under the skin, but it is not so movable in the breast substance as is a fibro-adenoma. Very soon bands of fibrous tissue that connect the breast with the skin become involved, and by their contraction prevent free movement of the skin over the swelling, and cause dimpling and puckering. If the tumour is situated anywhere near the centre of the breast milk-ducts become involved in the growth, and as they contract cause retraction of the nipple. If a nipple, previously well formed, becomes retracted, this is a very important sign, though it is to be remembered that nipples are often permanently retracted. Many cancerous tumours, even when extensive infiltration has occurred, cause shrinkage, so that the affected breast may appear smaller than the healthy one, and in the atrophic form the gland may almost disappear. In the ordinary form (scirrhus) it will be rare to find any discharge from the nipple; a blood-stained discharge often indicates a duct-carcinoma. (See DISCHARGE FROM THE NIPPLE, p. 181.) After the disease has lasted six months the axillary glands are usually enlarged and hard, the first affected being those running along the lower border of the pectoralis minor. Too much attention must not be given to the absence of palpable glands, because, first, it is hoped that the diagnosis may be made before they are enlarged; and secondly, if the patient is at all fat, it is exceedingly easy to overlook them. Attention is to be centred on the lump itself. Its stony hardness may alone be sufficient ground on which to base a diagnosis. The two main conditions which have to be distinguished from an early carcinoma are fibro-adenoma and chronic mastitis. In the former, the swelling is well defined, elastic, and freely movable; in the latter, a tumour cannot be felt distinctly with the flat of the hand; it is soft, and the whole breast is often nodular.

The difficulties in diagnosis are great and the sources of error numerous; none of the swellings may be typical; they may be obscured by the obesity of the patient, and a fluid swelling may be so tense as to simulate a solid one. This being so, the course to adopt, whenever the slightest doubt arises, is to incise the swelling and submit a portion to microscopical examination. Seeing the vital importance of avoiding mistakes in this connection there is a growing feeling among surgeons that all tumours of the breast, whatever the belief as to their character, should be removed, or at least cut into, so that their true histological constitution may be ascertained early and with accuracy.

Sarcoma of the breast is rare. It generally occurs in women under the age of thirty. In the early stage it is not easily distinguishable from a fibro-adenoma, particularly one

which is enlarging rapidly on account of a cyst or intracystic growth. It is soft, grows rapidly, infiltrates the tissues, and forms a large fungating tumour. It disseminates rapidly, both via the lymphatics and by the blood-stream. *George E. Gask.*

SWELLING, PELVIC.—There are so many swellings which may rise up out of the pelvis into the abdomen, and also which may appear to be pelvic when they are really primarily abdominal, that a list in tabulated form may be of value :—

Bladder.—Simple distention. New growth.

Vagina.—Hæmatocolpos.

Uterus.—Pregnancy : normal or abnormal, or associated with tumours of the uterus or ovary.

New growths : Fibromyoma. Sarcoma. Carcinoma. Chorion-epithelioma. Hæmatometra.

Ovary.—Cysts. Solid new growths.

Fallopian Tubes. —Hydrosalpinx	Carcinoma
Pyosalpinx	Tubal gestation
Salpingo-oöphoritis	Progressive extra-uterine gestation.
New growths	

Pelvic Peritoneum.—Encysted peritoneal fluid

Hæmatocele due to extra-uterine gestation

Hæmatocele due to hæmorrhage from a corpus luteum

Pelvic abscess | Hydatid cysts

Ascites | Retroperitoneal lipoma.

Pelvic Cellular Tissue.—Cellulitis. Pelvic hæmatoma.

Appendix Vermiformis.—Abscess around

Appendicitis with pregnancy.

Pelvic Bones.—New growths of.

Omentum.—New growths of. Cysts of.

Phantom Tumours.

Pancreatic Cysts.

Kidney.—Tumours of. Hydronephrosis. Pyonephrosis.

Gall-bladder.—Distention of.

Spleen.—Enlargement of.

Urachus.—Cyst of.

It is obvious that many of these lesions are not pelvic at all ; but they are not omitted from the list because they are liable to be mistaken for pelvic tumours. Thus *pancreatic, renal, splenic,* and *gall-bladder tumours* may reach the pelvic brim, but the history ought to show that they have grown down from above, not up from below. Further, *renal tumours* may be associated with urinary changes, or absence of urinary secretion on the affected side, as detected by the cystoscope. *Splenic enlargements* may be associated with blood-changes, and *gall-bladder distention* with icterus. *Pancreatic cysts* are the least likely to be mistaken for pelvic swellings, but they have been difficult to distinguish from ovarian tumours with long pedicles.

Naturally, the commonest difficulty which arises in the diagnosis of pelvic swellings is to differentiate between the *distended bladder, pregnant uterus, ovarian cyst,* and *uterine fibromyoma,* and the commonest mistakes are made between these swellings. The *distended bladder* is clearly the easiest to dispose of, because the passage of a catheter will settle the question : and yet the neglect of this simple procedure has led to more than one abdomen being opened.

The history is of value in differentiating the other swellings, for amenorrhœa is the rule in pregnancy, menorrhagia in fibromyoma, and no change in menstruation in ovarian tumours. These assumptions are correct in almost 99 out of every 100 cases, but exceptions do exist. The cardinal point in diagnosis is not to think of the possible fallacies until the common rule has been considered thoroughly. Normal menstruation during pregnancy is almost unknown, but it is believed that menstruation is possible up to the third month. This is physiologically unsound, for menstruation represents the

failure of the uterus to receive a fertilized ovum, and should not be even possible if conception does occur. That hæmorrhages occur during the early months of pregnancy is true; but in most cases these hæmorrhages represent threatened abortion, and not menstruation. Further, fibroids are associated with hæmorrhages. This is true in the case of interstitial or submucous growths; but there may be no disturbance of menstruation in subperitoneal fibroids. Ovarian tumours only disturb menstruation when they are double, and destroy all ovarian tissue. As long as a small piece of ovarian tissue remains there is no reason why menstruation should not occur normally.

Palpation of these tumours may be fallacious, although there is no difficulty in distinguishing fetal parts when the fetus is big enough. In the early months the pregnant uterus may fluctuate like a cyst; a softened fibroid may do the same, whilst on the other hand a tense ovarian cyst may feel so hard as to be mistaken for a fibroid. Whilst the presence of the fetal heart is characteristic of pregnancy, its absence cannot be taken as evidence of a fibroid or of an ovarian tumour. It is not always possible to hear the fetal heart even in advanced pregnancy. If the pedicle of a tumour can be felt definitely attached to one uterine cornu it is strong presumptive evidence of an ovarian tumour. It is useful to pull down the uterus with a tenaculum, at the same time pushing up the tumour so as to make tense the pedicle, which might then be palpated by the vaginal touch. When small tumours are in question the first point which arises is, Can the tumour be separated from the uterus bimanually? If so, it can be neither a fibromyoma of the uterus nor a normal uterine pregnancy. This point can only be made out by careful bimanual examination, and undoubtedly may require considerable skill in some cases.

Early pregnancy in a retroverted uterus should not give rise to diagnostic difficulties if it be remembered that the soft, boggy fundus is felt through the posterior fornix, that the cervix looks down the vagina or forwards to the symphysis, and that the posterior mass is continuous with the cervix. If the retroverted uterus is associated with vesical distention the picture is usually clear enough. The history of constant dribbling of urine (distention with overflow), amenorrhœa, other signs of pregnancy, the presence of two tumours—one in front, tense and elastic, the other behind, soft and boggy—and finally, the passage of a catheter, will settle the question. The diagnosis of solid ovarian tumours is not always possible, for the pedicle is often short, and the tumour is then so close to the uterus that the two cannot be separated. They are therefore likely to be mistaken for fibroids of the uterus. They do not often cause menorrhagia, however, and this may be remembered as a cardinal point.

Large tumours arising in the pelvis are not often difficult to differentiate from one another, bearing in mind that ovarian tumours, uterine fibroids, pregnancy, and ascites are the common conditions which are met with. In this connection, it cannot be repeated too often that amenorrhœa stands for pregnancy, and occasionally for ovarian tumours when double. Menorrhagia goes with uterine fibroids except in the case of subperitoneal tumours. Exceptions to these general statements are uncommon, and mistakes in diagnosis will occur but seldom if they are borne in mind. Ascites has to be differentiated from ovarian cysts, and occasionally from hydramnios. In general, ascites gives dullness in the flanks on percussion, with resonance over an area somewhere about the umbilicus, whilst ovarian cysts give dullness over the front of the abdomen, with resonant areas in the flanks and epigastric angle. When ascites exists along with ovarian tumours the free fluid may be so large in amount that the tumour cannot be felt; as a rule, however, it can be touched on dipping through the fluid. Ascites with an ovarian tumour does not necessarily mean malignancy, but it may do so. Fibroma of the ovary, and simple ovarian cyst, with a twisted pedicle, will always be accompanied by some fluid.

When *pregnancy is associated with tumours*, the diagnosis may be of great difficulty. This does not lie in the recognition of the pregnancy; amenorrhœa, breast changes, fetal movements, and the fetal heart will usually make that clear enough; it lies in deciding the nature, or even the presence, of a tumour along with the pregnant uterus. In the early months, when the presence of two tumours can be demonstrated, the diagnosis is easier, but in the later months the great size of the abdomen, and the way in which the swellings merge into one another, may obscure the picture. The relation to the uterus, whether a part of it, or attached to it by a pedicle; the feel of the tumour, whether solid or cystic, soft or hard; and the previous history; will always be of assistance in making

out the nature of the growth. Fibroids are extremely likely to soften and degenerate during pregnancy, so that they are liable to be mistaken for ovarian cysts.

In the case of *ovarian tumours*, it is often impossible to be sure of the exact nature of the growth, and this has to be decided microscopically after removal. It is, however, important to distinguish malignancy in growths of the ovary, and certain points will stand out in favour of this. Thus, fixation of the growth in the pelvis, obvious ascites, emaciation of the patient, and rapid growth in size of the abdomen, are points in favour of malignancy.

In the case of definitely *uterine tumours*, the diagnosis of malignant growths is not often difficult, but may have to be settled by microscopic examination of curetted fragments. Fibroids are only likely to be mistaken for malignant growths when they produce constant bleeding as a result of extrusion, infection, and sloughing. Rapid growth of a fibroid is more likely to be the result of degenerative changes, such as formation of cysts or necrobiosis, than to the development of a sarcoma or other malignant growth along with it.

With small tumours confined to the pelvis, or rising only a little above the brim, diagnosis is often a matter of extreme difficulty. In practice, however, *extra-uterine gestation* and its resulting blood-tumours stand out pre-eminently as swellings which must be recognized at once, if successful treatment is to be adopted. Before rupture or abortion has occurred a tubal gestation is essentially a small tumour in one postero-lateral corner of the pelvis, attached to the uterus, indefinite in consistence, and perhaps—though not always—associated with amenorrhœa of short duration, and attacks of pain in the pelvis of an acute nature. Definite signs of pregnancy may be entirely wanting. It may be mistaken for a chronic salpingo-oöphoritis, a small cystic ovary, a small pedunculated fibroid, or a small ovarian dermoid. The differential diagnosis may be absolutely impossible; but attacks of pain unassociated with menstruation are not likely to occur in any of the latter conditions. The attacks of pain are usually the result of over-distention and stretching of the tube from hemorrhage into its wall or lumen around the fertilized ovum. When tubal abortion has occurred, or tubal rupture, the signs of internal bleeding, accompanied by sudden pain and collapse, with hemorrhage from the uterus, usually make an unmistakable picture. Hemorrhage is more commonly severe and copious in tubal rupture than in tubal abortion. If the patient recovers from the initial bleeding the clinical picture may be that of a retro-uterine *hematocele*, or of a peritubal *hematocele*. In this form the uterus is pushed forwards and upwards against the symphysis pubis, and the mass of blood-clot can be felt posteriorly bulging the posterior fornix, and also the anterior wall of the rectum. The tumour is usually partly resonant in front, because intestine adheres to it. Tubal abortion is most likely to be mistaken for an ordinary uterine abortion; but the presence of a mass on one side of the uterus, with a closed cervix, and the absence of uterine contractions or extrusion of any products of conception, should make the case clear.

Progressive extra-uterine gestation is a rare occurrence, and is the result of continued growth of an embryo after a partial separation from the tube as a result of rupture, or extrusion from the limbriated end (abortion). The continued enlargement of a mass beside the uterus, with amenorrhœa and progressive signs of pregnancy, are the most characteristic points. The diagnosis, however, is difficult, because there is always some effused blood which is likely to obscure the outlines of the uterus, and make it appear to be a part of the pelvic mass.

The swellings due to *salpingo-oöphoritis* are usually quite easy to distinguish. They form fixed masses in the pelvis, seldom of any definite shape, but occasionally presenting the characteristic retort shape, with its narrow end near the uterus, which the tube assumes when distended with fluid. The history is usually that of an acute illness at some period, with pain in the pelvis, rise of temperature, and peritoneal irritation. It is preceded, as a rule, by uterine discharges and menorrhagia. This inflammatory disturbance in married women is associated with long periods of sterility, owing to the sealing up of the tubes. The diagnosis of suppuration with salpingo-oöphoritis is often impossible, but is always important, because the treatment may depend on it. Constant rises of temperature of the hectic type, wasting, and daily sweating, are the usual accompaniments of suppuration here as elsewhere.

A large *pelvic abscess* may accompany salpingo-oöphoritis, or may occur alone without infection of the tubes, as we see occasionally in puerperal septic infections. When it does occur, it is of course peritoneal; it fixes the uterus in a central position, bulges into the posterior fornix and rectum, tends to rupture into the rectum, is acute in onset, and accompanied by signs of local peritonitis. It is likely to be confounded with *pelvic cellulitis*, in which the uterus is fixed in a laterally displaced position. It bulges one lateral fornix, tends to burrow along the round ligament to the groin, is slow in onset, chronic, and not accompanied by signs of local peritonitis. It always follows labour, whereas pelvic abscess of peritoneal origin may occur with salpingo-oöphoritis quite apart from pregnancy. Pelvic cellulitis never bears any relation to salpingo-oöphoritis.

Eucysted peritoneal fluid, hydatid cysts, and retroperitoneal lipoma are generally diagnosed as ovarian cysts, and their true nature is only discovered at operation. There are no definite signs by which these conditions may be diagnosed, and as they all require operative treatment, post-operative diagnosis meets their requirements.

Distention of the vagina by menstrual fluid is not likely to be mistaken for anything else, if only on account of the absolute closure of the hymen which gives rise to it. Hematocolpos is practically the only central tumour met with between the rectum and the bladder reaching from the hymen to the pelvic brim. The uterus can usually be felt like a cork movable upon its upper extremity.

Uraeal cysts occur in front of the uterus and in close relation to the bladder; but in spite of this they are usually mistaken for ovarian cysts. It is to be remembered, however, that ovarian cysts only get in front of and above the uterus when they are large. Uraeal cysts rarely attain a large size.

Appendicitis with pregnancy occurs occasionally, and may be mistaken for such a condition as torsion of an ovarian pedicle. The swelling due to appendix inflammations is, however, in close relation to the anterior superior spine of the ilium, and apparently adherent to the iliac fossa. The lump is ill defined, and rarely fluctuates unless there is a large abscess. The acute onset may be similar to that of torsion of an ovarian pedicle. There is usually a definite fluctuating tumour when an ovarian cyst is present, and some interval between it and the iliac crest can usually be felt.

Phantom tumours are due to diaphragmatic contraction, causing the abdominal wall to bulge. They are usually mistaken by patients for pregnancy, but are not accompanied by any of the signs of pregnancy. Amenorrhœa must be excepted from this, however, because these cases usually occur about the menopause. Their true nature can usually be discovered by making the patient breathe normally, relaxing the diaphragm; but if any doubt exists, the protrusion will disappear under an anæsthetic.

Growths of the pelvic bones are very rare tumours, usually cartilaginous or sarcomatous. They are only likely to be mistaken for adherent inflammatory masses, due to salpingo-oöphoritis. They will be found to be continuous with the bones forming the pelvis, and when growing from the sacrum may have the rectum in front of them; all other tumours have the rectum behind them. They may, however, bear no relation to the rectum at all if they occur on the right side of the pelvis. In most cases of this nature the uterus and adnexa can be palpated bimanually, and shown to be free from disease and unconnected with the mass. When complicated by the presence of a pregnant uterus their true nature may be very difficult to determine. Bearing in mind that they are absolutely fixed and continuous with the bones of the pelvis, the diagnosis ought not to be uncertain.

Thos. G. Stevens

SWELLING, PERINEPHRIC.—(See KIDNEY, ENLARGEMENT OF, D. 352.)

SWELLING, POPLITEAL.—Popliteal swellings may be divided into:—

1. Fluid Swellings:

Bursa	Varicose veins	Aneurysm.
Baker's cyst	Abscess	

2. Solid Swellings not connected with Bone:

Enlarged glands	Malignant tumours	Innocent tumours.
-----------------	-------------------	-------------------

3. Solid Swellings connected with Bone:

Exostosis	Periostitis
Sarcoma	Separation of the epiphysis.

FLUID SWELLINGS.

Bursa.—The bursa underneath the insertion of the semimembranosus muscle into the posterior aspect of the inner tuberosity of the tibia is often enlarged. When the leg is extended it stands out as a tense fluctuating swelling on the inner side of the popliteal space; on flexion it disappears completely. It may be found enlarged in young athletes and cause no symptoms whatever. On account of its frequent communication with the knee-joint it is often distended when that joint is the seat of osteo-arthritis, and the changes found in the synovial membrane of the knee are found also in the synovial membrane lining the bursa, for the two are continuous. When much fluid is present, fluctuation can be detected between the joint and the bursa.

The bursa under either of the two heads of the gastrocnemius muscle may be enlarged similarly, but this is rare.

Baker's Cyst occurs in connection with chronic tuberculosis of the knee-joint, and is formed by the extension of a chronic abscess which spreads along a plane of fascia. Such an abscess may present itself in the popliteal space. The condition of the knee-joint will indicate the disease.

Varicose Veins are often present; the diagnosis presents no difficulties, as the veins in the lower part of the leg will be varicose also.

Acute Abscess is recognized by the signs of acute inflammation: the skin is red and oedematous, the pulse and temperature are raised, and the swelling is very painful. The knee is kept flexed in order to minimize the tension of the part. The abscess may be caused by suppurating lymphatic glands or by suppurative periostitis or necrosis of the lower end of the femur. In the former case the abscess will be superficial, and in the latter deep to the popliteal vessels.

Aneurysm of the Popliteal Artery (*Plate XXX*) gives rise to an expansile pulsating tumour, the pulsation being synchronous with the heart's beat. Pressure on the femoral artery above will cause a diminution in size of the swelling and cessation of pulsation. The pulse at the ankle on the affected side may be smaller than that on the opposite, and delayed. If a stethoscope be placed over the swelling a distinct bruit can be heard. The complaint of the patient will probably be of pain, which may be referred down the leg if either popliteal nerve is pressed on, or in the site of the swelling if the bone is eroded. Varicose veins are almost always present also, on account of pressure on the popliteal vein. Owing to its pulsatile character, an aneurysm is not often mistaken for anything else, but it must be remembered that every swelling that pulsates is not an aneurysm. A soft vascular sarcoma growing from the end of the femur may be pulsatile, and over it a bruit may be heard, but the tumour is not as compressible as an aneurysm, and the effects on the distal pulse are not so marked. A skiagram will usually settle the question at once. Distinction must also be drawn between a tumour that pulsates and a tumour to which pulsation is communicated. For instance, an abscess or a solid swelling lying over the popliteal artery may appear to pulsate, but the movement is heaving in character and not expansile. In the rare event of an aneurysm having become filled with clot it might be taken for a solid tumour growing either from the soft parts or from the bone. Under this delusion a leg has been amputated for sarcoma.

SOLID SWELLINGS NOT CONNECTED WITH BONE.

Enlarged Glands.—It is not common to find the popliteal glands enlarged from any cause. It is possible that they may become infected with pyogenic organisms from a sore on the back of the leg.

Tumours are rare. They may be innocent, e.g., *lipoma*; or *sarcomatous*, starting in the connective tissue of the popliteal space, or attached to one of the muscles. The innocent tumours are of long history and well defined; the malignant, rapidly growing and infiltrating.

SOLID SWELLINGS CONNECTED WITH BONE.

In all cases of bony tumour a skiagram is of immense service, and should always be obtained if possible.

Innocent Tumours.—*Cancellous exostoses* may be found, generally in children and young adults, growing from the region of the epiphyseal cartilage of the femur (*Fig. 281*,

PLATE XXX

POPLITEAL ANEURYSM

*Reproduced by permission from a water-colour painting in the London Museum,
Guy's Hospital.*

p. 670). There may be others in other parts of the skeleton, and sometimes several members of the family are affected similarly. The swelling is of slow growth, well defined, and rarely gives any trouble. It is most often found at the inner side of the popliteal space. There is one thing that may be confounded with it, namely, *ossification of the insertion of a tendon or muscle*. The adductor longus muscle is the one most commonly affected.

Malignant Tumours are endosteal and periosteal sarcoma. *Central sarcoma* in its early stages resembles chronic osteitis and periostitis so closely that it may be impossible to come to a correct conclusion without the aid of a skiagram. With this help the difficulty vanishes, for a myeloid tumour is seen clearly as a well-defined tumour causing enlargement of the bone (compare *Figs. 284, 286, 287*, pp. 672, 673).

Periosteal sarcoma causes a general enlargement of the whole of the lower end of the femur or upper end of the tibia (*Fig. 283*, p. 674), not swelling in the popliteal space only. It is mentioned here because of its occasional confusion with periostitis and popliteal necrosis.

Periostitis.—Popliteal necrosis with abscess formation may give rise to a big swelling. The signs of inflammation will usually be well marked and accompanied by constitutional symptoms and leucocytosis. Chronic periostitis, or chronic abscess of the bone, or central necrosis, may be extremely difficult to distinguish from a periosteal sarcoma. A skiagram should be taken, and if necessary an incision made down to the tumour for a piece to be removed for histological examination. (See SWELLING ON A BONE, p. 667.)

Separation of the Epiphysis.—In the somewhat rare accident of separation of the lower epiphysis of the femur, the lower fragment becomes displaced backwards, forms a prominence in the popliteal space, and presses on the vessels, sometimes to a dangerous extent.

George E. Gask.

SWELLING, PULSATILE.—When a tumour can be felt pulsating, the first point to decide, if possible, is whether the pulsation is expansile or whether it is merely transmitted by a non-expansile tumour which is in direct contact with large pulsating vessels. The distinction is sometimes obvious, especially when the tumour has developed in a place where there are no particularly large blood-vessels to transmit pulsation, for instance in the foot, or in direct connection with a long bone at some spot not immediately adjacent to the main artery of the limb. The chief difficulty arises when the mass is either in the root of the neck or in the abdomen and, to a less extent, when it is in the axilla, the inner aspect of the upper arm, in front of the elbow, in the groin, or in the popliteal space. Careful palpation is probably the best means of determining whether there is actual expansile pulsation or not; in the case of the abdomen it is important to examine the patient not only when he lies on his back, but also in the knee-elbow posture, for sometimes a tumour which is in contact with the aorta in the former position falls away from it and ceases to transmit pulsation in the latter.

If it can be decided definitely that the tumour is itself pulsating, most probably it is either an *aneurysm* of an artery or else a very vascular growth, especially *osteosarcoma*. The existence of egg-shell crackling with pulsation in a tumour would be highly suggestive of osteosarcoma, though it is conceivable that it might also be felt over an aneurysm that had extensively eroded the adjacent bones. Aneurysm will be the probable diagnosis when the markedly pulsatile swelling occurs directly along the course of a known artery. Absence of pulsation does not, however, exclude aneurysm, for the latter may either be situated too deeply for the pulsation to be felt, or else the sac may be filled partly or wholly by organized or organizing clot.

Sometimes there may be doubt as to whether there is really pulsation or not, when digital examination alone is relied upon; in such cases, direct application of the ear to the part in such a way that the pinna is in uniform contact with the patient's skin will sometimes bring pulsation to the notice very clearly when its amount, appreciable to the membrana tympani, is too slight for the hand to detect; this applies particularly to deep-seated intrathoracic aneurysms.

It must be remembered, on the other hand, that marked pulsation may suggest aneurysm without any being present, particularly at the root of the neck and in the abdomen (*Fig. 288*); a normal subclavian artery may sometimes seem to be abnormal,

particularly if it is pushed forward or displaced by a mass below or behind it, for instance an accessory cervical rib. Undue pulsation of the abdominal aorta, especially in women, is also to be remembered as a possible source of erroneous diagnosis (see PULSATION, UNDEUE ABDOMINAL AORTIC, p. 543).

It should also be remembered that normal arteries cause very violent pulsation in cases of marked aortic regurgitation, and in severe cases of exophthalmic goitre, in which the whole neck, including the enlarged thyroid gland, may be seen to be pulsating vigorously.

We need not here discuss in detail the differential diagnosis between one kind of aneurysm and another, though one might mention in particular the so-called cirroid aneurysm of the scalp (*Plate XXXI*), which is rather a conglomeration of many abnormally dilated arteries in the form of an arterial naevus than a true aneurysm. Its position on the scalp will at once suggest the diagnosis.

A pulsatile orbital tumour will generally be due either to an osteosarcoma, or to an arteriovenous aneurysmal communication between the internal carotid artery or its ophthalmic branch, and the cavernous sinus. The presence of a loud bruit would be in favour of the latter.

It is important not to mistake for the ordinary pulsatile tumours those which may move synchronously with respiration, for instance hernia pulmonalis, hernia cerebri, and certain congenital abnormalities of the brain and spinal cord, such as meningoencephalocele (*Fig. 102*, p. 230).

It is unlikely that a pulsatile liver will be mistaken for any other kind of pulsatile tumour. The cases in which it occurs are those of chronic failure of cardiac compensation, generally mitral stenosis and tricuspid stenosis with œdema of the legs, lividity, orthopnea, and perhaps ascites, which have generally been present for some time before the nutmeg liver becomes obviously pulsating.

Rarely, the cardiac pulsations may be transmitted direct to fluid contained in a pleural cavity, so that the bulging intercostal spaces may pulsate synchronously with the radial artery and simulate some more serious pulsatile tumour. The history and the physical signs, including displacement of the heart towards the opposite side, will generally

Fig. 288. Photograph illustrating the difficulty which may arise in diagnosing between abdominal aneurysm and carcinoma of the stomach. This patient had a large rounded epigastric tumour (demarcated by painting with ink before the photograph was taken) which pulsated forcibly, and the pulsation seemed to be expansile. Aneurysm of the coeliac axis was diagnosed, but post-mortem examination revealed a large carcinoma of the stomach, and no aneurysm.

indicate the correct diagnosis, though there may be some trepidation on the part of the operator who decides to insert the exploring needle into the pulsating swelling.

Herbert French.

SWELLING OF THE SALIVARY GLANDS.

Epidemic Parotitis Mumps—is the commonest cause of swelling of the salivary glands; it is discussed on p. 617.

Infective Parotitis is characterized by a sudden, acute and generally unilateral enlargement, and is accompanied often by a rise of temperature or a rigor. It is not an uncommon complication in certain specific fevers, e.g., typhoid fever and pneumonia; and in surgical practice it may complicate any septic case, but especially abdominal, pelvic, and genito-urinary operations, puerperal infection, and pyæmia. Resolution usually occurs, but suppuration may ensue.

Salivary Calculus.—A calculus may be found in Stenson's duct, but is more common in the duct of the submaxillary gland. In the early stages such a calculus gives rise to sudden intermittent swelling of the affected gland at times when the stimulus of food gives

PLATE XXXI

CIRSOID ANEURYSM

*Reproduced by permission from a water-colour portrait in the Girdle Museum,
Guy's Hospital.*

rise to active secretion of saliva. As the result of long-standing distention and chronic inflammation, the gland may become permanently swollen. The diagnosis of stone may be made with the finger in the mouth, by pricking the calculus with a needle through the buccal mucous membrane, by passing a fine probe up the duct and feeling the grating on the stone, and by the use of the x-rays.

Parotid Tumours.—Both innocent and malignant tumours arise in the parotid gland. The innocent tumours (fibromyxoma, endothelioma, teratoma) are encapsuled, grow slowly, press aside the rest of the parotid gland, shell out freely, and if removed do not recur. If left alone they may attain a large size in the course of years. The malignant tumours (sarcoma and carcinoma) grow rapidly, soon affecting the whole gland, extending deeply among the important structures behind the ramus of the jaw and soon involving the facial nerve, causing facial palsy.

The diagnosis has to be made from simple enlargements of the gland and from enlargement of the pre-nitular lymphatic glands due to infection with pyogenic organisms, tubercle, or syphilis.

Tumours in the Submaxillary Salivary Gland are similar to but rarer than those which occur in the parotid gland.

Bilateral Salivary Swelling—Miculicz's Syndrome.—This condition is characterized by a chronic bilateral swelling of the parotid, submaxillary and sublingual salivary, together in many cases with simultaneous swelling of the lacrimal glands (*Fig. 3*, p. 25), and it is sometimes associated with enlargement of the spleen and lymphatic glands, and with changes in the blood. The general appearances of the face are those of persistent mumps, so to speak. The syndrome is not a disease in itself, but results most often from *lymphadenoma* or *lymphatic leukaemia*; less often from some infection, including *tuberculosis* and secondary *syphilis*. A few cases have been attributed to *gout*. Each case should be investigated for any source of pyogenic infection from the mouth or gums, for syphilis by the Wassermann test, for leukaemia by blood examination (p. 24), and for any evidence elsewhere of tuberculosis.

George E. Gask.

SWELLING, SCROTAL.—It is first essential to prove that the swelling is really limited to the scrotal region, and this is best done by grasping the root of the scrotum between the fingers and thumb, and thus ascertaining if the swelling does or does not extend into the inguinal region along the cord. Failure to take this obvious precaution has led to the tapping of a hernia with disastrous results. True scrotal swellings may arise in any of the following tissues: (1) Skin; (2) The various connective-tissue coverings of the testicle; (3) Tunica vaginalis; (4) Testicle; (5) Epididymis; (6) The lower end of the spermatic cord; (7) The urethra; (8) The bones of the pubic arch.

1. The nature of **swellings affecting the Skin** is usually obvious. The only common ones are: Boils, soft sores and chancre, sebaceous cysts, warts, and epithelioma. The latter soon ulcerates, commonly occurs in sweeps, and the groin glands soon become enlarged.

2. **Swellings of the various Connective-tissue Coverings** are very rare, but occasionally a fibrosarcoma may occur. These swellings are movable upon the testicle. The symmetrical enlargement called *elephantiasis scroti*, due to the *Filaria sanguinis hominis*, is limited to the tropics.

3. The **Tunica Vaginalis** may become distended with fluid, thus forming the ordinary *vaginal hydrocele*. Except in late cases this is translucent, and is thus distinguished from a hamatocele of the same cavity. It should not be forgotten that a hydrocele with thick walls may fail to give translucency. When proved to be translucent, it has to be distinguished from encysted hydrocele of the epididymis and encysted hydrocele of the cord. Vaginal hydrocele occupies the lower part of the scrotum and *envelops the testicle*, which cannot be felt as a separate object. *Encysted hydrocele of the epididymis* is placed *behind and above the testicle*, from which it is distinct, although attached at the upper and posterior part. Moreover, this variety of hydrocele never attains a large size, rarely getting larger than a Tangerine orange. It is not tightly distended, but is usually flabby, and it contains a characteristic milky fluid in which cholesterol crystals (*Fig. 124*, p. 254) are present. *Encysted hydrocele of the cord* is placed *above the testicle*, which can be felt as a separate object. It rarely attains a large size, and is often elliptical in shape, extending upwards

along the cord. All the hydroceles fluctuate. To test for this it is necessary to fix the swelling against some hard object. Bleeding may occur into any of them as a result of injury or constitutional disease. It is almost impossible to distinguish between an opaque hydrocele and a hamatocele without tapping the swelling. In syphilitic disease, with irregular adhesion between the parietal and the visceral walls, a loculated hydrocele may occur.

4. **Swellings of the Body of the Testicle** may be inflammatory or neoplastic. Acute inflammatory swellings rarely attain a large size, and they are usually associated with enlargement of the epididymis, and occur as a part of acute epididymo-orchitis due to urethritis of some kind, or to *mumps* or as a *post-typhoidal* phenomenon. Chronic inflammatory swellings give rise to more difficulty. They are usually either *tuberculous* or *syphilitic*, or else due to *chronic torsion*. In the former disease, swelling of the epididymis is practically always primary and more advanced: but in infants the body of the testis becomes involved at a very early stage. The enlarged epididymis can be felt enveloping the posterior border, and the upper and lower poles of the testicle. There is often a little hydrocele which may obscure the shape of the testicle. If there is adhesion, with perhaps an abscess or a sinus at the posterior and lower part of the scrotum, it is characteristic of suppurative disease of the epididymis, usually of a tuberculous nature. Moreover, in tuberculous disease the vas is thickened, usually in a nodular manner. It is important to examine all the palpable part of the vas, for sometimes the nodules are limited to the inguinal region. Von Pirquet's tuberculin reaction is a valuable aid if its limitations are remembered. In striking contrast with this, syphilitic enlargement of the testicle leaves the epididymis unaffected, and is limited to the testicle, which enlarges unevenly, often affecting the tunica albuginea and the tunica vaginalis in a nodular manner. The syphilitic testicle rarely attains three times the natural size. It is curiously devoid of pain. The testicular sensation is often lost, and there is little or no thickening of the cord. Its anterior surface is uneven and may become adherent to the coverings, which may later ulcerate, and ultimately give rise to a *hernia testis* on the front of the swelling. This contrasts with the postero-infero-lateral position of tuberculous sinus or hernia testis. *Chronic torsion of the testis* is generally the result of a blow, or of an injury in the saddle: the symptoms may be obscure until the testicle begins to swell. Operation is generally resorted to with the idea that the condition is tuberculous or malignant, and even then the diagnosis may be in doubt until microscopical examination of the organ has been made.

It is often very difficult to distinguish syphilitic enlargement of the testicle from that due to *growth*: but a course of large doses of antisyphilitic remedies and the Wassermann reaction may settle the matter. Malignant new growth nearly always grows steadily, and being entirely within the tunica albuginea it maintains the shape and smooth surface of the testicle until it reaches a size much larger than that of a syphilitic testicle. Moreover, it causes much more pain, and usually some thickening of the cord, with later enlargement of the glands in the pelvis. In some cases the diagnosis between syphilitic testicle, growth, and hamatocele may be so difficult and so urgently necessary as to demand an exploration.

Malignant growths of the testicle can be divided into four varieties: (a) Carcinoma; (b) Sarcoma; (c) Embryoma; (d) Endothelioma.

Carcinoma is far more common than sarcoma, although the contrary has been believed for many years, owing to the fact that many carcinomatous growths with small alveoli have been wrongly labelled sarcoma. The average age of patients with carcinoma testis is 43, and of those with sarcoma testis, 31. The average duration of carcinoma before operation is 1½ years; of sarcoma, 14 months. Sarcoma advances much more rapidly and kills earlier than carcinoma. The former disseminates through the veins, whereas the latter travels along the lymphatics and infects the lumbar glands. Embryoma is, according to Nicholson, "the commonest new growth of the testicle, but it is often overlooked." It can be shown to contain structures derived from all the three blastodermic layers of the embryo. The average age at the time of operation is 29, the average known duration before operation is 5½ years. "Although not necessarily malignant, it may produce metastases composed of all the tissues of the primary growth, or one tissue may become actively malignant, in which case the deposits will be formed of

that tissue alone." It may spread along the lymphatics or disseminate through the veins.

5. **The Epididymis** may become enlarged as the result of (a) Inflammation; (b) New growth; (c) Cystic degeneration.

a. *Inflammatory swellings* are characterized by being elongated in a vertical direction; by their relation to the testicle, which they overlap at its posterior border, and its upper and lower poles; and lastly, by being flattened from side to side, so that the antero-posterior diameter is greatly increased. Inflammatory swellings may be:—(i) Gonorrhoeal; (ii) Septic, secondary to some other form of urethritis; (iii) Tuberculous.

i. The *gonorrhoeal* variety is distinguished by its acuteness, great tenderness, the surrounding œdema, and the bacteriological examination of the urethral discharge. Its onset is usually between the second and tenth week. Occasionally a subacute form develops later, at any time during the course of gleet. This is very difficult to distinguish from the tuberculous variety. Most cases of tuberculous epididymitis end in suppuration, but the gonorrhoeal variety very rarely breaks down.

ii. The inflammation of the epididymis following other varieties of *urethritis* (such as ulceration near a stricture or due to impacted calculus, instrumentation, or prostatectomy), is often sufficiently indicated by the history if care be taken to go into this thoroughly. The swelling following prostatectomy is apt to suppurate. Some of these can be mistaken very easily for tuberculous disease.

iii. *Tuberculous epididymitis*, as a rule, is far more insidious and painless in its onset than other forms of epididymitis; but it should not be forgotten that early subacute or even acute attacks of inflammation may accompany this disease, and that these are often the means of drawing the patient's attention for the first time to a disease which has been going on insidiously for some months. It has frequently been said that tuberculous nodules are limited to the globus major, and that those left after gonorrhoeal urethritis are confined to the globus minor. It is more true to say that the latter are limited to the globus minor, whereas tuberculous disease may attack any part of the epididymis. Wherever the tuberculous disease starts, the inflammatory products soon spread through the thin fibrous capsule of the epididymis, and then gravitate towards the postero-infero-lateral corner of the scrotum, where adhesion occurs, followed later by an abscess and a sinus. In the diagnosis of tuberculous from other forms of epididymitis, the general state of health, and especially the presence or absence of other tuberculous lesions, are of great importance. Nodular thickening of the vas deferens and of the vesiculae seminales and prostate are also valuable signs when the disease is well advanced. It should be remembered that the disease travels upwards along the vas, so that in its early and hopeful stages the upper part of the vas and vesiculae seminales are not enlarged.

b. *Primary new growth* of the epididymis is excessively rare, so that it need not give rise to much concern in diagnosis; it will generally be regarded as tubercle until after operation and microscopical examination of part of the tissue excised.

c. *Cystic disease* of the epididymis may occur in the form of: (i) Solitary cysts (*vide supra*); (ii) Multiple cysts. The latter condition rarely occurs except in men past middle age, and is analogous to cystic degeneration of the breast. The condition is almost painless and harmless. These swellings are translucent.

6. **Swellings of the Lower End of the Cord.** The most important swelling of the lower part of the spermatic cord is *varicocele*. It is apt to be mistaken for omental hernia, but the mistake should never be made, because of the characteristic feel of the varicocele, and the reappearance of the swelling after it has been completely reduced and the finger is firmly pressed on the external abdominal ring.

7. **Urethral Conditions.**—Occasionally a *peri-urethral abscess* may form a swelling in the scrotum. Tenderness, œdema, and fluctuation, together with the history and evidence of urethral disease, serve to make the diagnosis clear. *Primary epithelioma of the urethra* is distinguished by the great pain and urethral obstruction that it engenders.

8. **Diseases of the Pubic Bones.** Inflammatory products may travel into the scrotum from disease of the bones of the pubic arch, especially from the neighbourhood of the symphysis pubis. *Acute necrosis* of these bones is sufficiently indicated by the grave constitutional symptoms which always accompany it. *Caries* gives rise to more difficulty. The writer has known a case of tuberculous caries of the lower part of the symphysis pubis

in which the inflammatory products gravitated backwards and to the left, so as to form a large firm swelling in the left half of the serotum, where it gave rise to much difficulty in diagnosis, and was thought to be either a sarcoma arising from the fibrous covering of the crus penis, or possibly a gummatous mass in the same situation. Sufficient attention was not paid to the fact that the man had chronic phthisis. George E. Gask.

SWELLING OF THE TONGUE is a condition the nature of which is generally obvious on inspection and palpation, if the history is taken into account at the same time, and many of the causes given in the following list need little detailed discussion :—

1. Causes of Acute Swelling of the Tongue :

- | | |
|---|---|
| A bite or sting—wasp-sting for example | (4). Variola |
| Injury, for instance by a fish-bone, or by biting during an epileptic fit | (5). Serum injections and other conditions liable to cause giant urticaria |
| Angina Ludovici | (6). Angioneurotic œdema |
| Corrosives or acute irritant applications | (7). Raynaud's disease |
| Acute œdema, secondary to :— | Œmorrhage with swelling of tongue, as in scurvy, leucæmia and other causes of purpura (p. 552). |
| (1). Inflammatory conditions within the mouth—Stomatitis (p. 542) | |
| (2). The effects of certain drugs, especially mercury | |
| (3). Erythema bullosum or pemphigus (p. 98) | |

2. Causes of Chronic or Persistent Swelling of the Tongue :

(1). Where the swelling is general :—

Macroglossia	Myxœdema	Acromegaly
Ecthinism	Mongolian idiocy	Chronic dyspepsia.

(2). Where the swelling is local or asymmetrical :—

Irritation by a tooth-plate or decayed tooth	Gumma	Ranula
Epithelioma	Tuberculous infiltration	Suprabuccal cyst
Leukoplakia (chronic superficial glossitis)	Actinomycosis	Angioma
	Calculus in a sublingual salivary gland	Sarcoma.

If the nature of the tongue enlargement is not obvious from the history and simple inspection and palpation, as will probably be the case when it is due to a *bite, sting, injury, corrosive* or *irritant* application, after the use of *mercury, serum*, or other drugs, *variola* or *pemphigus*—it may be so from the concomitant symptoms, as in the case of *ecthinism* (p. 234), *acromegaly* (p. 237), *mongolian idiocy* (p. 190), or *myxœdema* (p. 38). The swollen tongue of *dyspepsia* is seldom very large, though it may cause the patient discomfort at times from the sense of its being too big for the mouth; it is seldom difficult to recognize from its pale flabby look and its marginal indentation by the teeth.

Simple *macroglossia* is rare; when it does occur, the history is that it dates from youth or childhood, and the patient may otherwise be perfectly normal, unless he also has some other congenital peculiarity, such as macrocheilia (blubber-lips).

The chronic local lesions associated with swelling are in many cases associated with superficial ulceration, and the difficulties that may arise in distinguishing *simple, syphilitic*, and *epitheliomatous* trouble are discussed under *ULCERATION OF THE TONGUE* (p. 738). *Tuberculous* and *actinomycotic* lingual mischief are both very rare, and on that very account may be mistaken for malignant or syphilitic disease unless bacteriological or histological methods of diagnosis are resorted to. *Ranula* and *sublingual salivary gland calculus* or *cyst* both cause swellings that are beneath the front part of the tongue rather than in its substance; generally bulging up one side of the floor of the mouth near the frenum lingue. A *ranula* is a distended mucous gland, and after enlarging slowly to the size of a chestnut perhaps, it often ceases to grow further; but it does not fluctuate in its dimensions in relationship to meals, like a salivary gland swelling often does.

A *suprabuccal cyst* is situated in the root of the tongue posteriorly, where it arises from remains of the obsolete thyroglossal duct. It is seldom large; its nature may be suggested by its situation.

An *angioma* of the tongue is rare; sometimes, however, after remaining latent for years, it grows with rapidity and necessitates an operation. The diagnosis may be suggested by the colour of the tumour, but histological examination subsequent to removal may be required before one can be sure whether the tumour is a simple angioma, or whether it has taken on the malignant characters of an angiosarcoma or is a pure *sarcoma*.

Hæmorrhage in the substance of the tongue, with consequent great swelling of the organ and inability to use it for speaking or eating, may result from many of the different blood conditions that produce purpura. Only in very exceptional cases would such spontaneous bleeding be confined to the tongue, though conceivably this might be the first symptom in a case of acute lymphatic leukaemia, for example, or of purpura hæmorrhagica. Other hæmorrhages would follow, however, and indicate the need for blood-counts and other measures that are discussed under the heading of PURPURA (p. 552).

Raynaud's disease (p. 256) affects the fingers and toes more commonly than any other parts; it may, however, involve other distal tissues in a similar way, including the penis, the ears, the nose, and the tongue. In the latter it sometimes produces acute attacks of purple or almost black cyanosis, followed occasionally by local necrosis and subsequent scarring; acute swelling of the tongue may ensue when the paroxysm of vasoconstriction is passing off. I have never seen a case, however, in which the tongue alone was affected, and when the fingers and toes are attacked at the same time as the tongue the diagnosis is easy.

There remain for discussion acute œdema of the tongue due to *severe stomatitis*, *angioneurotic œdema of the tongue*, and *angina Ludovici*. The latter is an acute, virulent and generally fatal condition, in which streptococci or other organisms attack the floor of the mouth and root of the tongue and—without producing much pus, or even none at all—spread almost like wild-fire through the deeper structures of the mouth, throat, and neck, and cause extreme swelling of all the tissues in the neighbourhood: there is high fever, often a severe rigor, the patient is soon in a state of being hardly able to breathe, and extreme œdema of the glottis is apt to cause death from asphyxiation even when multiple incisions have been made into the brawny swollen parts. The condition is almost unmistakable; fortunately it is rare. It may be simulated by similar widespread œdema that results from infection of the deeper parts secondarily to one or other of the types of stomatitis discussed on p. 542; indeed, such stomatitis, when it has spread to the deeper tissues in this way, has virtually led to a secondary *angina Ludovici*: the latter name, however, is applied as a rule only to cases in which the acute overwhelming infection described above arises without any obvious preceding inflammation of the tongue or mouth.

Angioneurotic œdema of the tongue is rare, but it is of great importance because it is one of the purely functional conditions which may kill the patient. As a rule there is a history of similar attacks in other parts of the body previously (*Fig. 178*, p. 412), and other members of the family will be familiar with acute causeless swellings from personal experience, for it is a familial affection. Should it involve the tongue during a first attack, however, it would be mistaken for *angina Ludovici* very easily, especially as the patient may have pyrexia or a rigor notwithstanding the functional nature of the malady. Tracheotomy has been resorted to as the only means of saving the patient's life, and the diagnosis has only become clear when the œdema of the tongue and adjacent parts has subsided almost as rapidly as it came on, and the patient has had similar neurotic œdema, probably in other parts, on subsequent occasions. *Herbert French.*

SWELLING, VULVAL.—The differential diagnosis of vulval tumours must necessarily include not only true swellings of the vulva, but also swellings which appear at the vulva as a result of the displacement of other structures, such as occur in prolapse and cystocele, and in addition lesions like kraurosis vulvæ, which are not strictly swellings at all. The lesions of the vulva may be tabulated under various headings, as set forth in the following scheme:—

Inflammatory Lesions.—

Simple vulvitis		Syphilis:	Furunculosis
Gonorrhœal vulvitis		Hunterian chancre	Leukoplakic vulvitis
Soft chancre		Condyloma	Kraurosis vulvæ
Papillomata		Tertiary lesions	Pseudo- elephantiasis
		Tuberculosis	Esthiomene.

Cystic Swellings.—

Hydrocele of the canal of Nuck	Sebaceous cysts Mucous cysts	Implantation cysts Dermoid cysts.
--------------------------------	---------------------------------	--------------------------------------

Blood Cysts.—

Varicocele	Rupture of a varicose vein	Traumatic hematoma.
------------	----------------------------	---------------------

New Growths.—

Caruncle	Neuroma	Squamous-celled carcinoma (epithelioma)
Fibroma	Fibromyoma of round ligament	
Lipoma		Columnar-celled carcinoma
Angioma	Endothelioma	Sarcomata of various kinds.

Hernie.—

Inguinal	Posterior labial	Perineal.
----------	------------------	-----------

Displacement.—

Prolapse of urethral mucous-membrane	Cystocele	Fibromyoma of the vaginal wall.
Prolapse of uterus	Inversion of the uterus	

Unclassified.—Simple anasarca.

Certain of these lesions stand out pre-eminently as presenting difficulties in diagnosis. The general principles by which solid tumours are distinguished from cystic, inflammatory swellings from new growths, or new growths from hernie, need not be insisted upon here. Perhaps the commonest difficulty which arises in practice is the diagnosis of gonorrhœal vulvitis from simple vulvitis, and also between the gonorrhœal soft chancre and the syphilitic condyloma, the latter differentiation being of much more practical importance than the former as far as the patient is concerned. In the acute stage of a *gonorrhœal vulvitis* there is a chance of recognizing the gonococcus in the discharge, if filus made from it are suitably stained. Practically, *all* acute forms of vulvitis appear alike clinically, so that the recognition of the gonococcus becomes a matter of importance (see p. 185). In chronic gonorrhœal infections with vulval swelling, as a rule the organism cannot be found in the general vulval discharge, but might be found in the urethra or in the cervix. A gonorrhœal infection may be suspected if the patient gives a history of an acute onset, accompanied by scalding on micturition, and when there are redness of the orifices of Bartholin's glands, and much redness and swelling of the caruncle myrtiliformes. Papillomata or warts of the vulva may occur also in chronic gonorrhœal infections, and there is no evidence of a reliable nature to show that they occur in any other kind of infection.

The *soft chancre of gonorrhœa* may be mistaken for the *condyloma of secondary syphilis*, but as a rule this difficulty should not occur. The soft chancre is a typical punched-out ulcer with a somewhat red base and clean edges, discharging pus. The condyloma, on the other hand, is a raised, flat-topped excrescence, with sodden, epithelium-covered surface. Soft chancres are not very numerous, as a rule, and are generally limited to the vulva. Condylomata are numerous, and may occur all over the labia, around the anus, and even on the skin of the thighs and gluteal region. Condylomata are from the start, or very soon after, accompanied by a sore throat and a typical papular skin rash, for they are secondary syphilitic lesions. Soft chancres clear up with antiseptics; condylomata persist for long periods, but clear up in two or three weeks as a rule under mercurial treatment or salvarsan. It must not be forgotten that soft sores and condylomata may occur together in the same patient, in which case the diagnosis may be still more difficult.

Another practical differentiation which gives rise to anxiety is that between the *Hunterian chancre* or primary syphilitic sore, and *squamous epithelioma* of the vulva. This is a question which is of vital importance to the patient if valuable time is not to be lost in the treatment of a malignant epithelioma. The two lesions look much alike at first; they form raised hard indurated masses in the skin, which may ulcerate quickly as a result of necrosis of the superficial portions. Both give rise to a thin watery discharge, and to enlarged glands in the inguinal region which do not suppurate at first, but may do so later in the case of an epithelioma. It must not be forgotten that a primary chancre is very seldom seen in women, whilst squamous epithelioma is relatively common. Of course

the chancre will be followed in due course by secondary lesions, but it is not safe to wait for these to appear in a doubtful case. The only reasonable way to deal with such a case is to excise the doubtful swelling at once and submit it to microscope examination by an expert. A squamous epithelioma is easily detected in this manner in quite early stages, and does not in the least resemble a syphilitic lesion microscopically. The *Spirochæta pallida* may be recognized in scrapings of a hard chancre by the Indian ink method, or when fixed and stained by Giemsa's or Levaditi's methods (Plate XXI, Fig. J, p. 614). In sections, too, the spirochæte may be demonstrated, but it must be remembered that for this purpose the excised growth *must* be fixed in 5 per cent formalin solution. Wassermann's serum test may assist the diagnosis.

Tertiary syphilitic lesions are by no means common on the vulva. When they do occur they give rise to spreading ulceration with great destruction of tissue, and scarring in the older healed portions. Here, the only likely lesions to be mistaken are some forms of epithelioma, and tubercle. Obviously, in such conditions the only reliable method of diagnosis is to be found in excision of parts of the lesion and microscopic examination of sections made from them. The disease known as *esthiom'ne* is probably a tertiary syphilitic affection.

Pseudo-elephantiasis of the vulva is usually a syphilitic affection of the labia minora, giving rise to great enlargement, with a rough and thickened appearance of the skin. It could only be mistaken for real elephantiasis due to lymphatic obstruction by the *Filaria sanguinis hominis* (Plate XXI, Fig. F, p. 614), a disease which is practically never seen in this country.

Unilateral œdema of a labium minus is a fairly common condition, and is usually associated with an infected wound or with a primary syphilitic chancre. *Bilateral œdema* is almost always associated with general anasarca, the result of renal disease, cardiac disease, or pressure upon pelvic veins. It is not likely to be mistaken for any other disease.

Leukoplakic vulvitis and *kraurosis vulvæ* have certainly been confounded with one another clinically, and also in the published descriptions of the lesions. In the former the labia majora and minora and the prepuce of the clitoris are affected, whilst the vestibule always escapes. In the latter the lesion affects the vestibule, the orifice of the vagina, and the labia minora. There is much greater contraction of the vaginal orifice in kraurosis. Leukoplakia often precedes a squamous epithelioma; kraurosis is said not to do so. Leukoplakia occurs at all ages, whilst kraurosis is a disease of post-menstrual life. Leukoplakic vulvitis appears as a white sodden hardening of the skin, with flattening and shrinkage of the labia. Kraurosis at first looks red and swollen, but later takes a yellowish tinge. Leukoplakia causes intense itching; kraurosis gives rise to great pain and tenderness, with a very severe form of dyspareunia.

Apart from a cyst developing in Bartholin's gland or duct, cystic swellings of the vulva are not common. A *Bartholinian cyst* is recognized by its position on one side of the vaginal entrance, distending the posterior part of the conjoined labia, and also within the hymeneal ring. As a rule the orifice of the gland can be seen on the inner side of the cyst. The contents of this form of cyst may be glairy mucoid fluid, or pus. In practice, a Bartholin cyst is not likely to be mistaken for anything else; but it is wise to remember that the *posterior labial hernia* occurs in the same situation, and that new growths of the vulva may occur there as elsewhere. Bartholin cysts are always the result of infection, and as a rule a history of vulval inflammation can be obtained.

Varicocele of the vulva occurs practically only in connection with pregnancy, and is unmistakable. It has the same 'bag of worms' feel as a varicocele in a man, and as the veins are close to the skin a bluish colour is always to be noted. It is attended by much aching pain, especially on standing. The veins are degenerate, and liable to rupture as a result of labour or traumatism.

Hæmatoma of the vulva is recognized as a blue or violet-coloured swelling covered by tense shiny skin, and often spreading up into the pelvis by the side of the vagina. The history alone will often decide the nature of the swelling, but the appearance is quite typical as a rule. Hæmatoma of the vulva may occur apart from pregnancy, and then is always traumatic.

Urethral caruncle and *prolapse of the urethral mucous membrane* may be mistaken for one another. The former, however, is always a pedunculated or sessile new formation.

invariably springing from the posterior wall of the urethral orifice. It bleeds readily, is often, but not always, exquisitely painful, and is usually the result of infection. Prolapse, on the other hand, appears as a raised projection with rounded margins, and with the urethral canal in the centre as a dimple. The prolapsed portion may not necessarily include the whole ring of the mucous membrane. It may give rise to pain, and being always more or less strangulated, it is prone to bleed, much in the same way as a caruncle. It occurs as a result of some straining effort, or may accompany pelvic floor prolapse: it is not the result of infection.

The differential diagnosis of the new growths of the vulva presents no points of difference from their diagnosis in other parts of the body. The only common benign tumour is the *pedunculated fibroma*, or *molluscum fibrosum*, whilst *squamous carcinoma (epithelioma)* is the only malignant growth which occurs at all frequently.

If the general characters of a *hernia* are borne in mind, there should be no risk of overlooking or mistaking any of the varieties which occur in the vulva. The resonance on percussion if the hernia contains bowel, the reducibility of the contents, and the protrusion through a pre-existing opening, will usually suffice to distinguish hernie from other swellings. An obstructed or strangulated hernia is not so easy to recognize, but the accompanying acute symptoms and the previous history usually suffice to make the case clear.

Hydrocele of the canal of Nuck, an uncommon condition, may be mistaken for an inguinal hernia: but as a rule it is irreducible, definitely fluctuating and circumscribed, and has no obvious neck running into the inguinal canal. When the canal of Nuck has a patent peritoneal communication the swelling disappears as the patient lies down, but it is not reducible in the characteristic manner of a hernia. Such a condition is very rare.

The *displacements* included in the list above are all dealt with under the heading of PROLAPSE OF THE UTERUS (p. 538).

Thos. G. Stevens.

SYNCOPE.—(See COMA, p. 117.)

TACHE CÉRÉBRALE is the term used to denote that condition in which, after the finger has been drawn with moderate firmness across the patient's skin, the line along which it has passed becomes of a bright red colour from dilatation of the superficial arterioles and capillaries; the phenomenon develops within thirty seconds or a minute of the finger stroke, and the red mark remains evident for two or three minutes, or more. If letters or figures are marked out on the skin in this way, they appear as though they had been written in red, so that the condition has also been termed dermatographia. It was at one time thought to be a characteristic symptom of tuberculous meningitis, but not only is it sometimes absent in cases of the latter, but it is also present in a very large number of other different conditions, and sometimes in perfectly healthy people. All forms of meningitis may give rise to it, so that it is not even a means of distinguishing one type from another. It is seen in an extreme degree in cases of urticaria, particularly the factitious variety in which numerous wheals may develop as the result of hardly more than ordinary touching of the skin. A similar condition has sometimes been observed in the later stages of severe febrile illnesses in general.

Herbert French.

TACHYCARDIA, or abnormal rapidity of the heart's action, might, strictly speaking, be held to include every condition under which the pulse-rate is faster than the normal; but by common consent it is restricted for clinical purposes to cases in which there is no pyrexia. Nearly all fevers produce undue rapidity of the heart's action, though some, such as typhoid fever, tuberculous meningitis, cerebral abscess, yellow fever, and influenza, do so to a much less extent than others. The rapid heart-action of fevers, however, does not generally come into one's mind when one uses the term tachycardia; indeed the latter is chiefly employed for conditions in which it is rapid without there being anything which at first sight would seem to be a sufficient cause. Probably the best example of it is to be found in cases of pronounced *Graves's disease*.

The following is a list including this and some other causes of tachycardia:—

- Graves's disease or exophthalmic goitre
- Paroxysmal tachycardia
- Nervousness and excitement

Exertion, especially when the patient is out of training or anemic

Tobacco heart

Mitral stenosis

Pneumogastric irritation by:—

Casous glands, Mediastinal fibrosis, Thoracic aneurysm, Thoracic new growth.

Pneumogastric 'neuritis' after:—

Diphtheria, influenza, and other microbial affections.

Drugs:

Digitalis

Alcohol

Belladonna

Thyroid extract.

The four classical symptoms of *Graves's disease* are: A staring appearance of the eyes, generally spoken of as exophthalmos, though there need be no actual protrusion of the eye-balls (*Fig. 222*, p. 527); moderate and almost symmetrical enlargement of the thyroid gland; a pulse-rate between 120 and 180 per minute—usually about 140 when the attack is moderately severe; and extreme nervousness, with fine tremor of the outstretched fingers. When all these symptoms are present at the same time, there can be no doubt as to the diagnosis, but very often some of them are absent, and it is possible for tachycardia to be the only symptom of the disease; indeed, in a patient, particularly a woman between twenty and forty years of age, a persistent pulse-rate of over 120 would arouse serious suspicion that the case was really one of *Graves's disease*, even if the other three classical signs were absent.

Paroxysmal tachycardia should be distinguished at once from *Graves's disease* in which tachycardia alone has developed, by the fact that the tachycardia is not persistent, but recurs periodically with intervals of normal pulse-rate; the patient is more often a woman than a man, and may have long periods of perfect health; almost suddenly, the result

Fig. 289. Electrocardiogram in a case of paroxysmal tachycardia in a man. Lead 1 is from right arm to left arm. Lead 2 from right arm to left leg. Lead 3 from left arm to left leg. P, Atrial wave. R, T, Ventricular wave. Time marking in 1/2 seconds. At first sight the tracing looks normal, but when time relationships are considered, it will be seen that there are 16 heart-beats in each 25 one-fifths of a second, so that the heart is making 208 beats per minute. The tracing is from a young man seemingly in perfect health, who had presented himself for examination as a recruit. It was found that when he had been lying perfectly still for a little time his pulse-rate was 72 per minute, but upon any exertion, such as holding his breath as long as he could, or upon 2 to 3 frog-his-traces, or on walking about, he felt a curious sensation in his chest lasting for a few minutes, and small enough to be passed off as ordinary work, and there was no trace of any other abnormality. The condition appeared to be one of simple paroxysmal tachycardia.

sometimes of a fright or shock, sometimes without apparent cause, there is a sense of something being the matter in the precordial region, amounting as a rule to little more than a fluttering or palpitation, together with a feeling of faintness and lack of strength, and perhaps of numbness or of pins-and-needles in the extremities; when examined the patient may present no other abnormality than a pulse-rate of perhaps 160 or even 200 to the minute (*Fig. 289*). The attack may last a few minutes, or an hour or two, or for days, or

more rarely for weeks: it is apt to cease as suddenly as it began, and a similar attack is almost certain to recur after a longer or shorter interval—the main symptom of the complaint being summarized by the title 'paroxysmal tachycardia.'

The very rapid heart action that may be produced by *nerveousness*, or *excitement*, or by some ordinary exertion such as coming rather rapidly upstairs when one is *out of training*, or when the patient is suffering from *anæmia*, or during *convalescence* after an illness, or after the over-use of *tobacco*, is a familiar phenomenon; the tachycardia disappears rapidly when the patient rests, and the diagnosis is not as a rule difficult. If ordinary resting for a while does not cause the rate of the heart-beat to return nearly or quite to normal, there may be doubt as to the diagnosis, unless the patient can be re-examined on another occasion: if there is persistent tachycardia a suspicion of Graves's disease will be aroused, or there may have been acute overstrain of a weakened *fatty, fibroid, rheumatic, alcoholic, or syphilitic* myocardium, followed by long-continued tachycardia without bruit, but perhaps with *auricular fibrillation*: electrocardiograms may be required before an exact diagnosis can be arrived at in many of these cases.

Mitral stenosis is of all the valvular lesions of the heart the most liable to lead to rapidity of the heart's action; but it seldom happens that the pulse-beat is fast until there has been other evidence of failure of the cardiac compensation. The diagnosis will generally be obvious from the history of acute rheumatism or chorea, the typical facies and malar flush, and the cardiac bruits.

It is exceedingly difficult to be certain of a diagnosis of *irritation of a pneumogastric nerve* within the thorax unless the existence of mediastinal *new growth, aneurysm, or fibrosis* is already known on account of the abnormal physical signs, the *x-ray* appearances, the visible tumour, or the varicose distention of the superficial thoracic veins: if an intrathoracic abnormality is known to exist, and tachycardia becomes a prominent feature of the case, it will probably be due either to mechanical interference with the heart's action or to similar interference with one or other vagus nerve. *Casneous glands* irritating the pneumogastric nerve are still more difficult to be sure of; but occasionally one ventures upon this diagnosis when a child who has been fed on untested or unsterilized cow's milk, develops obscure ill-health associated with persistent tachycardia. Such diagnosis would be still further suggested if there were at the same time enlarged glands in both sides of the neck, if there were pyrexia without any obvious explanation of it, or if there were any evidence of obstruction to the right bronchus, for the right bronchial gland is enlarged far more often than is the left. An *x-ray* examination may serve to confirm the suspicion (*Fig. 61, p. 149*).

Diphtheria, influenza, and possibly other microbial infections, are occasionally followed by marked and persistent tachycardia during convalescence, or even for weeks, months, or years afterwards. After diphtheria the condition is generally fatal. Influenza is always a dangerous diagnosis because it is so difficult to establish, but in certain cases in which the original diagnosis has been influenza, tachycardia to the extent of 200 heart-beats per minute may be present for months without the patient suffering from any severe cardiac symptoms, and the condition ultimately terminates in recovery with a return of the heart-beat to the normal rate. Precisely what is the nature of these cases it is impossible to say, but it has been thought by some that the symptom is due to inflammatory changes in the pneumogastric nerve, produced by whatever one means by the toxins of the disease. Whether this be so or not, the fact that persistent tachycardia may arise out of febrile illnesses should be borne in mind.

There are certain drugs which cause the heart's beat to be very rapid, the best known perhaps being *digitalis, belladonna, thyroid extract, and alcohol*. Certain patients suffering from cardiac symptoms seem unable to bear digitalis, the heart being driven into the condition spoken of as *delirium cordis*, though the reverse effect—slowing of the heart, bradycardia—is to be expected in persons who take digitalis well over a long period. When alcohol is the cause of the tachycardia, the fact may be obvious, the only difficulty arising in patients, mainly women, who may be regarded by all as entirely above reproach, but who nevertheless may be addicted to secret drinking. Belladonna in small doses slows the heart, but there are great variations in the degree to which different patients tolerate this remedy, even pharmacopœrial doses sometimes producing toxic symptoms of which tachycardia is one. Widely dilated pupils and dryness

of the tongue will help to point to the diagnosis in cases in which the belladonna is taken otherwise than medicinally. Tachycardia is the chief symptom by which one recognizes that a patient for whom thyroid extract has been prescribed is receiving too large a dose.

Herbert French.

TALIPES. (See CUT-B-FOOT, p. 111.)

TASTE, ABNORMALITIES OF. Abnormalities of taste may be grouped under three main headings, namely: (1) *Impairment or loss of ordinary taste sensations*; (2) *Perverted taste sensations*; (3) *Sensations of a foul taste in the mouth*. The following conditions may produce these:

1. Impairment or Loss of Taste (*Igeustia*):

(a). *Due to nerve lesions*:

Paresis or paralysis of the lingual branch of the fifth nerve	Glosso-pharyngeal nerve paralysis
Paralysis of the facial nerve, including the chorda tympani	Bulbar paralysis
	Cerebral tumour, especially of the uncinate gyrus
	Hysteria.

(b). *Due to affections either of the mouth or nose*:

A common cold	Adenoids
Hay fever (<i>coryza e feno</i>)	Other varieties of nasal obstruction
Atrophic rhinitis	Bromism
Hypertrophic rhinitis	Iodism
Nasal polypus	Mercerial and other varieties of stomatitis

(c). *Febrile conditions*, especially when associated with coating of the tongue.

(d). *After destruction of the nerve endings* in the tongue by corrosives taken accidentally or with suicidal intent.

2. Perverted Taste Sensations (*Parageustia*):

Pregnancy		Hysteria	Epileptic aura	Insanity.
-----------	--	----------	----------------	-----------

3. Foul Taste in the Mouth (*Cacogeustia*):

(a). *Local conditions of the mouth or nose*:

Caries of the teeth	Septic stumps under tooth-plate
Retention of food particles between healthy teeth	Gumma of the tongue or palate
Furred tongue from any cause	Epithelioma of the tongue or mouth
Excessive smoking	Stomatitis from any cause (p. 542)
Mouth breathing at night	Septic infection of the antrum of Highmore, or an ethmoid, sphenoid, or frontal sinus.
Gumboil	

(b). *Severe fevers* associated with dryness of the mouth and coating of the tongue, especially in:

Pneumonia	Typhoid fever	Peritonitis	Septicæmia, etc.
-----------	---------------	-------------	------------------

(c). *Septic lung conditions*, especially

Phthisis, with secondary infection of cavities	Gangrene of the lung
Bronchiectasis	Empyema ruptured into the lung
Bronchioectasis	Liver abscess ruptured into the lung
Fetid bronchitis	Subdiaphragmatic abscess ruptured into the lung.

(d). *Certain drugs or poisons*, especially —

Mercury		Bromides	Guaiacol
Copper		Sulphides	Valerian
Arsenic		Paraldehyde	Cod-liver oil
Lead		Asafoetida	Castor oil.
Iodides		Creosote	

(e). *Certain foods*, such as:—

Garlic	Leeks	Shallots.
Onions		

(f). *Hysteria and functional conditions*.

From a diagnostic point of view, impairment of taste sensations is of importance only in rare cases. When the impairment is unilateral, it is almost certainly due to a lesion involving either some portion of the third branch of the *fifth nerve*, the *chorda tympani*, or the *glosso-pharyngeal nerve*. It is not often difficult to distinguish between these three. If the chorda tympani is involved, it is almost certain that the facial nerve will also be affected upon the same side, and this will be evidenced by paresis or paralysis of the face of the infranuclear type (p. 493); there may be excessive watery secretion from the sub-maxillary gland upon the same side; the commonest condition to cause these symptoms is disease of the middle ear extending to the Fallopiian canal. If it is found that taste is impaired only in the posterior third of the tongue upon one side, the lesion probably affects the glosso-pharyngeal nerve, and it is very possible that there may be paresis of the same side of the palate or partial paralysis of the pharynx at the same time. When the lingual branch of the fifth is involved, the impairment of sensation is in the anterior two-thirds of the tongue on the same side. The lesion may be a tumour or an injury affecting the lingual nerve in the mouth; or it may be part of a more general affection of the fifth nerve of that side, with corresponding interference with cutaneous sensibility of more or less of the skin of the face, according to the extent to which the different branches of the fifth nerve are involved; if the motor root is affected, the fact can be ascertained by feeling the masseter and temporal muscles, which, when the patient clenches his teeth, do not harden so much on the affected as on the sound side.

When sensation on both sides of the tongue is affected, it is possible that the lesions described above may be bilateral; but it is much more likely that the defect is then not primarily nervous, unless it is due to *bulbar paralysis*, the progressive labio-glosso-pharyngolaryngeal weakness of which is pathognomonic.

When the cause of impaired sensation is in the nose, as in the case of *coryza*, *rhinitis*, *polypi*, or *adenoids*, it will be found that some substances can be tasted easily and others not at all; this depends upon the fact that taste consists of two parts, flavour and savour; savour depends upon sensation transmitted by the olfactory nerves—the so-called taste of roast beef for instance; savours will be defective when the nose is the cause of abnormal taste-sensations; while flavours such as the taste of sugar, gentian, or salt, which are transmitted by the gustatory nerves of the tongue, will still be fully preserved.

The differential diagnosis of the other conditions enumerated in the above list need not be detailed, for the conclusion come to will depend upon the result of careful inquiry into the history, investigation of the abnormal physical signs, and the other symptoms in the case. One would only emphasize the possibility of caries, or decomposing food between teeth that superficially look sound, or septic infection of the accessory sinuses of the nose being long overlooked, though in each case abnormal taste sensations may be prominent.

Herbert French.

TEETH, GRINDING OF. (See GRINDING OF THE TEETH, p. 265.)

TENDERNESS IN THE CHEST implies that pain is felt when some part of the chest wall is touched or pressed; it is a common symptom; in some instances the pain felt is a direct pain, due to stimulation of sensory nerves actually in the diseased area; in others—perhaps the majority—the pain is a referred pain ('somatic pain'), felt in the skin and subcutaneous tissues that are tender, but due to a visceral lesion remote from the tender area.

CAUSES OF TENDERNESS IN THE CHEST.

These may be classified according to the situation of the lesion to which it is due.

I. Lesions of the Chest-Wall: the pain is for the most part direct:—

Inflammations of the skin and underlying tissue	Affections of the ribs and sternum	Intercostal neuralgia
Intercostal myositis	Blood diseases	Hysteria
Myalgia	Intercostal neuritis	Herpes zoster
Pleurodynia	Injury of the intercostal nerves	Pleurisy
		Mediastinal disease
		Pericarditis.

2. **Lesions of Thoracic and Abdominal Viscera:** the pain is usually a referred pain; felt in lesions of the —

Lungs	Diaphragm	Liver.
Heart and aorta	Stomach and oesophagus	

Lesions of the Chest-Wall. Tenderness in the chest is probably the chief complaint in *superficial inflammatory lesions* of the chest wall, such as bruises, burns, cuts, mastitis, and superficial infections of all sorts, the diagnosis of which will probably leap to the eye, and need not be discussed further.

Pain will be the chief complaint in *intercostal myositis*, often vaguely called rheumatic, that occurs after chill or strain of the intercostal muscles; but the affected muscles will also be tender on pressure, the tenderness being in the deeper structures, not in the superficial tissues. The condition is also known as *intercostal myalgia* or *pleurodynia*; it has to be distinguished from pleurisy by the absence of friction-sounds on auscultation; and from disease of, or pressure on, the intercostal nerves. No doubt the tenderness is due to irritation of the sensory fibres in the intercostal muscles. Similar, but more transient, pain and tenderness may be met with in the *stitch* to which the untrained athlete is prone.

Tenderness in the chest may result from *disease or injury of the ribs or sternum*, when it will be localized to the injured spot; fracture, inflammation, or new growth may be the immediate cause. If *fracture* is present, a history of injury should be obtainable; the x-rays may show the fracture; or crepitus between the fragments on movement, or deformity may be made out. *Sternal or costal osteitis, or periostitis*, may follow injury; or occur in the course of such diseases as enteric fever, tuberculosis, pyaemia or septico-pyemia; the local signs of inflammation (pain, redness, heat, swelling) and the general condition of the patient should make the diagnosis fairly simple. Tenderness in the chest due to *new growth* in the ribs or sternum — such as hydatid, sarcoma, secondary deposits from carcinoma — is a rarity that need only be mentioned. Tenderness of the ribs and sternum, as well as of the long bones of the limbs, is not uncommon in certain *blood diseases*, in which hyperplasia of the red marrow, or excessive accumulation of white cells in it, may occur: such as pernicious anaemia or leukaemia. The diagnosis here must be made on the results of examination of the blood (p. 24). In all these instances the tenderness is deep, and due to irritation of the sensory nerves of the periosteum or bone; the pain felt on pressure is a direct pain.

Tenderness at certain points of, or all along, the course of an *intercostal nerve* is common in various affections of these structures. The particularly tender spots are three in number, and correspond to the points at which the posterior primary, the lateral cutaneous, and the anterior cutaneous branches are given off, near the spinal column, the mid-axillary line, and the sternal margin, respectively. Such tenderness may be marked in *intercostal neuritis*, which is rare; in *intercostal neuralgia*, which is often diagnosed when some more serious intrathoracic disorder is really present, such as pneumonia or pleurisy; and in cases of pressure on an intercostal nerve, such as may be set up by *abscess* about the spinal column, *aneurysm* of the descending aorta, or *new growth* invading the spinal canal. Whenever a patient complains of severe or obstinate pain and tenderness in the side, careful and repeated physical and x-ray examinations should be made, the possibility that some such deep-seated disease may be present being kept in view before the diagnosis of intercostal neuralgia, or of functional nervous disease (hysteria), is made. In exceptional cases of *hysteria*, zones of tenderness in the chest, possibly, too, Charcot's spasmodic zones, may be found.

Pain and tenderness along an intercostal nerve are common in *herpes zoster*, and may be present before, during, and after the appearance of the characteristic rash. The tenderness often has the three spots of maximum development mentioned above; it is particularly when it occurs in the second half of life that herpes may be followed by a long period of pain and tenderness along the course of the affected nerve. Until the rash has appeared, or in the comparatively infrequent cases when the rash leaves no scarring behind it, the diagnosis of herpes may be difficult; the rash, once seen, can hardly be mistaken.

Lesions of the Underlying Viscera. Tenderness in the chest is very frequently a symptom of disease in the underlying viscera, thoracic or abdominal, when the pains to which it gives rise are in most cases referred pains. The tenderness is therefore as a

rule superficial, confined to the skin and subjacent areolar and fatty tissues; if these can be drawn aside, pressure can be made on the deeper tissues that normally underlie the tender area without provoking pain. Properly speaking, 'tenderness in the chest' can only refer to tactile hyperæsthesia, or the eliciting of pain on pressure whether light or heavy. Such tactile hyperæsthesia, or the production of unpleasant sensations or pain by the very lightest touch, is common in neuralgia and in neuroses, or in cases of referred pain. But a similar hyperæsthesia for cold, or less often for heat, sometimes occurs in the chest—in tabetic patients, for example; this may perhaps be regarded as a special form of 'tenderness.' In the same way hyperæsthesia for pain, or hyperalgesia, in which a normally painless stimulus or impression becomes transformed into an acutely painful sensation, is to be regarded as a form of 'tenderness' in the chest. Further, perversions of sensation sometimes occur in organic nervous diseases, such as syringomyelia or tabes. Thus, tenderness may be elicited by the continuous application of a pressure that is painless if applied only for a short time (summation of painful stimuli); or the pain may be first felt some little time after the application of the stimulus to the tender area (retarded sensation).

Tenderness of the chest is a common complaint in *pleurisy*. The physical signs should suffice to make the diagnosis simple if a careful physical examination be made. The tenderness is deep as a rule, and not in the skin and loose subcutaneous tissues.

The sternum may be tender in the rare cases of *mediastinal inflammation* or *tumour* that are met with from time to time; tenderness and direct pain may similarly be caused by the pressure of *aneurysms* on the internal surface of the chest-wall. The diagnosis in these cases must be made on the results of the physical and x-ray examination of the patients.

Tenderness with pain over the precordia is fairly common in *pericarditis*, diagnosed by the canter rhythm and the pericarditic rub. It may be so extreme as to preclude percussion or a satisfactory physical examination. Similar pain and tenderness have also been found at the epigastrium and the upper costal angles in these cases; due, perhaps, to involvement of the diaphragm in the inflammatory process.

Chest tenderness is not rare in cases of *acute* or *chronic disease of the lungs*, particularly *tuberculosis*: in these, it is hard to be sure that one is not dealing with referred pains due to old or recent pleurisy or pleural adhesions. The tenderness may be either superficial or deep: sometimes it is so marked as to be elicited even by the pressure of the clothes. It is generally felt most about the region of the apices of the lungs, the curve of the shoulder, or the scapula. It is often a very chronic trouble, vanishing during periods of general improvement, returning again when the patient's health is low or the pulmonary lesion is progressing. Similar tenderness is often met with in *acute bronchitis*, or with *chronic bronchitis and emphysema*: the diagnosis must be made on general lines. It must be remembered that identical areas of referred chest-tenderness may be observed in disorders of such various organs as the heart, lungs, liver, and stomach; and that a patient may be long treated for 'rheumatism' of the shoulder, for example, when he is really suffering from such widely different disorders as tuberculosis, gall-stones, gastritis, carcinoma mammae, or coronary artery sclerosis.

Direct tenderness about the precordia is sometimes prominent in *heart disease*: as a rule, however, the tenderness is due to hyperæsthesia of referred origin. It is most marked in *angina pectoris*, and often persists after the anginal pains have passed off. Both the pain and the tenderness are felt within the area of distribution of the first to the eighth dorsal nerve-roots: the roots usually receiving the first and most intense impressions are the second dorsal. The left ventricle, the commonest primary seat of pain, is in relation with the second to the fifth dorsal nerve-roots: the auricle with the fifth to the eighth: the ascending aorta with the third and fourth cervical and the first to the third dorsal. These nerve-connections explain the extensive radiation and wide distribution of the tenderness and pain in the superficial tissues that may form such prominent symptoms of heart disease: for the chest, neck, and arm may all be affected. The tenderness of *angina pectoris* commonly occupies the same areas as the pain, takes the form of a soreness, smarting, or of hyperalgesia to touch, and may last for days after the pain is over. In some cases, touching or stimulating the hyperalgesic area on the chest, arm, or neck, may reflexly induce an anginal attack—even the pressure of a stethoscope applied for

auscultation may suffice—which is a strong argument for regarding the tenderness as a viscerosensory reflex or a referred tenderness. Such anginal attacks and tenderness are commonest in coronary sclerosis, aortic aneurysm, aortic reflux, and acute aortitis; they may also be seen in any form of heart-disease in which hypertrophy and dilatation have taken place, and the heart has to do more work than it can manage, for example with raised blood-pressure and arteriosclerosis, or with adherent pericardium. In well-marked cases, the cardiac origin of areas of tenderness in the chest should not be difficult to diagnose, owing to their association with severe anginal pains on the one hand, and with the fact that the pain is brought on by exertions or emotions that increase the work of the heart. Identical areas of tenderness may be found in pleurisy or chronic pulmonary tuberculosis; but here the pain will be connected with respiration or coughing in an unmistakable manner, and there will be the history and signs of pulmonary rather than of cardiac disease. Identical areas of chest tenderness may be found in diseases of the stomach, in the areas of distribution of at any rate the fourth and fifth dorsal nerves; the diagnosis here will turn on the history of gastro-intestinal disorder, and on the radiation of the pain and the discovery of tenderness in the epigastrium.

Tenderness in the chest may result from *injuries* or *inflammations of the diaphragm*, the lower costo-chondral margin being affected. The diaphragm is innervated by the phrenic nerves mainly, and so is connected with the third, fourth, and fifth cervical nerve-roots; accordingly, referred diaphragmatic pain and tenderness may also be felt in the top of the shoulder, an area innervated by the fourth cervical nerve. In most cases, the tenderness of these areas will be due to *diaphragmatic pleurisy*.

Diseases of the stomach, particularly *gastric ulcer* and *flatulent dyspepsia*, may give rise to pain and tenderness in the chest that may be very hard to distinguish from those due to cardiac disease. As a rule, the history of gastric disturbances should be of great assistance in coming to a correct diagnosis; although it must be remembered that flatulence and temporary gastric upsets are seen not infrequently in true angina pectoris. Further, the pain and tenderness due to diseases of the stomach are mainly abdominal, are in the epigastric and left hypochondriac regions, and in the lower half of the back of the chest; whereas in cardiac disorders they are characteristically situated higher up in the chest and back. Electrocardiograms may be required to show whether the heart action is normal or not.

It is possible that disease or painful stimulation (as by hot drinks) of the *oesophagus* may produce an area of referred tenderness in the chest, over the lower third of the sternum and in the middle line, in correspondence with the pain that is felt here in these conditions.

Tenderness in the right side of the chest near the costal margin is not rare in *diseases of the liver* and *gall-bladder*, corresponding to the cutaneous distribution of the seventh, eighth, and ninth dorsal nerves; for the most part, however, the pain and tenderness are in the epigastrium and the right hypochondrium. The right phrenic nerve (third to fifth cervical) sends twigs to the liver and gall-bladder, so that tenderness and pain may also be felt in the right shoulder, just as they may be in disorders of the diaphragm. It is particularly in cases of gall-stone or biliary colic that these areas of tenderness are likely to be found. In patients with hepatic abscess, the spread of inflammation to the chest-wall may give rise to direct pain and tenderness in the chest, with the development of characteristic local and general symptoms and signs; the diagnosis here will have to be made from such things as axillary abscess, empyema making its way through the chest-wall, or abscess arising in the chest-wall.

A. J. Jee-Blake.

TENDERNESS IN THE EPIGASTRIUM. (See PAIN IN THE EPIGASTRIUM, p. 436.)

TENDERNESS OF THE HYPOCHONDRIUM.—(See PAIN IN THE HYPOCHON-
DRIUM, p. 459.)

TENDERNESS IN THE ILIAC FOSSA. (See PAIN IN THE ILIAC FOSSA, p. 452.)

TENDERNESS IN THE JOINTS. (See JOINTS, AFFECTIONS OF THE, p. 337.)

TENDERNESS IN THE LIMBS. (See PAIN IN THE LIMBS, GENERAL, p. 463; and
SENSATION, SOME ABNORMALITIES OF, p. 604.)

TENDERNESS IN THE SCALP occurs in two main varieties:—

1. Direct Tenderness, due to injury or disease, such as—

Bruising or infected wounds	Lupus erythematosus, von Recklinghausen's disease
Inflammation or suppuration complicating pediculosis, ringworm, favus, eczema, pruritus, acne, etc.	Sclerodermia, Brocq's 'pseudopelade'
Herpes and dermatitis herpetiformis, erysipelas	Diseases of the skull—rickets, syphilis, tumour.

2. Referred Tenderness, either due to disease elsewhere, or functional:—

Meningitis, increased intracranial pressure, intracranial tumour or abscess, concussion of the brain, otitis media	Neuralgia, major and minor, whether primary or due to disease of the eyes, ears, teeth, or viscera
	Neurasthenia and hysteria.

Fig. 290 exhibits the cutaneous nerve-supply of the scalp and face, indicating the areas in which tenderness and pain are to be expected when disease or disorder of the various nerves is present.

If tenderness in the scalp is due to *bruising* or *wounds*, it should not be difficult of diagnosis when the history has been obtained. A similar tenderness is naturally to be expected when inflammation or suppuration occurs as a complication or later stage of any of the numerous skin diseases to which the scalp is liable, such as *pediculosis*, *ringworm*—a suppurating ringworm is known as *kerion seborrhoeic dermatitis*, *favus*: the itching of *eczema* or *pruritus* may be so severe as to lead to scratching which breaks the skin, with the result that impetigo ensues. In young men and women *acne* may spread back to the scalp from the forehead, face, or neck; *acne decalvans* is a mild staphylococcal infection of the hair-follicles that creeps slowly across the scalp, and leaves it bald by destroying the hair-follicles. *Furunculosis* of the scalp, and inflammation of a *sebaceous cyst*, need only be mentioned in this connection.

Fig. 290.—The cutaneous nerve-supply of the scalp. G A, Great auricular nerve; G C, S O, and Th O, Great, small, and third occipital nerves; V₁, V₂, V₃, Ophthalmic, superior maxillary, and inferior maxillary divisions of the trigeminal (or fifth cranial) nerve.

In *herpes ophthalmicus*, or herpes zoster of the area supplied by the ophthalmic or first branch of the trigeminal or fifth cranial nerve, extreme tenderness over the affected area may be noted while the eruption lasts; and after it has disappeared, tenderness and itching may be left behind for many months or years, sometimes with abnormal pigmentation.

Dermatitis herpetiformis (p. 755) is a somewhat similar grouped vesicular or bullous eruption, with ringed and other erythematous lesions, but characterized by a much more extensive distribution than herpes zoster: when it involves the scalp much tenderness may ensue, although the chief complaint will be of itching, and the course of the disorder is long and uncertain. *Erysipelas* is common in the scalp, and should be diagnosed readily. *Lupus erythematosus* of the scalp may cause tenderness while progressing actively, when it may resemble even a severe persistent erysipelas: as a rule it is a very chronic, slowly progressive disorder, commoner in females than in males, starting between the ages of twenty-five and forty-five. It produces smooth and depressed areas of complete and permanent baldness, reddened by abundant injected venules. In *von Recklinghausen's disease*, subcutaneous neurofibromas are found all over the body, in association with freckling and pigmentation: occurring on the scalp, these tumours will make it tender, whereas the tumours of fibroma molluscum (*Fig. 291*), a disorder at first sight resembling von Recklinghausen's disease, are not sensitive to pressure. *Sclerodermia* of the scalp may occasion much tenderness, particularly in its early stages: it is a chronic diffuse infiltration of the skin that ends in atrophy, and by many is supposed to include the 'pseudopelade' of Brocq, an atrophic indurative affection of the scalp giving rise to depressed areas of absolute and permanent baldness that adhere to the underlying skull, and connected by Brocq with alopecia areata.

Tenderness of the scalp is common in *rickets*, and is the main cause of the head-rolling and restlessness of the recumbent rickety child. It is due to hyperæmia and disordered growth of the cranial bones; and can often be diagnosed at sight by the thinness of the hair or positive baldness of the occipital region to which the head-rolling leads. A similar tenderness of the cranial bones is seen in *congenital syphilis*, and is caused by the rarefying (craniotabes) or hyperplastic (hot-cross-bun skull) osteitis present. In adults with neglected syphilis the skull may be tender from *secondary syphilitic periostitis* or *tertiary gumma*; besides the tenderness, pain is present, and is characteristically worse at night. *Tumour of the cranial bones* may give rise to tenderness of the overlying scalp or periosteum; in adults such tumours are usually secondary to malignant disease of the breast, thyroid gland, testis, or prostate. In children they are often secondary to sarcoma of the suprarenal gland, and may be the first clinical evidence that anything is amiss.

Tenderness in the scalp may be due to organic disease that is not in direct connection with it. In *meningitis*, whether syphilitic, tuberculous, or due to pus-producing microbes, local or general tenderness of the scalp may be a marked feature; and the same is true in cases with *increased intracranial pressure* due to any cause whatever. The chief complaint, however, will be of HEADACHE (p. 293). In *intracranial tumour* the scalp and periosteum are sometimes tender to pressure in the neighbourhood of the growth; the associated

Fig. 201. —Molluscum fibrosum in a comparatively early stage.
(From photograph lent by Dr. A. Rendle Short.)

signs, such as vomiting on change of position, slow pulse, optic neuritis, and local paresis or paralysis, should aid the diagnosis. Tenderness of the scalp in the occipital region and below it has often been noted after *concussion of the brain*, whether mild in degree or severe, and apart from neurasthenia; the pain and tenderness may each be both superficial and deep.

Tenderness of the scalp is often marked in *neuralgia*, a vague term applied to any severe pain that follows, or seems to follow, the distribution of a nerve. In *trigeminal neuralgia*, *neuralgia major*, or *tic douloureux*, the pain and tenderness often spread back to the vertex and parietal eminence, in correspondence with the cutaneous distribution of the first or ophthalmic branch of the fifth nerve. Pressure over the tender area will often bring on a paroxysm of pain; yet while the pain is raging, the patient often gains some relief by firm pressure over the painful part. When the paroxysm is recently past, pressure does not have any obvious effect in some cases. Identical neuralgic pain and tenderness may be met with in the rare cases where a tumour presses on the trigeminal nerve or its roots, as may happen in patients with meningeal new growths. Definite loss of sensation occurs if the nerve is involved in a tumour, whereas in *tic douloureux* there is no anaesthesia; in addition, the other signs of intracranial tumour should be looked for.

In another group come the cases of *neuralgia minor*, in which pain and tenderness in the scalp form a visceral reflex, and are due to disease in the eyes, teeth, ear, and thoracic or abdominal viscera. A referred visceral pain usually brings with it superficial tenderness, and both the pain and the tenderness are found over 'segmental' areas, or areas that

do not correspond with the distribution of the peripheral nerves, but follow a central distribution (*Figs. 292, 293*). In other patients, however, the same lesions produce areas of pain, and less often of tenderness also, that do follow distributions corresponding with those of the peripheral nerves; and these are described as cases of *neuralgia minor proper*. To give examples of reflex neuralgia, disease of the *upper bicepspids* may cause pain and tenderness in the temporal region; disorders of the *eye*, particularly astigmatism and hypermetropia, iritis, and glaucoma, may cause headache and tenderness spreading from the forehead to the vertex and to the temporal area; suppuration in the *middle ear* may make the whole side of the head tender. Certain areas on the head are segmentally united with other areas on the body: the temporal area of the scalp is connected thus with the seventh dorsal segment, and so diseases of the *heart, lungs, or stomach* may all bring about temporal pain and tenderness, associated with the segmental area of cutaneous tenderness about the level of the epigastrium that directly represents the seventh pair of dorsal nerves. It is probable that a number of patients with undetected disease of the teeth, eyes, ears, or viscera, are treated for 'neuralgia' for long periods, when a more careful examination of their history and investigation of their physical condition would lead at once to the proper diagnosis. In a certain number of cases pain and tenderness in the scalp are due to *general diseases* such as diabetes mellitus, malaria, and rheumatism: a fact that leaves room for much latitude in diagnosis.

THE SEGMENTAL AREAS OF THE SCALP (after Head.)

In both *neurasthenia* and *hysteria* complaints of pains and tenderness are common, and the scalp may be affected just as any other part of the body may. The neurasthenic often has occipital tenderness, with pain referred to the hair: brief mental effort may bring on pain and tenderness in the sinciput or vertex. The hysterical patient may be prostrated by headache, with extreme tenderness of the scalp. It is not necessary to say that the greatest care to exclude organic disease of every sort should be taken before the diagnosis of neurasthenia or hysteria is made in a patient complaining of tenderness in the scalp. It is noticeable that any conditions tending to build up the strength and improve the nutrition of neuralgic, neurasthenic, or hysterical patients, are likely to lessen the pains and areas of tenderness of which they so often complain. Conversely, these persons are always much worse when their health is low, and particularly when they are anæmic.

A. J. Jex-Blake.

TENDERNES IN THE SPINE occurs in two different sets of conditions. In the first it is due to local disease of the skin or subcutaneous tissues, fasciæ, muscles, bones, or nerve-tissue in the immediate neighbourhood of the spine: and the pain felt when the tender spot is touched is a direct pain. In the second there is no local disease, and the pain felt on stimulation of the tender area is a referred pain, due in most cases to organic disease of one or other of the viscera, in a few to some obscure nervous disorder. The tenderness varies widely in degree. In the severest cases, whether direct or referred, the pain may be such that the patient cannot endure even the light pressure of the clothes ordinarily worn, and is in agony the moment a finger is laid upon the tender place.

When due to **Local Disease**, the tenderness is usually associated with rigidity of the spine in the tender section, a protective reflex designed to give rest to the diseased part. This is particularly well marked when it is bone—the vertebral column—that is diseased. A similar but less complete and more extensive rigidity will be noted when the local disorder is in the muscles or fasciæ of the back. Should the local disease or injury

be so extensive as to involve or compress the spinal cord, special symptoms (girdle-pain, paresis, anæsthesia, etc.) will be added. The chief morbid states in which such tenderness of the spine occurs are summarized in the following table :—

<i>Diseases of the skin and subcutaneous tissue</i>	}	Injury, infected wounds, abscess-formation, etc.
<i>Diseases of the muscles, fasciæ, or nerves</i>		Gout, rheumatism, injury, herpes, etc. Tuberculosis and other infections Caries sicca, spondylitis deformans, ‘ typhoid spine ’
<i>Diseases affecting the vertebrae</i>	}	Erosion by aortic aneurysm Invasion by malignant disease Injury
<i>Traumatic neurasthenia, with local lesions that are not demonstrable</i>		‘ Railway spine.’

To consider these lesions in detail: Obviously the skin and subcutaneous tissues may be tender over the spine after falls or blows on the back, infected wounds, in acne and furunculosis, in abscess-formation, whether the infection is derived from without, or from within as in pyæmia: a *psous abscess* may point and discharge on the back over the vertebral column. Tenderness in the spine due to *affections of the fasciæ and muscles* may be experienced by any ill-trained person who over-uses or strains his spinal muscles: it is also common in *gouty* patients: and frequently it is associated in the rheumatic with attacks of *lumbago*. Deep-seated inflammations in this region are not rare, and are seen usually in connection with *spinal caries*: less often the inflammation may be due to *pyæmia*, *empyema* perforating spontaneously, *trichiniasis* and other very rare forms of *myositis*, when they chance to attack the spinal region. In a few instances, no doubt, *disease of the spinal nerves*, particularly when their posterior primary divisions are affected, gives rise to tenderness in the spine as well as along the course of the nerves themselves: this may occur when pressure on the nerves or their roots exists, and in cases of *herpes zoster* or *neuritis*. Most of the causes of spinal tenderness enumerated above should not be difficult of diagnosis if a careful examination of the patient be made, and his other signs and symptoms of disease be noted.

The cases in which the tenderness is due to disease of the vertebrae are far more important than the above, and probably commoner also, as well as far more serious from the point of view both of prognosis and treatment. Excluding spinal trauma, which usually declares itself obviously and is considered below, the three disorders to which the vertebrae are liable in this connection are *tuberculosis*, invasion by *malignant disease*, and erosion by an *aneurysm*. In other rarer instances they may be affected with similar symptoms and results by *actinomycosis*, *pyæmic abscess*, the spread of infection from adjoining parts (retropharyngeal, mediastinal, subdiaphragmatic, perinephric, or pelvic abscesses), *hydatid disease*, *spondylitis deformans*, and *vertebral arthritis* due to the gonococcus and other microbes. When caused by *vertebral tuberculosis*, the spinal tenderness is local, and is generally accompanied by more or less angular deformity of the spinal column, collapse of the diseased and softened anterior part of the vertebral body, causing abnormal projection of its dorsal spine at the same time. If it is the posterior part of the affected vertebra that collapses, the spinous process will sink inwards: it must be remembered, however, that congenital defect or deficiency of a spinous process is not very rare, and may be mistaken for the result of injury or disease. Whether deformity accompanies spinal caries or no, rigidity of the diseased part of the spinal column is sure to be present. It is maintained by involuntary contraction of the appropriate muscles, and becomes conspicuous when the patient is encouraged to bend his back in any direction, or to rotate the body on the pelvis. In addition, pain will be felt in the back when the patient's vertex, shoulders, sacrum, or legs are jarred: his gait, too, and method of holding himself and turning, designed to relieve the diseased part of the spinal column from shock or strain, will be characteristic. In children who are not well looked after, this spinal tenderness and deformity may be unnoticed and the diagnosis of spinal caries not established until a *psous abscess* has formed and has declared itself by pain in the leg, or lameness. The importance here of early diagnosis cannot be overstated: spinal tuberculosis is commonest in children,

but may occur at any age. It often happens that rickety children are suspected of 'spinal disease' by their parents; they present marked spinal curvature, due to flabbiness of the muscles, and, like all their bones, their spines may be tender on pressure. But there is no localized spinal tenderness in rickets, there is no angular deformity, the spinal curvature vanishes when the child is suspended by the head or arms, no pain is caused by jarring or rotating the spinal column, and there is no rigidity of the back; the other ordinary evidences of rickets will be present, so that the diagnosis should not be difficult. In adults, however, and particularly during the second half of life, it may often be difficult to determine whether a persistent tenderness over some part of the spine, associated with pain and rigidity, is due to *tuberculosis*, *aneurysm*, or *malignant disease* affecting the vertebral column. The occurrence of angular curvature, due to softening and collapse of the vertebral body, would argue in favour of tuberculosis, being comparatively rare in aneurysm or malignant disease; evidence of tuberculous mischief in the patient's joints, lungs, or larynx, a history of cough or blood-spitting, or a marked family history of tuberculosis, would all point in the same direction. Aortic aneurysm, eroding the vertebral column and causing pain and tenderness by pressing on the nerves in its vicinity, would be suggested if the patient were a middle-aged man giving a history of syphilis. Examination under the x-rays and testing for Wassermann's reaction might be of great assistance here; deep abdominal palpation, under an anaesthetic if necessary, might reveal the expansile pulsation of an aortic aneurysm. Secondary deposits of malignant disease, invading or encompassing a vertebra, may occasion marked spinal tenderness and pain in the back of the severest description; in rare cases, the malignant growth may be primary. The vertebrae are the bones most often invaded by secondary malignant growths; the primary growths most frequently responsible for secondary deposits in the bones are carcinoma of the thyroid, testis, prostate, and mamma, primary sarcoma of bone, and melanotic sarcoma. Here again the diagnosis may be very difficult, in the earlier stages of the disorder particularly, because the primary growth may be small and deep-seated, and may have given rise to no signs or symptoms leading to its discovery, so that the presence of secondary deposits is not suspected. In the later stages, the growth often burrows into the spinal canal, and causes symptoms of paraplegia by compressing the spinal cord. When this occurs the diagnosis is easier, for the site of the compression may be indicated by a girdle-pain and a zone of hyperaesthesia; while anaesthesia, with paresis or paraplegia, is found below it, the sphincters are affected, the knee-jerks are increased, and ankle-clonus and Babinski's extensor plantar reflex can be elicited. But, as has been pointed out already, it may be impossible to find any definite physical signs in a patient complaining of very severe and intractable pain and tenderness in some part of his spinal column; and most physicians of experience must have met with sad cases where such patients have been treated as malingerers, the honesty of their complaints failing to win recognition until a pathological basis for them has been established at an autopsy.

Little more need be said about most of the other local diseases that may make the affected region of the spine both tender and painful. *Caries sicca* is the name given to an obscure rarefying osteitis of chronic course, non-suppurative, that may attack the vertebrae. The signs and symptoms of *vertebral actinomycosis* resemble those of tuberculosis. In *chronic pyemia* a vertebral abscess may arise, and in patients with abscesses in the spinal region—such as *pelvic*, *perinephric*, *subdiaphragmatic*, *mediastinal*, or *retropharyngeal*—a spread of infection to the vertebrae may conceivably occur, giving rise to tenderness in the affected part of the spine; *hydatid disease* of the spinal canal or vertebral column may do the same in persons exposed to echinococcus infection. But in all these instances the tenderness in the spine will be but a minor symptom of a serious and more or less acute disorder, with other features that are more characteristic. Tenderness in the spine is often marked in *spondylitis deformans* (Fig. 274, p. 648), the name given to practically any chronic non-suppurative form of vertebral arthritis. It is no doubt an infectious process, and occurs after gonorrhoea, influenza, enteric fever (the 'typhoid spine'), tonsillitis, and other bacterial disorders. It is characterized by stiffness in some portion of the vertebral column, with irregular deposits of new bone in the adjoining ligaments, particularly the anterior common ligament, well seen by the use of x-rays. The chief sign is stiffness in the back, and in a few of the cases osteo-arthritis of some joints of the limbs occurs as well; in instances where the hip or shoulder are thus involved the disease has been named '*spondylose rhizo-*

mélique by Marie. Men are affected four or five times as often as women, and the disease usually begins between the ages of twenty and fifty. Its diagnosis may be difficult, because the chief complaint may be of pain in the hips, legs, abdomen, or thorax, or of 'sciatica' or 'lumbago,' so that disease of the vertebral column may be neither suspected nor looked for. In most patients, the affected region of the spine is tender; much spasm of the dorsal muscles is found in the more acute cases, while in those of long-standing, atrophy from disuse will be found. The *typhoid spine* is a rare sequela of enteric fever, usually occurring early in convalescence. The patient complains of tenderness and the most acute pain in the lower part of the vertebral column, after an initial stage of backache. Fever is present at first in half the cases, and no doubt the condition is commonly due to vertebral periostitis set up by the *Bacillus typhosus*. The symptoms last for many months as a rule, and deformity of the spine is left in half the patients; but suppuration of the affected vertebra seems to be unknown. Men are affected more often than women. In milder cases no physical signs of vertebral disease appear, and so the affection has been described as hysterical, the spine as an irritable spine: in yet other instances, the spinal cord appears to be involved, as if the periostitis affected the spinal canal, loss of control over the sphincters being observed, with paresis of the legs, and changes usually increase in the reflexes.

Tenderness in the spine due to *injury* may be the expression of either organic or functional disease resulting therefrom, and the precise diagnosis may be extremely difficult. The trauma is usually a railway or other accident of locomotion ('railway spine'), a fall, a sudden shock or concussion; in another group of cases it is either a single sudden muscular over-strain, due to over-exertion or the effort to avoid an accident, or the more chronic over-strain to which rowing men, football players, and the like are exposed. A gross injury may produce fracture of a vertebra, with or without displacement of the fragments such as can be demonstrated by the use of *x-rays*; subperiosteal or subdural hæmorrhage, hæmorrhage into the spinal canal, hæmorrhage into or bruising of the cord, all of which will give rise to localizing cord-symptoms (girdle-pain at the level of the lesion, varying degrees of paresis and anaesthesia below it) when the lesion is marked. At the other end of the scale are found the sufferers from *traumatic neurasthenia*, who have been exposed to identical injury or over-strain, but present no definite signs of disease in the spine or cord, although quite incapacitated for months or years, by weakness and severe pains in the injured region. These patients often have increased knee-jerks and even ankle-clonus; but definite evidences of organic disease are wanting, the sphincters are unaffected, Babinski's extensor plantar reflex is not obtained, muscular wasting is not found, unless from disuse, and the various pains and tendernesses of which complaint is made have a neurasthenic or even a hysterical distribution and character. Traumatic neurasthenia may follow surgical operations or comparatively slight injuries to the head, back, or testicle, in addition to the severer traumas and strains already mentioned; and it must be noted that a delay of one or more weeks, an incubation-period, may intervene between the receipt of the injury and the development of the neurasthenic pains. It would be unfair to take such a delay as evidence of a hysterical factor in the case, or of malingering.

It is clear from the foregoing paragraph that traumatic neurasthenia includes cases in which it is not possible to say for certain whether a local organic lesion of the spine exists or not. Such instances form a natural transition to those in which there is:

Tenderness in the Spine due to Functional Disorders, or to Disease in Other Parts of the Body. In very few of these is there any deformity of the spinal column; it is flexible and not rigid; and pain is rarely produced when it is carefully bent, twisted, or jarred, so long as direct stimulation of the tender part is avoided. As a rule, the tenderness is superficial rather than deep, and it is often associated with other areas of tenderness in the side or front of the body. In *hysteria*, complaint of pain and tenderness in the spine and back is not rare—the 'hysterical spine.' The tenderness over the vertebrae is often accompanied by tenderness on either side of them; in extent it may change from time to time, involving a single vertebra or even most of the vertebral column. In *neurasthenia* the spine may be tender from top to bottom, and more or less rigidity is often found also. When the tenderness is localized to a small part of the back, it may easily be taken as evidence of local organic disease; but the presence of other neurasthenic symptoms—headache, irritability, fatigability after brief exertion—and the absence of signs of definite local disease or involvement of the cord, should help in the diagnosis. To distinguish clearly

between neurasthenia and hysteria is often difficult, and particularly so in the milder cases of traumatic neurasthenia, because they may develop hysterical features such as areas of anaesthesia, a craving for sympathy, a tendency to exaggerate the symptoms, and so forth. The harmful effects of mental worry on neurasthenia, of the uncertainty attaching to an impending law-suit in which, perhaps, damages for injury are being claimed, are well known.

Tenderness in the spine is very commonly a reflex from disease in one or other of the thoracic, abdominal, or pelvic viscera. The tenderness is characteristically superficial in these cases, and acute pain may result from light pressure on the area involved; and if the tender tissues can be pulled aside sufficiently, it will be found that pressure on the spine itself causes no pain whatever. The different viscera produce this tenderness with some regularity in different and definite spinal areas, a scheme of which is given in *Fig. 294*.

The organs and diseases most often giving rise to this referred tenderness and pain in the spine are as follows: The *aorta*, in aortitis, arteriosclerosis, and aneurysm; the *heart*, in coronary sclerosis particularly, myocarditis, myocardial fibrosis, acute dilatation and failing compensation; the *stomach*, in gastric ulcer, malignant disease, gastritis; the *liver*, in cholelithiasis, cholangitis, new growth, and the venous congestion of tricuspid reflux; the *intestine and rectum*, in acute inflammatory disorders, constipation, and carcinoma; the *uterus*, in labour, menstruation, inflammatory affections, and new growth. It

would appear that the lungs, whether inflamed or wounded, do not give rise to a referred tenderness: on the other hand, the whole or any part of the thoracic spine may become tender in disorders of the *pleura*, such as pleurisy, pleural adhesions, or new growth. To illustrate the frequency with which pain and tenderness of the spine occur, the axiom of many hospital out-patient departments may be quoted, that there is no woman in London who has not got a pain at the bottom of her back—a libel on the sex, one may hope.

The importance of distinguishing between the cases in which the physical signs of organic disease in the vertebral column or cord are absent, and those detailed in Class 1 above, need not be emphasized further. The referred pains and tenderesses disappear or are relieved with the cure or relief of the cardiac, gastric, or other disorder to which they are due. The diagnosis of the cause of tenderness over the fourth dorsal vertebra, for example, which may be due to disease of

Fig. 294.—Areas of referred spinal pain and tenderness (after Mackenzie). A, In diseases of the heart; B, In diseases of the stomach; C, In diseases of the liver; D, In diseases of the rectum and uterus.

the heart, pleura, or stomach, must be made on general lines, and by consideration of the other signs and symptoms exhibited by the patient.

A. J. Jee-Blake.

TENESMUS signifies frequent and painful inclination to go to stool, associated generally with straining and gripping but with very little evacuant result. A precisely similar condition affecting the bladder is spoken of sometimes as *vesical tenesmus*, but a better known term for this is **STRANGURY** (p. 649).

The severest examples of rectal tenesmus are afforded by *acute dysentery*, in which, after the acute onset of the disease, copious loose fecal motions are passed to start with, then smaller and smaller quantities at a time, and after this, when there is practically nothing left to come away from the bowel, the desire to defecate urgently and repeatedly may still recur perhaps every ten minutes with painful straining, causing the patient to groan or cry out, but with practically no evacuant result beyond a little fluid with mucus and blood. The diagnosis in these cases is generally based upon the fact that the patient is or has been resident in some part of the tropics where dysentery is endemic; the nature of the dysentery itself, whether due to the ameba of dysentery, or to Shiga's dysentery

bacillus, or to other less well known bacilli, is made upon the results of bacteriological investigations of the stools.

Similar tenesmus may also occur in acute *cholera* when the stage of rice-water stools has been reached; here again the diagnosis depends upon the fact of residence in a part where cholera is endemic, or in a district in which cholera has recently broken out in epidemic form; it is confirmed by the discovery of the comma bacilli of cholera in the stools.

In this country there are various types of *acute infective diarrhoea* which may simulate cholera to such an extent that, although not cholera at all, they have been grouped together under the heading of *cholera nostras*, and in such cases tenesmus may be extreme. Temporary acute diarrhoea with much tenesmus may arise in school-boys and others from the eating of unripe apples or other fruit; after a brief but acute illness, and perhaps a drastic purge, rapid recovery is the rule. More serious are the acute attacks of vomiting and diarrhoea which are familiar under the name of *ptomaine poisoning*, the cause being bacilli allied to Gaertner's bacillus ingested along with some article of diet. Cases of ptomaine poisoning may be sporadic, but occasionally as the result of many persons eating the same cold pork pie perhaps, or something of that kind at a public function, acute epidemics are recorded, some of the cases ending fatally. The bacteriology of the condition is complex; different micro-organisms, including not only Gaertner's bacillus, but also Morgan's bacillus A, Morgan's bacillus B, and probably others, are at the root of different outbreaks. The diarrhoea is at first painless though frequent, but severe tenesmus ensues after the bowel has become empty of practically everything but a little fluid together with mucus and exuded blood.

Chronic dysentery is less often associated with tenesmus than is the acute form, but a considerable degree of tenesmus may none the less be complained of by those who have suffered from dysentery in the tropics and, having returned home not yet cured, still suffer from repeated diarrhoea to the extent of perhaps twelve or fifteen motions a day. The same applies to cases of *colitis*, whether mucous-membranous or ulcerative, arising at home. It may be very difficult in some such cases to exclude malignant disease of the bowel unless the history is too long for this. In cases of doubt much may be learned by passing the sigmoidoscope and actually seeing the inflamed or ulcerated mucous membrane of the lower part of the bowel.

Intussusception will only cause tenesmus when the lower end of the intussusceptum has reached the pelvic colon or the anus. The symptoms will be those of intestinal obstruction, and when the intussusception is felt per rectum or seen protruding per anum, the only difficulty will be to distinguish it from a rectal polypus, or prolapse of the rectum. The condition is very much commoner in infants about nine months old than in any other class of patient, and at this tender age tenesmus will not as a rule be obvious. In older patients a subacute or chronic intussusception is fortunately very rare, and it is seldom diagnosed accurately previous to operation.

Acute summer diarrhoea and vomiting of infants is allied to ptomaine poisoning and is similarly due to one or more of the enteritic micro-organisms; tenesmus may be very severe in infants as well as in adults.

Another malady allied both to ptomaine poisoning, to tropical dysentery, and to acute summer diarrhoea and vomiting of infants, is so-called *asylum dysentery*, of which the symptoms and results are very similar indeed to those of tropical dysentery; asylum dysentery also has a bacterial cause, and the micro-organism producing it has been the subject of considerable investigation. The difficulty of deciding the precise nature of the infecting organism in all these cases depends upon the similarity between the different possible bacilli and the ordinary bacillus coli which always abounds in the evacuations.

Acute tenesmus may be a marked feature in some cases of *poisoning by arsenic*: the diagnosis of this cause may be obvious either on account of the patient having taken an over-dose with intent to commit suicide, when choleraic diarrhoea and much tenesmus may come on subsequent to the initial vomiting and collapse; or because, in less acute cases, the patient is known to be taking large doses of arsenic in his medicine—for instance, in the treatment of chorea or of pernicious anaemia; indeed, the occurrence of diarrhoea with gripping rectal pains and tenesmus is one of the difficulties that presents itself in continuing the arsenical treatment of pernicious anaemia and other blood diseases to the extent that one would like. On the other hand, even when arsenic is the cause of diarrhoea and

tenesmus, it may sometimes be very difficult indeed to make certain of the fact, although some suspicion of it may have arisen in the mind of the physician. Accidental contamination of the water or of some food may have occurred; or, still more important, some member of the household may be administering arsenic surreptitiously, either with a view to getting rid of the individual concerned, or occasionally even without any particular object. For instance, in the case of some hysterical servant girls, who have been known to administer poisons in a household in this way apparently without any material object at all. The circumstances of the case may make one suspicious and lead to a careful watch being kept, or perhaps an analysis of the water-supply or of some suspected food will lead to the detection of the arsenic. In case of doubt one might have to resort to the expedient of taking the patient entirely away from the house in which she has been living, and from amongst the individuals with whom she has been associated, in order to see whether the symptom persists when she is secluded in a nursing-home or elsewhere, or whether it disappears there to return again when she goes home. Analysis of the hair for arsenic in cases of this kind will seldom be available as a test of the diagnosis, because it is only in the hair that is growing during the time arsenic is being administered that excess of arsenic is stored, and when sufficient doses to produce tenesmus have been administered they will generally have been large, and therefore have been given over only a short period.

Besides arsenic, other irritant drugs may produce tenesmus, especially perhaps *cantharides*, *calomel* in repeated doses, *colocynth*, *gamboge*, and indeed most of the powerful purgatives. The diagnosis depends upon a knowledge of the drugs that are being administered.

There remain for discussion a number of other conditions which may produce painful and frequent but fruitless straining at stool, the cause being either irritation of the rectum or obstruction to it or within it. These may be enumerated as follows:—

1. Causes within the Lumen of the Rectum :

Impacted faeces	A foreign body that has been inserted	Concretions Worms.
-----------------	---------------------------------------	-----------------------

2. Things in the Wall of the Rectum :

Carcinoma	Adenoma	especially if	Fissure
Rectal prolapse	Hæmorrhoids, thrombosed		Proctitis.
Polypus or polypi			

3. Things Outside the Rectum :

Enlarged prostate	Vesical calculus	Pelvic hæmatocle
Periprostatic abscess	Ovarian cyst	Ectopic gestation.
Periproctal abscess	Uterine fibroid	
Ischio-rectal abscess	Retroverted gravid uterus	

The diagnosis of all the above depends upon careful examination of the anal region, the rectum, and the vagina, by inspection, direct or through a speculum, proctoscope or sigmoidoscope, or with the finger.

Impacted faeces may, from their symptoms, simulate rectal carcinoma very closely; but when there is carcinoma of the rectum, one's finger when inserted seldom comes upon a mass of faeces, whereas with faecal impaction the mass is generally well within reach of the finger. The diagnosis will be confirmed by removing the mass itself piecemeal with a spoon, followed by enemata or other local measures, after which the patient recovers completely.

Rectal concretions differ from impacted faeces only in the material of which they are composed; for instance, instead of being ordinary faecal material, they may consist of hard lumps of *bismuth*, *magnesium*, *chalk*, or other drug that has been given by the mouth, or of the husks or products of some unusual meal, as an example of which one may mention the case of a boy who having stolen a bundle of cinnamon sticks, chewed them up and swallowed them, and a day or two afterwards suffered extremely from tenesmus as the result of a mass of undigested bits of cinnamon stick that had been impacted in his rectum. *Hair balls* have caused similar trouble, though they are even rarer in the rectum than they are in the stomach.

Adenomata, or long finger-shaped non-malignant polypi of the rectum, occur sometimes

in such a way as to produce a kind of entanglement, in which feces become impacted higher up than the finger can reach, and the patient will be thought to be suffering from carcinoma of the sigmoid colon or of the pelvic colon; there will, however, as a rule be much less wasting than there would be with malignant disease, though both conditions produce their symptoms at a similar age. The diagnosis will depend upon examination with the proctoscope or the sigmoidoscope, and perhaps upon excision of such polypi as can be reached, followed by microscopical examination.

Another condition which may simulate rectal carcinoma very closely is *periproctal inflammation* followed by the formation of an abscess round the pelvic colon. The tenesmus which results, the constant painful straining, and the unsatisfactory evacuations, may be associated with obvious ill-health; anaemia from loss of sleep; and loss of weight; so that malignant disease will frequently be thought the almost certain diagnosis. The condition is by no means so easy to detect as might be supposed; sometimes it is not until the patient has been anesthetized with a view to further examination with the proctoscope and sigmoidoscope that the nature of the condition is indicated by a sudden gush of pus escaping past the instrument as the result of the bursting of the abscess. The cause of such a condition is generally some previous local inflammation in the rectum, associated, for instance, with piles, or a polypus which has hitherto produced no symptoms at all; in some cases there may be both carcinoma and abscess, the latter the result of the former.

A *vesical calculus* causing tenesmus will generally be one situated in a pocket of the bladder posteriorly; it is a very rare cause of tenesmus, and generally there is or has been hæmaturia to indicate the need for examination of the bladder either with the sound or the cystoscope.

The remaining conditions in the above list need not be discussed in detail; they will be diagnosed by rectal or vaginal examination, or a combination of the two.

There remains still one other very important cause of tenesmus, namely, *tubes dorsalis with rectal crises*. The symptom is not so uncommon as might be supposed. Not a few cases of tubes dorsalis complain that they are unable to go about their duties as early in the morning as they would like, because after going to the closet in the ordinary way after breakfast, they find that at intervals of perhaps half an hour they suffer from repeated urgent and painful re-calls, extending over perhaps two or three hours before the bowels settle down to comparative comfort for the rest of the day. Not much is passed after the first one or two visits to the closet, but the patient dares not be far away whilst the recurrent crises continue, for the call is urgent and very painful; but as a rule, after two or three hours of suffering of this kind he finds that he is free until the next day. The condition is quite distinct from the incontinence of feces which may result at a later stage of the malady; it is an example of purely nervous tenesmus, which, however, may simulate carcinoma of the bowel very closely. It may last for months or years, and then cease to trouble the patient spontaneously, just as the lightning pains of tubes may. The patient's complaint is generally of diarrhœa, but upon careful inquiry it is found that the diarrhœa in the sense of fluid evacuations is much less pronounced than the tenesmus—that is to say, the recurrent painful call to stool without material evacuation. The diagnosis depends upon detecting the absence of knee-jerks and the existence of Argyll Robertson pupils.

Herbert French.

TESTES, ATROPHY OF. (See ATROPHY, TESTICULAR, p. 66.)

TETANIC CONTRACTIONS.—(See CONTRACTIONS, p. 137.)

THERMO-ANÆSTHESIA.—(See SENSATION, SOME ABNORMALITIES OF, p. 604.)

THIRST, EXTREME. Cases of extreme thirst may be subdivided into two main groups; namely, those with and those without polyuria. To the former belong such conditions as diabetes mellitus, diabetes insipidus, hysteria, and so on, which are discussed under POLYURIA (p. 531). To the other group belong such conditions as are for the most part so obvious as to require no more than simple enumeration under main headings, as follows:—

1. Prolonged abstention from drinking; purposeful, or the result of necessity.
2. Fevers and febrile states.

3. Excessive loss of fluid: (a) From the skin by profuse perspirations, natural or pathological; (b) From the stomach, from repeated vomiting; (c) From the bowel, from excessive diarrhoea; (d) Into serous membranes, as in acute peritonitis.

4. After severe hæmorrhage: (a) External, e.g., post-partum; (b) Internal, e.g., from duodenal ulcer, ruptured tubal gestation, leaking aneurysm.

5. Gastroctasis due to pyloric stenosis, owing to the fact that the stomach absorbs little fluid as compared with the intestines.

6. Poisoning by such drugs as dry up the secretions of the mouth, notably belladonna and its allies, or astringents such as alum, gallic acid, tannic acid, or perchloride of iron.

7. The exhibition of excess of various salts, particularly sodium chloride, either as such, or incorporated in various food-stuffs.

It is clear that in some cases more than one factor at a time may be causing extreme thirst.

Herbert French.

THRILLS, PRECORDIAL.—In order to arrive at a diagnosis of the cause of any thrill which is felt over the præcordia, two facts must first be ascertained, namely (1) *The situation of the thrill*; and (2) *Its rhythm*. Having discovered a thrill over the mitral area, that is, in the region of the apex beat, and found that it is presystolic in rhythm, it is obvious that it is due to *mitral stenosis*. The valvular lesion will be confirmed by the presence of a presystolic bruit, as it is rare to find the thrill without a bruit being associated with it. On the other hand, if the thrill be systolic in time, and *mitral regurgitation* be present, the thrill is due to this valvular lesion. A systolic thrill at the cardiac apex may also be caused by *pericardial friction fremitus*, or *pleuritic fremitus*. A pericardial friction fremitus can be distinguished from an endocardial thrill by being more rubbing in character, usually occurring both during systole and diastole, while an endocardial thrill is a more purring vibration, and it is confined to either systole or diastole. The pericardial friction is confirmed by auscultation. *Pleuritic fremitus* in this region may be distinguished from an endocardial thrill and pericardial friction fremitus by asking the patient to hold his breath, when the fremitus will disappear unless it is due to pleuro-pericarditis. These distinguishing features between endocardial thrill, pericardial friction fremitus, and pleuritic fremitus, apply to any area in which thrills are detected. A pericardial friction fremitus may be present over the whole or any part of the præcordia, but the most common situation is to the left of the sternum near the base of the heart.

A systolic thrill in the second right intercostal space close to the sternum may be due to *aortic stenosis*, *thickening of the aortic valve*, *atheroma*, or *dilatation or aneurysm* of the ascending portion of the thoracic aorta, and the diagnosis of the cause of the thrill can only be made by the other physical signs which indicate the morbid condition present. Thus, if there be dullness in the second right intercostal space, over which the thrill is felt, there is dilatation or aneurysm of the arch of the aorta. There is no dullness in this situation when the thrill is due to aortic obstruction or to atheroma of the aorta. Not only may dullness on percussion accompany the thrill, but there may be pulsation, and even a pulsating tumour, in this region, showing that there is an aneurysm; an *x-ray* examination (*Fig. 100*, p. 209) helps in confirming the diagnosis.

A diastolic thrill may also be felt in the second right intercostal space close to the sternum, but it is rare; when present, it is due to *aortic regurgitation*, and is accompanied by the characteristic diastolic bruit and waterhammer pulse. Sometimes the thrill, like the bruit, is most marked in the third left space close to the sternum.

In the pulmonary area, viz., in the second left intercostal space near the sternum, systolic thrills are due to *congenital affections* of the heart, especially pulmonary stenosis and patent ductus arteriosus. An extensive thrill over the base of the heart in young children is nearly always due to congenital malformation. The apex beat is generally near its normal position. The cardiac dullness usually extends to the right of the sternum as the result of the enlargement of the right ventricle, and there is commonly a loud universal systolic bruit, having its point of maximum intensity over the base of the heart. The following signs of congenital malformation of the heart, other than patent ductus arteriosus, are also to be expected: cyanosis, either continuously present or occurring at intervals, dyspnoea, especially upon exertion, clubbing of the fingers and toes, and polycythæmia; with patent ductus arteriosus (p. 156), there may be no symptoms accompanying the abnormal physical signs.

A thrill occurs very occasionally in the second left intercostal space close to the sternum, in association with a *functional pulmonary bruit*. In such a case the functional origin of the thrill may be distinguished by the general condition of the patient, who will be suffering from anaemia or some debilitating condition; and the signs of congenital heart disease, just mentioned, will be absent.

Presystolic and systolic thrills sometimes, but very rarely, occur to the right of the sternum in the *tricuspid area*, due to *stenosis* and *incompetence* of this valve.

J. E. H. Sawyer.

THROAT, SORE.—(See SORE THROAT, p. 613.)

THYROID GLAND ENLARGEMENT.—An enlarged thyroid gland gives rise to a swelling in the front of the neck, internal to the sternomastoid muscles and the carotid vessels, which, if the swelling is large enough, are pushed outwards. The gland is connected intimately with the larynx; hence the most important sign of a thyroid tumour is that it rises and falls with the larynx and trachea during deglutition. In the great majority of cases the presence of this sign alone is sufficient to make a correct diagnosis. There are two sources of fallacy: (1) A swelling not thyroid in origin but lying in front of it, such as a sub-hyoid bursa or sebaceous cyst, or a suppurative or syphilitic perichondritis of the thyroid cartilage, may present the above sign; (2) A thyroid swelling, if fixed, as it may be by inflammation or malignant growth, may not present it. In the vast majority of cases, however, a swelling in the position of the thyroid gland which moves on deglutition indicates an enlargement of that gland.

Varieties of Enlargement and their Differential Diagnosis.—During *menstruation* and *pregnancy* the thyroid becomes enlarged, but seldom sufficiently so to cause symptoms; if the gland happens to be the seat of pre-existing disease the increase of swelling may be sufficient to induce respiratory difficulty.

Parenchymatous Goitre, or a general hypertrophy of the whole gland, is the commonest form of enlargement. All parts of the gland are affected more or less equally; the tumour being bilateral, the normal shape is preserved. The swelling is freely movable, painless and soft. It is rarely congenital, and more often appears about puberty. Its rate of growth is usually very slow, and it may attain an enormous size without causing any other symptoms.

Cystic Goitre is a loose term used to cover any form of enlargement of the thyroid which is caused chiefly by the presence of one or more cysts. If the cyst is large and lax, fluctuation may be made out. The cysts, however, are often small and tense, and cannot be distinguished from solid adenomata. Cysts are rarely present without some enlargement of the rest of the gland.

Adenomatous Goitre.—The common cause of unilateral enlargement is the presence of an adenoma, a definite encapsuled tumour which may contain cysts and grow to a large size. A hæmorrhage into one of these cysts may cause a very rapid enlargement, and so give rise to a suspicion of malignancy; cases have also been reported in which an intra-thyroid hæmorrhage has been followed by acute dyspnoea and death. Adenomata may be single or multiple; when present in both lobes, the enlargement may be difficult to distinguish from the parenchymatous form.

Fibrous or Ligneous Goitre is a rare condition, due to a primary chronic inflammation of the whole gland, and resulting in a firm dense enlargement.

Malignant Disease is seldom met with. It occurs with equal frequency in both sexes, and is rarely seen before the age of forty. In the early stages, while still confined within the capsule of the gland, it may be difficult to differentiate from the other forms of goitre. It should be recognized by its rapid growth, its hardness, and irregular bossy outline. When the neoplasm has penetrated the capsule and invaded surrounding structures, the diagnosis is made with more ease. The tumour may become fixed, no longer moving on deglutition; often one or other vocal cord is paralyzed, a condition rarely seen with innocent goitre; and involvement and ulceration of the trachea is common. The lymphatic glands may be enlarged, but as those first implicated are placed deeply, defying detection, not much help is gained from this source. There is a special liability for metastatic secondary deposits to occur in bones, particularly in the vertebrae and cranium.

Exophthalmic Goitre (Graves's disease, von Basedow's disease) is far more common

in women than in men (*Fig.* 113, p. 236), and rarely occurs before puberty or after middle life. The most prominent features of the disease are: (1) Exophthalmos; (2) Tachycardia with palpitation; (3) Enlargement of the thyroid gland, often pulsatile; (4) Tremulousness of the hands and general nervous excitability; (5) Breathlessness on exertion. The vision is normal, but when the eyeball is moved downwards the upper lid does not follow as in health (von Graefe's sign). The palpebral aperture is wider than in health, owing to retraction of the upper and lower lids (Stellwag's or Dalrymple's sign). Pigmentation of the skin may be intense (*Fig.* 222, p. 527) and simulate Addison's disease, but the mucous membrane of the mouth is not affected as in the latter malady.

A well-marked case is quite characteristic, but there are others extremely hard to separate from simple parenchymatous enlargement, for with this, especially in young girls, anaemia is often associated, and with it the symptoms of tachycardia, palpitation, and breathlessness. It often becomes a matter of opinion whether a given case should be styled simple parenchymatous goitre or incipient Graves's disease.

The above are the commonest forms of enlargement. Others much rarer are: *Enlargement due to pyogenic infection*, either acute or chronic. In pyaemia it is not uncommon to find the thyroid the seat of multiple abscesses. *Tuberculous and gummatous disease* may also cause enlargement, and a slight degree of goitre has been noted in *typhoid fever, acute rheumatism, malaria, variola, cholera, and secondary syphilis*. *Hydatid cysts* of the thyroid gland have been noted on a few occasions. It having been ascertained that the swelling in the neck is definitely thyroid in origin and its nature defined, it remains to see whether there are any pressure signs on the surrounding structures.

Pressure on the Trachea.—Dyspnoea is by far the most important of all the symptoms that may be produced by enlargement of the thyroid gland. It may be the only thing complained of by a patient not even aware of the presence of a goitre. The size apparently is not so important as the shape and situation, for one reaching to the waist may cause no obstruction, and one the size of a cherry, if situated between the sternum and trachea, may give rise to intense dyspnoea. If the goitre is unilateral, the trachea is pushed over towards the opposite side and flattened; if bilateral, as in the parenchymatous form, it is compressed laterally. The dyspnoea may be constant and distressing, or only noticeable on exercise or on lying down. Most such patients like to lie high in bed, propped up on pillows. An idea as to the amount of pressure on the trachea may sometimes be gained by a question on this point.

Pressure on Nerves.—Unless malignant, a goitre rarely causes much pressure on nerves. Those that may be involved are: (a) The recurrent laryngeal, resulting in paralysis of a vocal cord; (b) The cervical sympathetic, shown by contraction of the pupil on the affected side and ptosis; (c) The vagus; (d) Rarely the nerves of the brachial and cervical plexuses. If any of these nerves are involved, suspicion must arise as to the malignancy of the tumour.

Pressure on the Oesophagus.—Being placed behind the trachea, the oesophagus generally escapes pressure by a goitre, though this is to be remembered as a rare cause of dysphagia.

Pressure on Veins is common, particularly on the internal, external, and anterior jugulars. The pressure is rarely more than sufficient to make them stand out prominently.

George E. Gusk.

TINEA, VARIETIES OF. (See FUNGUS AFFECTIONS OF THE SKIN, p. 246.)

TINNITUS is a symptom which occurs in a large proportion of cases of disease of the ear, and occasionally when there is no obvious lesion of the auditory mechanism. The sounds complained of are usually subjective, but they may occasionally have an objective origin. Tinnitus may be continuous or intermittent. Its intensity and character vary greatly in different patients; to some it is an intolerable annoyance, and occasionally has even been the cause of suicide. The character of the sound may give some clue to the cause. Thus a pulsatile or rhythmical sound may be produced by the flow of blood through the internal carotid artery, which in its course through the carotid canal is separated from the tympanum only by a thin plate of bone, which may be deficient. A creaking noise may be produced by cerumen, or a foreign body, in the external auditory meatus. A bubbling noise may be due to the presence of catarrhal exudation in the middle ear.

A cracking or clicking sound may be caused by spasmodic contraction of the dilatator tubæ and salpingopharyngeus muscles which are attached to the Eustachian tube. When the character of the sound is described as humming, hissing, roaring, whistling, or musical, it is practically always subjective, and due to some irritation of the auditory nerve, rarely cerebral or in its course, but usually at its terminations in the labyrinth. In rare cases the tinnitus may be associated with an intracranial murmur which can be detected on examination of the head with the stethoscope. An audible intracranial murmur associated with tinnitus may be due to the following causes: (1) Possibly venous murmurs associated with increased intravenous pressure due to excessive pulsation of the brain; (2) A *bruit de diable* in the jugular bulb which may occur in anemia, plumbism, syphilis, and serofula; (3) Intracranial aneurysms. The sudden explosive sounds in the insane and others may be due to similar causes.

A distinction must be made between tinnitus and hallucinations of hearing, the latter usually taking the form of hearing voices, and indicating mental trouble, usually of a serious nature. Tinnitus, however caused, is usually influenced markedly by the general health and environment of the patient. Thus, sometimes the noises are less marked when the patient is in the open air, when his attention is occupied by other matters, or when the sense of hearing is occupied by listening to objective noises. Similarly, the trouble may be present only at night, but may appear in the day-time if the patient closes the external auditory meatus with his finger. Generally speaking, tinnitus becomes less marked and more bearable when the general health of the patient is good, and increases when the sufferer is out of health or overworked, either mentally or physically. Working in close, stuffy rooms, or in proximity to noisy machinery, over-indulgence in alcohol, and excessive smoking, have a bad effect; in women the trouble may be increased during pregnancy, menstruation, or the menopause.

Though tinnitus is very common in diseases of the ear, yet serious lesions of the middle ear, internal ear, or auditory nerve, may be present without this symptom. There is no constant relation between tinnitus and deafness. The former may be present with perfect hearing, but when long continued the hearing nearly always becomes impaired. The sounds, too, may persist when the patient has become totally deaf.

Tinnitus may occur in the following diseases of the ear:—

1. The presence of *verruca, anal polypi, or a foreign body* in the external auditory meatus. Removal of the offending body will in this case probably lead to the cessation of the tinnitus.

2. In any *inflammatory disease, acute or chronic, suppurative or non-suppurative, of the middle ear*. In catarrhal inflammation of the middle ear, the noise frequently has the character of bursting bubbles, and is due to movements of the viscid exudation in the ear itself. In otosclerosis, tinnitus is a very prominent and usually early symptom. It may occur before any alteration in hearing is present.

3. In diseases of the internal ear, tinnitus is especially liable to occur in a severe and intractable form. Thus, it is especially likely to be present in *Ménière's disease, syphilitic disease* of the internal ear, and in those lesions of the internal ear which may arise in the course of *typhoid* and other *specific fevers*. *Extension of suppuration to the labyrinth* from the middle ear is also an important cause; and it may be present, usually associated with deafness, after a *fracture of the base of the skull*.

Tinnitus has been recorded as resulting from a *cerebral tumour* involving the roots of the auditory nerve, but this is a very unusual condition.

'Noises in the ears' may be complained of in a considerable number of general diseases, either with or without a lesion of the ear. Thus, they are frequently present in *anæmia*, and in diseases such as *leukæmia* or *pernicious anæmia*, in which anæmia is a prominent symptom.

Some *cardiac lesion*, especially aortic regurgitation, may be found in the pulsatile variety of tinnitus. *Gout, chronic nephritis, uræmia, and arteriosclerosis* with high blood-pressure, may also be responsible for tinnitus, and it may occur during attacks of *migraine*. Sometimes it has apparently a reflex origin, being associated with neuralgia or digestive disturbances, especially in *gouty dyspepsia*. *Malaria* may also be a cause, though here the trouble is likely to be the result of large doses of *quinine*. Other drugs likely to cause the trouble are *salicylates, antipyrin*, the excessive use of *tobacco*, and after *anæsthetics* such as chloroform or ether.

In persons who constantly use the telephone tinnitus may occur, associated with pain and some deafness—a condition known as 'telephone ear.'

Philip Turner.

TONGUE, SWELLING OF.—(See SWELLING OF THE TONGUE, p. 698.)

TONGUE, ULCERATION OF.—(See ULCERATION OF THE TONGUE, p. 738.)

TREMOR occurs when the normally continuous contractions of a muscle at work, or the normally uniform tone of a muscle at rest, are replaced by a succession of separately perceptible muscular twitches. In these circumstances, a movement which is normally uniform becomes tremulous; a position that can be maintained steadily under normal conditions is now kept unsteadily or shakily.

The normal muscular contraction is due to the discharge of a rhythmic series of nervous impulses from the motor neurons that govern the muscle. It is estimated that, in health, from five to fifty such nervous impulses leave the motor nerve-cells and reach the contracting muscle-fibres every second, the actual number per second varying in different motor neurons, and also in the same neuron according to its temporary condition of nutrition or fatigue. It is when the number of nervous impulses received per second by the contracting muscle-fibres becomes low, that steady and apparently uniform muscular contractions are likely to be replaced by tremors.

Tremors are of very various periods, amplitudes, and general characters in different cases. Their physiology and pathology are not at present fully understood, so that it is not yet possible to classify them etiologically. From a clinical point of view they may be classified roughly in accordance with their more obvious physical characteristics—their fineness, periodicity, regularity, and the circumstances that favour or inhibit their production; but an unbroken series of graduated tremors can be traced in various diseases, passing by imperceptible degrees from the rapid and minute oscillations observed in paralysis agitans to the extremely coarse and irregular movements composing the intention-tremor of disseminated sclerosis. A similar variety of regular tremors may be observed sometimes in a normal person, as the temperature of his body falls from exposure to cold, or during the occurrence of a rigor. Hence a rigid clinical classification of tremors is impossible.

CLASSIFICATION.

Fine Tremor.

Exposure to cold	Senile tremor	Tobacco	Mercury
Nervousness, emotion	Paralysis agitans	Absinthe	Lead
Muscular fatigue or weakness	General paralysis of the insane	Morphia	
Convalescence	Graves's disease	High pyrexia	
Congenital and familial tremor	Occupation neurosis	Hysteria	
	Chronic intoxications, e.g., by Alcohol Cocaine	Neurasthenia	
		Railway spine	
		Uremia.	

Unilateral Fine Tremor.

Cerebral tumour	Chronic hemiplegia	Hysteria	Chorea.
-----------------	--------------------	----------	---------

Coarse Tremor.

Exaggerated degrees of fine tremors	Familial and hereditary ataxias	Chronic hemiplegia.
-------------------------------------	---------------------------------	---------------------

Intention Tremor.

Disseminated sclerosis	Hysteria Congenital cerebral diplegia	Some cerebral or cerebellar lesions.
------------------------	--	--------------------------------------

FINE TREMOR.

Fine tremor consists of regular oscillations of small amplitude due to alternating contractions in antagonistic muscles or groups of muscles, repeated from three to nine times per second. It is usually most marked in the extremities, but may also—as in old age and in paralysis agitans—affect the head and neck. It may occur only when some movement is attempted; or it may continue also when the patient is at rest. Fine

tremors cease almost invariably during sleep; emotion habitually increases them. They are not purposive, and should be distinguished from the fibrillar contractions (see CONTRACTIONS, p. 134) of individual muscle-fibres or muscle-bundles, seen in some muscular degenerations.

Fine tremors occurring in consequence of *cold, nervousness, excessive emotion, concidescence, and muscular fatigue or weakness*, are matters of common daily observation. They tend to pass off as the patient's condition of mind or body improves, and should occasion little trouble in diagnosis.

Congenital and familial fine tremors occur mostly in children or young adults, mainly in the hands and arms, face, or tongue. The oscillations are often absent while the patient is at rest, but make their appearance whenever movement is attempted, and are increased by nervousness or emotion. They can often be suppressed for a time by a strong effort of the will, and in many instances they disappear as the patient grows older. They cause practically no inconvenience, and are not accompanied by any other abnormalities in the neuro-muscular apparatus. Their diagnosis should be made plain by the patient's personal and family histories.

Senile tremor and paralysis agitans may be considered together. Senile tremor comes on with old age in the form of fine regular or irregular oscillations affecting the arms and the head. Both sides of the body are involved, the head early, and the tremor ceases during repose and in sleep. The muscles of the affected parts are neither rigid nor weak. These senile tremors must be carefully distinguished from the tremors of paralysis agitans, or Parkinson's disease, a progressive and more serious disorder: in this the tremors are of several varieties. A fine oscillatory to-and-fro tremor, with from three to six excursions per second, affects the extremities and head in some cases. In others, the tremor is coarser, rhythmical, slower, and to some extent purposive: in typical instances it produces the alternating movements in the thumb and index finger described as 'bread-crumbling' or 'cigarette-rolling.' These may be combined with more irregular movements of flexion and extension at the wrist, pronation and supination of the forearm. The progressive development of these tremors and movements is often characteristic: beginning in one hand, the fine tremor may spread to the other after some months or years, and ultimately the lower limbs, the head and neck, the lips and tongue, and even the muscles of the trunk, may become involved. As a rule, the movements continue when the patient is sitting, or lying at rest: in severe cases they may persist even during sleep. In most instances they can be lessened by an effort of the will, and diminish also on passive or voluntary movement. If, on the other hand, they increase on voluntary movement, a tolerable imitation of an intention tremor may result. They are augmented by emotion or excitement. In cases of some duration a well-marked coarse shaking of the arms may be a noticeable feature: while contractions alternating in the flexor and extensor muscles of the legs may cause the feet to chatter when they are placed on the floor: the thighs are commonly held in adduction.

Paralysis agitans is characterized by other signs that facilitate its diagnosis, and the chief of these are:—(a) *Muscular rigidity*, causing a fixed, expressionless facial aspect (see FACTS, p. 236), a monotonous voice, a bent and rigid carriage, and a shuffling, hesitating gait, with festination, propulsion, and retropulsion. Festination implies that the patient in walking from one point to another, starts with slowness and difficulty, but accelerates as he goes along, much as if he were running after his own centre of gravity, and at the end he may even fall forwards unless there is some object at hand for him to catch hold of. Propulsion, retropulsion, and the rarely observed lateropulsion, are terms meaning that the patient, sent off with a vigorous push to walk forwards, backwards, or sideways, exhibits the same acceleration and proclivity to fall down at the end—forwards, backwards, or sideways. (b) *Muscular weakness* of the tremulous or rigid parts. (c) *Paræsthesiæ*, such as aching pains about the limbs or body, flushes of heat or cold. The sphincters and mental faculties are not affected, while the deep reflexes are usually normal, but may be increased. Cases of Parkinson's disease occur in which tremor is absent: the presence of the other signs mentioned above, however, should suffice for its recognition. *Bilateral cortical degeneration*, with its slowly increasing rigidity and muscular weakness, and its set facial expression, may resemble paralysis agitans: but it is accompanied by progressive mental failure, increase of the deep reflexes, sphincter troubles, and the other evidences of cortical degeneration.

The tremor of certain types of *general paralysis of the insane* is a fine, irregular oscillation, often with a twitching character. It first appears in the hands and arms, and may spread till it is conspicuous in the tongue, lips, and face, when it is associated with the characteristic changes—slowness and blurring—in the speech. For the most part this tremor occurs on exertion; it varies in extent, and may almost disappear during periods of general improvement. In the later stages of the disease a coarse universal tremor sets in, combined, perhaps, with grinding of the teeth. In these patients the moral and intellectual changes, tottering gait, alterations in the tendon- and pupil-reflexes, and other phenomena of general paralysis, will probably not escape attention.

In *Graves's disease* a fine, regular, and rapid tremor, about eight to the second, on exertion, is one of the cardinal signs. It affects the hands most, the arms much less, and least often the legs; it is increased by movement or by excitement. In addition, attacks of trembling that affect the whole body may occur. It is only in aggravated cases, however, that these tremors are so severe as to interfere with the customary employments of the hands. The tremors of Graves's disease are likely to be of comparatively sudden onset, and the patient will generally exhibit many of the other prominent signs or symptoms of hyperthyroidism, such as thyroid enlargement, exophthalmos and the other ocular phenomena, tachycardia, attacks of palpitation, wasting, sweating, or mental changes, so that the diagnosis ought not to be difficult.

Fine tremors are observed frequently in many of the *chronic intoxications*, particularly those due to alcohol, absinthe, lead, mercury, nicotine, carbon disulphide, morphine, cocaine, and many other organic compounds that may be taken in excess in rare cases, whether intentionally or by accident. *Alcoholic tremor* is fine, regular, and rapid; it is well shown in the outspread fingers of the extended hand and in the feet. In many cases it can be felt by the observer's hand more readily than it can be perceived by his eye; or it may be rendered more conspicuous by laying a sheet of paper on the backs of the outspread pronated fingers and hand. It is absent during rest, and is increased by movement, excitement, or fatigue. It may also affect the tongue, lips, and facial muscles, taking the form of a rapid and rather irregular twitching, increased on exertion. This tremor is an early sign of alcoholism, and is often more marked in the morning hours, when it is due, perhaps, to fatigue and want of alcoholic stimulation; it can be controlled to some extent by the will. Associated with it is a certain general nervousness and jumpiness; in addition, the patient will no doubt exhibit some of the other signs of chronic alcoholism—venous stigmata or acne rosacea on the nose and face, restlessness, insomnia, gastric disturbances—particularly the morning vomiting of mucus on an empty stomach—paræsthesia and weakness of the extremities, mental and moral deterioration. If the main facts of the case can be made out, tremors due to alcoholism should not be hard to diagnose. A history of chronic alcoholism should always be inquired after most carefully, both from the patient, who may deny it *in toto*, and from the patient's friends, who may hasten to admit more than the facts warrant. This is of importance, because mere nervousness at the prospect or realization of an interview with a medical man, will often bring on a fine but temporary tremor, indistinguishable, for the time being, from the lasting fine tremor of the drinker. If such a tremulous, but teetotal, patient has indigestion and acne rosacea, and repudiates any veiled suggestion of alcoholism with apparently unnecessary warmth, there is some danger lest these evidences be taken as confirming the erroneous diagnosis of alcoholism.

The tremor of *mercurial poisoning*, a very rare complaint nowadays, is at first fine, but later coarse and even choreiform. It is met with amongst workers in furs, hatmakers, and others who use skins that have been cured with mercurial compounds. It begins in the face, hands, and arms, and may spread to all parts of the body. At first it is brought out only by excitement, or on attempted movement. Later, it may persist even during sleep, and speech may be interfered with from involvement of the muscles of the tongue, pharynx, and larynx. Other prominent symptoms of mercurialism that should not be absent are profuse salivation, stomatitis, anemia, and cerebral symptoms of various kinds. Mercurial tremors may have to be diagnosed from those of paralysis agitans or disseminated sclerosis.

In *lead poisoning* a fine tremor of the affected limb is sometimes met with in cases marked by paralysis. The oscillations may also be seen in the tongue and lips, particularly

in the rarer instances of chronic plumbism that exhibit cerebral symptoms and simulate general paralysis of the insane. The diagnosis of these unusual cases would be difficult unless a suspicion of lead-poisoning were aroused, either by a history of exposure to the intoxication, or by the occurrence of other signs and symptoms of plumbism (see p. 34).

In *hysteria* the clinical picture of any or every disorder of movement or sensation may be more or less closely reproduced; and tremors of every variety may be met with in hysterical patients. The diagnosis may be extremely difficult until hysteria is suspected, when it may be confirmed by the discovery of signs and symptoms that, singly or together, are pathognomonic (p. 465). The diagnosis of hysteria should never be made lightly; but only after a careful consideration of the history, signs, and symptoms, and when all evidences of organic disease have been looked for and found wanting. Unless a careful examination be made, the tremor of intracranial tumour, for example, or of disseminated sclerosis, may be wrongly diagnosed as hysterical.

Unilateral Fine Tremor is but rarely seen. It may be a *hysterical* manifestation, functional, and significant of no underlying lesion of the central nervous system. Unilateral tremor may occur in *tumour of the frontal region of the brain*; if present, it occurs in both arm and leg, and only on the same side of the body as the tumour. The patients will often exhibit mental changes, such as inattention, incoherence, loss of memory, alterations in character; sometimes, too, irritative phenomena occur.

Unilateral fine tremor may develop on either the same or the opposite side of the body in *tumour of the mid-brain and sub-thalamic region*. The general symptoms of cerebral tumour will be present, and in addition certain localizing signs may make their appearance. The chief of these would be paralysis of the third nerve, loss of sensibility over the area supplied by the fifth nerve, eccentric position of the pupil, defective reaction of the pupil to light, and weakness of the upward movements of the eyeballs.

It may be added that fine tremors occasionally occur in the parietic limbs after *hemiplegia*. The history of the case and the presence of other signs characteristic of hemiplegia should make the diagnosis here a comparatively straightforward matter. Fine tremor may be seen in *chorrea*, and may be unilateral in such cases.

COARSE TREMOR.

Coarse tremors may develop as temporary exaggerations or later developments of the fine tremors occurring in several of the morbid states already considered. Thus, when the body is thoroughly chilled or fatigued, or when a patient is in a rigor, the initial fine tremor will often pass on into a very coarse tremor, as the amplitude of the involuntary muscular contractions increases, their rhythm remaining much the same. The fine tremor of paralysis agitans or general paralysis may similarly grow into a coarse tremor; coarse tremors are not infrequently seen in hysteria. The diagnosis in all these cases must be made on the lines already indicated.

Coarse tremor is met with sometimes in the various forms of familial and hereditary ataxia. Thus in *Friedreich's disease* (p. 512), in addition to the intention tremor considered below, irregular involuntary motions, described as coarse tremors in some cases, as choreiform in others, take place in the arms while the patient is at rest. Irregular nodding or tremulous movements of the head and trunk, also occur in advanced cases; the muscles of articulation and of the face may exhibit irregular purposeless contractions or quiverings when conversation is attempted. In *spino-cerebellar ataxia*, irregular choreiform movements, or constant tremors, large and small, may be seen in the head, trunk, and limbs whenever the attempt is made to hold them steady, but unsupported. Similar disturbances have been recorded in *cerebellar ataxia* and in the *olivo-ponto-cerebellar atrophy* of Dejerine and Thomas. In all these conditions the ataxia is the prominent symptom, the coarse tremor being no more than an occasional epiphenomenon; the diagnosis between them must be sought in special manuals, and also under the heading ARXXY (p. 55).

The coarse tremor of the affected limbs seen in patients with chronic or spastic *hemiplegia* or *diplegia*, and in some other cerebral disorders, is a variant of the athetoid or choreiform movements that are characteristic of those conditions. They are considered under the heading CONTRACTIONS (*Paramyoclonus multiplex*), p. 137. As has been mentioned already, it is practically impossible—were it, indeed, desirable—to draw any

hard-and-fast line between the grosser fine tremors and the finer coarse tremors. In the same way, coarse tremors merge insensibly into the lesser degrees of athetotic and choreiform convulsions.

INTENTION TREMOR.

Intention tremor—known also as *action* or *volitional tremor*—has been defined as tremor produced, or if not produced at least exaggerated, by voluntary movements. These tremors affect the upper extremities, and sometimes the head and trunk also; the limb is quiet when not in actual use, but as soon as voluntary movement is attempted, irregular and involuntary to-and-fro motions begin in it, and are superadded to the intended movement. These to-and-fro motions become more marked, and sometimes more rapid the more nearly achievement of the desired movement is reached. The greater the amount of precision demanded by the voluntary action, the greater becomes the amplitude of these involuntary excursions. Wishing to drink, the patient may lift the cup from the table steadily enough; but as the cup approaches his lip, the involuntary movements appear and rapidly increase till its contents are jerked wildly in all directions as it reaches his mouth. The tremor may spread from the muscles that are being put into action, and cause extensive jerky movements of the head and trunk. The pathogeny

of intention tremor is obscure. Very possibly it is due to destruction of the short intersegmental nerve-fibres in the substance of the spinal cord. The destruction of these fibres would render impossible the accurate mutual adjustment of the contractions of antagonistic muscle-groups that is essential for the smooth performance of even the simplest willed movements.

Intention tremor is one of the most characteristic features of *disseminated sclerosis*. The arms are affected most often and most markedly, but careful observation will often show that none of the voluntary muscles escape. The head may oscillate when the patient is holding it up; the trunk may exhibit jerky movements when he sits or stands; the legs when he stands or walks, after the disease has made some progress. Disseminated sclerosis is a protean disorder. Typical examples, however, may be recognized by the

Fig. 295.—Movements in intention tremor.

Fig. 296.—Movements in ataxy.

The dotted lines show the direction of the movement attempted.

occurrence of intention tremor (Fig. 295), muscular rigidity, nystagmus, pallor of the optic discs, and staccato or scanning speech. The deep reflexes are increased; the gait is spastic or ataxic; Babinski's sign is present; subjective sensory signs are far commoner than objective; and control over the sphincters may sometimes be impaired fairly early in the disease. In many instances, however, some, or even many, of these characteristics are absent; the diagnosis of disseminated sclerosis may then be far from easy, especially in its early stages. In *hysteria*, for example, intention tremor may occur in just the same way as a fine or a coarse tremor may; and other points of correspondence between hysteria and disseminated sclerosis may often be found in the age and sex of the patient, in the remittent course pursued by either of the disorders, in the frequent occurrence and partial recovery of various paralyses and of amblyopia with contraction of the visual fields, and in exaggeration of the deep reflexes. But distinct differences between the two are, fortunately, not wanting. In hysteria, the objective sensory signs are well marked, the optic discs are not affected, nystagmus is absent, Babinski's sign probably never occurs, and control over the sphincters is not lost. Attention to these points should suffice to clear up the diagnosis between hysteria and disseminated sclerosis; but in the earliest stages of the latter it may be necessary to keep the patient under observation for some little time before a definite opinion can be pronounced. Intention tremor has also been described as an exceptional feature in patients suffering from *neurasthenia*.

An intention tremor is not very rare in the *familial* and *hereditary ataxias*, especially Friedrich's disease and cerebellar ataxy; but the disturbance of movement in these

disorders is characteristically an ATAXY (p. 65). It also occurs in some cases of *congenital or acquired cerebral diplegia* of backward or mentally defective children, occasionally appearing as a familial disease, and characterized by bilateral spastic paralysis affecting the limbs, or limbs and body. It is athetosis that is characteristic of these cases; but disordered movements of all sorts occur in them. In addition, the sphincters are commonly affected, the deep reflexes are increased, optic atrophy or inequality of the pupils are frequent; and if the patient is able to get about, a spastic or 'scissor' cross-legged gait is to be seen. Congenital cerebral diplegia in which the spastic weakness is most marked in the legs is described as *Little's disease*. The intention tremor occurring in birth palsy or in infantile hemiplegia has, unfortunately enough, been described under the name *chorea spastica*.

Intention tremor has also been recorded in a few instances of lesion of the *superior cerebellar peduncle, corpora quadrigemina, or optic thalamus*, particularly when the tegmentum, red nucleus, and rubro-spinal tract are involved. It may be noted in patients with *extra-cerebellar tumours* growing in connection with the eighth nerve, and occupying the posterior fossa of the skull between the pons and cerebellum. It is seen in a certain proportion of the cases of cerebellar atrophy, whether the degeneration is primary parenchymatous, progressive and due to interstitial and vascular lesions, or acute and following some acute specific fever. Intention tremor is also present in some patients with *olivoponto-cerebellar atrophy*. The diagnosis of these rare instances will naturally depend upon the development of other general and localizing signs of intracranial disease.

A. J. Jer-Blake.

TRISMUS, or lockjaw, signifies a maintained closure of the jaws by tonic muscular spasm, so that the mouth cannot be opened. It is seen best in tetanus. The term does not include mechanical inability to open the jaws owing to such affections as mumps, alveolar abscess with surrounding inflammatory oedema, angina Ludovici, quinsy or severe tonsillitis, an odontoma, epithelioma of the mouth, myositis ossificans, and so forth; but there are at least two mechanical conditions that may not at first sight be obvious, but which may lock the jaws together and simulate true trismus—*impaction of a wisdom tooth, and arthritic changes in the temporo-maxillary joint*. These will be diagnosed as the result of a careful local examination of the teeth and of the joint respectively, and in the latter case there may be osteo-arthritic changes in other joints also.

Circumstantial evidence will generally serve to distinguish trismus due to *hysteria* or to *facial neuralgia*; and if there is any doubt at first, this will disappear if the patient can be watched for a while. If there are convulsive seizures in a hysterical patient with trismus, they can generally be distinguished from those due to tetanus or to strychnine poisoning by their polymorphous character, and by the fact that touching the patient, and other similar stimulation, does not bring them on so certainly as would be the case with strychnine or tetanus.

The rigidity of the face muscles in certain cases of *tuberculous or posterior basal or cerebrospinal meningitis* never occurs by itself, and is a minor symptom amongst others that point to the correct diagnosis. The same applies to *epilepsy* and to *aravmia*.

Malingering may sometimes take the form of lockjaw, and it may be a little while before the fraud can be detected; sleep is sure to come in time, and as the result of fatigue the malingerer's muscles relax completely.

Catalepsy may include trismus amongst its varieties of maintained muscular contractions; the general mental symptoms will assist the diagnosis, and as a rule there are no convulsive seizures.

Trichinosis is very rare nowadays, but if infected pork is eaten raw, or insufficiently cooked, the larvae of the parasites find their way to many different muscles, and they show some predilection for those of the tongue, mouth, and jaws. The resultant irritation, pain, and stiffness cause trismus, whose nature may be difficult to determine unless the history points to pork as the origin. The patient is very ill in the earlier stages, with high fever, and the condition is often fatal. There may be an epidemic of the malady. The blood exhibits eosinophilia. The final criterion of the diagnosis is the discovery of the typical parasites coiled up in their little oval cysts amongst the affected muscle fibres. In a certain proportion of acute cases the embryos can be detected in films prepared from the centrifugized deposit from 5 c.c. of the patient's blood after the red corpuscles have been laked.

Hydrophobia and **tetany** seldom exhibit trismus as a prominent symptom. The former, though it is almost unknown in Great Britain now, would suggest itself if any convulsive illness developed after a definite bite by a dog, wolf, or other similar animal, particularly if the spasmodic muscular difficulty was markedly increased by efforts at swallowing. The symptoms may not develop for weeks or months after the bite, so that the patient may fall ill when he has come home after being bitten abroad. *Tetany*, also rare, is at once distinguished by its typical carpo-pedal contractions (*Fig. 1, p. 3*).

Strychnine poisoning gives rise to generalized twitchings and convulsions long before trismus, the lateness of the development of the latter serving to distinguish it from tetanus. There may be evidence of strychnine having been taken or administered, either by the mouth or hypodermically: the symptoms develop very acutely, and are apt to be rapidly fatal.

Tetanus is the cause par excellence of trismus: the diagnosis is often obvious if the illness develops steadily in an otherwise healthy person or new-born infant, starting with stiffness of the neck muscles, spreading to those of the face and jaw, and thence to the rest of the trunk and limbs, with a tendency to extremely painful exacerbations on the slightest stimulation, even by a stroke with a leather or the banging of a door: risus sardonicus; opisthotonos; no complete relaxation of the stiffening muscles unless chloroform is given; a duration of days rather than hours, and a termination in death more often than in recovery; especially if all these things follow a few days, or a week or more, after infection of the umbilical cord or a small penetrating wound with a rusty nail, or a piece of stick or other similar body that may have been contaminated with tetanus bacilli from the soil. It may be possible to demonstrate the drum-stick bacilli in films prepared from the deeper parts of the wound (see *Plate XXI, Fig. T, p. 614*). The chief difficulty arises when there is no clear history, or when the wound has been so small that it has healed or cannot be found. Even then, most cases are so typical that they can be diagnosed as tetanus without much difficulty. Unnecessary anxiety arises chiefly in cases of impacted wisdom teeth, or of hysteria, where tetanus may be suspected at first: the subsequent course of the malady soon serves to exclude this.

Herbert French.

TUMOURS.—(See SWELLING, pp. 655 to 702.)

TUMOURS OF THE SKIN.—The malignant tumours which affect the skin include carcinoma, epithelioma, Paget's disease, sarcoma, mycosis fungoides, and xeroderma pigmentosum.

As a rule, *cancer en cuirasse* and *nodular (lenticular) cancer* are secondary to cancer of the breast or other parts, and their diagnosis is self-evident. In *melanotic carcinoma* the tumours differ greatly in size, and also in colour, varying from a slate tint to bluish-black; they appear more frequently on the genitalia and the extremities than elsewhere. The only condition from which melanotic cancer requires to be distinguished is *pigmented sarcoma*, and for this histological examination is necessary.

Paget's disease, occurring chiefly in women after the age of forty, begins as a reddening of a patch of skin, usually on or around the nipple, followed by branny desquamation. Infiltration soon produces a bright-red, granular, indurated surface, with a sticky, yellowish discharge, which by forming crusts may obscure the nature of the lesions, save at the border, which continues to be characteristic—sharply defined, indurated, and sometimes distinctly raised. After a period, which is usually about two years, but may be much longer, deep-seated parts may become affected, this extension of the disease showing itself on the breast by retraction and induration of the nipple and the formation of a tumour in the substance of the gland. In the early stage Paget's disease has to be distinguished from *chronic eczema*, which it resembles closely. Its differentiating features are the bright-red, granular surface exposed after removal of the crusts, the induration at the well-defined edge, the intractability, the age of the patient, and (later) the retraction of the nipple. The diagnosis may be made certain by microscopic examination of scrapings in iodized serum or liquor potassa, when the bright, oval, nucleated bodies styled psorosperms will be seen, some still contained within the host-cells, others surrounded by distinct capsules.

Epithelioma begins usually as a single growth, superficial, deep-seated, or papillary, but all the forms alike are marked by peripheral extension, infiltration and destruction

of neighbouring parts, central ulceration, and (except in rodent ulcer, for which see *ULCERATION OF FACE*, p. 735) a tendency to the formation of secondary growths in lymphatic glands, in viscera and elsewhere. Epitheliomata have a predilection for the natural orifices, for such moist parts as the glans penis, for exposed regions, and parts exposed to friction and trivial injuries. A wart, a mole, an ulcer, lupus vulgaris lesions, or an x-ray cicatrix, may be the starting-point. If the tumour begins in the skin, it appears first as a papule; if in a gland, as a nodule. In the former, the more frequent case, the papule becomes firmer and extends laterally; infiltration is evidenced by the hard, raised, pearly border. Ulceration occurs in the centre of the growth while extension is proceeding in the depths and at the sides. If the necrotic process involves the vascular tissue, there is more or less hæmorrhage. If the lateral extension predominates, the discoid type of epithelioma, as in sweep's cancer of the serotum, is the result; the surface is raised, with a steep border, and is bright-red, with a firm, granular surface. If the granulations are of large size, the growth is of the papillary type. The chief diagnostic features of epithelioma are: the origin as, usually, a single growth, the site, the starting-point, the slight discharge, the characteristic border, the secondary growths in glands and elsewhere. From a wart or a mole, epithelioma can be distinguished conclusively only by microscopical examination or by long-continued observation, and should signs of ulceration or crusting appear in such growths, epithelioma should be suspected. The so-called tubercular ulcerating syphilides are, as a rule, multiple, and not rounded, but rather segmental. (For the diagnosis of epithelioma from lupus vulgaris, see under *NODULES*, p. 102).

Sarcoma of the skin is most frequently secondary to growths commencing in the lymphatic glands or the deeper structures. Sarcomata vary considerably in colour, from reddish to brown or bluish-black, and also in consistence; those of the spindle-celled type are fairly firm, the small-celled ones soft, with all intervening grades of density. They may appear in any part of the body, but are often found on moles, warts, and ulcers. The diagnosis usually depends upon histological examination, and it must suffice to say that a tumour which arises in previously healthy skin, or in a mole or wart, or at the site of an injury, which is soft and reddish from the vascularity that is a marked feature of this kind of tumour, or bluish from pigment, and which, after a period of slow growth, enlarges rapidly, projects above the surface, and readily ulcerates and bleeds, is probably a sarcoma.

In the early stage of *mycosis fungoides* the lesions are dull-red or livid patches, sometimes slightly tinged with yellow, varying in size from the area of a finger-nail to that of the palm of the hand, with border sometimes well marked, sometimes fading off, most frequently raised or thickened, but occasionally flat. At first the patches are smooth and dry, afterwards they become scaly, and later still they may be moist or covered with crusts. Presently the surface becomes infiltrated, and tumours as small as a pea or as large as an apple, firm and lobulated, broader at the free than at the attached end, and somewhat resembling tomatoes, project above the level of the skin ('fungoides'). As a rule, progressive thickening occurs, leading on to fungation. The lymphatic glands may be enlarged throughout the body. In the premycotic or eczematous stage—which is sometimes absent—the diagnosis may hesitate between *mycosis fungoides* and an eczematous or urticario-eczematous condition, and in some cases it may be impossible at this stage to distinguish definitely between the two; but in *mycosis fungoides* the lesions will make little response to therapeutic measures, the red of the patches may be slightly tinged with yellow, and they are more persistent than those of eczema. The only malignant condition which *mycosis fungoides* in the mycotic stage at all resembles is sarcoma, but there is seldom any difficulty in distinguishing between the two.

The initial lesions of *acrodema pigmentosum* (Kaposi's disease) are small spots resembling freckles, but rather darker, which appear chiefly on the face, neck, arms and legs, and generally begin within the first two years of life. Usually they disappear in winter and return in summer; but after a time they become permanent, and often quite black. At first the condition suggests nothing but excessive freckling, but presently amid the 'freckles' appear white, glazed, atrophic spots, telangiectases, and superficial ulcers discharging pus which dries into yellow crusts. After some years, small, warty-looking growths develop on the 'freckles.' Tumours now form and ulcerate, producing fungous masses, and the process extends both widely and deeply, and destroys every tissue it

encounters, not excepting bone. It is only in the earliest stage that there can be any difficulty in recognizing this very distinctive disease. In that stage it may be mistaken, as is suggested above, for simple lentigo, from which there may be nothing but the more extensive distribution to distinguish it. With the appearance of the later lesions lentigo will be dismissed from consideration, and it should be not less easy to rule out scleroderma.

The *benign* tumours of which the diagnosis may be, in very different degrees, open to doubt, are sebaceous and dermoid cysts, fibroma molluscum, von Recklinghausen's disease, neurofibromata, myoma cutis, myxoma, the xanthomas, rhinoscleroma, molluscum contagiosum, colloid milium, benign adenoides cysticum, and keratosis follicularis.

Sebaceous cysts, seen most frequently on the scalp, the face, and the back, rounded, often somewhat flattened on the top, and sometimes as large as an orange, are distinguished from *fatty tumours* by the absence of lobulation and the fact that the sebaceous contents can be squeezed out when there is an opening; in *Dercum's disease* (p. 410) the deposits of subcutaneous fat may be less well defined, but the diagnosis is generally obvious from the alcoholic history. *Dermoid cysts* may resemble *fibromata*, but if they are incised a sebaceous-looking material escapes. *Fibroma molluscum*, a pear-shaped or rounded fibrous tumour, usually covered by smooth skin and pedunculated, varying in size from a pin's head to an orange, and nearly always multiple (*Fig. 291*, p. 711), differs from a sebaceous cyst by its solid structure, and from a fatty tumour by its usual pedunculation and the absence of lobulation. *Von Recklinghausen's disease*, of which the lesions consist of nodular tumours, on and around which there is coffee-coloured pigmentation, is differentiated from ordinary fibroma in that the tumours are composed of fibrous and nervous, and not simply of fibrous, tissue. There is also a perceptible thickening of the nerves of the arms. *Neuro-fibromata*, which have their origin in the tendon-sheaths or the sheaths of the nerve fibres, and range in size from a pin's head to very large dimensions, are sometimes mistaken for rheumatic nodules, but instead of specially affecting the region of the elbows and the scalp, they occur on the trunk and extremities generally, nor is there (except from coincidence) a history of rheumatism.

Superficial *myoma cutis* occurs in the form of nodular tumours on the arms, back, chest, and cheek; the deeper kind, originating in the subcutaneous muscular structures, occurs as a solitary tumour, commonly on the breasts and genitals. The former growths are soft and elastic, and, like the latter, are often painful. The distinctive clinical feature of myoma cutis generally is that it contracts under the influence of cold. This, with the pain, the absence of any tendency to ulceration, and the aspect and slow course of the growth or growths, should enable the affection to be identified.

Myxoma, when it arises in the skin—most frequently in the loose skin of the scrotum and labia—usually forms rounded, pedunculated, translucent tumours which tend to enlarge slowly. They have to be distinguished from *molluscum contagiosum*. This begins by the formation of small growths that have been likened to tiny mother-of-pearl shirt-buttons. They are usually flattened at the top, where as a rule there is a depression in which can be seen a small aperture leading into the interior of the tumour. Through this orifice a whitish material, or sometimes a milky fluid, can be squeezed out. When they are very small the tumours resemble the vesicles of *varicella*, but a microscopic examination of the contents will obviate the confusion. A small molluscum body on the genitals may resemble a hard chancre, but similar growths will be found elsewhere.

Xanthoma planum, often associated with jaundice and migraine, and characterized by the formation of yellow or yellowish-white plaques (rarely nodules), usually in the upper eyelid and sometimes affecting also the lower lid, is easy of recognition, the appearance of the yellow patches embedded in the corium, and almost imperceptible to the touch, being absolutely distinctive. *Xanthoma multiplex*, however, is not identified quite so easily. Here the lesions are nearly always nodular, and often observe a linear grouping, and the colour varies, a blackish or reddish pigment being mixed sometimes with the yellow. Usually the nodules occur in connection with hepatic disease. The condition has been confounded with *urticaria pigmentosa*, but there is no itching, there are no wheals, and it is impossible to produce factitious lesions. The tumours may be indistinguishable from multiple dermoids of the skin until microscopic examination is made. *Xanthoma diabeticorum* differs from other forms of xanthoma, *inter alia*, in the presence of a raised red area around the yellow spots. This feature has led, in the early stages of the affection,

to confusion with *acne*, but if the lesions are punctured they will prove to be solid. In the same stage the lesions may simulate those of *lichen planus*, but the resemblance soon disappears.

Rhinoscleroma begins, usually before the age of forty, in and around the nostrils as nodules in the cutis, and in the deeper layers of the mucous membrane. These coalesce to form a hard, smooth, glistening growth which spreads inwards from the lip and downwards to the pharynx from the posterior nares. The growth does not break down spontaneously, but is generally slowly progressive. It is not likely to be mistaken for anything but *epithelioma*, which is prone to ulcerate, generally has infiltrated edges, seldom attacks the upper lip, and usually begins later in life. In *rhinophyma*, pustules are often present, the growth is soft, and there is vascular dilatation.

In *colloid milium*, small, yellow, cyst-like formations containing a gelatinous substance appear in the skin, chiefly on the upper part of the face. They may become depressed in the centre and be absorbed slowly, or may inflame and dry up. The only condition from which colloid milium needs to be distinguished is *epithelioma adenoides cysticum*, in which the tumours, shining and translucent, contain one or more white, brightly refracting, milium-like bodies. The face is the part attacked most frequently, but the growths may appear on almost any part of the body. They are not yellow, like the growths in colloid milium, nor are they soft.

Keratosis follicularis begins as small brown or yellow crusts, hard and dry, which, when detached from the underlying tissue, are found to present on their under surface a softish prolongation which dips into a follicle. At first discrete, the lesions may become confluent, and there is thickening of the affected parts until nodular masses are formed, from which oozes an offensive discharge. The affection is slowly progressive. At the outset the condition may be mistaken for *keratosis pilaris*, but it is not confined to the situations affected by that disease. The prolongation into a follicle gives it some resemblance to *molluscum contagiosum*, but it has a less limited distribution, nor have the growths the pearly appearance of the molluscum bodies, while the aperture in the individual lesions is larger.

Malcolm Morris.

TYMPANITES.—(See METEORISM, p. 388).

ULCERATION OF THE CORNEA. The course of all corneal ulcers conforms to a general type, though the clinical varieties may vary. The process begins with an infiltration in the substance of the cornea, either central or peripheral; the result of this infiltration is a local loss of transparency, though in early stages the surface of the cornea may still retain its polish. The infiltration proceeds to suppuration, which is followed by a loss of substance, the corneal surface being dull and irregular, and, in the centre of the ulcer, depressed below the surrounding level. The base of the ulcer is grey or yellowish, and the surrounding portion of the cornea may be opaque with more or less grey infiltration.

The suppuration is followed, in cases which have a favourable termination, by vascularization, superficial vessels from the surrounding conjunctiva encroaching on the cornea and invading the suppurating area. The vascularization is followed by cicatrization, the surface of the cornea again becoming polished but flattened and opaque. The opacities resulting from corneal ulcers are localized, well defined and opaque, in contrast to the diffuse indefinite haze which follows such non-suppurative forms of inflammation as interstitial keratitis. Corneal ulcers may not heal, but occasionally lead to perforation of the cornea, prolapse and adhesion of the iris, anterior polar cataract, or panophthalmitis. Iritis, iridocyclitis, and pus in the anterior chamber (hypopyon) may also be associated conditions. The usual subjective symptoms are pain, photophobia, and lachrymation. The presence of corneal ulcers is demonstrated most satisfactorily by the instillation of a drop or two of fluorescein, which stains necrotic corneal epithelium or exposed corneal substance, green. The brightly-stained ulcer shows up in marked contrast to the surrounding clear cornea.

Corneal ulcers may occur in the following clinical varieties:—

Catarhal, or simple infective ulcers. These usually occur as minute grey infiltrated spots in the centre or periphery of the cornea. They heal very rapidly as a rule. They may follow injury to the corneal epithelium by foreign bodies, or may be associated with acute conjunctivitis or rhinitis.

Phlyctenular ulcers are associated with phlyctenular conjunctivitis, the ulcer forming after the epithelium on the top of a phlyctenule has been rubbed off. They are usually marginal, but may occasionally make their way on to the cornea, a leash of conjunctival blood-vessels trailing after them. Similar ulcers may be associated with *acne rosacea*.

Hypopyon ulcer, or *ulcus serpens*. This is a shallow ulcer affecting chiefly the superficial layers of the cornea in or about its centre. The middle layers of the cornea are comparatively unaffected, but at the posterior surface the infiltration again becomes dense, with much fibrin and débris, associated with the formation of more or less pus in the anterior chamber. The ulcers often perforate; they are usually due to infection with the pneumococcus (*Plate XII*, p. 232). The pus in the anterior chamber is always sterile, unless there is perforation of Descemet's membrane. These ulcers do not react to ordinary methods of treatment as a rule, but require cauterization, either by pure carbolic acid or the galvanic-cautery. The hypopyon then disappears rapidly.

Moore's ulcer, or rodent ulcer of the cornea, is a chronic serpiginous ulcer, usually affecting the eyes of elderly people. It begins at the margin of the cornea and spreads slowly over the whole surface, the advancing edge being much undermined. The ulcer is always shallow, and perforation never occurs; the ulcer may heal in places, but this is seldom permanent, and the ulceration usually spreads over the whole surface of the cornea whatever method of treatment may be employed to arrest its progress, though recently radium has been used with some success. No specific organism has yet been discovered.

A *dendritic ulcer* is characterized by its peculiar shape—a long central stem with small linear ramifications. It is not really an ulcer, but an infiltration under the corneal epithelium, which in the later stages may become necrotic and break down. It is best treated by rubbing off the affected corneal epithelium with a pointed stick dipped in absolute alcohol.

Corneal ulcers may occur in association with pannus in *trachoma*, their usual site being at the margin of the vascular area. Occasionally they penetrate more deeply into the corneal substance.

Corneal ulcers frequently follow *gonorrhoeal* and *diphtheritic conjunctivitis*. They spread rapidly, and often lead to perforation of the cornea and panophthalmitis. The diagnosis depends on bacteriological methods and the discovery of the causative micro-organisms.

Keratomalacia, a disease of childhood, is associated with night blindness and xerosis or dryness of the conjunctiva. Characteristic foamy white patches are seen on both sides of the cornea (*Plate XII*, p. 232). The cornea becomes dull, grey, and cloudy, and ultimately disintegrates from purulent infiltration, associated with very slight signs of ocular inflammation. The ocular condition is associated with marasmus and malnutrition. The prognosis, both as to eye and vision, is bad.

Keratitis e lagophthalmo is associated with paralysis of the seventh nerve. Owing to the failure of the orbicularis palpebrarum the eye cannot be closed, and does not remain closed during sleep. The lower part of the cornea is exposed, becomes dry, and the corneal epithelium dies, with consequent ulceration of the cornea. The condition can be cured by diminishing the palpebral aperture by sewing the eyelids partially or completely together.

Similar exposure of the cornea and consequent ulceration is seen occasionally in cases of EXOPHTHALMOS (p. 229), for instance in severe *Graves's disease*.

Keratitis neuroparalytica. In paralysis of the fifth nerve, or as a result of excision of the Gasserian ganglion, the cornea becomes dull and cloudy and necroses in the centre, only the periphery remaining clear. A hypopyon forms, and in some cases the whole eye is destroyed, though occasionally the keratitis may lead only to a permanent opacity. The condition is due to arrest of lachrymal secretion and absence of corneal sensation, which is followed by abolition of the winking reflex. Foreign bodies lodge on the cornea and are not removed. The prognosis is bad, and is little affected by treatment.

Corneal ulcers may be associated with *herpes frontalis*, vesicles forming on the cornea simultaneously with the vesicles on the skin, especially along the course of the supra-orbital nerve. The ulceration is often severe and may lead to perforation and destruction of the eye, and is in any case followed by considerable corneal opacity. The cornea is usually insensitive, and the intra-ocular tension may be raised.

Tuberculous ulceration is not common fortunately, but it should be borne in mind as a possibility in chronic or resistant cases. The diagnosis depends on the history, the presence

of tuberculous glands or other similar lesions, positive reaction to the various tuberculin tests, and, most conclusively of all, upon the detection of tubercle bacilli in the discharge from the ulcer itself.

Herbert L. Eason.

ULCERATION OF THE FACE. The ulcers most often met with on the face are lupous, scrofulous, syphilitic, or malignant. In *lupus vulgaris*, the ulceration is extremely chronic. The lesion begins as a papule, develops into a nodule, and after a while, in the majority of cases, the lupous tissue breaks down and forms a granular sore covered with greenish-black crusts; but around the ragged edge will still be seen the characteristic 'apple-jelly' nodules in different stages of development. The ulceration may extend through the whole thickness of the skin and may become the seat of warty vegetations. In the nose, where the integument is thin, it may cause necrosis of cartilage. The course the pathological process runs, from the papule onwards, as here described, and the frequent presence of the different lesions simultaneously, shed sufficient light on the character of the ulceration. I need only say further that the ulcer of lupus, however deeply it may extend, never erodes bone. This alone is sufficient to differentiate lupus from the ulcers of syphilis and cancer. It nearly always begins before the age of twenty.

In the ulcers of *scrofula*, though they have no absolutely distinctive characters, it will often be noticed that the edge is undermined and the surrounding skin blue and of low vitality. Their occurrence in children of strumous aspect, or in elderly persons who bear the stigmata of scrofulous lesions dating from childhood, and their tendency to become chronic owing to the feeble resistance offered by the tissues to morbid processes, leave no room for doubt as to their true nature.

It is in the late secondary and the tertiary stages of *syphilis* that cutaneous lesions on the face, as elsewhere, are prone to ulceration, instead of to the resolution to which typical secondary syphilides tend. The whole structure of the skin, or mucous membrane, is frequently involved, the ulceration is deep, and the ulcers, while healing in the centre, are prone to extend at the margins, and so assume the characteristic circinate or serpiginous form. The appearance of the ulcers, with the history, and the marks of earlier syphilitic lesions, will supply all the guidance the diagnostician needs: Wassermann's serum test and the effects of mercury and iodide of potassium or salvarsan may serve to clinch the diagnosis.

As a rule *rodent ulcer* occurs in persons of more than middle age, and its favourite points of attack are the outer edge of the orbit and the side of the nose. It begins as a small, circumscribed nodule, dull brownish-red in colour, flat, depressed in the centre, and firm to the touch. After, it may be, years, the cuticle covering it is broken, and an ulcer is formed with depressed granular centre and infiltrated border. Very slowly this extends, both in circumference and in depth, infiltrating and destroying the subjacent tissues, including bone. Usually the destruction of the underlying parts is more marked in the centre, so that the ulcer becomes crateriform. Its invariable features—the inconsiderable suffering it inflicts, the singular slowness of its progress, its depressed centre, and the firm, raised, rolled edge, its failure to affect neighbouring glands, and its incurability except by extirpation or by physiotherapy—are so characteristic as to leave little scope for diagnosis. Epitheliomatous in structure, it differs from epithelioma in that the latter growth has a very hard and everted edge, and a foul base roughened with granulation, is often attended by severe pain, is much more rapid in its course, and infects the glands in its vicinity. It differs from *lupus vulgaris* in its mode of onset, in the absence of the 'apple-jelly' nodules, and in not being a disease that starts in childhood. It may be diagnosed from tertiary syphilitic ulcers by the characters described above, and also by its usually solitary character and its resistance to treatment.

Malcolm Morris.

ULCERATION OF THE FOOT.—The ulcer which attacks the foot specially, though not exclusively, for the hand may be affected in the same way, is that known as perforating ulcer (*Fig. 297*). The exciting cause is pressure upon or injury to a foot in which there is interference with the nerve supply, either from peripheral lesion, as in peripheral neuritis, or from damage to the nerve-trunk, as in leprosy, syphilis, or diabetes mellitus, or to the nerve-centre, as in *tubes dorsalis* and general paralysis. The commonest situation of the ulcer is at the point of greatest pressure—the under aspect of the metatarso-phalangeal

joint of the big or little toe. The ulcer, which is more a sinus than a true ulcer, usually painless, may be simple or multiple, and both feet may be affected. It often begins by supuration under a corn. When the horny covering is cast off, a track is seen which extends downwards until the bone is exposed. The process is usually very slow, and if the pressure from walking is continued the thickened epidermis forms a kind of corn-shield around the opening. The more essential symptoms of the disorder of which perforating ulcer is but an incidental manifestation will disclose the true nature of the lesion. The only malady with which it can be confused is a suppurating corn. From this it is distinguished by the absence or small degree of pain, and by its irresponsiveness to the simple surgical treatment to which a suppurating corn yields readily.

Ulceration of the foot is also apt to arise as the result of rubbing, irritation, or other injury to parts whose nutrition is impaired, for example in cases of talipes from nerve disorders, or when sensation is impaired, as in cases of syringomyelia (p. 608), or paraplegia (p. 510).

Mycetoma is a fungous disease that is known alternatively as Madura foot, because, endemic in Madura and other parts of India, it usually affects the foot or the leg, though sometimes the hand, and in rare cases the shoulders or the scrotum. The affection appears in several forms, according as they are due to different species of discomycetes and aspergillus. The lesions may be black ('melanoid') or pink ('ochroid'). The disease begins with slight swelling and redness or local induration, and as it progresses the foot swells and the surface becomes dotted with small nodules, each containing the opening of a sinus which discharges a viscid, syrupy, slightly purulent, sometimes blood-streaked fluid, in which are suspended rounded greyish, yellowish, or black granules. As the foot enlarges, the leg, from disuse, atrophies. The only condition from which mycetoma needs to be discriminated is *actinomycosis*. This affection usually begins in the bone or other deep structures of the jaw, face, or neck, may thence spread to the surface, and may involve the viscera. In the discharge the ray fungus may be found in the form of tiny, friable, yellowish or greyish bodies, though microscopical methods and the discovery of the characteristic ray fungi

Fig. 297.—Perforating ulcer of foot: from a case of talipes clausilis.

(Plate XXVIII, Fig. S, p. 614) will generally be required before the nature of the case can be confirmed.

Malcolm Morris.

ULCERATION OF THE LEG may be classified under three headings:—(1) *Non-infective Ulcers*.—These include those that are not due to any specific infection, but which are caused by various factors which interfere with the vitality of the part by injury, lack of circulation, or deficient innervation of the tissue. (2) *Infective Ulcers* resulting from the direct action of a definite specific infection, e.g., tuberculosis or syphilis. (3) *Ulcerating Tumours*.—These are malignant tumours, which have originated in or invaded the skin.

Non-infective Ulcers.—*Varieties and Causes.*

Varicose Ulcer.—The presence of varicosity in the veins of the leg diminishes the free return of blood, and so leads to congestion and interference with nutrition, and thus to ulceration. In the majority of cases the ulcer is situated on the inner side of the leg about three inches above the ankle. It may be small, or may encircle the limb. For some distance round the ulcer the skin suffers from the effects of passive congestion; it becomes indurated and of a purplish-brown colour, and numerous small varicose veins may be seen in it. Any slight injury may cause abrasion of this weakened skin and thus another ulcer.

The presence of varicose veins associated with an ulcer will usually lead to the conclusion that the latter is dependent on the former, and that view will probably be correct, but it may not be the whole truth, for syphilitic and varicose ulcerations may be present at the same time. Before the introduction of Wassermann's test for syphilis it was common practice to give anti-syphilitic remedies in order to clear up the diagnosis, and this may still be done when the serum test cannot be carried out.

Lymphatic Obstruction also leads to loss of nutrition, and ulceration may result. The best instance is seen in elephantiasis due to *Filaria sanguinis hominis*. In this country elephantiasis is rare. Other instances that may be cited are swellings of the leg following a badly united fracture; the cicatricial contractions of extensive burns; phlegmasia alba dolens, or white leg, during pregnancy or after labour.

Atheroma of the Arteries leads to a feeble or imperfect circulation of the blood, and so to loss of nutrition. Ulcerative conditions of the lower part of the leg are therefore common in such cases, and even gangrene may result.

Old Age. Owing to a weaker condition of the tissues, ulcers are much more frequent in old people than in the young.

Cold.—A similar condition is brought about by exposure to cold, especially in persons whose nutrition is imperfect, whether from bad or insufficient food. The first effect of cold is to produce a chilblain; this if rubbed or irritated may degenerate into an ulcer.

Trauma.—In a normal individual, any lesion of the skin of the leg, such as that caused by a kick, a scratch, or a cut, will heal quickly, and no ulcer result. Circumstances may arise which interfere with the healing process. Perhaps the most frequent cause which leads to the formation of an ulcer is infection with pyogenic organisms, and the prevention of the discharge from the wound. Occasionally there is also accidental contamination of the wound with some specific organism, such as that of diphtheria or phagedena.

An important cause of want of healing of an ulcer is interference with its contraction. If contraction is impossible, as when a sore is situated over and adherent to a bone, healing may come to a standstill.

Deficient Immersion leads to loss of nutrition. Examples are seen in infantile palsy; rubbing of the foot or pressure of an instrument is prone to be followed by an obstinate ulcer. In cases of hemiplegia, even when the patient is lying on a water-bed, ulceration in the form of bedsores will occur much more rapidly on the paralyzed side than on the other. Perforating ulcer of the foot is a well-known sequel of *tuberc dorsalis*, its other common cause being *diabetes mellitus*; ulceration and GANGRENE (p. 255) are prone to occur because the resistance of a diabetic individual to micro-organisms is lowered, also because the arteries are often atheromatous, and possibly because the innervation of the whole body is interfered with.

Infective Ulcers. The legs may be attacked by any form of acute infective ulcer, such as *anthrax* or *glanders*, but such an event is rare. The chief ulcers that belong to this group are chronic, and due to syphilis or tuberculosis.

Syphilitic Ulcers are the result of gummata which have formed in the subcutaneous tissues. These ulcerated gummata are almost always circular, and present a punched-out appearance (Fig. 298); they are generally multiple and tend to run into each other, so that the ulcer has a serpiginous outline. They tend to heal at one side while they progress at another. The scars are thin and supple, and if in the lower part of the leg, usually pigmented round the edges, white and slightly depressed in the centre. Gummata are often found with varicose veins or ulcers, and it seems probable that the low state of nutrition of the tissues caused by the obstruction of

Fig. 298. Diagram of a gummatus ulcer. Clearly punched out. Slough on base.

venous return is favourable to their formation. Diagnosis can in most cases be made on the distribution and shape of the ulcer, especially if they are on the outer aspect of the lower third of the leg; on the presence of other signs of syphilis; and on the effect of giving iodide of potassium or salvarsan. In cases of doubt, a Wassermann's reaction is of service.

Tuberculous Ulcer usually follows the formation and bursting of a tuberculous abscess, starting either in the subcutaneous tissue or in a bone, and the history may help materially in diagnosis. The ulcer is very chronic, and is characterized by undermining of the skin for a considerable distance from the edge (*Fig. 299*). The surface is pale, and the granulations are very small, with here and there small areas of caseation. Primary tuberculosis of the skin, or lupus, is not often found on the leg, though it may occur there as in any other part of the skin. A useful guiding rule is that lupus never starts later than the age of twenty and lasts for years, whereas a gumma starts at a later period and tends to heal spontaneously. In lupus the chief characteristic is the presence of minute, semi-transparent nodules at the margin of the ulcer and in the skin around, resembling apple jelly. If further methods of diagnosis are required, a diagnostic injection of Koch's old tuberculin may be used, or von Pirquet's skin test applied. A particular variety of tuberculous ulcer of the legs is described on p. 404 under the heading of Bazin's disease, or erythema induratum scrofulosorum.

Ulcerating Tumours.—*Epithelioma* may develop in a simple varicose ulcer that has existed for many years. The change may be very slow, or rapid. The ulcer spreads, the edges become heaped-up, everted, and indurated (*Fig. 300*). The femoral lymphatic glands become enlarged, and if the disease is allowed to progress, the bone is attacked. If any doubt arises as to a change in the character of an ulcer, a piece from the edge should be removed for histological examination.

Rodent Ulcer (*Fig. 301*) usually attacks the face (p. 735), though it may be found on any part of the body.

Sarcoma, starting in the deeper tissues, may fungate through the skin, which has given way before the pressure of the tumour.

ULCERATION OF THE THROAT. (See SORE THROAT, p. 613.)

ULCERATION OF THE TONGUE.—To enable a good view to be obtained of the affected part, the patient should be seated in a strong light and the protruded tongue gently wiped with a piece of soft linen to remove moisture. The presence of an ulcer being ascertained, its nature may be considered under the following heads:—

- | | |
|------------------|---|
| 1. Carcinomatous | 4. Tuberculous |
| 2. Syphilitic | 5. Dyspeptic |
| 3. Dental | 6. Ulcer in connection with stomatitis. |

Carcinomatous Ulcer is much commoner in men than in women, probably owing to the fact that chronic glossitis due to smoking and syphilis is more common in the male sex. It is practically unknown before the age of thirty, and rarely starts before forty-five. The ill and wearied expression of the patient may awaken suspicion before the tongue is seen, for the pain and trouble caused by an epithelioma have a rapid and marked effect. The tongue in a normal individual can be protruded from one to one and a half inches beyond the teeth; if the protrusion is limited, or if the tongue is not protruded straight, it can generally be inferred (except in cases of paralysis) that there is some tumour binding it down. The position of the ulcer is to be studied, and its relation to any sharp and carious tooth. Usually an epithelioma is on the side of the tongue, but there is no rule; it may be anywhere on the upper, lateral, or under surfaces, or on the floor of the mouth.

As regards the ulcer itself, the typical appearance, when fairly developed, may be described as irregular, deep, foul, sloughy, with raised nodular everted edges, and a surrounding area of induration. The lymphatic glands are enlarged and hard, and they may be fixed. The submaxillary set is generally the first affected, but the disease sometimes misses these and infects the carotid and even the supraclavicular glands. Examination, therefore, should not be concluded before the whole of the neck had been palpated. The diagnosis should have been made, however, before the disease had developed thus far: in its earliest stages an epithelioma may be represented by a superficial ulcer no more than

PLATE XXXII

CANCER OF THE TONGUE. VERY EARLY CONDITIONS

(From drawings kindly lent by the Late Sir HENRY T. BUTLIN, F.R.C.S.)

from 'The Medical Annual.'

Fig. A. Old leukoplakia of many years' duration. Quite recent development of epithelioma, in the form of a very slightly raised smoothed nodule, feeling about as thick as a sixpence. Between it and the middle line is a tiny nodule resembling a pimple.

Fig. B. Area of thin leukoplakia on the right border of the tongue, with a small epithelioma, which had developed in the site of a late received several months previously.

Fig. C. Leukoplakia of many years' duration, with the very earliest condition of epithelioma to the left of the middle line in the form of a very small area of leukoplakia on slightly more raised and a little firmer than the rest. The diagnosis depended as much on the slight hardening as on the appearance.

a sixteenth of an inch in diameter, by a crack or a small lump, without any enlargement of the glands. In all these conditions, however, the ulcer is already hard, and very resistant to any form of treatment. Any ulcer of the tongue occurring in a middle-aged man, and lasting for more than two or three weeks, should awaken suspicion.

Diagnosis from Syphilitic Ulcer.—This may be a very real difficulty, owing to the fact that the two conditions may exist side by side, and that the syphilitic leucoplakia or leucomic wart may be the actual precursor of a cancer. A positive Wassermann's reaction, therefore, is not proof that an epithelioma is not present. If a well-formed gumma is present, anti-syphilitic remedies soon make a great change in its appearance, and a diagnosis may be made in this way, but not more than ten or fourteen days should be allowed to pass in uncertainty. There are many cases in which the cleverest surgeon is in doubt, and seeing the rapid course this disease runs, and the vital importance of securing an early diagnosis, it is urged here with the greatest possible insistence that the only certain method, and the one to be employed early, is that of taking out a piece of the ulcer, or, if small, the whole ulcer, and submitting it to histological examination.

Diagnosis from Dental Ulcer. The ulcer in this case is caused by a bad tooth, and therefore is in a position on the tongue corresponding to the latter. Further, the ulcer is soft to the touch, and heals rapidly when the offending tooth is stopped or extracted. There is seldom difficulty in differentiation except when the ulcer is of very long standing.

Syphilitic Ulcer.—This may be primary, secondary, or tertiary. *Primary Syphilis* or *Chancere* is certainly rare on the tongue and, owing partly to its rarity and partly to the fact that it is unexpected, it is frequently missed. It is more common in men than in women, but it may occur even in children. It starts as a small pimple, which ulcerates and becomes indurated, though the induration is not so marked as when it is situated on the glans penis. The appearance of a secondary rash with general enlargement of the lymphatic glands would indicate the diagnosis with certainty, which might be confirmed by Wassermann's serum reaction, and the detection of spirochætae (*Plate XXVIII, Fig. J, p. 614*) in serum from the sore. Furthermore, the sore heals rapidly under the influence of mercury.

Secondary Syphilis manifests itself by the formation of mucous patches and superficial ulcers. The latter are almost always multiple, and situated along the edges and tip of the tongue, and with them are also found similar sores on the mucous membrane of the cheek, lips, palate, and tonsil, and at the edges of the mouth. The ulcers are small, round, painful, with sharply cut edges and a greyish floor. Other secondary symptoms will be present to make the diagnosis clear.

Tertiary Syphilis or *Gummatous Ulcerations*. These are divided into superficial and deep. *Superficial* gummata begin as small round-celled infiltrations in the mucous and submucous tissue. The ulcers are usually shallow, often irregular and associated with chronic glossitis, fissures, and leucoplakia. They are extremely important, for, as stated above, such a condition is often followed by an epithelioma. They are also very resistant to anti-syphilitic remedies other than salvarsan. The ulcers themselves are not at first indurated, but if surrounded by interstitial fibrosis may appear hard; therefore a histological examination is eminently desirable if there is the least doubt. A *deep* gumma starts as a hard swelling in the substance of the tongue; later it softens, breaks down, and shows itself, generally in the middle line, as a deep cavity with irregular, soft, undermined walls, and a wash-leather-like slough at its base. It is not painful, and does not increase progressively in size. The important thing is to distinguish it from epithelioma and tuberculous disease. Unlike epithelioma, it is not hard, and its history is short. Furthermore, it yields very rapidly to potassium iodide or salvarsan.

Dental Ulcer is due to repeated small injuries from the sharp edge of a decayed tooth. It is therefore situated in such a position, generally on the side of the tongue, that it is opposite the tooth. The ulcer is single, small, superficial, and not indurated unless it is of long standing. It is therefore not easily mistaken for any other kind of ulcer, or if doubt arises it is allayed by the healing of the ulcer on stopping or extracting the tooth.

There is a form of dental ulcer which is found on the frenum of the tongue in children suffering from whooping-cough; during the violent expiratory spasms peculiar to the illness, the under surface of the tongue may suffer from rubbing over the lower incisor teeth.

Tuberculous Ulcer of the Tongue is rare, but it occurs at that period of life during which tuberculous disease of the lung is common, that is to say, between the ages of fifteen and thirty-five. It is due to infection with tubercle bacilli brought up into the mouth, and if a patient is found to be suffering from tuberculous disease of the lungs or larynx and also from an ulceration of the tongue, there is a strong probability that the latter is of the same nature as the former. The ulcer itself may be situated on the tip or side of the tongue; it has an irregular outline, and the base is nodular, sloughy, or caseous. It has often been mistaken for epithelioma or gumma. The fact that it is not hard, and that phthisis is present, should put one on one's guard. As against gumma, a Wassermann's reaction would be negative; moreover, the ulcers are often small and multiple, more nearly resembling dyspeptic ulcers. A von Pirquet's test or a diagnostic injection of Koch's old tuberculin might be employed, but a more reliable method is the removal and microscopical examination of a piece of the ulcer, when the histological appearances of tubercle will be seen. The tubercle bacillus (*Plate XXI, Fig. K*, p. 614) is not always found.

Dyspeptic Ulcer, as the name implies, is connected with disorders of digestion. The ulceration is often multiple, each ulcer being round, small, often covered with a greyish slough, and with a bright ring of inflammation round it. They are situated on the dorsum and edges of the tongue near the tip. The mouth, too, is very foul, there may be similar ulcers on the inner aspects of the lips and cheeks, and the cervical glands may be enlarged.

Ulcers in connection with Stomatitis (Ulcerative Stomatitis).—Septic infection of the mouth due to a variety of causes, such as irritation from decayed teeth, alkalies, acids, or mercury, may be accompanied by the formation of small vesicles which, on bursting, give rise to superficial ulcers. They are not limited to the tongue, but appear on the mucous membrane of the cheeks and gums as well. Aphthous stomatitis commonly occurs in conjunction with the febrile diseases of childhood. It is characterized by the formation of whitish spots on the buccal mucous membrane, and by the shedding of epithelium small superficial ulcers may be formed. The ulcers of the tongue are here, so to speak, accidental, occurring in the course of a general inflammation of the mouth, and will hardly be confounded with any other form of ulcer except so-called dyspeptic ulcers, and there is no real line of demarcation between the latter and the stomatitic variety.

UNCONSCIOUSNESS.—(See COMA, p. 117.)

UNEQUAL PULSES.—(See PULSES, UNEQUAL, p. 550.)

UNEQUAL PUPILS.—(See PUPIL ABNORMALITIES OF THE, p. 551.)

URATE DEPOSIT IN THE URINE. A precipitate of urates is often recognizable at once by its pink colour, due to their carrying down with them the uroerythrin pigment of the urine. Urates themselves are white, however, and if, as is sometimes the case, there is no uroerythrin present for them to carry down, they form a white precipitate which may be mistaken for mucus, phosphates, or pus. They may be distinguished at once, however, by warming the urine back to body temperature: they re-dissolve long before boiling-point is reached. They are also soluble in liquor potassæ, unlike phosphates. Microscopically they are nearly always amorphous, though in rare cases they assume the form of small spheres with irregular projecting spicules—the so-called 'thorn-apple' or 'hedgchog' crystals.

Their only significance from a clinical point of view is that they indicate a concentrated urine. It does not follow that a urine is not concentrated if no precipitate of urates occurs, but the fact that the urates re-dissolve on warming serves to show that, although there may be enough water to keep them in solution at body temperature, the urine becomes supersaturated with them as it cools, and precipitates them out. The reason for the urinary concentration has to be learned from collateral evidence. It may be that there has been much sweating, and in hot weather a precipitation of pink urates is a very common physiological condition, which is apt to alarm some patients when they first notice it. On the other hand, the concentration may be due to pathological conditions, of which the commonest are fevers, chronic valvular disease with heart failure, and maladies which lead to loss of fluid by vomiting, sweating, or diarrhœa. The urates themselves afford hardly any clue to the cause of the concentration, and their appearance is just the same whether their deposition is due to physiological or pathological changes.

The most marked examples of uratic deposits are to be seen in cases of acute rheumatic fever, lobar pneumonia, and chronic heart disease with failing compensation. It is a general rule, moreover, that when the kidneys are themselves affected there is decidedly less tendency for uratic deposits to form than when the primary disease is in the heart or lungs: thus when one may be in doubt as to whether a given case of chronic heart failure is due to primary renal disease or primary heart disease, an abundant urate deposit affords some evidence in favour of the latter and against the former. It is no absolute rule, however, and almost any concentrated urine may precipitate urates.

Students are a little apt to confuse the significance of urates with that of uric acid, though the two are entirely independent from a clinical standpoint. *Herbert French.*

URETHRA, DISCHARGE FROM. (See DISCHARGE, URETHRAL, p. 181.)

URETHRA, FÆCES PASSED THROUGH. (See FÆCES PASSED PER URETHRAM, p. 238.)

URIC ACID DEPOSIT IN THE URINE.—The most typical form taken by a precipitate of uric acid in a urine is the cayenne-pepper deposit, seldom voluminous, of characteristic light-brown, prismatic crystals (*Fig. 302*), arranged either as separate 'whetstones,' or in overlapping bundles, or 'rosettes'; occasionally, crystallization is imperfect, and they appear as 'dumb-bells.' Intrinsically, they are colourless; but they differ from all other urinary deposits in that they carry down with them the ordinary yellowish-brown urochrome pigment of the urine. For clinical purposes the best test for them is the microscope.

Fig. 302. Uric acid crystals of various types.

Besides the cayenne-pepper deposit, uric acid crystals may be present in considerable numbers in the midst of other precipitates, such as mucus, or oxalate of lime; in which case they may not be discernible without the use of the microscope; or, again, they may become aggregated together into small pellets or calculi, which the patient may be conscious of as 'gravel' on micturition.

A deposit of uric acid is generally found in a decidedly acid urine of high specific gravity; but it may occur in urines of almost any reaction or specific gravity. A great deal more importance than it deserves has been attached to the supposed relationship between this uric acid and gout. *A cayenne-pepper deposit by no means indicates gout;* indeed, it may be perfectly physiological, occurring abundantly sometimes in healthy young persons, particularly boys. It does not even follow from its occurrence that there is excess of uric acid, either in the urine or in the tissues: for the precipitation depends nearly as much upon the relative proportions of phosphates, chlorides, and inorganic sulphates to uric acid, and upon the absolute and relative amounts of sodium, potassium, and other bases in the urine, as upon the absolute amount of uric acid. The greater the tendency of the bases to form phosphates, by mass action or otherwise (see PHOSPHATURIA, p. 523), the less the tendency for the soluble quadrinates, and the greater the liability for

less soluble biurates, to be produced, the relatively insoluble uric acid being liberated from the latter and deposited in crystalline form.

Considerable care has to be exercised, therefore, before any useful clinical deductions can be drawn from the fact that a urine contains a deposit of uric acid. It is true that a persistent tendency to it is often associated with gout; but the latter should be diagnosed from the collateral evidence rather than upon the uric acid crystals in the urine. Many gouty subjects precipitate no uric acid in their urine at all. Naturally, there will be a greater tendency to such deposition when the total amount of uric acid present is greater than normal. Uric acid in the urine is derived from two sources—exogenous and endogenous. The exogenous are such foodstuffs as are rich in nucleo-proteid, and in the so-called xanthin bases, or purin, or alloxuric bodies, xanthin, guanin, hypoxanthin, adenin, heteroxanthin, paraxanthin, episarkin, epiguanin, methylxanthin, and eurnin, which are mainly derived from nuclein. Analyses of the various foodstuffs as to purin bases need not be given here, for it is easy to remember that, broadly speaking, these substances are contained in largest quantities in the richest food. A considerable proportion of the xanthin bases are excreted as uric acid, and it is common knowledge that rich foods tend to increase uric acid in the urine. Endogenous uric acid, on the other hand, is derived from the patient's own tissue metabolism. Birds excrete nearly all their nitrogenous waste as uric acid; man excretes his mainly as urea, and only to a minor extent as uric acid. Sometimes, however, too much of his nitrogenous metabolism stops short at the stage of uric acid, instead of the latter being nearly all converted into urea; he then excretes an abnormal total quantity of uric acid, with the result that it may be precipitated in crystalline form. One repeats, that this does not necessarily constitute gout, however; it occurs in certain healthy subjects, in leukaemia, in pernicious anaemia, during the course of certain fevers, and in some cases of chronic heart disease. Perhaps one of the best ways of avoiding too narrow a conception in regard to this uric acid is to remember that in some respects the human body is a fire; fires may burn their coal well or badly; if well, the residue is but a little ash; if badly, the residue is not ash, but clinker; uric acid is the clinker of the human body, and many different things that make human nitrogenous metabolism incomplete may cause a deposition of this clinker in the urine. Gout is one such thing; but excessive eating, deficiency of exercise, biliousness, and various chronic imperfections of the circulation, or digestion, may do so; and the same may occur in apparently healthy subjects who have never had any untoward symptoms at all. Oxalate of lime (see OXALURIA, p. 123) is possibly derived in part from similar imperfect combustion of carbohydrates or fats, and it is noteworthy how often crystals of uric acid and of oxalate of lime occur, either together, or alternating with one another. Still further, error of metabolism may produce glycosuria in association with uric acid crystals, so-called gouty glycosuria.

Besides being evidence of overloading, or of imperfect combustion in a general sense, the occurrence of a uric-acid deposit may be of particular clinical importance in certain cases of *frequency of micturition*; of *urethritis*; and of *renal calculus*. Necessity to micturate frequently, only small quantities of urine being passed at a time, is a symptom that in young people suggests cystitis, possibly tuberculous; enlargement of the prostate in men over sixty; or some uterine or other pelvic malady in women. It is important to remember, however, that undue acidity of the urine, with a tendency to deposit crystals of uric acid, or oxalate of lime, may produce the same symptom in considerable degree. It is sometimes spoken of as irritability of the bladder; the highly acid urine irritates the vesical mucosa, and it may produce actual cystitis. The same irritation may inflame the urethral mucosa, and produce a 'gouty' urethritis; and, perhaps, epididymo-orchitis, which may be mistaken for the gonococcal form, unless pus films can be shown to contain no gonococci.

If the patient has suffered from renal colic, haematuria, or vesical pain, suggestive of calculus in the kidney, ureter, or bladder, the discovery of abundant uric acid crystals in the urine affords confirmation of the diagnosis of a uric-acid stone, particularly if they are obviously aggregated together into tiny calculi; there are generally red corpuscles, excess of leucocytes, and tailed epithelial cells from the renal pelvis, or pyriform cells from the deeper layers of the bladder mucosa, at the same time.

The danger of diagnosing glycosuria in the absence of sugar when uric acid is abundant

in a urine needs special mention. Uric acid has considerable power of reducing Fehling's solution. It seldom gives the copious brick-red or orange-yellow precipitate that is characteristic of abundance of sugar, but it may give just enough reduction or change of colour to make it doubtful whether sugar is present or not. More than a few proposers for life insurance have suffered unfairly on this account; no such partial reduction should be regarded as due to sugar until the presence of glucose has been confirmed by other means, particularly the phenylhydrazine and the fermentation tests.

Herbert French.

URINE, ABNORMAL COLORATION OF. This may be due to: (1) The presence in abnormally large quantities of certain urinary pigments, such as uroerythrin or hæmatoporphyrin; (2) The presence of pigments formed in the organism, but which are not normally excreted in the urine, such as hæmoglobin and the pigments of the bile; (3) The presence of pigmentary substances derived from drugs or foods, or administered directly by the mouth.

Urines of unusual tints may be classified conveniently according to the colours which they exhibit, as follows: (I) *Yellow and orange urines*; (II) *Pink and red urines*; (III) *Brown and black urines, including such as are of normal tint when passed, but darken on exposure to air*; (IV) *Green and blue urines.*

Yellow and Orange-coloured Urines.—The normal yellow tint is wholly due to urochrome, for other urinary pigments are present in traces so minute that their presence has no obvious effect. However much it be diluted, normal urine remains yellow as long as any tint is visible. In some cases of diabetes insipidus the urine is almost colourless, and the abundant urine of diabetes mellitus usually exhibits a peculiar pale bright greenish-yellow tint (*Plate XXXII*, Fig. 11, p. 748), which has not yet been explained.

Urobilin, when present in large amount, imparts a rich orange-yellow colour; and when seen in very thin layers, as near the apex of a conical glass, urines rich in urobilin have a pinkish tint, due to selective absorption in the middle of the spectrum. Such urines, when examined with the spectroscope, show a dark absorption band near the solar F line (*Fig. 36*, p. 80).

Urobiliuria—the excretion of excess of urobilin—may result from widely different causes, and as a consequence, its clinical significance is not so clear as might be expected. The symptom is met with in connection with hæmolytic diseases, such as *perniciosa anemia*, in *diseases of the liver*, such as *cirrhosis*, and in cases in which *excessive bacterial action* is going on in the intestine. The bulk, if not the whole, of the urobilin of urine is derived from the intestine, where it is formed by the action of the bacteria present upon bilirubin. It is present in abundance in normal faeces, and in traces in normal urine. The test for it is given on page 324.

Uroerythrin—the highly unstable pigment to which the colour of pink urate sediments is due—when abundantly present in solution in the urine imparts to it a rich orange-red colour, which may even be mistaken for that due to blood. The colour is changed to a pale greenish-yellow by addition of an alkali. Hepatic derangements of almost all kinds, including the most trifling functional disturbances, may lead to the appearance of uroerythrin in the urine; but the most intensely pink urate sediments are seen in cases in which the liver is the seat of pronounced morbid changes, such as *cirrhosis*, or the passive congestion due to cardiac disease.

Choluria. Urine which contains bilirubin has a rich orange colour with a greenish tint at the edge of the meniscus. The foam formed by shaking it has a yellow colour, whereas that of bile-free urine, even when deeply pigmented, is colourless. The colour of the urine may be much modified by the presence of biliverdin, in addition to bilirubin, and may approach to black or dark green.

The presence of bile pigment may be demonstrated by *Gmelin's test*. This is best carried out by allowing the urine to flow gently on to the surface of some nitric acid in a test tube; on gently shaking, the familiar play of colours is seen at the junction of the liquids, and the urinary layer often retains the green tint of biliverdin for a considerable time. Again, a green ring is observed when diluted tincture of iodine is allowed to flow on to the surface of the urine in a test tube (*Plate XXXI*, p. 750).

When the quantity of bile pigment present is very small, the above tests may fail to reveal its presence, and *Huppert's test* may then be resorted to. A precipitate is formed by

the addition, to a much larger volume of urine, of a solution of barium chloride and baryta water, or of calcium chloride and lime-water. The precipitate, which carries down any bile pigment which may be present, is filtered off and washed into a test tube with alcohol. Dilute sulphuric acid is then added, and the test tube is heated in a beaker of boiling water. If bile pigment be present, the acidulated alcohol acquires a rich green tint, due to biliverdin.

Choluria is merely a symptom of jaundice, but the appearance of bile pigment in the urine may precede any yellow coloration of the conjunctive or skin, or, as in cases of acholuric family jaundice (*Plate XIII*, p. 332), the skin may be tinted although the urine is free from bile pigment. In the very rare cases in which a fistula exists between the biliary and urinary tracts, choluria of pronounced degree has been observed, apart from any jaundice.

Certain *drugs* impart to urine a tint which, although yellow, is abnormal. This is seen when *santonin* is administered, or *chrysophanic acid*, which is a constituent of rhubarb and senna. In either case, the urine turns pink on addition of an alkali, but the pink colour is far more brilliant after santonin than after chrysophanic acid has been taken.

Pink and Red Urines.—The conditions which lead to the excretion of a pink or red urine may be classified as follows: (1) *Hæmaturia*, in cases in which the blood pigment appears in the urine mainly as oxyhæmoglobin; (2) *Hæmoglobinuria*—usually in cases which do not belong to the paroxysmal class; (3) *Hæmatoporphyrinuria*; (4) Administration of rosaniline as a drug; (5) Eating of sweetmeats coloured with eosin; (6) Presence of chrysophanic acid in an alkaline urine.

Hæmaturia and *hæmoglobinuria*. For the significance of these symptoms, and the detection of blood pigment in urine, the special articles dealing with them may be referred to (p. 275 and p. 284).

Hæmatoporphyrinuria is a condition in which urine is passed which has a pink, port-wine, or nearly black colour, and which contains considerable quantities of the hæmoglobin derivative, hæmatoporphyrin. In the darker specimens the colour is mainly due to other little-known pigments which accompany the hæmatoporphyrin. For the recognition of the condition spectroscopic examination is necessary. It is most liable to be mistaken for hæmoglobinuria, but when the urine contains no albumin the distinction is not difficult; when albumin is present in a pink urine, the diagnosis is more difficult, because the spectrum of hæmatoporphyrin in the combination in which it usually occurs in such cases resembles that of oxyhæmoglobin somewhat closely. However, the addition of hydrochloric acid changes the spectrum to that of acid hæmatoporphyrin instead of to that of acid hæmatin (*Fig. 34*, p. 80).

If a mixture of 10 per cent calcium chloride solution and lime-water be added to the urine, the precipitate formed carries down all the abnormal pigments, and the filtrate is yellow. From the precipitate the hæmatoporphyrin may be extracted with acidified alcohol, and its highly characteristic spectra may be observed and identified. The trace of hæmatoporphyrin present in normal urine escapes detection by such means, but the increased quantities present in a variety of morbid conditions may be revealed by faint bands, even in cases which do not fall into the class under consideration, and in which the urine shows no obvious anomaly of pigmentation.

In the great majority of cases, hæmatoporphyrinuria results from prolonged administration of *sulphonal* in medicinal doses, and forms one of a group of toxic symptoms of much gravity, which often usher in a fatal ending. These symptoms may only develop after the drug has been taken for months or even years, and even some days after its administration has been stopped. Their development calls for the free administration of sodium bicarbonate. It is a remarkable fact that such toxic effects of *sulphonal* are seldom seen except in women, and the few male cases on record have mostly been of a mild kind.

Much more rarely, hæmatoporphyrinuria, with deep red urine, is met with in cases in which it cannot be ascribed to any drug. Several patients have been sufferers from *hydropertivale*, others from tuberculosis, and others from maladies so different from each other that no definite diagnostic significance can yet be assigned to the symptom. In such cases the hæmatoporphyrinuria does not appear to have the grave import which it has in sulphonal cases, nor is there manifested any special liability of the female sex.

Coloration by constituents of foods and drugs.—*Rosaniline*, which was at one time employed in the treatment of albuminuria, imparts a pink colour to the urine which, provided that it be known that the drug is being taken, offers no diagnostic difficulty. Aniline dyes

have also, ere now, been deliberately added to the urine for the purpose of simulating hæmaturia.

Eosin has been employed extensively for the coloration of pink sweetmeats and lozenges, and the urine of those who eat such sweetmeats in considerable quantities acquires a rich pink colour, and shows a brilliant green fluorescence. The nature of such pigmentation can hardly be mistaken by anyone who is aware of the fact that eosin is so employed.

Drugs which contain *chrysophanic acid* are used so frequently as aperients that this compound may rank as a common constituent of urine; and if, from any cause, the urine be alkaline, it acquires a pink or red colour, which may easily be misinterpreted. However, the history of the taking of rhubarb or senna, and the fact that the addition of an acid changes the colour of the urine to a bright yellow, renders the diagnosis easy. The pink colour which alkalis impart to the urine of patients taking santonin is so fugitive that it does not call for consideration here.

Brown and Black Urines.—The urine may be brown or black in the following conditions: (1) Jaundice; (2) Hæmaturia; (3) Hæmoglobinuria; (4) Hæmatoporphyrinuria; (5) Indicanuria; (6) Melanuria; (7) Alkaptonuria; (8) Carboluria; and after the administration of certain other drugs, such as salol, salicylates, resorcin, gallic acid, and *uva ursi*.

In some of the above conditions the urine has such coloration when passed; but in others, such as melanuria and alkaptonuria, the urine is usually of normal tint when freshly passed, and only darkens on standing in contact with the air.

Brown and black *jaundiced urine* is met with chiefly in cases of long-standing icterus, in which the skin has acquired a dull greenish tint, and the urine contains biliverdin as well as bilirubin.

In some of the early recorded cases of black urine, the colour was certainly due to *blood pigment*, and the smoky colour of many urines which contain blood pigment in the form of methæmoglobin is familiar to all. In *paroxysmal hæmoglobinuria* also, the urine is not infrequently almost black. The ordinary tests for hæmoglobin, together with microscopic and spectroscopic examination, serve to reveal the nature of such cases (*Figs. 30 et seq., p. 80*).

That the urine of *hæmatoporphyrinuria* may approach to actual blackness, owing to the abundant presence of purple pigments which have no characteristic spectra, has already been mentioned in the account of that symptom above.

Indicanuria. Urines which contain much indican may show no abnormality of tint; but occasionally, and especially in extreme cases, there are present in the urine, in association with the colourless indoxyl sulphate, other and higher oxidation products of indol, which impart to it a brown colour, intensified or developed on exposure to air. This variety of brown or black urine is recognized less than it should be, and it is probable that the condition has been mistaken not infrequently for melanuria. Such urine is not blackened, as that of melanuria is, by the addition of ferric chloride, nor by nitric acid in the cold, but does blacken when heated with nitric acid. The ordinary tests for indican reveal its presence in large amount. Thus, if a specimen of the urine be heated with an equal volume of hydrochloric acid, and a drop of a dilute solution of bleaching powder, or a drop of nitric acid, it becomes black. If, after cooling, the dark-coloured liquid be shaken with chloroform, the latter takes up indigo-blue or red and acquires a deep purple colour; but the supernatant liquid remains black. If the chloroform extract be separated and evaporated to dryness, the indigo-red may be dissolved out of the residue with alcohol, whereas the indigo-blue, which is insoluble in alcohol, may be taken up afterwards with chloroform.

Indicanuria signifies abnormal amount of protein decomposition in the alimentary canal, brought about by intestinal bacteria; but it is stated that it may also have its origin in collections of putrid pus, such as putrid empyemata. In such a case recently under the writer's care, the abundant indican disappeared from the urine when a dose of calomel was given, and was probably of intestinal origin.

Melanuria. This is a symptom which is met with in some cases of *melanotic sarcoma*. The urine, when freshly passed, contains a colourless chromogen, melanogen, and usually has a normal tint. On exposure to air, it darkens quickly, owing to oxidation of the melanogen to melanin, becomes brown, and eventually quite black. When nitric acid is added to such a urine, it causes prompt blackening, even in the cold, and immediate blackening also follows the addition of a solution of ferric chloride. This is the most valuable and charac-

teristic of the tests for melanuria. Bromine water produces a yellow or brown precipitate which quickly blackens.

As a rule, melanuric urines, when treated with liquor potassæ and sodium nitroprusside, yield a deep Prussian blue on acidification with acetic acid, but this reaction is not due to the melanogen as such, is yielded by some other urines, and cannot be taken as diagnostic of melanuria.

It is stated frequently that melanuria may be met with apart from melanotic growths, in cases of wasting and other diseases. There is little doubt that some of the cases quoted in support of this contention, and which were recorded before the more distinctive tests for the condition were known, were, in reality, examples of indicanuria, such as have been described above, and the writer has never met with true melanuria save in cases of melanotic sarcoma. Even in such cases it is not seen so long as the tumour is confined to its primary seat, but only when it has invaded the viscera, and especially the liver. Indeed, the quantity of melanogen excreted is apparently dependent upon the extent to which the liver has been invaded, and the amount of pigmentation in the growths of which it is the seat. Hence it happens usually that the diagnosis of the case has already been established before the peculiar pigmentation of the urine is developed.

Alkaptonuria is the outward sign of a very rare anomaly of metabolism which is almost always congenital, and persists through life without any serious detriment to the health of its subjects. The peculiar properties of the urine are due to the excretion in it of an aromatic acid, homogentisic or hydroquinoneacetic acid, a product of katabolism of tyrosin and phenylalanin. It is, in all probability, a product of normal metabolism, which in normal individuals undergoes complete destruction.

Alkapton urine seldom exhibits any abnormality of tint when passed; but darkens quickly on exposure to air, undergoing changes through brown to black, which resemble in the closest manner those seen in melanuric urines. However, the two conditions are distinguished readily by means of simple tests. When a dilute solution of ferric chloride is added to alkapton urine, a deep blue colour appears for a moment, and reappears after each subsequent addition of the reagent, until oxidation of the homogentisic acid is completed. Unless the reagent be very dilute, oxidation occurs too rapidly, and the blue colour is missed.

The addition of an alkali causes very rapid darkening, with absorption of oxygen, and heat increases the rate of blackening.

As homogentisic acid is a powerful reducing agent, alkapton urines give some of the reactions of glycosuria. Fehling's solution is reduced freely with the aid of heat, but the blackening effect of the alkaline reagent gives a peculiar appearance to the reaction. No black precipitate is obtained with Nylander's reagent, but the alkali therein causes conspicuous darkening. The safranin reaction is not obtained, and alkapton urine is optically inactive. An ammoniacal solution of silver nitrate is reduced rapidly even in the cold, a reaction which is made use of for the quantitative estimation of homogentisic acid. It is because alkaptonuria is so rare, rather than because its recognition presents any special difficulty, that its properties are not widely known and not infrequently fail of recognition.

Ochronosis, i.e., a blackening of the cartilages, and deep pigmentation of regions of the skin, a bluish-black coloration of the ears, and pigment spots on the conjunctivæ (*Plate XXXIII*), is sometimes the outcome of alkaptonuria; but there is a group of cases in which similar pigmentation results from the application of carbolic acid to chronic ulcers over long periods of years. There is also some reason to believe that the lesions of joints which sometimes accompany ochronosis may also be results of alkaptonuria.

Carboloria.—A darkening of the urine, increased by exposure to air, is seen frequently after the administration of certain drugs which contain phenol, in carbolic acid poisoning, and as the result of outward application of carbolic acid. A carbolic acid compress applied to the head of a child for the destruction of pediculi quickly induces carboloria, and the taking of salol is another common cause. The urine has a smoky tint, or in cases of carbolic acid poisoning may be actually black. In the slighter cases it is best described as brown with a greenish tinge, and the meniscus, when seen from the side, appears black.

There is no direct chemical test for carboloria, and the diagnosis is usually based upon the knowledge that phenol, or some derivative or compound thereof, has been administered or applied. After boiling the urine for some time with Fehling's solution, a slight reduction

PLATE XXXIII

OCHRONOSIS

The face is coloured dark brown (C), and bears a striking resemblance to a case of Addison's disease; the ears have a bluish appearance, and hands (A) show a similar discoloration. Note the small bluish patch which was present on each cornea (B).

is observed; but this is in no way comparable with that seen with alkapton urine. Indirect evidence is obtained by the addition of a solution of barium chloride, which in cases of carbo-huria produces a very slight precipitate or none at all. If, however, the urine be first boiled with hydrochloric acid, a precipitate is obtained such as is yielded by normal urines. This is due to the fact that, in the presence of abundant phenol and oxidation derivatives thereof, the sulphates of the urine are for the most part, or even wholly, combined as aromatic sulphates, which yield no precipitate with barium salts, whereas, when the aromatic sulphates are broken up by hydrochloric acid, a precipitate of barium sulphate is thrown down.

The diagnosis of the other varieties of brown or black urine which have their origin in the administration of drugs, is based upon the fact that salicylates, or other drugs capable of producing such pigmentation, have been taken.

Green and Blue Urines.—In some cases of jaundice, the bile pigment excreted is so largely in the form of biliverdin that the urine has a dark green colour; but with this exception, practically all green urines met with in practice owe their colour to the taking of methylene blue, either as a drug or in sweetmeats. When the dose is small, the tint may be a rich green; but after larger doses, the urine is frankly blue. It is not always easy to account for the origin of such coloration of urine, for the patient may be quite unaware that he has taken methylene blue in any form, although examination of his urine may leave no doubt that he has done so. Sweetmeats are sometimes coloured with this pigment, as they are with eosin, and it is sometimes used to correct the colour of white sweetmeats. Again, a pill of methylene blue has before now found its way, either by accident or design, into a supply of pills of another kind. Absence of a known cause does not, therefore, by any means exclude this kind of pigmentation; and experience shows that unless it can be shown, by careful examination, that the colour of the urine is not due to methylene blue, it is needless to search for any other causation.

Although the green urine which follows the taking of methylene blue may appear perfectly limpid, the blue pigment is not held in solution but in suspension, and is, to a large extent, removed even by a single filtration. The green colour of the filtrate is greatly reduced, and the filter paper shows a blue stain. The pigment upon the filter yields a blue solution in chloroform, and if the chloroform solution, or the blue extract obtained by shaking the urine with chloroform, be shaken with liquor potassæ in a test tube, the chloroform is decolorized, and the supernatant alkaline liquid acquires a pink tint. The original urine, or the chloroform extract, shows an absorption band in the red of the spectrum which may be mistaken for that of indigo-blue.

There is no reason to think that indigo-blue ever produces a green or blue coloration of urine similar to that due to methylene blue. By the spontaneous breaking down of indoxyl-glycuronic acid, usually in alkaline urines, indigo-blue may be set free, and may form a dark blue sediment, or may impart a blue colour to the phosphatic film upon the surface; and when, in the earlier years of the last century, indigo-blue was employed somewhat frequently as a drug in the treatment of epilepsy, a dark purple colour of the urine of patients so treated was observed, but under no circumstances are indigo pigments formed spontaneously in quantities sufficient to bring about such a result. *A. E. Garrod.*

VEINS, VARICOSE ABDOMINAL.—The point at which distention of veins becomes varicosity is arbitrary: most conditions that produce undoubted varicosity of the veins of the abdominal wall in some cases, merely dilate them in others. When this dilatation is considerable (*Fig. 393*), it nearly always has much diagnostic significance, particularly if the direction of blood-flow is reversed. Veins, however, may seem to be dilated when they are but unduly visible owing to wasting of the subcutaneous fat: or they may, in very rare cases, be simply varicose, like veins in the leg, owing to idiosyncrasy or hereditary predisposition. In neither of these cases, however, is the blood-current in them reversed.

PLATE XXXII

URINE TESTS

1. Urine, normal. 2. Urine, normal. 3. Urine, normal. 4. Urine, normal. 5. Urine, normal. 6. Urine, normal. 7. Urine, normal. 8. Urine, normal. 9. Urine, normal. 10. Urine, normal. 11. Urine, normal. 12. Urine, normal.

To test the direction of blood-flow, part of a vein should be chosen where there are no side branches, and the blood should be expressed from it by means of two fingers pressed down on the vein close together, and then drawn asunder, whilst pressure over the vein is maintained by each: when a length of the distended vein has been emptied in this way, one of the two fingers is taken off, and the time taken by the vein in refilling is noted; the procedure is repeated, the other finger being taken off this time: it is then generally easy to decide whether the vein fills from below upwards or from above downwards. Normally, the blood flows from above downwards in the veins of the lower two-thirds of the abdominal wall: when the blood-flow is from below upwards there is almost certainly obstruction to the inferior vena cava, the blood which is unable to return by it finding a collateral circulation via the superior vena cava.

Obstruction to the inferior vena cava is due to one or other of three main groups of conditions, namely:—

1. **Great general increase in the intra-abdominal tension**, owing to such conditions as: ascites: ovarian cyst: great splenic or hepatic enlargement.

2. **Thrombosis** without external obstruction.

3. **Obstruction by local compression**, especially by secondary growths in the retroperitoneal glands.

When the obstruction of the inferior vena cava is due, not to the vein itself being thrombosed or invaded by new growth, but to the *general intra-abdominal pressure* becoming so great that the vein is, so to speak, flattened out, the varicosity of the veins upon the abdominal wall is but a late symptom, and the diagnosis will be made from the cause of the great abdominal distention, generally ASCITES (p. 63), or a big tumour. If there is marked varicosity of the superficial veins early in a case of ascites the probability is that both are due to malignant disease.

When the inferior vena cava is obstructed by 'simple' thrombosis, the probability is that the clotting will not have started there, but will have extended to it from branches either in the legs or in the pelvis. (Edema of the legs will be a prominent symptom: and if a clear history is obtainable it may generally be ascertained that one leg became oedematous and painful before the other: when this is so it is always very suggestive of thrombosis starting in the saphenous or femoral veins, the other leg becoming affected later when the clot has spread up through the iliac veins of the one side to the inferior vena, and thence down the iliac veins of the other side. The higher the thrombus extends the higher up the back will the oedema spread: and when the renal veins have been reached, albuminuria, with tube casts, and even haematuria, may ensue. Ascites may also be present. Distention or varicosity of the veins of the abdominal wall will be of assistance in distinguishing such a case from one of acute or subacute nephritis, besides which there will be no oedema of the eyelids or face.

If there is no very tense distention of the abdomen: if the way the case began does not suggest thrombosis in one leg, or in the pelvis, extending upwards: and if, nevertheless,

Fig. 903. —Varicose thoracic and abdominal veins in a case of syphilitic mesenteritis of some years' duration.

there is marked varicosity of the veins of the lower part of the abdominal wall, with the blood-flow in them reversed, so as to be from below upwards, the history being a relatively short one,—the probability is that the inferior vena cava is being obstructed by something that is in immediate contact with it. There will very likely be symmetrical œdema of the legs, and possibly albuminuria and hæmaturia. It is surprising how seldom an aortic aneurysm, or other non-malignant mass, obstructs a large vein sufficiently to produce this collateral varicosity; hence, the presumption is that such varicosity indicates *malignant disease*. It is worthy of note that carcinoma of the kidney is prone to extend into the renal veins, and thus into the inferior vena cava by a process of direct extension (*Fig. 304*)—sometimes the malignant clot reaches as far as the right auricle, and produces a pedunculated polypus in the latter. In such cases there has generally been hæmaturia or other renal symptom before evidence of inferior vena-caval obstruction arose, whereby cases of growth in the kidney invading the inferior vena cava may be distinguished from cases of secondary growth in the retroperitoneal glands, which if they produced hæmaturia at all,

would do so by first obstructing the inferior vena cava, and thence involving the renal veins. In such cases there are often other symptoms pointing to primary growth in some organ whose lymphatics drain into the retroperitoneal glands; the testes and ovaries should not be overlooked in this respect.

It is often said that *cirrhosis of the liver* leads to varicosity of the veins around the umbilicus—the so-called *caput medusæ*. It is a very rare condition indeed, the great majority of cases of cirrhosis of the liver causing no distention of the superficial abdominal veins until such time as the general intra-abdominal tension has been greatly increased by the tenseness of the ascites which occurs late. Not even the telangiectases that occur so commonly in men past middle age around the lower part of the chest, in a line with the attachments of the

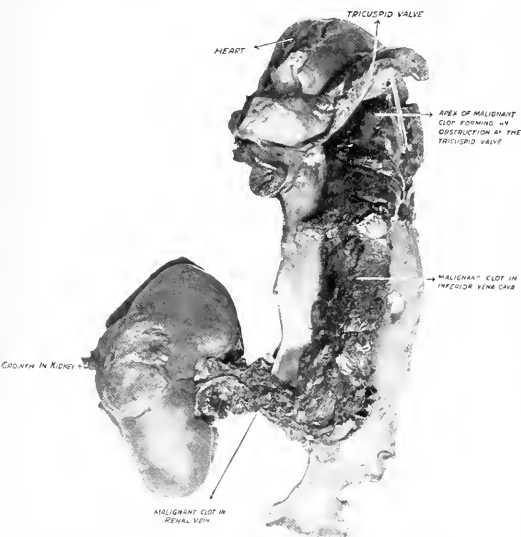

Fig. 304.—Renal growth extending into the inferior vena cava and right auricle and ventricle.

diaphragm, indicate cirrhosis; they are quite as common in cases of emphysema without cirrhosis.

In short, varicosity of the superficial abdominal veins generally indicates either thrombosis of the inferior vena cava, secondary to direct spread of thrombosis up to it from veins in the pelvis or in the leg, or else stenosis of the vena cava by secondary malignant disease.

Herbert French.

VEINS, VARICOSE THORACIC.—Much of what has been said above about varicose abdominal veins applies also to those of the thorax. The veins on the chest wall may merely be unduly visible; but if they are really distended, there is probably obstruction to one or other innominate vein or else to the superior vena cava; and the suspicion that this is so becomes a certainty if the blood current in the distended veins can be shown to be from above downwards instead of from below upwards. If the distention is bilateral, and

PLATE XXVI

URINE TESTS

GUNSBERG'S TEST

3

1. The same test for bile pigment in urine. 2. Gmelin's test for bile pigment in urine.
3. Gunsberg's test for free HCl in 250 cc. urine.

associated with œdema of both arms, and both sides of the neck, face and head, it is the vena cava that is obstructed; if the distention is unilateral, with œdema of the corresponding arm, but little if any of the neck or face, the obstructed vessel is probably one innominate vein. The superficial varicosity may be only slight (*Fig.* 99, p. 208), but sometimes it is extreme.

In arriving at a diagnosis of the cause of the venous obstruction, *malignant disease* within the thorax will be uppermost in one's mind—especially mediastinal sarcoma, starting in the thymus or in the lymphatic glands. It is only when the history and course are too long for primary or secondary malignant neoplasm that other causes of venous obstruction will be regarded as more likely, such as *thrombosis* extending to an innominate vein or to the superior vena cava from a whitlow, boil, or other inflammatory affection of the hand, arm, axilla, head, face, neck, shoulder, or front of chest; or *chronic fibrous mediastinitis*, sometimes tuberculous or gummatous; (*Fig.* 303, p. 749) but often rheumatic in origin, and resulting from repeated attacks of pericarditis and pleurisy, with matting together, not only of the pleuræ to the diaphragm and pericardium, but also of all the structures in the superior, posterior, and anterior mediastina to one another; or, far less commonly, to *aneurysm* of the thoracic aorta or a *non-malignant mediastinal tumour*, such as a hydatid cyst (*Fig.* 137, p. 291), a dermoid cyst, or a large congenital fibroma, which may have been quiescent within the chest for many years before starting to enlarge and obstruct structures in its neighbourhood; the latter conditions, except aneurysm, are rarities, and although an aortic aneurysm does sometimes obstruct the superior vena cava sufficiently to cause distention or varicosity of the veins upon the chest wall, such varicosity is so much more marked in a case of intrathoracic malignant disease that one may say that when the diagnosis lies between neoplasm and aneurysm the presence of marked distention of the veins of the chest-wall indicates the former rather than the latter, though the converse of this is not true.

Herbert French.

VERTIGO, popularly known as dizziness or giddiness, depends upon a disturbance of the sense of equilibrium. In slight cases the trouble is perceptible to the sufferer either as the apparent movement of motionless objects (objective vertigo), or his own body may appear to be moving in relation to surrounding fixed structures (subjective vertigo). In more severe cases it may lead to reeling or staggering, and unless the patient can grasp some fixed support he may fall.

The equilibrium of the body is maintained by the co-ordinated action of various groups of muscles, and the nervous mechanism for this co-ordination is situated in the cerebellum. Afferent impulses are brought to the cerebellar centres from the muscles, skin, joints, eyes, and the semicircular canals. The cerebellum is also connected with the motor centres of the cerebral hemisphere, and thus the requisite contraction of the necessary muscles is ensured. Disturbances of equilibrium may therefore be the result of a lesion in the cerebellum itself or in one of the afferent tracts. True vertigo depends mainly upon interference with the afferent impulses from the semicircular canals or from the eyes, and it is often accompanied by nystagmus during attacks.

Occasionally vertigo may be the result of altered cutaneous impulses due to such causes as anesthesia of the soles of the feet. Some people experience a slight feeling of giddiness on stepping on to some soft material such as turf or india-rubber pavement after walking on a hard road. Unusual cutaneous impulses are the probable explanation.

Interference with the afferent impulses from the muscles themselves, such as occurs in *tabes dorsalis*, leads to reeling and staggering rather than to true vertigo. The ocular impressions correct the false sensations from the muscles, and hence loss of equilibrium is more likely to occur in the dark, or when these impressions are cut off by covering the patient's eyes.

Vertigo is sometimes divided into 'general' vertigo and 'special' vertigo. In the latter, objects appear to move, or the patient tends to fall in a definite direction. Special vertigo points to a lesion of a particular semicircular canal. Thus, if there is a lesion of the external semicircular canal, objects appear to move in a horizontal plane, and the patient tends to fall towards the affected side. When the superior canal is the source of the trouble, objects rotate in a vertical plane, and the patient falls forward. Temporary vertigo, even of a very severe nature, may be produced readily in a healthy individual by

prolonged movements of rotation or of swinging. In this case the cause of the giddiness is probably unequal pressure in the endolymph in the different semicircular canals. The dizziness with which many people are affected when near the edge of a high cliff is most likely ocular in origin, and depends upon the sudden cessation of visual impulses from near objects. Some persons are exceedingly susceptible to alterations in these impressions, and travelling by train or the movement of a boat may be sufficient to cause considerable dizziness.

Vertigo may also be of *toxic origin*. Alcohol and tobacco are familiar examples; the dizziness associated with ptomaine poisoning, and in some cases of gastric disturbance, is also probably of this nature.

Vertigo is not infrequently of cerebral origin, either with or without some gross lesion. Thus it occurs in *migraine*, and is also a frequent *aura of an epileptic fit*. Vertigo may depend upon alterations in the blood-pressure, and this is the probable explanation of its occurrence in *arteriosclerosis* and *nephritis*, where the blood-pressure is increased. It may also occur in cases where the blood-pressure is diminished, as in *Addison's disease*, some *anæmic states*, and during *convalescence* from any prolonged illness. This may be due to defective nutrition of the central nuclei. Attacks of vertigo occurring in elderly people with atheromatous arteries or suffering from *chronic nephritis* or *arteriosclerosis* must always be regarded as of serious import, since they may be the precursor of cerebral hæmorrhage or thrombosis. Severe vertigo may be one of the symptoms of a *cerebral tumour*. It is more likely to be present when the growth is in the cerebellum, especially if the middle lobe is involved. A tumour involving the auditory nerve in its intracranial course will also give rise to this symptom. A *cerebral* or *cerebellar abscess* may also cause vertigo, but in this case there may also be suppuration in the middle ear, and the giddiness may be of labyrinthine origin. Optic neuritis should be looked for in every case of vertigo.

Vertigo may be of *ocular origin*. It is especially likely to occur when there is some lesion of the nerves or muscles leading to diplopia.

Laryngeal vertigo is a very rare condition; spasm of the glottis is accompanied by severe giddiness which causes the patient to fall down, and he may lose consciousness for a few seconds. Complete recovery ensues in a short time, but the attacks are likely to recur. This trouble may be of an epileptic nature.

Vertigo is, however, most commonly of aural origin, and is a frequent symptom of diseases of the ear, especially of the internal ear or labyrinth. In its most intense form it is one of the symptoms of '*Ménière's disease*.' Its onset is then sudden, and so severe that the patient falls to the ground and even loses consciousness. Associated with the giddiness are severe tinnitus, and unilateral or bilateral deafness, while nausea, vomiting, and pallor of the face are frequently present. The vertigo passes off after a few hours or days, but impairment of hearing and tinnitus persist. The attacks tend to recur. Ménière's disease is probably caused by a sudden increase in pressure in the endolymph, and, in some cases at any rate, appears to be due to hæmorrhage into the semicircular canals. In some cases an embolism may be the cause. True Ménière's disease is very rare; but the occurrence of the symptoms, *viz.*, vertigo, deafness, and tinnitus, in a less acute and sudden form, is by no means uncommon. They may be present without any obvious lesion of the middle or external ear, though sometimes there is some abnormality in one of these portions of the auditory apparatus. Vertigo may be traumatic in origin, *e.g.*, after a fracture of the base of the skull.

Syphilitic disease of the internal ear may produce symptoms closely resembling those of Ménière's disease, in that giddiness, tinnitus, and labyrinthine deafness are associated, the onset being quite sudden. Vertigo is, however, occasionally absent. The trouble is usually unilateral, and may occur in the secondary or tertiary stages. The diagnosis will depend on the history of syphilis or other evidences of the disease. Similar symptoms may occur in congenital syphilis, usually between the ages of ten and fifteen years, though occasionally much later. Eustachian-tube obstruction is usually present also, but treatment of this fails to improve the hearing, and other characteristic troubles, especially interstitial keratitis, may be found. Aural vertigo may also be associated with some lesion of the external or middle ear. Thus in the former case there may be a *foreign body*, or even a plug of *impacted cerumen*, as the exciting cause.

Vertigo is not infrequently present in chronic middle-ear suppuration. This may be

due to labyrinthine inflammation or irritation, but a definite labyrinthine lesion is not necessarily present. In many cases the giddiness is caused by pressure on the stapes or the fenestra rotunda. Some patients with a perforation of the tympanic membrane become giddy whenever the ear is syringed. Occasionally the use of unduly hot or cold lotions produces this trouble. It is usually the result of pressure on the stapes, though occasionally the vertigo may have the special character associated with a lesion of the external semicircular canal (*vide supra*). When this is the case there is probably some erosion of the bony external canal. Similar giddiness may occur from a like cause on syringing the ear after a radical mastoid operation.

Vertigo may occur in *otosclerosis*, though it is not common in this disease, and is always of less importance than the DEAFNESS (p. 163) and TINNITUS (p. 722). Gout and gouty dyspepsia, with or without evidence of arteriosclerosis, may also be the cause of attacks of vertigo.

When a patient complains of vertigo, the ears should always be examined carefully. The hearing should be tested, and if the cause of the trouble is in the labyrinth, the deafness will have the characters of nerve deafness (p. 166). The onset of the trouble must be investigated carefully, and any associated symptoms ascertained. The eyes and ocular muscles must be examined, and if nystagmus is present the character of the movements should be observed. A general examination of the patient should also be made for some general constitutional cause such as gout, albuminuria, or arteriosclerosis. *Philip Turner.*

VESICLES.—One of the primary lesions, the vesicle may be defined as a circumscribed epidermal elevation varying in size from a pin's head to a small pea, and containing serous fluid, which may become sero-purulent or be mixed with blood. Serous elevations larger than a small pea are classified as BULLÆ (p. 96). To bullæ, therefore, vesicles bear the same relation as papules bear to tubercles. They differ from bullæ, however, not only in size, but in their mode of formation. They are always the result of an inflammatory process, whereas in the case of bullæ there is a veritable cleavage of the epidermis. Vesicles, again, often contain a number of chambers, at any rate in the beginning, whereas bullæ are from the outset unilocular. They may originate as vesicles, or may develop from papules. Vesiculation may be either parenchymatous or interstitial. In the one case, as in varicella, the plasma accumulates *within* the Malpighian cells, and the unicellular vesicles which are thus formed run into each other. In the other case, as in eczema, the plasma accumulates *between* the Malpighian cells.

In shape, vesicles are usually rounded, conical, or acuminate; but they may tend to the oblong form, as in scabies, or they may be both oblong and irregular, as in dermatitis herpetiformis. The larger ones are occasionally umbilicated, as in variola, and instead of being tense, as is usual with vesicles, may be flaccid, as in herpes and dermatitis herpetiformis. At first the liquid they contain consists almost invariably of pure plasma, and is quite clear, or with the faintest tinge of yellow; but exceptionally the fluid is from the beginning mixed with blood. After a time the clear fluid becomes turbid. In some conditions, as in varicella and miliaria, they remain discrete and few in number; but usually, as in herpes, eczema, and dermatitis herpetiformis, there is a plentiful crop of them, forming groups or closely-set clusters. As a rule, they are of short duration; either they rupture and crust over, as in eczema, or they dry up and a crust is formed, as is usual in herpes; or they enlarge into blebs, as frequently occurs in dermatitis herpetiformis; or they are transformed into pustules, as in variola. On mucous membranes and the lips, and in folds of the skin, they break more quickly than in other situations, and leave excoriations. Since, as already stated, vesicles are the result of a more or less inflammatory process, they usually give rise to much burning and itching, though in some conditions, as in hydrocystoma, these symptoms are absent.

The most distinctively vesicular affections are herpes simplex and herpes zoster. In *simplex herpes* the face and the genital organs are affected chiefly. The characteristic lesion is a cluster of transparent vesicles varying in number from two or three to twenty or more, seated on an erythematous patch, and surrounded by a narrow red zone. First, a slightly red spot appears on the skin; effusion quickly takes place under the epidermis, and vesicles are formed; these become opaque—sometimes purulent—shrivel up, and form yellowish-brown crusts, which after a few days become detached, usually leaving no

scar, but a brownish stain that slowly fades and disappears. These four stages in the evolution of the lesion are styled the congestive, vesicating, desiccating, and macular stages. On mucous membranes the lesion runs a rather different course. Here the vesicles are quickly reduced to a whitish pulp, which presents the appearance of a false membrane. When this becomes detached, it reveals a number of roundish excoriations, either scattered about irregularly or running into each other and forming largish ulcers. The favourite situations of the vesicles in herpes genitalis are, in men, the prepuce, especially its inner surface, the meatus, the sulcus, and the glans; in women, the labia and the cervix. In men, the vesicles are usually discrete, and the patient complains only of the itching and burning; but if they are neglected, or irritated by the application of caustics, there may be severe and extensive ulceration, with swelling of the inguinal glands. In women, the vesicles tend to become confluent, and the perineum, the inside of the thighs, and the mons veneris may be invaded. There may be a great deal of swelling, excoriation, and discharge, with intense itching and burning, and, as in men, there may be enlargement of the neighbouring glands. The vesicles of genital herpes are too characteristic to be mistaken if they are seen before their real significance is obscured by ulceration. If, however, the ulceration is considerable, and especially if there is much suppuration, the herpes may be mistaken for *chancre* or *chancroids*. Generally, however, soft sores are multiple, have a fouler base, excavate more deeply, and the healing process is much slower. Soft sores, further, are flattened at the base, secrete very little liquid, and are auto-inoculable. In some cases there may be doubt as between herpes genitalis and true *chancre*, especially as, according to Fournier, a chancre not infrequently develops in the midst of a premonitory eruption of herpes. The points of differentiation are the absence, in herpes, of induration, the less considerable and more transitory gland-enlargement, the multiplicity, irregular form, and small size of the ulcers, and the intense burning and itching.

In the crusted stage, facial herpes may resemble *impetigo*, but the rapid course it runs, its limited distribution, the facts that it is not auto-inoculable, and that in *impetigo* the lips are seldom attacked, should suffice to obviate the confusion. The points which distinguish herpes facialis from vesicular eczema are touched upon below.

In *herpes zoster* (zona, shingles), clusters of vesicles seated on an erythematous base appear in the region of skin distribution of one or more of the posterior spinal nerve roots, preceded or accompanied by neuralgic pain and tenderness in the part. The erythematous patches, more or less oval, with the long axis parallel to the underlying nerve, come out in crops, the number of lesions varying from two or three to twenty or thirty. Soon the surface of the patches is studded with papules, which are quickly transformed into vesicles, from ten to twenty on each patch, sometimes discrete, sometimes running into each other to form bullae. An important diagnostic feature of the eruption is, that in the great majority of cases it is unilateral, and appears much more frequently on the right side than on the left. In rare cases, however, it forms a complete girdle round the body. The usual limitation to one side of the body, the distribution in one or more nervous territories, and the preceding or accompanying neuralgia, usually suffice to distinguish herpes zoster from erythema multiforme and from dermatitis herpetiformis. Another important point in diagnosis is the history, for zoster is not a recurring disease. These various characters serve to distinguish it also from herpes simplex and herpes genitalis. The neuralgic pain may be mistaken at first for pleurisy, but the course the affection runs soon clears up the confusion. I should add that in herpes zoster the forehead, the conjunctiva, and the eyeball are frequently attacked, and sometimes the mouth, especially the tongue. In rare cases the lesions on the tongue are not associated with an eruption on the lips or the palate.

Although the vesicular stage is not, as some authorities consider, a necessary phase in the evolution of *eczema*, the vesicle is undoubtedly the most constant of all the primary lesions met with in that condition. Usually, following sensations of itching and burning, an erythematous blush appears, which is soon studded with numerous tiny vesicles. These grow larger and often coalesce, but they soon rupture or are broken by scratching, and a clear fluid exudes, the 'weeping' continuing as later vesicles break. In mild cases, the inflammation subsides gradually, and as the discharge ceases, scales or crusts are formed; but much more frequently fresh crops of vesicles start up around the edge of the earlier patches, while new centres are formed in other parts, until nearly the whole cutaneous

surface may be involved. In some cases papules are the predominant feature, in others erythematous lesions; in yet others pustules, and in extensive cases, the several kinds of lesions may be all present simultaneously. From herpes in general, eczema is distinguished by the characteristic exudation, by the crowds of tiny vesicles, which coalesce without forming distinct groups, by the slower evolution of the disease, and by the fact that as a rule there is some inflammatory thickening. From herpes zoster it is differentiated by the peculiar distribution of the vesicles in that affection (see above).

Acute vesicular dermatitis is precisely similar to acute eczema in its actual lesions, but differs from it in that a definite irritant cause exists and it does not recur, as does eczema, spontaneously, but only if the external cause is re-applied. The effects of certain plants, notably *primula obconica* and *rhus toxicodendron*, are familiar in this respect; so also is the vesicular eruption produced in some individuals by sugar (grocer's dermatitis), by the use of certain soaps (soap dermatitis), by the sawdust of satin-wood, by the use of lime in making mortar, by the hairs of certain caterpillars, and by various applications and lotions (application dermatitis), including tincture of arnica montana, mesotan, essence of vanilla; and of course all the well-known vesicating drugs such as cantharides, croton oil, capsicum, mineral acids, caustic alkalies, strong iodine and turpentine, and so on. The diagnosis is afforded by a knowledge of exposure to any of these, and in obscure cases is sometimes suggested by the fact that exposed parts only are affected, or that the patient is ill only when living in certain places or doing certain work.

Doubt can seldom arise as between eczema and *dermatitis herpetiformis*. It is true that the earliest and perhaps the most characteristic lesion of the latter disease is a vesicular eruption, appearing on an erythematous base; but the disposition of the vesicles in herpetiform groups should prevent confusion between the two conditions. The vesicles soon dry up and form scabs, but later they tend to coalesce into bullae, which scarcely ever burst spontaneously but, as their contents thicken, slowly shrink, and finally, if left to themselves, shrivel up to a thick brown scab. The 'weeping' of eczema is therefore absent in dermatitis herpetiformis, of which, further, multiformity is a more pronounced feature—erythematous, vesicular, pustular, papular, and urticarial elements being mingled in all stages of evolution. Eosinophilia is more pronounced with dermatitis herpetiformis than it is with eczema (p. 99).

The vesicles of *impetigo contagiosa* are distinguishable from those of eczema by the larger size and discrete character of the former, and by their tendency to dry and form yellowish crusts without breaking, or as soon as they have broken. Even when the lesions run together and large crusts are formed, there will be discrete vesicles and papules which will point to the true nature of the affection.

Miliaria rubra may sometimes resemble the vesicular stage of eczema, but here again the lesions, though numerous, remain discrete; they do not run together to form patches, they do not rupture, and there is no 'weeping.' Miliaria of all forms is a very transitory affection, and instead of the intense itching of eczema, the patient describes his sensations as those rather of pricking and tingling. In the form of miliaria known as hydrocystoma, or dysidrosis of the face, small vesicles like those of miliaria appear on the face, but they are so grouped as to form patches, which show no tendency to spontaneous involution.

Scabies is another affection in which the vesicles, like those of impetigo and of miliaria, are discrete. Sometimes the lesions, usually consisting of papules and pustules as well as of vesicles, take on an eczematous character, but they are not localized as are those of eczema, and instead of being small, acuminated, or circular, they tend to be linear. In uncleanly persons, the burrows between the fingers and elsewhere which mark off scabies from all other affections, can hardly be overlooked. When they cannot be found, either because they have not yet been formed or because they have been laid open by scratching, the diagnosis of scabies must rest upon the irregularity of the lesions—vesicles, bullae, and pustules being mingled with the marks of the finger-nails and the results of secondary inoculations—and upon the distribution, the parts most affected being those where the skin is least thick, namely, the webs between the fingers and toes, the front of the wrist, inside the umbilicus, on the lower abdomen, the genitalia, the nipples in women, and the axillary folds. The face nearly always escapes, except in infants in arms.

Another vesicular condition in which the hands are specially attacked is *cheiropom-*

pholyx, in which numerous minute vesicles deeply imbedded in the skin, and showing through the epidermis like boiled sago-grains, are distributed symmetrically on the extremities—always on the palms and fingers, and frequently also on the soles and toes. The general features of the affection—the limitation of the vesicles to the hands and feet and their proneness to unite and form bullæ which dry up, the tendency to recovery followed by repeated recurrence, and the constant association of the eruption with the summer season—are sufficiently distinctive, and the diagnosis is seldom in doubt. In some slight cases there is a general resemblance to certain subacute and limited cases of eczema in which the lesions may present the sago-grain aspect; but instead of rupturing and ‘weeping,’ the vesicles in cheiropompholyx tend to run together into bullæ, which shrink and crust over. This formation of bullæ by coalescence of vesicles differentiates the condition also from pemphigus.

In *erythema multiforme* the vesicle can seldom be difficult of interpretation, even in *erythema iris*, or as it is also styled, *erythema vesiculiformis*. In one form of this affection a small red spot appears, upon which is formed a vesicle that is quickly surrounded by a zone of redness. When the central vesicle dries up it leaves a small scab, and a ring of secondary vesicles soon appears on the red zone. On the separation of the central scab, the skin beneath has a blue, congested appearance. The whole process may be repeated time after time until the concentric rings of vesicles and reddened skin suggest comparison with a target. In the form of *erythema iris*, which sometimes is infelicitously called *herpes iris*, a large central bulla is encircled by vesicles of considerable size. Outside the first ring of vesicles another circle may develop, and outside the second, sometimes a third. The symptoms of vesicular *erythema multiforme* are so characteristic that the affection can hardly be mistaken for anything else.

Lichen planus is so characteristically a papular affection that the absence of vesicles is one of the points which distinguish it from eczema. In some cases, however—very rarely in adults, and rather less infrequently in children—vesicles appear, but never so as to confuse the diagnosis. In *lichen urticatus* a vesicle appears on the summit of the small wheal, and the condition may offer some resemblance to eczema; but the individual lesions do not tend to run together nor to spread centrifugally, as in eczema, and the itching is usually more intense.

The vesicular form of *secondary syphilis* is so rare that by some authorities its existence is not recognized, and Stelwagon, who has never met with a case, justly points to the possibility of its being due, at any rate occasionally, to drug idiosyncrasy. The vesicles are reported as occurring in several forms; they may be minute, eczematoid, disseminated and grouped, or larger, irregularly scattered, or disposed in herpetiform groups; and cases have been reported which simulate herpes zoster. The vesicles in syphilis are usually associated with papules, and they have a papular base, the disappearance of which leaves a long-persisting dark stain. The papular base and the slow evolution are important diagnostic points; and usually other signs of syphilis will be present.

In *lymphangioma circumscriptum*, even more than in vesicular syphilis, the significance of the vesicles can hardly be missed. In circumscribed areas of the skin there is an eruption of clusters of small, deep-seated, thick-walled vesicles, straw-coloured, sometimes marked with red striae, and filled with a clear alkaline fluid which contains a few lymph-corpuscles. The affection, which consists in the over-growth and dilatation of lymph-vessels and the formation of new ones, is probably congenital, though not generally noticed until early childhood.

Varicella—to come to the eruptive fevers—is an essentially vesicular affection; only occasionally do the vesicles develop into pustules. They are usually preceded by reddish spots of slight elevation, and the commonest situations are the face, chest, shoulders, back, and scalp, but they may also be found on the mucous membrane of the palate, mouth, or lips. As a rule the rash comes out within twenty-four hours. Often there is but trifling systemic disturbance. In the infrequent cases in which the varicellar eruption becomes pustular, it may possibly be confused with a pustular syphilide; but in the syphilide the lesions are pustular from the outset, or develop out of papules, and although the lesions of varicella start as papules, these are almost invariably small and evanescent. The absence of itching in syphilis is another point of difference. In exceptional cases of strophulus the vesicle on the summit may develop until it becomes

visible macroscopically, and it may then be confused with varicella; but the cases are so rare as to be negligible.

It is with *small-pox* that chicken-pox is most often confused. In small-pox the vesicles are usually multilocular; in chicken-pox they are usually unilocular. In small-pox they are frequently umbilicated; in chicken-pox they are never umbilicated, and seldom even dimpled. The differences between the two exanthems in respect of the rash and the lesions generally, as summarized by Ricketts in "The Diagnosis of Small-pox," are these: In variola, the rash is most abundant on the face and limbs, and least abundant on the abdomen and chest (Fig. 305); in varicella, the abdomen and chest are covered as thickly as the face, if not more thickly. In variola, the rash is much more abundant on the back than on the abdomen; in varicella, the abdomen and the back receive equal attention. In variola, the rash is more abundant on the shoulders than across the loins, and on the chest than on the abdomen; in varicella, the distribution as between these parts is indifferent. In variola, the rash favours the limbs and is distributed centrifugally; in varicella it tends to avoid the limbs, and when it invades them is centripetal. In variola the rash, unlike that in varicella, favours prominences and surfaces exposed to irritation, and tends to avoid protected surfaces and depressions. As to the lesions generally, in variola they are deep-seated and have an infiltrated base; are generally circular in outline and homogeneous in character; whereas in varicella they are superficial and have no infiltrated base, are frequently irregular in outline, or else oval or elongated, and are not, as a rule, homogeneous.

Vaccinal eruptions may consist (1) of tiny vesicles or small superficial papules, or of a combination of those elements; or (2) of a small papule with a vesicular or pustular head. In the second case the eruption may simulate modified small-pox, but almost always the vaccinal lesions are more superficial than those of the mildest cases of small-pox, and show a preference for the trunk.

In eruptions due to the use of *bromides, iodides*, and other drugs, the vesicle is but one of the elements, and the nature of the affection is usually indicated with sufficient distinctness by the history of the case, the remission that occurs when the drug is withheld, and the recurrence that takes place when its administration is resumed. Vesicles that follow the bites or stings of *gnats, mosquitoes*, etc., are always easily recognizable from the history, and from the central punctum to be seen in the lesions; nor can there be any doubt as to the significance of those due to such accidental causes as *frostbite* and pressure from *splints*.

Malcolm Morris.

FIG. 305.—small-pox. Showing distribution of the eruption, particularly on the face and limbs rather than on the neck and trunk.

VISION, DEFECTS OF.—This subject may be considered in the following order:—(I) *Normal vision*, (II) *Amblyopia*, (III) *Partial blindness*, (IV) *Complete blindness*, (V) *Colour blindness*, (VI) *Abnormal sensations of size*, (VII) *Day- and Night-blindness*.

NORMAL VISION.

1. **Visual Acuity.**—The act of vision comprises the perception of form, colour, and brightness; and, in vision with two eyes, the perception of space and distance. These faculties are possessed by all parts of the retina, though in varying degrees, and they are of

varying importance. It is necessary to distinguish between peripheral and central vision ; or, in other words, between merely seeing a thing and looking at it. An object is seen by any portion of the retina that has visual perception ; but an object is only looked at when its image falls upon a particular portion of the retina, the yellow spot, which is situated at the posterior pole of the globe on the outer side of the optic disc. The act of so directing the eye that the image of a given object shall fall upon the yellow spot, is termed 'fixation.' The vision obtained by the fixation of the eye is termed 'central vision,' and owing to the anatomical structure of the retina at the yellow spot, the vision here is the most acute of which the eye is capable, though its area is very limited. In the normal eye, central vision is capable of distinguishing two points or parallel lines, which are separated by a space which subtends an angle of 1'—approximately the diameter of a sixpenny-piece at 200 feet—and it is on this basis that ordinary test-types are constructed. Central vision, however, though acute, is very limited in extent, and it is estimated that the field of acute vision is only about the size of the thumb-nail held at arm's length, all vision outside this area being comparatively blurred and indistinct. This limitation of the field of acute central vision is barely appreciated under ordinary circumstances, owing to the rapidity with which the retina receives consecutive visual impressions, and the constant movements of the eyes. Compared with the visual acuity of the central portion of the field of vision, peripheral vision is relatively poor, though it is of extreme value in a different way. To appreciate the importance of peripheral vision it is only necessary to try to walk about looking through a roll of music ; though central vision is unimpaired, and the smallest object can be seen distinctly, locomotion is almost impossible, owing to the inability to see where one is going or to ascertain one's position in relation to surrounding objects, the peripheral portion of the field of vision being responsible for the automatic appreciation of these. On the other hand, a person from some cause deprived of central vision can see to get about quite well, and has useful vision for many purposes, though he is unable to read or write, recognize people when looking directly at them, or do any work in which fine vision is required.

2. Colour Vision.—A person with normal colour vision can recognize six or seven distinct colours in the solar spectrum, and is able to appreciate many hundreds of varieties of colour caused by mixtures of them, and the colour perception of the normal person is most acute in the central portion of the field ; but the field of vision for colours under equal illumination has by no means the same boundaries as the field of vision for white. The fields of vision for all colours are smaller than that for white, and the fields for red, green, and blue vary in extent among themselves. The field for blue is the largest, for red is next in point of size, and the field of vision for green is the smallest of all, being roughly only about half to a third the diameter of the field for white.

3. Brightness Perception.—The central and peripheral portions of the field of vision vary very much in their perception of brightness. In ordinary illumination the central portion of the field is the most efficient, but in a very weak illumination the peripheral portion has a higher efficiency than the central part ; in other words, there is in very dim lights a relative central scotoma or loss of vision. This fact has long been known to astronomers, who have found that in counting stars of low magnitudes, vision is much better if the particular constellation or group of stars is not looked at directly, the Pleiades being a well-known example ; more of these stars can be counted when the vision is directed to a point a little above or below them or to one side, whereas direct vision is comparatively dim and confused ; and the same holds good of vision for any object in a dim light. Walking along a country road on a dark night, it will be found that a foot-path or track can be seen more easily if the gaze is directed forwards and not at the ground itself. These facts concerning vision may be correlated with the actual anatomical structure of the retina itself. It is found that in the region of the yellow spot—the area of the retina endowed with acute vision—the cones are very numerous, with few rods ; towards the periphery of the retina the cones become fewer and the rods more numerous. It is now generally held that the function of the cones is to work in light of considerable brilliance, that they are capable of extremely acute vision for small objects, and are also concerned in the perception of colour. The rods, on the other hand, have no perception of colour ; their perception of form is poor compared with that of the cones ; but in very weak lights their visual acuity is greater than that of the cones. In support of this theory may be mentioned the fact that the retinae of nocturnal animals are more fully provided with rods than cones.

AMBLYOPIA.

Amblyopia is the term applied to defective vision in which there is little or no evidence of any ocular condition which might account for the visual defect. It is not, therefore, employed where there is any obvious intra-ocular or intracranial lesion. The commoner forms of amblyopia are (1) Amblyopia ex anopsia; (2) Uræmic; (3) With nystagmus; (4) Due to alcohol, tobacco, lead, quinine, organic forms of arsenic such as atoxyl; (5) Migraine; (6) Cortical or crossed amblyopia; (7) With hysteria.

Amblyopia ex Anopsia is usually associated with a squinting eye, which may or may not have been put straight by operation. It is still open to discussion whether the amblyopia in such conditions is due to the loss of use by reason of the squint, or whether the squint is due to the visual defect; but the fact remains, that in many squinting eyes the visual acuity is very much below normal, though objectively the eye exhibits no abnormal symptoms.

Uræmic Amblyopia, or Amaurosis, may be recognized by its association with renal disease, whether complicated by pregnancy or not. It is characterized by its comparatively sudden onset, vision failing either partially or completely within a few hours. The failure of vision may be accompanied by well-marked retinitis in both eyes; but in many cases this is absent and the discs appear quite normal. The failure of vision lasts for from thirty-six to forty-eight hours, and then slowly disappears, the whole attack lasting, as a rule, under a week. In the majority of cases, unless there is some definite injury to the optic nerve or retina as the result of retinitis, the vision recovers entirely. In some cases of uræmia the blindness is complete.

Amblyopia with Nystagmus is usually associated with evidence of visual affections in very early life. At birth, fixation is not developed, and the higher visual acuity is only acquired after the first few months of infant life. Any affection of the eyes, therefore, that obscures the vision during the earlier weeks or months of life, prevents the due development of central vision and leads to a permanent amblyopia, as a rule associated with nystagmus. Such affections are ophthalmia neonatorum, which leaves more or less corneal opacity; perforation of the cornea with anterior polar cataract as the result of this ophthalmia; congenital defects, such as a persistent hyaloid artery or macular coloboma; and any retinitis or choroiditis affecting the region of the yellow spot.

The **Amblyopia due to Lead, Alcohol, Tobacco, Quinine, or Atoxyl,** is usually described as a toxic amblyopia, and the symptoms are somewhat similar in all the varieties. In tobacco amblyopia there is a central loss of vision for colours, green only in the earlier stages, subsequently green and red, and in extreme cases even a central scotoma for white; total blindness is practically unknown. The patient also states that he sees better in a dull than in a bright light, and that he is incapable of reading or writing, or distinguishing silver from gold coins. The ocular signs are usually very slight, being limited to some redness and blurring of the optic disc in early cases, or pallor of the outer side of the disc in later stages. Alcoholic amblyopia resembles in most of its symptoms the amblyopia due to tobacco, though vision for red is usually lost before vision for green. Amblyopia due to lead or atoxyl is rare, but it is also usually characterized by a central scotoma associated with some slight optic neuritis or atrophy. In quinine amblyopia the retinal vessels are extremely constricted, the disc is pale, and the field of vision is diminished peripherally.

The **Amblyopia of Migraine** is usually transitory, and may occur either in the form of a central scotoma, hemianopia, or monocular blindness. It is more rarely seen in the form of a quadrant hemianopia or a ring scotoma. In all cases the diagnosis is comparatively easy, as the amblyopia seldom lasts more than a few minutes, and is followed later by the characteristic headache and sickness of migraine.

Amblyopia has also been described as due to **disease of the Visual Cortex**, and rare cases have been described of a **Crossed Amblyopia** or defect of vision in one eye due to disease of the visual cortex of the other. The loss of vision is, however, usually associated with some slight defect of vision in the opposite eye, and hemianopia is much more commonly the symptom of disease of the visual cortex.

Hysterical Amblyopia may, like other hysterical affections, take various forms, such as loss of visual acuity, a loss of colour vision, or diminution in the visual field. The characteristic form of the visual field in hysteria is either a spiral contraction or an extreme concentric limitation. The symptoms, however, vary very much at different examinations, a point of much importance in diagnosis. In certain cases there may be a functional loss of

vision in one or both eyes, which can be recognized as hysterical by the employment of Snellen's coloured types or some other device for deceiving the patient.

PARTIAL BLINDNESS.

This may be (1) *Definite*, or (2) *Indefinite*.

1. **Definite**: (a) *Hemianopia*; (b) *Central scotoma*; (c) *Peripheral constriction*.

(a). *Hemianopia* (see HEMIANOPSIA, p. 300).

(b). *Central Scotoma*.—A scotoma is a local defect in the visual field, and, from its position, may be either central or peripheral; it may also be negative or positive. A negative scotoma is one where the defect of vision exists, but where the patient notices nothing abnormal. The best example of a negative scotoma is the blind spot in the field of vision caused by the entrance of the optic nerve. This area is blind, but the individual is not conscious of any visual defect. Scotomata of this character exist where there is some injury of the visual layers of the retina itself, or of the optic nerve or tract.

A positive scotoma is one in which the visual defect is noticed as a black or coloured spot or cloud which obscures the vision in some part of the visual field. Such positive scotomata are due to lesions of the retina, such as hemorrhages or patches of pigment which do not destroy the visual layers. Vision still remains; but it is obscured by some unusual opacity in the retina itself or in the adjacent portion of the vitreous.

Scotomata frequently exist in the peripheral portion of the field of vision without being noticed, as they are of little importance in direct vision, and are not discovered unless looked for carefully. A central scotoma, on the other hand, is noticed at once, however minute, because it affects direct vision and produces a considerable defect in the visual acuity. A central scotoma may be either relative or absolute, and may exist for colours only or for objects. Central loss of vision for colours, more particularly red and green, is associated with *tobacco* and *alcohol poisoning*. The colours cannot be recognized in small objects when looked at directly, though a red or green object in the peripheral portion of the field of vision will be recognized as such. This scotoma is associated with greater or less diminution of the general visual acuity, and vision in such cases is generally better in a dull than in a bright light.

Absolute central scotomata are met with in *disseminated sclerosis*, in certain forms of *hereditary optic atrophy*, and may persist after the acute affection of the optic nerve known as *retrobulbar neuritis*, or in rare cases after severe attacks of *migraine*. In nearly 25 per cent of all cases of disseminated sclerosis a central scotoma exists, and the diagnosis in such a case will be confirmed by its association with the general symptoms of the disease and with other ocular symptoms, such as optic atrophy, paralysis of accommodation, paralysis of the extrinsic ocular movements, or nystagnus. There is usually some pallor of the optic disc, though this is no indication as to the amount of visual defect. The diagnosis of a *hereditary optic atrophy* depends to a great extent upon the history of a similar affection among family relations and its usual period of incidence, namely, early adult life. It is associated with either neuritis or atrophy of the optic disc. *Retrobulbar neuritis* usually occurs in young adults, commonly attacks one eye only, and is sudden in its onset, vision failing from normal to no perception of light in a few hours. In the great majority of cases vision commences to return after the lapse of a day or two, and is ultimately restored in a fortnight or three weeks. If any defect remains it is usually central, and is due to some injury to those axial fibres of the optic nerve which supply the macular region. Central scotomata after *migraine* are rare, but may be ascribed to that cause when there is a definite history of sudden loss of sight associated with the characteristic hemiparesis and vomiting. It is to be noted that central scotomata are not always easy to map out on a chart, owing to the patient's loss of power of fixation; a careful use of the perimeter by an experienced observer is necessary. A small central scotoma may cause considerable failure of vision, even though it is too small to chart on the ordinary perimeter. Scotomata may also be *paracentral*, in the immediate neighbourhood of the fixation point, but not actually upon it, or may take an *annular* or *ring form*.

(c). *Peripheral Constriction*.—Peripheral constriction of the visual field occurs commonly in affections such as acute or chronic *glaucoma*, *optic atrophy*, *disseminate choroido-retinitis*, *retinitis pigmentosa*, and *various functional conditions*. The constriction of the visual field in *glaucoma* is usually most marked on the nasal side, and can be recognized

from its association with the acute symptoms of glaucoma, the circumcorneal injection, steamy insensitive cornea, dilated fixed pupil, hazy vitreous, and general symptoms such as trigeminal neuralgia, headache, and sickness. In chronic glaucoma it will also be associated with atrophy and cupping of the optic disc (*Plate XX, Fig. V, p. 418*). Central vision may remain quite good, even though the field of vision is extremely limited. The field of vision is, as a rule, most limited in *retinitis pigmentosa*, where the failure of sight will be found to be associated with night-blindness and characteristic ophthalmoscopic appearances, a small, ill-defined, waxy-looking disc, slender vessels, and diffuse superficial pigmentation of the periphery, the retina in patches resembling Haversian bone corpuscles. This condition often occurs in two or more members of the same family, and may exist where the parents have been first cousins. A limitation of the field similar to that of retinitis pigmentosa is often met with in cases of *disseminate choroido-retinitis* (*Plate XIX, Fig. G, p. 416*) and consequent optic atrophy: but may be distinguished from it by abundant evidence in the eye of deeper changes in the retina and choroid. Constriction of the field of vision may also occur in certain *functional states*, but may, as a rule, be recognized by its variable character and the absence of all evidence of organic ocular or general nervous disease.

2. Indefinite.—A defective visual acuity may exist with no evidence of any ocular or nervous disease (see *AMBLYOPIA, p. 759*). Defective vision may also be due to errors of refraction, to opacities of the cornea, aqueous, lens, or vitreous, to affections of the choroid and retina, and to lesions of the optic nerve. Opacities of the cornea can easily be recognized on illumination of the eye with a strong light concentrated by a lens, and intra-ocular causes of defective vision can be discovered by ophthalmoscopic examination. Detailed differential diagnosis of all the ocular causes of diminished vision requires a special knowledge of ophthalmology.

COMPLETE BLINDNESS.

Total loss of vision, blindness, or amaurosis, may be (1) *Bilateral*, (2) *Unilateral*.

Bilateral Blindness. Total blindness in both eyes may be congenital or acquired. Congenital blindness may be due either to absence of the eyes themselves, *congenital anophthalmos*, or to *congenital defects* in the development of the eyes themselves. Nearly 90 per cent of all cases of total blindness in the United Kingdom are due to *ophthalmia neonatorum*. Such cases can be recognized by the history of profuse inflammation or discharge shortly after birth, by the diffuse opacity on the surface of the cornea associated, in some cases, with thinning and protrusion of the anterior part of the eye, and more or less nystagmus. There is a peculiar congenital malady known as *amaurotic familial idiocy*, in which several members of a family suffer from complete blindness owing to bilateral optic atrophy associated with idiocy due to slow development of the brain. The diagnosis is made from the family history and from the presence of optic atrophy dating from infancy.

Total blindness may also be caused by *bilateral inflammatory affections* of the eyes, such as iritis with blockage of the pupils and consequent glaucoma, or ultimate shrinking of the eyes, bilateral primary glaucoma, optic atrophy, or lesions of the optic chiasma. It is seldom due to lesions of the optic tracts, as this would only be caused by a bilateral lesion totally destroying the optic tract on both sides.

Total blindness of a *transient* nature may also occur in renal disease, and is termed *uræmic amaurosis*. This condition is recognized by its association with the symptoms of renal disease, whether in pregnancy or not, and by its sudden onset and short duration, the whole attack as a rule lasting not more than four or five days. In the majority of cases there is some evidence of renal retinitis, though in others the eyes are normal. The pupils usually react to light, though occasionally the light reflex is absent.

Another form of transient blindness occasionally met with, is apparently due to *spasm of the retinal arteries*. In these cases the loss of vision may last only a few hours, and during its continuance it will be found that the retinal arteries are of a very slender calibre. It is to be noted that no cataract ever causes total blindness. Provided that the rest of the eye is normal, a patient with the densest cataract can always perceive light, and also has the power of projection, or the recognition of the direction from which the ray of light is coming.

Unilateral Blindness. It is evident that unilateral blindness must be due to some lesion in the eye itself, or between the eye and the optic chiasma. Lesions of the optic tract above the chiasma do not cause monocular blindness, but *HEMIANOPSIA* (p. 360). Monocular blindness may be either sudden or gradual.

Gradual blindness may be due to any of the inflammatory affections of the eye mentioned above, or to such progressive diseases as optic atrophy or glaucoma.

Sudden blindness in one eye may be due to one of the following causes:—

Detachment of the retina (*Plate XX, Fig. T, p. 418*)

Embolism of the central artery (*Plate XX, Fig. S*)

Thrombosis of the central vein (*Plate XX, Fig. O*)

Vitreous hemorrhage

Acute glaucoma (*Plate XX, Fig. V*)

Injury to the optic nerve due to an accident or fracture of the base of the skull

Compression of the optic nerve from hemorrhage or dilatation of the nasal sinuses

Retrolbulbar neuritis

Migraine.

The diagnosis of the majority of these causes is simple, owing to the characteristic ocular or ophthalmoscopic appearances. The only cases which present any obscurity are those in which there is sudden loss of vision without any visible ocular changes. These cases are usually due to retrolbulbar neuritis, an acute affection of the optic nerve of obscure origin, characterized by sudden loss of sight, with some pain and tenderness on movement of the eye. The loss of vision as a rule lasts for not more than twenty-four or thirty-six hours, and coincidentally with the return of vision, more or less definite neuritis appears at the optic disc (*Plate XIX, Fig. K, p. 416*). In the majority of cases vision returns entirely, but if there is a permanent defect it usually takes the form of a central scotoma.

Blindness due to compression of the optic nerve by dilatation of the accessory nasal sinuses can only be recognized after a thorough examination of the nasal passages; sinus disease of any duration is always accompanied by certain well-defined appearances in the nose itself.

Monocular blindness may also occur in *migraine*, but in these cases it is of extremely short duration, seldom more than ten minutes or a quarter of an hour, and is followed by the characteristic headache and sickness.

COLOUR BLINDNESS.

Defects in colour vision may be either congenital or acquired. In congenital colour blindness there is inability to recognize in the spectrum the six or seven definitely distinct colours which may be apparent to a normal eye. The commoner cases of colour blindness are those who can only see three colours in varying shades of black and white, or people who can only distinguish two colours, the spectrum being made up of yellow and blue, the one gradually passing into the other. Red, orange, yellow, and green are seen as one colour, blue and violet as the other. Scarlet and grass-green appear very similar to these persons.

Cases of congenital colour blindness can be recognized by examination with coloured wools, as in Halmgren's test, or with much more precision and certainty in a dark room by means of a lantern with properly coloured glasses.

Acquired loss of colour vision may also occur in *tobacco* blindness or in *optic atrophy*.

Colour Defects.

Rainbow Vision.—Objects, especially lights, may be seen surrounded by a ring containing the colours of the spectrum. The causes of this are, as a rule, either *conjunctivitis*—in which there is a thin film of mucus on the surface of the conjunctiva—or *glaucoma*. The diagnosis in the two cases should present no difficulty, because the rainbow vision of glaucoma will be associated with the other important symptoms of this disease, viz., steaminess or lack of brilliancy in the cornea, a shallow anterior chamber, dilatation of the pupil, and some limitation of the field of vision, especially on the nasal side.

Erythropsia, or red vision, occurs after prolonged exposure to white or violet light in conditions such as electric or snow blindness. It is accompanied by much inflammation and redness of the eyes, conjunctival discharge, and intolerance of light. It may also occur in slight vitreous or retinal hemorrhages, though in severe vitreous hemorrhages vision is abolished entirely. Erythropsia, and in some cases blue vision, may occur after cataract extraction, and appears to be due to some fatigue of the retina.

Xanthopsia, or yellow vision, has been said to occur in jaundice or in poisoning by sautoin, amyl nitrite, cannabis indica, or picric acid, but it is hardly ever met with in practice.

ABNORMAL SENSATIONS OF SIZE.

Objects may appear rapidly to increase or diminish in size in the preliminary stages of an attack of epilepsy; and this variation in size of objects is a fairly common symptom in the slight delirium of infantile febrile disorders. *Micropsia*, or abnormal diminution in the size of objects, also occurs to many normal people during the act of reading. The book appears suddenly to recede to a great distance, and it and the type appear extremely minute, though absolutely clear. No satisfactory cause has yet been adduced for this phenomenon. It may be relieved by a momentary rest, and is of no pathological significance. A similar condition may be produced by the use of certain drugs, particularly *cannabis indica* and its products.

DAY-BLINDNESS AND NIGHT-BLINDNESS.

Day-blindness, or *hemeralopia*, is caused most commonly by *tabacco poisoning*, it being probable that this condition is due to a direct poisoning of the retinal cones, which are endowed with the faculty of effective vision in lights of high brilliancy. In *snore-blindness*, also, vision improves directly the light begins to fail, and defective vision in bright light is a common symptom of *albinism*. Except in the case of albinos, the retina may show no abnormal signs.

Night-blindness, or *nyctalopia*, occurs most frequently in *retinitis pigmentosa*, in which on ophthalmoscopic examination, the characteristic appearance of a small ill-defined optic disc, thin thready arteries and veins, and the characteristic spider-like pigment cells may be seen at the periphery of the fundus. It also occurs in cases of *quinine amblyopia*, *xerosis of the conjunctiva*, *disseminate choroido-retinitis*, and in *scurvy*. Patients suffering from *high myopia* may also suffer from defective vision in dim lights. Herbert L. Eason.

VISION, DOUBLE. (See DIPLHIA, p. 171.)

VOICE, ABNORMALITIES OF THE- (See SPEECH, ABNORMALITIES OF, p. 623.)

VOMITING.- Strictly speaking, the term vomiting implies the return and expulsion from the mouth of part or the whole of the stomach contents. There are several conditions in which vomiting may be simulated closely, although the vomited matter has never reached the stomach. It will be convenient to deal with these before discussing the causes and differential diagnosis of true vomiting or gastric regurgitation.

In certain *diseases of the œsophagus*, food may be swallowed and, after a varying interval of time, brought up again. These conditions are:—

Malignant disease	Pressure from without, as by aneurysm,
Fibrous stricture	new growth, etc.
Spasm	'Idiopathic' dilatation
	Diverticula 'pressure' pouches.

If the obstruction be of long standing, and near the lower end of the œsophagus, the interval between taking food and its regurgitation may be prolonged considerably, especially in cases in which the lumen has undergone much dilatation. This may occur with fibrous stricture, slow-growing carcinoma, or the very rare cases known as 'idiopathic' dilatation of the œsophagus.

A 'pressure' pouch produced by a hernia-like protrusion of the mucous membrane through the muscular coats of the upper part of the œsophagus, becomes filled gradually and, in addition to dysphagia caused by the pressure it exerts on the œsophagus below, may simulate vomiting when its contents are voided.

The differential diagnosis of these œsophageal causes of vomiting, or rather regurgitation, is usually easy. The returned matter is practically unaltered, and is undigested. It may be diluted freely with mucus. Blood may be present, and even portions of growth in cases of carcinoma. In œsophageal pouches, food may be retained for long periods and returned unchanged. The most important point to recognize is, that in such œsophageal conditions the returned matter is alkaline or neutral in reaction. The diagnosis is confirmed by examination with a bougie, or by the *x-rays* after administration of bismuth emulsion (*F/g.* 96, p. 196).

Certain individuals may acquire the power of voluntarily regurgitating portions of the stomach contents into the mouth, which may be ejected or again swallowed. There is no accompanying nausea. This condition, known as 'rumination' or 'MERYCISM' (p. 388), must be distinguished from vomiting.

Mention must also be made of conditions in which the mechanism of deglutition is deranged, and in which swallowing is interfered with to such an extent that the food or drink is returned. This may occur in cases of bulbar paralysis, myasthenia gravis, etc. Again, in diphtheritic paralysis the return of fluids through the nose, owing to the paralysis of the soft palate, may be mistaken for vomiting. A similar mistake has been made in cases the writer has met with of bronchiecstasis in which, during the act of coughing, large quantities of pus have gushed up, not only from the mouth but also through the nose.

The regurgitation of milk in healthy breast- or bottle-fed infants after a hearty meal is met with frequently, and is often wrongly regarded as vomiting. It is due to simple overfilling, or sometimes to too rapid feeding; air that has been swallowed is belched up, and drives out some of the milk with it.

A brief account of the *mechanism of vomiting* will facilitate a classification of its causes. The parts concerned are the muscular coats of the stomach; the sphincter at the cardiac orifice; the diaphragm, and the abdominal muscles; the vomiting centre situated in the medulla; the efferent nerve fibres in the vagus supplying the musculature of the stomach, the phrenics the diaphragm, and the spinal nerves the abdominal muscles.

In the act of vomiting, the walls of the stomach contract, the diaphragm is pushed violently downwards in full inspiratory position, while powerful contractions of the abdominal muscles take place. At the same time the cardiac sphincter is relaxed, and the gastric contents are expelled, chiefly as the result of the pressure thus exerted on the stomach by the diaphragm and the abdominal muscles, aided to some extent by reversed peristalsis. The pyloric sphincter is usually closed, but it may become relaxed, in which case bile and intestinal contents may enter the stomach and be found in the vomit. The vomiting centre may be excited to action by stimuli reaching it from the stomach itself, by afferent fibres in the vagus, or from other parts by many different afferent channels. The centre may also be thrown into action by toxic substances acting on it directly.

In *retching*, forcible contraction of the stomach wall, and of the diaphragm and abdominal muscles takes place as in vomiting, but there is no relaxation of the sphincter. In the condition known as *catechraash* or *pyrosis*, in which a quantity of clear fluid is brought up into the mouth, usually on rising in the morning, the complete act of vomiting does not occur; relaxation of the cardiac sphincter takes place without attendant muscular contraction of the diaphragm and the abdominal muscles.

It is obvious from the above that the causes of vomiting must fall into two great groups: (I) *Those acting directly on the vomiting centre*, such as certain poisons, e.g., apomorphine; (II) *Those acting reflexly on the centre*. The second group is a very large one, as it includes practically all the pathological states of the stomach, many visceral diseases, and disturbances of special senses.

1. CENTRAL CAUSES.

Certain drugs -	Acute yellow atrophy of the liver
Apomorphine	Addison's disease
Tobacco	Onset of acute infections, especially in children
Anæsthetics	Pregnancy
Uremia	Recurrent, periodic or cyclical vomiting in children.
Diabetes	

There may be some doubt as to whether Addison's disease, pregnancy, and recurrent vomiting should be included in this group, as their pathology is not fully known. The vomiting of pregnancy may be partly reflex, but there is strong evidence that a toxic element exists, and is probably the chief exciting cause. The differential diagnosis of these conditions presents little difficulty. The examination of the urine will give evidence of the existence of renal disease in uræmic vomiting, and the onset of drowsiness and coma in a diabetic patient may be attended by vomiting. Persistent vomiting occurring in a case of jaundice of apparently the common catarrhal variety should arouse suspicion of its proving acute yellow atrophy. The size of the liver should be determined carefully, and

any diminution noted; the urine should be examined for leucin (*Fig. 147*, p. 333) and tyrosin (*Fig. 148*, p. 333). Vomiting associated with asthenia, characteristic pigmentation of skin and buccal mucosa (*Plate XXI*, p. 526), and a persistent low blood-pressure, would be diagnostic of Addison's disease. The form of vomiting met with in young children, termed 'periodic,' or 'cyclical,' is very severe, and is accompanied by great wasting. The symptoms pass off after a few days, but tend to recur at intervals of months. The urine during the attacks often contains acetone and diacetic acid, and the condition may be regarded as an auto-intoxication, probably an acidosis (see ACIDOTICÆMIA, p. 3). The vomiting so frequently met with as one of the earliest symptoms in specific fevers, especially in children, is chiefly due to the direct action of the specific toxin on the cerebral centre, though reflex action may also have a share in it. The diagnosis does not usually present difficulty: the acute onset, vomiting, general malaise, headache, pyrexia, sore throat, rash, etc., speedily give the clue to the cause of the vomiting. In older patients, scarlet fever is the commonest specific fever to begin with nausea and vomiting.

We must next consider the chief characteristics of the vomiting due to reflex causes.

II. REFLEX VOMITING.

1. Gastric Causes.

Irritating articles of food (hard, indigestible substances)	Pyloric obstruction;
Emetics, such as zinc sulphate, mustard, etc.	Malignant disease
Poisons: Corrosives, irritants	Fibrous stricture
Gastritis:	'Hypertrophic stenosis' in infants
(a) Acute: (i) Simple,	Pressure on pylorus from without
(ii) Phlegmonous	Venous congestion, as in morbus cordis,
(b) Chronic	portal obstruction, cirrhosis of the liver
Dilatation and 'hour-glass' contraction	Ulcer
	Malignant disease.

2. Intestinal, Peritoneal, and General Visceral Causes.

Intestinal obstruction	Phthisis—vomiting may be of central origin or due to irritation of the bronchi or fauces
Appendicitis	Irritation of the fauces or bronchi by direct stimulation, or by severe coughing:
Intestinal worms	Pertussis
Following administration of enemata	Broncheectasis
Henoch's purpura	Fibroid lung
Peritonitis	Shock—blows on the epigastrium, injury of a testicle, a kick upon the internal scapular cartilage of the knee, etc.
Biliary colic	
Renal colic—movable kidney ('Dietl's crises')	
Acute pancreatitis	
Certain conditions of the female genital organs:	
Pregnancy	
Retroversion of the uterus	
Ovarian disease	
Extra-uterine gestation	

3. Affections of the Central Nervous System.

Special Senses :—

Offensive smells, tastes, repulsive sights.

Brain :—

Concussion	Cerebral hæmorrhage	Epilepsy
Cerebral tumour or abscess	Thrombosis of cerebral sinuses	Sea-sickness
Meningitis	Middle-ear disease; Meniere's disease	Functional or hysterical vomiting.
Hydrocephaly	Migraine	

Spinal Cord :—

Tabes dorsalis, gastric crises.

Certain general lines may be laid down of great importance in the accurate diagnosis of the cause of vomiting. Attention should be paid to its relation to food, if any, and at what interval after a meal it occurs; whether preceded or not by pain; whether attended or not by nausea. The absence of nausea is a point of great significance; this is usually

present in vomiting due to abnormal states of the alimentary tract and visceral organs, but is often absent in diseases of the brain.

The vomited matter should be inspected carefully, and its quantity and general character noted. Alcohol, and certain poisons such as carbolic acid and prussic acid, may be recognized by their *smell*, or a faecal odour may be distinguished. *Blood* may be present, either dark or bright red, or dark brown, resembling coffee-grounds. Slight streaks of blood are common with severe vomiting, and are usually due to rupture of small vessels in the œsophagus or pharynx. In whooping-cough, blood is often mixed with mucus from the respiratory passages, and the contents of the stomach are ejected during the paroxysms. The *condition of the food remains* should be noted carefully; the presence of substances, such as currants or seeds, taken it may be many hours or some days previously, would point to motor insufficiency of the stomach, either with or without pyloric obstruction; shreds of meat returned unaltered some hours after a meal indicate deficient protein digestion.

The *reaction* should be ascertained; in corrosive poisoning this may be strongly acid or alkaline according to the toxic agent. It need hardly be said that in any case of suspected poisoning the vomit should be kept for analysis. *Microscopical examination* may show sarcinæ (*Fig. 121, p. 241*), yeast cells, the Oppler-Boas bacillus, or cell elements from a malignant growth. Intestinal contents may be mixed with the vomit. *Bile* is often present in severe or protracted vomiting, and is recognized readily by its colour and the usual tests. Relaxation of the pyloric orifice in such cases allows of the return of the duodenal contents into the stomach. *Fæcal matter*, when present, is recognized by the characteristic odour and the brownish coloration it imparts to the vomit; it usually occurs as the result of intestinal obstruction. Gastro-colic fistula may give rise to faecal vomiting.

Gastric Causes.—Most *corrosive* and *irritant poisons* cause vomiting immediately after swallowing, accompanied by intense burning pain in the epigastrium. The vomit contains food, blood, mucus, and may have the characteristic odour of the poison. With some irritant poisons, e.g., arsenic, or phosphorus, the vomiting may come on later and resemble that of an acute gastritis. The diagnosis will depend largely on the chemical analysis of the vomit, and the associated signs and symptoms.

In *acute gastritis* there is repeated vomiting, usually very severe, and attended by nausea and abdominal pain. Vomiting occurs shortly after taking food, and causes some relief of pain. The vomited matter consists at first of food ingested, later of mucus and bile. There are often accompanying diarrhoea and febrile disturbances, especially in children. In the *phlegmonous* form the constitutional symptoms are exceedingly grave; pus is rarely found in the vomit, bile is often present.

In *chronic gastritis* the vomiting is associated with nausea and epigastric pain. There is usually much flatulence. The vomited matter consists of partially digested food, mucus, and a considerable quantity of sour-smelling fluid. Hydrochloric acid is usually reduced greatly in amount, or may be absent. When *dilatation* of the stomach is present, the quantity of fluid ejected is often very large; portions of food taken many hours previously may be returned. Fermentation takes place in the stagnant gastric contents, so that the vomit, when collected in a glass vessel, often shows an uppermost layer of brown froth, a middle greenish-grey layer of fluid containing streaks of mucus, and below this a semi-solid deposit containing food remains, sarcinæ (*Fig. 121, p. 241*), yeast cells, and bacteria; chemical tests show the presence of lactic acid and a diminution or absence of free or active hydrochloric acid.

Hour-glass' contraction, due to transverse constriction of the stomach by fibrous tissue, may be a cause of vomiting which resembles in most respects that associated with dilatation. Examination with the *x-rays* after a bismuth meal will generally establish the diagnosis (*Fig. 128, p. 268*).

The vomiting due to *pyloric obstruction* in adults presents no characteristics other than those associated with the dilatation of the stomach which usually results from it. The absence of free hydrochloric acid in the vomit would favour the diagnosis of carcinoma, the presence of free hydrochloric acid that of fibrous stricture; the presence of the Oppler-Boas bacillus is regarded by many as diagnostic of carcinoma. Persistent vomiting in young infants, especially if breast-fed, attended with wasting and constipation, should always arouse suspicions of the existence of *'hypertrophic stenosis of the pylorus.'* The

vomiting in these cases is very forcible, the milk being pumped up violently, often very shortly after a feed, and with little alteration. Visible gastric peristalsis and the presence of a small tumour in the epigastrium would complete the diagnosis.

Vomiting due to *gastric ulcer* (non-malignant) is very common. Pain occurs soon after taking food, and is relieved by vomiting, which usually occurs within an hour. The vomit consists of food, more or less digested, according to the time which has elapsed after a meal. It almost always contains at least the normal quantity of free hydrochloric acid, and blood may be present in varying quantity.

With *malignant disease*—carcinoma of the stomach—though the general character of the vomit may be very similar to that in simple ulcer, there is usually a great diminution or complete absence of free hydrochloric acid, and lactic acid and the Oppler-Boas bacillus are often present. Sarcinae may be present also when there is accompanying dilatation. Occasionally portions of the growth may be found in the vomited matter. In both simple and malignant ulcer, blood may be detected in the vomit microscopically or spectroscopically (see BLOOD PER ANUM, p. 75) when it is not recognizable by the naked eye. A bismuth and *x*-ray examination is almost essential (Fig. 130, p. 269, Fig. 131, p. 270, Fig. 132, p. 270).

Intestinal, Peritoneal, and General Visceral Causes. In *intestinal obstruction* vomiting sets in after an interval, the length of which may depend on the situation of the blocking. The vomiting is severe and persistent: the contents of the stomach are returned first, and later, mucus, bile, and intestinal contents. Faecal vomiting should be recognized at once by its odour; obvious pieces of faecal matter are rarely distinguishable, but the vomit may have a brownish colour. The vomiting is more severe the higher the obstruction is in the intestinal canal.

Vomiting is commonly present in *appendicitis*, but in slight cases does not persist after the onset. In the severe forms of the disease the vomiting may be a prominent symptom, and resemble that met with in intestinal obstruction; it is sometimes faecal in character.

Intestinal worms are a cause of vomiting in children, probably owing to the reflex irritation they set up. Occasionally a round-worm is found in the vomit.

Eumeta in certain individuals cause vomiting, and rare cases have been described in which the fluid injected per rectum has been returned by the mouth.

Vomiting is a common symptom in the condition known as *Henoeh's purpura*, and may be due to either gastric or intestinal stimulation. The vomit may contain blood due to haemorrhages from the mucous membrane of the stomach. It is usually accompanied by abdominal pain, sometimes of an acute and agonizing character closely simulating that occurring with intestinal obstruction, these symptoms being due to haemorrhage into the intestinal wall or the mesentery, which occasionally simulate or even give rise to intussusception. Recurrent attacks of vomiting and abdominal pain associated with a purpuric eruption in a boy or girl would point to the existence of this not uncommon disease.

In *acute peritonitis* vomiting is an early symptom, and causes great pain; rarely the vomit may have a faecal odour. The history, together with the rigidity and immobility of the abdominal wall, generally indicates the need for early laparotomy.

In *biliary* and *renal colic* the vomiting accompanying the attacks of agonizing pain presents no special features. The pain in the thorax and upper part of the abdomen, and the onset of jaundice, distinguish biliary colic from that due to renal calculus, in which the pain is in the loin or lower abdomen, shooting down towards the groin and testicle. Jaundice is absent if the stone is in the cystic duct.

Acute pancreatitis may simulate intestinal obstruction closely in that it is attended by nausea and vomiting, constipation, and severe abdominal pain. The vomit is not faecal in character; there is usually localized tenderness over the region of the pancreas. The diagnosis is seldom made, however, until laparotomy is performed on account of the urgency of the symptoms, when typical fat necrosis will be found in the omentum.

The other visceral causes of vomiting call for no special notice.

Affections of the Central Nervous System.—It has been pointed out that in most of the preceding conditions nausea accompanies vomiting, and this brings us to a most important distinction, namely, that in intracranial disease a special type of vomiting is met with, generally known as 'cerebral vomiting.' In this, nausea is absent, vomiting occurs suddenly and often without warning, and bears no relation to the ingestion of food,

The whole or part of the stomach contents are returned. Vomiting of this type, especially if accompanied by headache or ocular changes, should arouse grave suspicion of the existence of organic cerebral disease,—such as tumour, abscess, meningitis, or sinus thrombosis. 'Cerebral vomiting' may also occur in hydrocephaly due to increased intracranial pressure. Optic neuritis (*Plate XIX*, p. 416) should be looked for in all cases of vomiting associated with headache.

Cerebral hemorrhage may be attended by vomiting, more often when the cerebellum is the part affected than when other parts of the brain are involved.

In *Ménière's disease* vomiting may follow the attack of vertigo. Nausea and vomiting frequently accompany the severe headache associated with attacks of *migraine*.

Functional or hysterical vomiting is not attended by nausea or pain; portions of a meal are brought up, usually fluids; and although the vomiting may be a frequent occurrence, the general state of nutrition often remains good. Other hysterical manifestations are generally present in these patients (p. 465). Cases have been recorded in which the vomit contained faecal matter.

The *gastric crises* in tabes are attacks of vomiting accompanied by severe epigastric pain. The attacks usually last for several days, and tend to recur at intervals of weeks. Nausea may be absent. During the intervals digestion may be carried on normally. The diagnosis depends on the presence of the characteristic Argyll Robertson pupil and the loss of the knee-jerk.

The influence of anaemia upon vomiting, and the manner in which gastric ulcer may be simulated thereby, have been discussed in the article on ANÆMIA (p. 36).

H. Morley Fletcher.

VOMITING OF BLOOD.—(See HÆMATEMESIS, p. 265.)

WALKING, PECULIARITY IN.—(See GAIT, ABNORMALITIES OF, p. 251; and LIMPING IN CHILDREN, p. 362.)

WATERBRASH.—(See HEARTBURN, p. 296.)

WEIGHT, LOSS OF.—Loss of weight sooner or later accompanies all cases of cancer, phthisis, starvation from lack of food or from inability to swallow, and similar conditions; but in most such cases there are other symptoms pointing to the diagnosis. The present article is concerned chiefly with those cases in which, without other definite symptoms, the patient has been losing weight.

In the case of children, the commonest causes are malnutrition from injudicious feeding, the eating of sweets between meals, gastro-intestinal infections, and latent tuberculosis (see MARASMUS, p. 384).

If the patient is an adult and the loss of weight has been considerable, the first suspicion will almost certainly be that there is either *phthisis pulmonalis*, *deep-seated* or *latent carcinoma* or *sarcoma*, *tuberculosis* other than pulmonary, or *diabetes mellitus*. All the systems, including the urine, the rectum, and, if need be, the vagina, will need careful routine examination. Any sputum that may be obtainable should be examined for tubercle bacilli; the physical signs at the apices of the lungs should be watched with extreme care, particularly if there is any difference in the amount of subcutaneous fat on the two sides in this region; the *x*-rays may be of value in detecting mottling (*Fig. 70*, p. 159) at one or other apex when the mischief is too far from the surface to give abnormal physical signs to percussion or auscultation. Those who believe that the opsonic index to tubercle bacilli is of diagnostic significance, would estimate it before and after inoculations with small or moderate doses of tuberculin; the family history might be of assistance in indicating the likelihood of a lung lesion, whilst the personal history as to the drinking of much unsterilized milk would indicate the possibility of infection by so-called surgical tuberculosis in the lymphatic glands, abdomen, a joint, or the spinal column; von Pirquet's skin reaction (*Plate XXXVI*, p. 768), or, if thought advisable, Calmette's ophthalmic reaction to tuberculin may be tested (*Plate XXXVII*, p. 770). Von Pirquet's is nowadays preferred to Calmette's reaction on account of the occasional ill-effects of the latter upon the eye. The test is performed upon the skin by a procedure analogous to that of ordinary vaccination, but using tuberculin in place of calf lymph; the degree of positivity of the von Pirquet test

PLATE XXXVI
TUBERCULIN REACTIONS

PLATE XXXVI. (From *Proc. Roy. Soc. Med.*)

A, Control. **B**, Puncture through a layer of old tuberculin. **C**, Puncture through a drop of 25 per cent solution of old tuberculin.

A puncture (A) is made through the epidermis with a small toothed lance, as in (B), is a control. A similar puncture (B) is made likewise, through a layer of 25 per cent solution of old tuberculin (tubercin). A similar puncture (C) is made from the other, through a drop of 25 per cent solution of old tuberculin (tubercin). A similar reaction consists in the production of a hyperemic area in two or four hours which later becomes indurated and is surrounded by a distinct outflow of inflammatory reaction.

DERMAL REACTION (Hesse's)

A, Area of induration indurated by application of tuberculin (20 per cent solution).
B, Similar area treated with old tuberculin (hyperemic and indurated reaction).

The epidermis is removed from two slices of skin as in the application of tubercin, and after placed in twenty-five per cent solution of old tuberculin is rubbed on to one of the denuded surfaces and allowed to dry, the other serves as a control. Each epidermis covered with a small piece of protective gauze. A positive reaction is indicated by the induration and hyperemia of the inoculated area as contrasted with the control area.

is ascertained by using 5, 10, 15, 20, and 25 per cent strengths of tuberculin, supplied ready for the purpose by bacteriological laboratories; any reaction shows itself within twenty-four hours (*Plate XXXVI*). A negative von Pirquet's reaction is of more value in excluding tuberculosis, however, than is a positive one in proving that the patient's symptoms are due to tubercle; so many persons have latent tuberculous foci in glands or elsewhere that they may give a positive tuberculin reaction though their actual symptoms may be due to some entirely different malady which has developed—a colibacilluria for instance, or something else that is non-tuberculous. A positive von Pirquet reaction shows that the patient is the subject of tubercle, but it does not prove that the symptoms one is investigating in his case are due to the tuberculous infection so discovered. Sometimes, when there is doubt as to whether there is organic disease or not, the nails afford a clue; whereas longitudinal ridges on them matter little, a definite transverse ridge at the same level across all the nails is evidence of dystrophy due to illness at a time corresponding to that at which the ridged part was being produced from the matrix; roughly speaking, it takes a nail between four and six months to grow from matrix to tip, and of this time about two-thirds applies to the visible nail, one-third to the part that is growing but not yet visible; if, therefore, there is a definite transverse ridge on all the nails (*Fig. 306*) about half-way along each, the patient was in bad health between three and

Fig. 306. Transverse ridging of nails due to lobar pneumonia four months previously.

four months previously. There may have been a definite acute illness such as pneumonia; but quite often the dystrophy is due to less definite illness, and particularly to the effects of developing phthisis.

Notwithstanding the most careful investigations, however, doubt as to the cause of the loss of weight in not a few cases remains until, in the course of time, the patient either recovers the lost ground and gets quite well, or else develops other signs or symptoms of growth, tuberculosis, or other definite disease.

Young persons may lose weight as the result of change of surroundings, for instance from

active out-door school life to work in a city office; care and anxiety; the undertaking of serious responsibilities; sorrow; love; too strenuous a life of pleasure; irregularity of meals; too long hours of work; these are amongst the everyday causes of what at the time may appear to be serious loss of weight.

Any affection of the alimentary tract interfering with proper digestion and absorption of food may produce loss of weight, especially if there is cause for sapraemia at the same time; one may mention in this connection loss of appetite from too much smoking, excessive drinking, monotony of food or of existence, carious teeth, ill-fitting tooth plates, pyorrhoea alveolaris, dyspepsia, flatulence, the abuse of purgatives, and the constipation which results therefrom; gastric or duodenal ulcer; colitis in its many forms. The wasting is seldom severe in any of these; but when gastric symptoms are prominent for instance, it may be very difficult, for the time being, to tell whether the mischief should be labelled merely dyspepsia, or actual carcinoma ventriculi. Analyses of the gastric juice were at one time thought to be valuable in deciding between simple and malignant affections of the stomach, but this is by no means always the case (p. 270). If, under observation and treatment, the patient succeeds in gaining weight, or even ceases from losing more over a period of some weeks, the argument is against carcinoma; but if doubt remains, and surgical measures are to be adopted before carcinoma has passed the stage of curability, it will often be wise not to postpone laparotomy too long as a means of settling the diagnosis. It is too late if one waits until there is a tumour.

Any malady which produces sleeplessness or pain, or both, may lead to serious loss

of weight, and thus to difficulty in the diagnosis. A thoracic aneurysm, for instance, may erode the vertebrae and produce severe intrathoracic pain, which in turn produces insomnia, and may thus cause so much loss of weight that neoplasm may be suspected.

Chronic microbial infections may not be obvious in themselves, and yet they may produce loss of weight by interfering with the general nutrition: one sees this in many persons who have returned from the tropics after infection there by dysentery, yellow fever, malaria, dengue, and so forth. At home, chronic infections of joints, of the skin, the alimentary tract, the uterus, and genital organs may produce loss of weight in a similar way. One would mention in particular a common malady that has been recognized only of recent years, namely, coli bacilluria (see BACTERIURIA, p. 69), the diagnosis of which is possible only on bacteriological examination of the urine, though it may be suggested by the discovery in the latter of a trace of albumin and, on microscopical examination, excess of leucocytes.

Liver affections exert a prominent influence upon general nutrition, and the loss of weight exhibited by some sufferers from cirrhosis is familiar, though in the early stages the patient may be fat, and towards the end loss of weight may be masked by a false increase due to ascites. Pernicious anaemia is diagnosable with certainty only by blood examination (see ANÆMIA, p. 24), though it may be suggested by the primrose-yellow colour of the skin: but one marked feature of the malady is, that although the patient does not at first decrease much in bulk, the tissues, from conversion into or replacement by fat, become of less specific gravity than normal, so that he diminishes materially in weight.

The effect of alcohol upon body weight is variable, some persons becoming exceedingly stout, others not changing much, and others becoming extremely thin. Broadly speaking, it is spirit drinkers who decrease in weight, and in some cases serious doubts may arise as to whether the loss in such a patient is due to alcoholic habits only, or whether there is not some new growth or tuberculous affection as well. When alcoholism leads to peripheral neuritis there is rapid and extreme loss of weight as the result of the muscular atrophy, and the same applies to other conditions of multiple peripheral neuritis (p. 63).

Certain drugs have the power, especially in certain individuals, of reducing weight materially, even though the diet remain the same; the best known of these is *thyroid extract*, whilst a long way second comes *fungus vesiculosus*. It will seldom happen that either of these is being taken accidentally, so that the diagnosis of loss of weight due to them is generally obvious.

It is very difficult sometimes to be sure whether the loss of weight that may be complained of in a patient of sixty or seventy years of age is due merely to *old age*, or whether it is due to underlying growth or senile phthisis.

Diabetes, especially diabetes mellitus in young subjects, may have loss of weight for its earliest and most prominent symptom; but the diagnosis is easy when the urine has been examined.

Addison's disease is another affection in which, besides the progressive asthenia, loss of weight, though not essential, is sometimes marked. There may or may not have been syncopal or gastric attacks: the diagnosis depends almost entirely upon the discovery of abnormal pigment deposits in the form of patches or spots, not only upon the skin of the neck, limbs, and trunk, but also beneath the mucous membranes, particularly of the mouth (*Plate XXI*, p. 526), where they are generally best seen inside the lips, or within the cheeks. The blood-pressure is sometimes very low in these cases, and if, on actual measurement, it is found to be 70 or 80 mm. Hg, this fact tends to confirm the diagnosis.

Just as the administration of thyroid extract diminishes weight, so may loss of weight be a prominent feature in cases of *Graves's disease*: sometimes, indeed, it may be the first symptom to attract attention, especially in those cases in which there is no exophthalmos. Tachycardia, nervousness, fine tremor of the outstretched fingers, and symmetrical but not extreme enlargement of the thyroid gland, would confirm the diagnosis.

Anorexia nervosa is a disease in which wasting from disinclination to eat any kind of food except in the smallest quantities is the most prominent symptom; the patient is nearly always a female, between the ages of fifteen and twenty-five; there may or may not be other evidence of functional nerve disorders. The patient, perfectly robust until puberty or shortly afterwards, begins to lose all appetite, the body wastes, and the weight

PLATE XXXVII

TUBERCULIN REACTIONS

POSITIVE REACTION (Type 3)

Partial view of positive reaction of old tuberculin (concentration 1:1000).

Old tuberculin glyceric acid (1:1000) and bulk of 1 mgm. is thoracically injected into the lower chest muscle of a 2 em. by means of 1 cc. syringe. A positive reaction is shown by the appearance of a redness to a diameter of 100 mm. after 48 hours, of 1/4 per cent. solution of old tuberculin. The subsequent appearance of a redness of small diameter is noted on some days.

Normal eye (control)

Positive reaction (concentration of 1 part of old tuberculin glyceric acid into 1000 parts of water) injected intracamerally into the sclera.

Positive reaction with injection of old tuberculin glyceric acid.

OPTHALMOLOGICAL REACTIONS

One or two drops of a 1 per cent. solution of old tuberculin glyceric acid are instilled into the conjunctival sac of an eye. A positive reaction is indicated by the appearance, within twenty-four hours, of hyperemia of the conjunctiva and plethysmularis of the treated eye, as compared with the untreated or control eye. Later, injection of the conjunctiva. Vessels may be noted, lachrymation and even purulent eye lags.

(From Drawings illustrating Post, J. W. H. Esch's *Handbook of Ophthalmology*, 1910, p. 100.)

declines even to so little as four or three and a half stone. One sometimes sees girls of 5 ft. 10 in. or more weighing less than five stone as the result, not of any organic disease, but of the simple functional absence of appetite—anorexia nervosa. In arriving at the diagnosis it is important to exclude the possibility of some deep-seated tuberculous lesion, especially phthisis pulmonalis or tuberc mesenterica. One of the best means of excluding these is the thermometer, for in anorexia nervosa there should be little if any pyrexia. Very careful examination of all the systems, including von Pirquet's and perhaps Calmette's tuberculin reactions, will lead to negative findings, and the diagnosis will be confirmed by the rapid increase in weight when measures for treatment by the Weir-Mitchell method are adopted.

Herbert French.

WHEALS.—The characteristic lesion of *urticaria* may be defined as a flattish, evanescent elevation of the skin, the result of an œdema of the derma. It may be regarded also as a special variety of the papule or the nodule. It is related to erythema, and is the expression of angioneurotic excitation, internal or external, which causes a dilatation of the vessels that permits an exudation of plasma. Wheals disappear rapidly as a rule without leaving any trace. They are usually pale in the centre, with a red periphery; but they may be uniformly rose-red, or may have a whitish periphery; or, as the result of hæmorrhage into them, they may be purplish. In size they vary from a pin-head upwards. The smaller ones may take the form of conical or acuminate papules, frequently surmounted by a tiny vesicle. As a rule, they are flat or very slightly raised; but the larger ones, when not the result of coalescence, are hemispherical. They may also be linear, several inches in length, and by running together, may form roughly circular plaques. They usually appear suddenly, and last only a few hours, but may be succeeded by others. They are always accompanied by itching or burning, which may be intense. The commonest causes are dietetic; some persons are more susceptible than others, but the kinds of food most likely to cause the symptoms are fried fish, crab, lobster, mussels and other shell-fish; strawberries constantly produce an attack in certain individuals.

It is not necessary to give a detailed description of the different forms of urticaria; the only other affection in which wheals appear is urticaria papulosa (strophulus), the differential diagnosis of which has been given elsewhere. The sudden onset, the presence of the wheals, the usually fugitive character of the eruption, the irregular distribution, and the severe itching, make up a clinical picture which is generally unmistakable. In *bullous urticaria*, however, in which the wheal is crowned or is replaced by a bleb, the affection may be confused with pemphigus or with the erythematous stage of dermatitis herpetiformis; but its true nature is indicated by the history of the case, the course of the eruption, and the almost invariable presence at some points of typical lesions. In cases in which the constitutional symptoms are pronounced, the rash may be mistaken at first for that of scarlet fever, or even for erysipelas; but the course of the lesions will quickly correct the error.

When wheals are due to such local and accidental causes as the *bites of insects*, or contact with the *stinging-nettle*, the diagnosis is furnished by the history, and in insect bites by the central punctum; when due to drugs, knowledge of what the patient has been taking is the basis of the diagnosis; the commoner remedies that may produce urticarial wheals are antipyrin, sulphonal, veronal, aspirin, salicylates, iodides, bromides, morphia, antimony, quinine, santonin, copaiba, and various normal or antitoxic sera.

 -- 451, 652, 658
Abscess, subdiaphragmatic,
general account of 451, 658
 -- heart displaced by 452, 659

Abscess, subdiaphragmatic, cont'd.
 - from hepatic abscess 451
 - kidney sepsis 658
 - leucocytosis with 451, 658
 - liver depressed by 367
 - - dullness, increased upwardly 367
 - - not pushed down by 451
 - from liver suppuration 658
 - pain in chest from 658
 - epigastric from 658
 - hypochondrium from 451
 - - physical signs of 658
 - pleurisy from 451, 658
 - - simulated by 658
 - pleuritic effusion from 659
 - pneumonia from 370
 - pneumothorax from 531
 - - simulated by 652, 658, 659
 - pointing through chest 469
 - pyopneumothorax 652
 - - duration from 652
 - - pyrexia 451, 658
 - - resonance over 451
 - - rizers from 595, 658
 - - rub over 658
 - - ruptured into lung 705
 - - septic look with 658
 - - shortness of breath from 658
 - - simulating emphysema 105
 - - sternal resonance with 611
 - - suppuration in 651, 652
 - - tenderness of spine from 713, 714
 - - umbilicus and anal with 656
 - - rays in shadowing 451, 592, 652, 658, 659
 - - subcutaneous 658
 - - pain from 429
 - - subphrenic (see Abscess, Subdiaphragmatic)
 - - temporosphenoidal, noises in the head of from 106
 - - of tests, acting at external abdominal ring in 622
 - - from chronic torsion 622
 - - enlarged prostate 622
 - - in testis 622
Abscess of testis, general account of 621, 622
 - from instrumentation 622
 - orchitis 478
 - - pyrexia from 622
 - - rizers from 622
 - - spermatocyst thickened with 622
 - - tests enlarged by 622
 - - ulcer of scrotum from 622
 - - from urethritis 622
 - - testicular (see Quinsy)
Abscess, tuberculous, of bone 669
 - lymphia simulated by 667
 - thyroid, in pyæmia 742
 - - tubercled, in tuberculous peritonitis 483
 - - urethral, acting in perineum from 471
 Abscesses, albuminuria with 16
 - metastatic, in pyæmia 596
 - in lungs, in pyæmia 596
 - - military, in newborn 557
 - - in throat, prolonged pyæmia from 567
 - - - septicaemia from 567
 Absent-mindedness, in epilepsy 436
 Absorbent, cone) from 418
 - heart irregular from 486
 - - papillation from 484, 486
 - tremor from 724, 726
 Academy, headache 296
 Acanthosis nigricans, herpes affected by 249
 - - prurigo and, burrows 189
 Acaris sech, burrows, skin wrists and fingers 540
 - - - cosmopolitan, rare from 219 (see see Sabosa)
ACCENTUATION of heart-sounds 1
 - pulmonary second sound, with nasal respiration 249
 - - reduplication and 588

Acersarous, nerve supply 198
Accidental albuminuria 15
 Accommodated, debetive, after diplopia 64
 - - paralysis of, in disseminated sclerotic 760
 - - pupil constricted in 551
ACCOUCHEUR'S HAND 2
 Acetabulum, bulged into pelvis 349
 Acetanilide, bulle) from 36
 - - cyanosis from 157
 - - methæmoglobinuria after 537
 - - polythaemia from 533
 - - reducing substances in urine after 157
 Acetate of cellulose, in acetone-plate varnish 334
 - - of lead, in Cammidge's reaction 100
 - - test for cystin 161
 - - solution, in phenylhydrazine test 262
 - - zinc, in uric acid test 325
 Acetic acid (see Acid, Acetic)
 Acetic-acetic acid (see Acid, Diacetic)
 Acetone, in acetoline varnish 334
 - - breath 264
 - - diabetes 261, 264
Acetone, test for 3
 - - (*Phab. A.A.A.I.F.*) 748
ACETONURIA 3
 - - cyclical vomiting 381, 365
 - - diabetes mellitus 356
 - - diabetes and 170
Acetonuria, various causes of 4
 - - without glycosuria 4
Achalasia 198
 Achill and pains, blue brain and 163
 Achillispark (see Ankle-spark)
 Aching all over, in Krickland's disease 616
 - - - from serum impurities 623
 - - in bark, in phosphoric diabetes 523
 - - general, in parvitis agitata 725
 - - in group, from spermatozooids 481
 - - - syphilitic testis 479
 - - kidney, from carcinoma of bladder 580
 - - lumps from bacteriuria 70
 - - from movable kidney 280
 - - - ovalium 281
 - - - pyelonephritis 576
 - - renal calculus 278
 - - new growth 578
 - - stone in kidney 577
 - - tuberculous kidney 279, 577
 - - ureteric calculus 578
 - - lumbar region, from spermatozooids 481
 - - - syphilitic testis 479
 - - - vesical growth 277
 - - lumbar-axillary region, from pyosalpinx 532
 - - perineum, (see Pain in the Perineum)
 - - shoulder (see Pain in the Shoulder)
 - - in testicular abscess 625
 - - testis, from spermatozooids 481
 Achromic jaundice 324, 325, 332, 333, 744
 - - - acute yellow atrophy 333
 - - - carbosia 332
Achloric jaundice, familial 332, 634
 - - (*Phab. A.I.I.I.I.*) 332
 - - - spleen enlarged in 331
 - - - from septicaemia 333
Achondroplasia (Fig. 117) 187
Achondroplasia, general account of (Fig. No.) 237
 Achthon achondrom, levis due to 246
 Achylia, diarrhoea from 172
 - - dyspepsia from 318
 Achylia, cont'd.
 - - gastric contents with 319
 - - HCl content in 250
Acid, amido-oxybutyric, acetone with 5
 - - acetic, in acetone test 5
Acid, acetic, in boiling test for albumin 4, 424
 - - carbonates, dissolved by 1
 - - in clearing up phosphates 1, 108, 183, 321, 374
 - - difference of urine with 1
 - - in extracting blood 81
 - - gastric contents 320
 - - Heimerstein's test 16
 - - meluria test 746
 - - uncoloured precipitated by 4
 - - in occult blood test 171
 - - stool examinations 170
 - - uric acid test 325
 - - benzene, erythema from 222
 - - glycolic acid from 261
 - - reaction by urine after 261
 - - - baric, erythema from 261
 - - in lavage of bladder 575
 - - urethral irrigation 581
 - - linitic, in gastric contents 320
 - - - reduction by urine in carbol-insulin 641
 - - coma from 418
 - - drizo reaction from 173
 - - erythema from 222
 - - ferric chloride reaction after 170
 - - glycolic acid from 261
 - - hæmaturia from 275
 - - hæmoglobinuria from 284
 - - hypothermia from 511
 - - ichthæmia from 528, 746
 - - reduction by urine after 261
 - - - scales from 692
 - - time, crinaria simulated by 223
 - - in treating psoriasis 746
 - - - - - album serpens 754
 - - - - - albumin test 720
 - - urine after 170
 - - in vomit 266
 - - chronic, hæmoglobinuria from 284
 - - chrysophanic, alkali test for 744
 - - - pink urine from 715
 - - in rhubarb 744, 745
 - - - - - serum 744, 745
 - - - - - yellow urine from 744
 - - diarrhoea, association with acetone 3
 - - in cyclical vomiting 381, 365
 - - diabetes 261, 264, 356
 - - test for 170
 - - (*Phab. A.A.A.I.F.*) 748
 - - in urine 170
 - - from starvation 71
 - - gallic, black urine from 745
 - - - - - thirst from 720
 - - glycolic, Baal's test for 261
 - - - - - methyl salts reduced 262
 - - - - - Fehling's solution reduced by 264
 - - - - - osazone crystals from 262
 - - - - - phenylhydrazine crystals from 260
 - - - - - phyloglucum test for 261
 - - in urine after drugs 264
 - - hæmatin spectrum (Fig. 34) 89
 - - linitic, Fehling's solution reduced by 261
 - - - - - mononitrate, alkalinuria and 746
 - - - - - estimation by silver nitrate 746
 - - - - - reducing power of 746
 - - hydrochloric, in Baal's test 261
 - - - - - Cammidge's reaction 400

Acid, antichloric, cont'd.
 - - carbolic acid 747
 - - in chloroform action 173
 - - - - - gastric, debauch with carcinoma of stomach 216, 426, 630, 652, 766, 767
 - - - - - in gastrostasis 766
 - - - - - in gastritis 766
 - - - - - in duodenal ulcer 751
 - - - - - gastric ulcer and 767
Acid, hydrochloric, in gastric juice 270, 316, 318, 366
Acid, hydrochloric, in gastric juice, absence of 73
 (*Phab. A.A.A.I.F.*) 750
 - - hæmatoporphyrin and 744
 - - hæmoglobinuria from 284
 - - - - - methionin 745
 - - - - - in Perle's test 24
 - - phyloglucum test for pentose 260
 - - tests for free 261
 hydrochloric-acetic, in kaptomuria and 746
 - - methylglyconuria, blue urine from 748
 - - lactic, in gastric contents 517, 529, 766
 - - - - - with carcinoma of stomach 316, 767
 - - test for 260
 - - in vaginal secretion 185
 - - methyl glycolic, erythema from 222
Acid, nitric, albumin test with 4, 5
 - - albumose ring with 45, 46
 - - brown ring in urine with 241
 - - - - - bulle) from 36, 97, 241
 - - - - - hæmoglobinuria from 284
 - - - - - methionin 745
 - - - - - meluria and 745
 - - - - - in hepatoid and 5, 424
 - - test for bile pigments 743
 - - urea decomposed by 5
 - - osme, in staining 40
 - - oxalic, amura from 108
 - - from vegetable 121
 - - coma from 418
Acid, oxalic, exogenous sources of 424
 hæmoglobinuria from 284
 hypothermia from 511
 nephritis from 9
 - - poisoning by, oxidized after 268
 - - strimury from 649, 650
 - - oxybutyric, association with acetone 261
 - - in diabetes 3
 - - phosphotungstic, albumose test 46
 - - - - - peric, eructum and 262
 - - - - - lactase and 262
Acid, picric, test for sugar 262
 - - xanthopuric from 262
 - - yellow skin from 329
 - - prussic, in vomit 766
 - - pyrogallic, hæmoglobinuria from 284
 - - - - - silvich, purpura from 553
 - - - - - sinusæ, leucocytosis from 560
 - - sulphuric, in diazoreaction 172
 - - sulphuric, in bile test 744
 - - hæmoglobinuria from 284
 - - in Zeld-Neesen strimury 641
 - - - - - lamme, thirst from 720
 - - - - - uricæ, in milky stool 317, 318, 319
 - - - - - in birds 742
 - - - - - calculus and 742
 - - - - - the choker of the body 742
 - - - - - crystals (Fig. 362) 741
 - - - - - diminished, in urine 742
 - - - - - yellow atrophy 333
 - - - - - Fehling's solution reduced by 261, 743
 - - - - - in leaves 742
 - - - - - Respirat. metabolism and 742
 - - - - - glycosuria simulated by 742

- Acid, uric, gout and* 741, 742
 — gravel due to . . . 741
 — in heart disease . . . 742
 — leukaemia . . . 742
 — life insurance and . . . 743
 — ovoid crystals with . . . 742
 — of lime and . . . 424, 742
 — in pernicious anaemia . . . 742
 — uric, sources of . . . 742
 — in urthritis and . . . 742
 — in urticaria . . . 641
- Acidity, gastric, estimation of** . . . 320
- Acidity of normal urine, general account of** . . . 523
 — sense of, from dyspepsia . . . 319
 — of stool, from fermentation . . . 170
 — urine, excessive, frequent micturition from . . . 742
 — vaginal secretion . . . 185
- Acidosis, in cyclical vomiting** . . . 281, 765
- Acidosis, general account of** — relation of hepatic glyco-gen to . . . 1
 — lactic, fatty, bacillus aerogenus capsulatus producing . . . 256
 — gangrene from . . . 255
 — leucocytosis from . . . 265
 — mineral, cystin dissolved by . . . 161
 — — dermatitis from . . . 755
 — — erythema from . . . 222
 — — strong, sore throat from . . . 613
 — ulcerative stomatitis from . . . 740
- Aene, from bromides** . . . 410
 — decaying . . . 918
 — from iodides . . . 98
 — papules in . . . 187, 189
 — rosacea (see Rosacea)
 — septicæmia from . . . 657
 — tenderness of scalp from . . . 759
 — vulgaris, age incidence of . . . 510
 — — comedones in 241, 189, 559, 560, 563
- Acne vulgaris, general account of** . . . 189
 — — nodule in . . . 189
 — — parts affected by 189, 560
 — — puberty and . . . 189
 — — pustules in 189, 557, 559
 — — rosacea distinguished from . . . 211
 — — sebaceous glands and . . . 189
 — — small-pox simulated . . . 562
 — — syphilis simulated . . . 559
 — — syphilitic simulated . . . 560
 — — xanthoma simulated . . . 753
- Acute, bradyponia from** . . . 84
 — — pyralism from . . . 542
- Acrometria, Poltzer's (Fig. 73)** . . . 164

 - pain in limbs in 165
 - phthoroidia from 325
 - polykæstosis in 572
 - polyorbitalitis with 107
 - pyæmia in 25, 572

Anæmia, severe, unnamed types of
 - some causes of 15
 - spinal cord changes from 610
 - from syphilis 527
 - tenderness of bones in 367
Anæmia, severe, unnamed types of
 - shortness of breath from 87
 - with sinus discharges 35
 - speaks before eyes in 72
Anæmia, splenic (see Splenic Anæmia)
 - in splenomegaly (inhibitions) 633
 - starvation 53
 - sterility from 46
 - in Still's disease 35, 378
 - with suppuration 44, 55
 - due to syphilis 21, 34, 569
 - systolic bruit from 90
 - pulmonary bruit from 90
 - in tubes 650
 - tachycardia from 703, 704
 - in thymic antithrombin 189
 - tintinnus from 723
 - from toxic conditions 32
 - in tuberculous 32, 33, 569
 - with tuberculous joints 35
 - peritonitis 46
 - with uræmia abdominal aortic pulsation 543
 - in uræmia 116
 - from urethral navus 284
 - uterine disease 52, 552
Anæmia, various types of simple 32
 - vertigo from 752
 - vomiting due to 36, 112, 768
 - from worms 519
Anæsthesia from cancer
 - epina tumour 32
 - cerebral artery lesion 38
 - cervical ribs 441, 508
 - combined sclerosis 110
 - cord compression 714
 - of cornea in melanoma 233
 - cotton-wool in testing 695
Anæsthesia, definition of 605, 606
 - in diabetes 63
 - dissociative, from hæmatomyelia 509, 608
 - post, int. cerebellar artery thrombosis (Fig. 291) 610
 - syringomyelia 510, 557, 508, 516
Anæsthesia, dissociative, in syringomyelia 608
 - in Erb's palsy 507
 - of face, from fifth nerve lesion 706
 - mid-brain tumour 727
 - from fracture of sacrum (Fig. 299) 608
 - in tarsal dislocation of spine 608
Anæsthesia, general notes 605
 - glove or stocking type 56, 134, 165, 606, 609
 - from hæmatomyelia 110
 - hemiplegic (see Hemiplegic thesis)
 - hyperæsthesia with 606
 - from hysteria 134, 168, 198, 505, 716
 - in Klumpke's palsy 507
Anæsthesia in leprosy 603
 - local, in examining larynx 199
 - in inter-ocular perlepsy 518
 - in 506
 - from myelitis 608
 - in neuræsthesia 716
 - from neuritis 518
 - from new growth in spine 714
 - paralysis of sciatic nerve 139
 - peripheral neuritis 56, 465, 511, 606, 607
 - in sciatic 458
 - severe type in 127
 - in sciatic palsy and 751
 - in spastic paraplegia 532
 - from spinal injury 715
 - in tubes 166, 511, 609

Anæsthesia, contd.
 - of tongue, in bulbar paralysis 706
 - of fifth nerve lesion 706
 - from transverse myelitis 516
 - 42, 419, 516
 - tumour of fifth nerve 611
 - of fifth nerve division 614
Anæsthesia in diagnosis 48
 - of abdominal tumour 664
 - of carcinoma 271
 - of cause of anal spasm 126
 - of gastric carcinoma 374
 - of hysteria 111, 112, 551
 - of hysterical contracture 111
 - of pancreatic tumour 664
 - of pharynx tumour 664
 - 14, 390, 659, 691
 - simple effusion 48
 - of subcutaneous abscess 678
Anæsthesia, ætiology of
 - aspiration pneumonia 4
 - after 259
 - Bruns's sign during 259
 - bronchopneumonia after 284
 - coma from 118
 - for curettagé 33
 - death from 282
 - delirium from 169
 - erythema from 222
 - hyperthermia from 711
 - status lymphaticus and 82
 - tintinnus from 723
 - vomiting from 764
Anal canal, congenital narrowness of 129
Anæsthesia, in Brown-Sequard paralysis 137
 - from cerebellar artery lesions 138
 - cervical rib 519
 - cerebral rib 441, 508
Anæsthesia, definition of 606
 - of muscles, in tubes 506
 - pain in testing 606
 - from post, int. cerebellar artery thrombosis (Fig. 291) 610
 - in syringomyelia 52, 60, 516, 518
 - tubes (Fig. 264) 110, 607, 610
 - ulnar, in tubes 441
Anæsthesia, in infantile (Fig. 31) 223
Anaphylaxis 626
Anarctic in ankylostomiasis 741
 - chronic mediastinitis 46
 - heart disease 104, 704
 - pleurid effusion with 104
 - from renal disease 42
 - 16, 51, 101, 731
 - vulval swelling from 709, 731
 - (and see Edema)
Anæsthesia, in clavicles absent 187
 - spinal 187
Anatomy of axillary lymph glands 656
Anatomy of inguinal glands 679
 - perineal, of adolones 603
Axillary plexus 684
 - axillary spirium, from 684
 - plexus abscess 241
Axillary nerve supply of 505
Axillary, abdominal, origin and sex in males 457
 - albuminuria from 701
 - bruit over 701
 - carcinoma of stomach 694
 - simulating (Fig. 288) 694
 - chronic nephritis from 694
 - colic simulating by 115
 - epigastric tumour from 271, 541, 634

 acute rheumatism 343
- Arthritis, rheumatoid,
 general account of 341, 342**
- joints affected in 343
- loss of weight in 35
- lymphatic glands en-
 larged in 35, 343, 378
- massage in 342
- muscular atrophy in . . . 343, 346
- osteo-arthritis com-
 fused with 343
- Arthritis, rheumatoid, osteo-
 arthritis distinguished
 from 346**
- pain in the back from . . . 128
- lead from 151
- lumps in 463
- passive movements in . . . 343
- pigmented skin in 342
- pulse rate in 341, 342, 346
- from pyorrhea alveo-
 laris 648
- prevexia with 35, 341
- protrusion of bone
 in (Fig. 156) 341
- recurrent exacerbations
 of 343
- sialyates, infective
 in 339, 341
- sex incidence of 342
- Arthritis, rheumatoid, contd.**
- - - spindled fingers in . . . 378
 (Fig. 153) 342, 378
- - - spindled joints in . . . 35
- - - spleen enlarged in . . . 35
- - - stiff neck from 648
- - - Still's type of 35
- - - sweating hands and
 feet in 342
- - - temperature chart in . . 341
- - - Thomsen's disease simu-
 lating 584
- - - ulnar deflection in . . . 342
 (Fig. 154) 342, 343
- - - ureteral calculus simu-
 lated by 461
- - - writer's cramp simu-
 lated by 151
- - - x-rays in diagnosing . . 343
- - - scarlatina 340
- Arthritis, septic, general
 account of 339**
- septic, leucocytosis with . . 339
- mistaken for rheuma-
 tic fever 339
- pyrexia of 339
- source of infection 339
- sweats due to 339
- of shoulder, aneurysm
 simulating 476
- hydatid cyst simu-
 lating 476
- mediastinal new growth
 simulating 476
- small-pox with 340
- spinal, rigidity of back
 from 461
- x-rays in diagnosing . . . 461
- suppurative, albumos-
 uria with 16
- of ankle 362
- limping from 362
- mistaken for acute
 rheumatism 328
- rheumatic fever 341
- from osteomyelitis 341
- pain in foot from 362
- septicemia from 341
- Arthritis, syphilitic, general
 account of 348**
- Arthritis, in syringomyelia
 349**
- talipes from 341
- temporary, villary, tris-
 mus simulated by 729
- traumatic, mistaken for
 acute rheumatism 328
- tubercle and 348
- tuberculous, age incu-
 dence of 347
- aneurysm from 35
- Baker's cyst with 692
- Charcot's joint simu-
 lating 349
- contractures from 142
- Arthritis, tuberculous, gen-
 eral account of 347**
- gonococcal arthritis . . . 341
- mistaken for 341
- Arthritis, tuberculous, of
 hip, general account of 363**
- hysteria simulating 142
- injury preceding 348
- joints affected by 347
- lactaceous disease with . . 348
- limping from 362
- mistaken for acute
 rheumatism 328
- muscle wasting with . . . 348
- pallor with 348
- phthisis rare with 348
- syphilitic joint simu-
 lating 348
- Arthritis, typhoidal, general
 account of 340**
- streptococcal in 341
- Arthritis, puritans from 540**
- Arthropathy, pulmonary
 (see Pulmonary Osteo-
 arthritis, see also)**
- Articular, ossealate from . . . 121**
- Articulation, cerebellar, de-
 fective, in bulbular para-
 lysis 125**
- in melanism 626
 (see also Speech)
- Ascaris, four taste from 765**
- Ascariis lumbricoides 520**
- - - appetite increased by . . 43
- - - bile duct obstructed
 by 325, 328
- - - no blood changes with . 26
- - - eosinophilia rare from . 219
- - - jaundice from 325
- - - length of 328
- - - ovum of (Fig. 247) 520
- - - passed per rectum 329
- - - in vomit 367
- - - without symptoms . . . 329
- Ascending cerebellar tracts,
 role in coordination 55**
- neuritis (see under
 Nephritis)
- nephritis, causes of
 chronic 7
- **ASCITES 43**
- abdominal distention
 from 43, 418, 655, 656
- from abdominal tubercle . 171
- abdominal veins distend-
 ed from 44
- from abscess of liver 330
- acute peritonitis 47
- acute, from twisted
 ovarian pedicle 156
- from adherent pericar-
 dium 46
- albuminuria from 13
- from aortic disease 46
- plastic aneurysm 46, 55
- with arteriosclerosis . . . 46, 46
- back pressure 46, 52, 212
- Bright's disease 46
- Ascites with Bright's
 disease 54, 55, 165**
- broncho-ecase from 292
- from bronchitis 46
- carcinoma of colon in . . . 329
- chondremia 51
- liver 46, 52, 329, 375
- ovary 49
- peritoneum 657
- peritonitis 49
- stomach 49, 51, 329
- suprarenal 51
- cardiac impulse displaced . 44
- **Ascites, causes of 43, 46**
- from chronic mediastino-
 tis 155
- - - nephritis 212
- - - peritonitis in 147, 373, 425
- Ascites, chylous, charac-
 ters of fluid in 50**
- - - chylous fluid in chest
 with 166
- - - chyluria with 169
- - - from elephantiasis . . . 50
- - - fibrinous 50
- Ascites, chylous, general
 account of 49, 50**
- - - from injury 50
- - - to thoracic duct 169
- - - leukemic 50, 166
- - - malignant disease 50
- - - nephritis 50, 166, 169
- - - new growth 166
- - - obstructed receptacu-
 lum chyli 50
- - - thoracic duct 50
- - - from cachexia 56, 51, 52,
 332, 371, 570, 655, 750, 770
- - - due to colon tumours . . 46
- Ascites, conditions simu-
 lating 44**
- - - constipation with 127
- Ascites, differential diagno-
 sis of causes 46, 55**
- - - dipping in 44
- - - distended bladder simu-
 lating 665
- Ascites, distinction from
 ovarian cyst 44, 45**
- from distonia hepaticum . 328
- dullness with 689
- due to, distribution of . . 44
- due to fluid tumours . . . 46
- in Egyptian splenome-
 galy 624
- from emphysema 46, 217
- Ascites, encysted 657**
- ovarian cyst simulated
 by 691
- pelvic swelling due to . . . 688
- Ascites, contd.**
- with enlarged liver 46
- - - portal glands 329
- - - epigastric angle widened
 by 43
- - - from fatty heart 46
- - - fibroid heart 46
- - - lung 46
- - - fibroid lung from 292

 from portal vein ob-
 struction 51, 272, 320
- - - thrombosis 45, 272
- - - proliferating papilloma-
 tous ovarian cyst 49
- Ascites, pseudochylous . . . 53**
- in pseudoleukemia 37,
 46, 55
- - - rectal examination in
 detecting 49, 57
- - - respiratory movements . . 44
- - - deficient with 44
- - - ribs pushed out by 45
- - - from sarcoma 46, 32, 329
- - - with severe anemias . . . 35
- - - sigmoidoscope in 49
- - - simulated by abdominal
 cyst 44
- - - tumour 44
- - - distended bladder . . . 44
- - - hydatid cyst 45
- - - hydropneumothorax . . . 45

Ascites, simulated, condt.
 -- by hydroys anuni .. 44
 -- by hysteria .. 390
 -- obesity .. 44
 -- ovarian cyst .. 44 689
 -- pancreatic cyst .. 45
 -- pleuronic tumour .. 44
 -- splenitis .. 44
 -- skin teise and shining
 from .. 43
 -- skodac resonance from 611
 -- in splenic anmia 16, 55, 572
 -- splenomegalic cirrhosis 633
 -- syphilis .. 52
 -- of liver .. 46
 -- thrill with .. 44
 -- tuberculous .. 45

Ascites, with tuberculous peritonitis 48, 150, 653
 -- portal glands .. 51
 -- twisted ovarian pedicle 689

Ascites, tympanites distinguished from 44
 -- umbilicus ani .. 43, 459
 -- uterus in .. 45
 -- vagin examination and .. 49
 -- from vena cava inferior obstruction .. 46
 -- vena cava inferior obstructed by 415, 749
 -- from vena cava thrombosis .. 52, 749

Ascaric fluid (see Fluid, Ascaric)

Aspergillus, haemoptysis from .. 287

Aspergillus flavus, in sputum .. 645
 -- fumigatus, in sputum .. 645
 -- Madura foot from .. 726
 -- ureter, limb affected by .. 290
 -- in sputum .. 645

Asphyxia, from abductor paralysis .. 158
 -- acute laryngitis .. 636
 -- angina laryngea .. 639
 -- borborismus from .. 22
 -- coma in .. 144
 -- convulsions in .. 111
 -- in epilepsy .. 145
 -- fatal, from tooth-plate in larynx .. 195
 -- in heart disease .. 146
 -- high blood-pressure from .. 14, 81
 -- from Lindry's paralysis .. 518
 -- paralysis of diaphragm .. 518
 -- intercostal muscles .. 518
 -- partial, shortness of .. 89
 -- breath from .. 589
 -- retracted head from .. 589
 -- from syphilis .. 158
 -- tetanus .. 158
 -- whooping-cough .. 145

Aspiration, in rhizomysing bursa, .. 676
 -- (and see Neoflinax)

Aspirin, anagomeurotic
 -- oedema simulated after 673
 -- erythema from .. 422
 -- rashes in the head from 406
 -- oedema from 410, 413, 415
 -- urticaria from .. 413, 417
 -- Assam, Kala-azar in 29, 623
 -- Astereostosis .. 58
 -- in tubes .. 609
 -- disseminated sclerosis .. 609

Asthma, aneurysm simulating .. 535
 -- bronchitic, spasmodic distinguished from by .. 219
 -- bronchitis with .. 150, 255
 -- simulating .. 429, 535
 -- and emphysema from 160
 -- simulating .. 160
 -- cardiac dyspnoea simulating .. 535
 -- from fatty heart .. 213
 -- spasmodic-distended head from by .. 219
 -- Charcot-Leyden crystals .. 102, 153
 -- clubbed fingers from .. 111
 -- constipation from .. 128
 -- Curschmann's spirals in .. 102, 153

Asthma, condt
 -- cyanosis from .. 160
 -- dyspnoea from .. 322, 429
 -- not cough the essential symptom of .. 535
 -- emphysema from .. 153, 219, 535
 -- eosinophile cells in sputum .. 182, 219
 -- foreign body simulating .. 535

Asthma, general account of .. 335
 -- acute simulating .. 535
 -- hysterical simulating .. 535
 -- insomnia from .. 321, 322
 -- mediastinal new growths simulating .. 535
 -- nasal discharge from .. 178
 -- orrhopharyx from .. 323, 418
 -- papillary of larynx similar .. 535
 -- larynx .. 335
 -- polyvitaminum from 532, 533
 -- pyloric from .. 335
 -- renal, spasmodic distinguished from by .. 219
 -- eosinophilia .. 219
 -- syphilis of bronchus simulating .. 535
 -- therapeutic tests for .. 535
 -- thymic .. 535
 -- urticaria simulating .. 535
 -- rays in diagnosing .. 537

Asthmatic, diplopia from 173
 -- eye-strain from .. 446, 521
 -- blepharitis from .. 449, 521
 -- hypermetropia with .. 447
 -- morning headache from 294
 -- neuralgia from .. 449

Atigmatism, optic disc in 417
 -- (Plate XX) .. 418
 -- pain in the eye from 446
 -- photophobia from 524
 -- tenderness of scalp from 712

Astley Cooper, on hernia of bladder 683

Astley Cooper, irritable breast of 431
 -- Atropine, thirst from .. 729
 -- Astronomy, vision and .. 758
 -- Astylum, entry .. 747

Ataxic paraplegia, ataxy with .. 251
 -- Babinski's sign .. 68
 -- lesions of .. 547
 -- neurotically simulated .. 313
 -- paraplegia from .. 514
 -- penis erection absent .. 313
 -- .. 313
 -- .. 313

ATAXY, acute cerebellar 58
 -- from alcoholism 56, 146
 -- asterosegosis with .. 58
 -- from ataxic paraplegia .. 251
 -- arthrosis with .. 58

Ataxy, from cerebellar lesions 58, 59, 251, 517, 592 610, 728
 -- cerebellar, intention tremor in .. 728
 -- from post. art. cerebellar artery thrombosis (Fig. 264) .. 610
 -- tremor in .. 727

Ataxy, cerebral causes of 58
 -- chorea distinguished from 153
 -- in combined degeneration of cord .. 57, 254
 -- from dipthheria .. 56
 -- in disseminated sclerosis .. 57, 307, 547
 -- due to loss of sensory impulses .. 56
 -- encephalitis .. 58
 -- eye-closure in detecting .. 56
 -- familial, intention tremor in .. 728
 -- Friedreich's (see Friedreich's ATAXY)
 -- hemiplegic .. 58
 -- after hemiplegia .. 58
 -- hereditary, tremor in .. 724
 -- hysterical .. 59
 -- in intantile hemiplegia .. 58
 -- influence of eye-closure on .. 57

Ataxy, condt
Ataxy from lesions of brain stem 58
 -- of lip .. 59
 -- from ocular paralysis .. 251
 -- of palate .. 59
 -- paralysis simulated by .. 500

Ataxy, from peripheral nerve lesions 56
 -- posterior cerebellar artery lesions .. 58
Ataxy from spinal cord lesions 57
 -- spinocerebellar, tremor in .. 727
 -- in tubes dorsalis 57, 116, 251, 106, 545
 -- of tongue .. 59
 -- vertigo with .. 58
 -- of vocal cords .. 59
 -- wringing movements in (Fig. 295) .. 728

Atelactis, cyanotic, bronchiectasis from .. 292

Atelactis, general account of 191

Atheroma, abdominal angina from .. 187
 -- angina pectoris with .. 559
 -- of aorta, clot upon .. 258
 -- embolus from .. 258
 -- pain in shoulder from 154
 -- aortic retraction from 207
 -- systolic bruit from 1,
 -- blood-pressure .. 53, 92, 298
 -- of cerebral arteries, dip .. 106
 -- sinus, gusseted at .. 406
 -- noises in head from 106
 -- thick radial arteries .. 406
 -- tortuous, temporal arteries with .. 106
 -- and arteriosclerosis, association between .. 274
 -- of coronary arteries, bruit black with .. 83
 -- diaphane .. 257
 -- epigastric pain from .. 437
 -- fluctance from .. 437
 -- gangrene from .. 737
 -- granular kidney with .. 274
 -- hamatemesia from 265, 274
 -- heart thumping from .. 486
 -- high blood-pressure with 274
 -- intermittent claudication and .. 506
 -- loud aortic second sound .. 53
 -- with muscular changes .. 53
 -- noises in the head from 295
 -- palpitation from .. 284
 -- of pulmonary arterioles, haemoptysis from .. 487
 -- artery .. 294
 -- from mitral stenosis .. 217, 289
 -- from syphilis .. 259
 -- thrill from .. 729
 -- tonusmus from .. 470
 -- unequal pulses from 550, 551
 -- vessels affected by .. 31

ATHETOSIS, hand in 129
 -- from cerebral dipthheria .. 729
 -- embolism .. 132, 133
 -- hemorrhage .. 132
 -- thrombosis .. 132
 -- chill causing .. 132
 -- from cortical lesions .. 202
 -- with dipthheria .. 132
 -- from encephalitis .. 132
 -- epilepsy and .. 132
 -- of face .. 493
 -- after fever .. 132
 -- of the hand (Fig. 574) .. 132
 -- hemiplegic hemiplegia with .. 204
 -- after hemiplegia .. 174
Atletosis, idiopathic 132
 -- in intantile hemiplegia .. 58, 493
 -- insanity and .. 132
 -- from instruments at .. 132
 -- birth .. 132
 -- meningeal hemorrhage .. 132
 -- optic thalamus lesion .. 133
 -- parts affected by .. 131

Atletosis, condt
 -- after polioencephalitis .. 132
 -- post-hemiplegic .. 133
 -- shock causing .. 132
 -- in spastic paraplegia .. 132

Archie, albuminuria of 15
 -- arctic disease in .. 209
 -- enlarged heart in 214, 299
 -- of epithelial bursa in .. 692
 -- heart changes in .. 15
 -- left ventricle enlarged in 206
 -- still in .. 131, 707

Atkinson, Dr. Rendell .. 79

Atmospheric conditions, shortness of breath from .. 89

Atomy of bladder .. 395
 -- stomach, dyspepsia from 319
 -- flatulence with .. 241
 -- gastrostasis from 174, 653
 -- sense of fullness from 244
 -- excession with 241, 544

Atoxyg, amblyopia from .. 559
 -- erythema from .. 222, 254
 -- central serotoma from .. 229
 -- optic atrophy from .. 759
 -- neuritis from .. 759

Atrophia cervicis (see Cervix Uteri)
 -- of vagina (see Vagina, closure of)

Atrophy, acute yellow (see Acute Yellow Atrophy)
 -- cerebellar .. 729
 -- of ears, from lupus erythematosus .. 602
 -- facial (Fig. 202) .. 494
 -- of hand, in amyotrophic lateral sclerosis .. 508
 -- from cervical rib 411, (Fig. 200) .. 508
 -- in bulbar poliomyelitis .. 627
 -- progressive muscular atrophy .. 61, 109
 -- in syringomyelia .. 508
 -- hypopharynx, from cerebral ribs .. 508
 -- progressive muscular atrophy .. 61, 110
 -- in ulnar paralysis .. 716
 -- of kidney, from atrophic calcidosis .. 578
 -- limbs, from dipthheria .. 65
 -- from mercury .. 65

ATROPHY, MUSCULAR 59
 -- in acute poliomyelitis .. 61, 500
 -- in amyotrophic lateral sclerosis 61, 62,
 -- .. 155, 508, 517
 -- from anaemia .. 61, 63
 -- anterior cranial nerve lesion .. 498

Atrophy, muscular, from anterior cruritis 439
 -- arthritic, no R.L.M. .. 352
 -- with arthritis 61, 63,
 -- 343, 346, 348, 354,
 -- .. 363, 363, 177, 583
 -- from brachitis .. 477
 -- brachial neuritis .. 443
 -- from plexus injury .. 506
 -- in rhabdomyositis .. 583
 -- from callus involvment nerve .. 763
 -- from candida equina .. 562
 -- tumour .. 61, 62
 -- cervical rib 61, 63,
 -- .. 110, 162, 508
 -- contractures with .. 110
 -- after dipthheria .. 512
 -- from disease .. 59
 -- fibrosal reactions .. 583
 -- with facial paralysis .. 493
 -- fibular contractures .. 134
 -- from fracture .. 64
 -- in Friedreich's disease 140
 -- general paralysis .. 59
 -- gonococcal arthritis .. 340
 -- gumma of toiva .. 61
 -- in hysteria .. 506
 -- from infantile paralysis (see 130) .. 59, 60
 -- injury to nerve .. 61, 63
 -- Jacksonian epilepsy .. 137

Bence-Jones albuminuria general account of .. 16
Benzene and chloroform, specific gravity measurement with .. 534
Benzoin, in mouth blood-test .. 171
Benzoin acid (see Acid, Benzoin)
Benzoin mercaptane yarm-b 334
Beri-beri, œdema from .. 33
 - **carburetic** from .. 33
 - **decocted rice** and 63, 226, 414
Beri-beri, diagnosis of .. 63
 - **muscle wasting in** .. 63
 - **œdema** in .. 63, 114, 415
 - **peripheral neuritis** from .. 61, 63, 414

- Beriberi, contd.*
 - rigor rare in . . . 595
 - in seamen . . . 414
 - on ships . . . 63
Bial's test . . . 261
 Bicarbonate of soda, heart-
 burn relieved by . . . 297
 - in inflating stomach . . . 317, 319
 - interscapular pain re-
 lieved by . . . 462
 Biceps, atrophy of . . . 513
 - of leg, nerve supply of . . . 498
 - myoclonus of . . . 137
 - nerve supply of . . . 504
 - paralysis of, in Erb's
 palsy . . . 507
 - root innervation of . . . 509
 Biceps-jerk, increased in
 brachial monoparesis . . . 502
 Bicipitals, upper, pain in
 temporal region from . . . 712
 Bilberries, black stools after . . . 75, 385
Bile, inspissated, jaundice
 from . . . 325, 328
 - pigment, tests for . . . 743
 - - (Plate V.XX.F) . . . 759
 - in urine (see Jaundice)
 and Urine, Bile
 Pigment in) . . . 321
 - salts, slow pulse from . . . 321
 - in stools, test for . . . 170
 - urine, foam test for . . . 743
 - in vomit . . . 766
 Bile-duct, carcinoma of
 (see Carcinoma of Bile-
 duct)
 - catarrh, jaundice from . . . 325
Bile-duct, cicatrization of
 325, 329
 - congenital obliteration of . . . 325
 - kinking of, from hepato-
 ptosis . . . 368
 - obstructed by ascaris
 lumbricoides . . . 328
 - carcinoma . . . 326, 330
 - obstruction, carcinoma
 simulated by . . . 371
 - from catarrh . . . 326
Bile-duct obstruction, causes
 of . . . 325
 - clay-coloured motions
 from . . . 326
 - by colour tumours . . . 330
 - by cirrhosis simulated by . . . 372
 - by distoma hepaticum . . . 328
 - enlarged portal glands . . . 30, 51, 330
 - by duodenal tumours . . . 330
 - gall-stones . . . 326
Bile-duct obstruction, general account of
 327, 328, 329, 330, 331
 - by hydatid cyst . . . 328
 - jaundice from . . . 325, 326, 369, 372
 - large liver from . . . 326, 369, 372
 - by liver tumours . . . 330
 - movable kidney . . . 331
 - oncocal tumour . . . 331
 - pancreatic tumours . . . 330
 - ovarian tumours . . . 331
 - pancreatitis . . . 326
 - right kidney tumours . . . 330
 - stomach tumours . . . 330
 - stools pallid with . . . 372
**Bile-ducts, congenital obli-
 teration of** . . . 329
 - rupture of hydatid into
 Bilharzia, cystoscopic ap-
 pearance (Plate XVI) . . . 284
 - hæmatobia, affecting
 bladder . . . 79
 - rectum . . . 79
 - anæmia from . . . 33
 - blood per anum from . . . 79
**Bilharzia hæmatobia, blood
 changes with** . . . 26
 - hæmaturia from . . . 39
 - cystoscopic in diagnosing . . . 282, 472
 - in Egypt . . . 79
 - œsophophila from . . . 219
 - geographical distribu-
 tion . . . 282
Bilharzia hæmatobia, contd.
 - hæmaturia from . . . 33, 275, 282, 581
 - - mucus in stools from . . . 79
 - - ova (Fig. 26) . . . 79
 - - in faces . . . 79
 - - urine . . . 282, 472, 581
 - - pyuria from . . . 575, 580, 581
 - tuberculous bladder . . . 581
 - simulated by . . . 282, 472
 - pain in penis from . . . 471
 - urinary coeli (see Colic, Biliary)
 Biliousness, carcinoma
 simulating . . . 462
 - from delicate exercise . . . 526
 - gall-stone simulating . . . 462
 - from injudicious diet . . . 526
 - interscapular pain from . . . 461, 475
 - pain in shoulder from . . . 526
 - photophobia from . . . 543
 - pythium from . . . 543
 - specks before eyes from . . . 742
 - uric acid and . . . 742
 - vertical headache from . . . 294
 bilirubin in stools . . . 170
 - urine . . . 743, 745
 - urobilin from . . . 743
 biliverdin in urine 743, 745, 747
 Bismann examination,
 carcinoma coli being . . . 354
 - in cases of febrile
 dysentery . . . 427
 - detecting fibrosarcoma . . . 386
 - tubal gestation . . . 468
 - in diagnosing pelvic
 tumours . . . 353
 - pulsatile liver . . . 269
 - differentiating pelvic
 tumours . . . 689
 - hypertrophy of cervix . . . 539
 - inversion of uterus . . . 539
 - for kidney . . . 352
 - in prolapse . . . 539
 Boer's breathing . . . 107
 - allied to Cheyne-Stokes' . . . 81
 - in tuberculous menin-
 gitis . . . 81
 Bird foods, sporotrichosis
 from . . . 290
 Birds, fenders of, asper-
 gillus of lung in . . . 645
 - oval red corpuscles in . . . 266
 - trypanosomes in . . . 28
 - uric acid in . . . 742
 Birth, injury at: Du-
 chenne's palsy from . . . 307
 - milk from breasts at . . . 332
 - palsey . . . 132
 - tremor with . . . 329
 - (and see Childbirth and Labour)
 Bismuth, black motions
 from . . . 385
 - enema, in diagnosing
 carcinoma coli (Fig. 51) 126
 - rectal concretion from . . . 718
 - salts, reduced by glucose . . . 262
 - - glyceronic acid . . . 262
 - - lactose . . . 262
 - - pentose . . . 262
 - substitute, in Holtzger's
 test . . . 262
 - Nylander's test . . . 262
 - sulphide, black stools
 from . . . 75
 - and rays (see X-Rays
 and Bismuth)
 Bite, dog, hydrophobia
 from . . . 158, 197, 730
 - snake (see Snake Bite)
 - tongue swollen from . . . 698
 - bites, lung, relapsing fever . . . 38
 - - spread by . . . 28, 336
 - glands enlarged from . . . 679
 - goat, swelling of face
 from . . . 674
 - - vesicles from . . . 757
 - hydrophobia from . . . 730
 - insect, itching from . . . 549
 - purpura from . . . 553
 - itching from . . . 549
 - leech, purpura from . . . 553
 - mesquite, malaria from . . . 29
 - swelling of face from . . . 674
 - various, fever from . . . 598
Bites, contd.
 - vesicles from . . . 757
 - wheals from . . . 771
 - wolf, hydrophobia from . . . 730
 Biting of tongue, in epilepsy . . . 594
 Biquet test for albumose . . . 16
 Black-dot ringworm . . . 248
**BLACK SPECKS BEFORE
 THE EYES** . . . 71
 - from plethoria . . . 221
 - from scotomata . . . 760
 Blacksmith's heart 130, 206, 484
 - cramp . . . 151
 Blackwater fever, coma in . . . 117
 - hæmoglobinuria in . . . 284
 - quinine acid . . . 284
 - malaria and . . . 284
 - purpura in . . . 555
**Bladder, abscesses opening
 into** 258, 283, 475, 581
 - affections of, pain in the
 back from . . . 428
 - - legs from . . . 442
 - - renal lesion simulating . . . 575
 - - appendicitis opening the . . . 258
 - - appendix adherent to . . . 582
 - - atony of, after recurrent
 over-distention . . . 326
 - - bilharzia affecting . . . 79
**Bladder, bilharzia of (Plate
 XVI)** . . . 284
 - blood-stain in, difficulty
 in micturition with . . . 398
 - carcinoma of (see Car-
 cinoma of Bladder)
 - - invading 258, 283, 394,
 375, 582, 649
 - - caseous gland opening
 into . . . 258
Bladder crises, in tabes 649, 650
 - - displaced, by hyper-
 trophy of cervix . . . 539
 - - distended, urachal cyst
 simulated by . . . 665
 - - catheter in diagnosing . . . 688
 - - cystitis from . . . 15, 665, 688
 - - from enlarged prostate . . . 15, 277, 665
 - - fibroid of uterus simul-
 lated by . . . 688
 - - hypogastric swelling
 from . . . 665
 - - incontinence from . . . 45
 - - ovarian cyst simulated
 by . . . 665, 688
 - - pelvic swelling due to . . . 688
 - - pregnancy simulated
 by . . . 665, 688
 - - from retroverted gravid
 ascites . . . 45, 665, 689
Bladder, distended, signs of 45
 - - simulating ascites . . . 44
 - - tapped in mistake for
 ascites . . . 665
 - - diverticulitis opening the . . . 258
 - - dysenteric bowel opening . . . 582
 - - emptying of over-dis-
 tended, anuria from . . . 49
 - - epithelioma of (see Car-
 cinoma of Bladder)
Bladder, extroversion of 539, 540
 - - simulating prolapse . . . 539
 - - full, prapism from . . . 538
 - - growth, enlarged prostate
 simulated by . . . 336
 - - urethra obstructed by . . . 336
 - - in hernia . . . 683
 - - idiopathic dilatation of
 (Fig. 271) . . . 665
 - - inflamed (see Cystitis)
 - - injury to (see Injury to
 Bladder)
 - - in urethritis, ovarialia and . . . 424
Bladder, irritable 388, 742
 - - stranguary in . . . 649
 - - lay use of (see Layzel)
Bladder, neuroses of 398
Bladder, new growths of 580
 - - - pelvic swelling due
 to . . . 688
 - - normal position of . . . 665
 - - palpable dilated . . . 395
 - - papilloma of (see Papill-
 oma of Bladder)
 - - paralysis of . . . 398
 - - pouch of . . . 678
Bladder, contd.
 - - pressure on, bearing-down
 pain from . . . 426
 - - prolapse of . . . 649
 - - pyosalpinx ruptured into . . . 582
 - - ruptured, from fracture
 of pelvis . . . 278
Bladder, stammering
 - stone in (see Calculus,
 Vesical)
 - - succussion in . . . 652
 - - tuberculous bowel open-
 ing into . . . 582
 - - (see Tuberculosis of
 Bladder)
 - - ulceration of (see Ulcera-
 tion of Bladder)
 - - villous tumour of (see
 Villous Tumour of
 Bladder)
 Blanching, from duodenal
 ulcer . . . 120
 - - leaking aneurysm 120, 651
 - - ruptured aneurysm . . . 434
 - - tubal gestation . . . 129
 - - severe hæmorrhage . . . 120
 - - in typhoid fever 120, 571
 - - (and see Pallor)
 Bleaching powder, Indian
 and . . . 745
**Bleaching Powder test for
 Indican** . . . 314
 Blebs (see Bulle)
 - - emphysematous . . . 531, 532
BLEEDING GUMS . . . 72
 Blepharitis, chronic mar-
 ginal, ectropion from . . . 220
 - - - epiphora in . . . 220
 - - (Plate XII) . . . 232
 Blind spot . . . 760
 Blindness, from amaurotic
 idiocy . . . 761
 - - from anophthalmos . . . 761
 - - cataract . . . 761
**Blindness, complete, general
 account of** . . . 761
 - - congenital, idiocy with . . . 511
 - - from detachment of
 retina . . . 762
 - - electric, erythropsia in . . . 762
 - - photophobia in . . . 762
 - - from embolism of retinal
 artery . . . 762
 - - focal, perimeter in
 mapping . . . 301
 - - from fracture of skull . . . 762
 - - glaucoma . . . 253, 761, 762
 - - hysteria . . . 610
 - - iris . . . 761
 - - migraine . . . 762
 - - monocular, in migraine . . . 759
 - - nystagmus from . . . 497
 - - from ophthalmia neon-
 atorun . . . 761
 - - optic atrophy . . . 761, 762
 - - chiasma lesions . . . 761
 - - nerve compression . . . 762
**Blindness, partial, general
 account of** . . . 760, 761
 - - rapid, from retrobulbar
 neuritis . . . 760, 762
 - - from retinitis pigmentosa . . . 761
 - - snow, erythropsia in . . . 762
 - - photophobia in . . . 762
 - - from spasm of retinal
 arteries . . . 761
**Blindness, sudden, list of
 causes of** . . . 762
 - - from thrombosis of retinal
 vein . . . 762
 - - unilateral (see Hemip-
 anopsia)
 - - in uræmia . . . 759, 761
 - - from vitreous hæmorr-
 rhage . . . 762
 - - (and see Vision, Defects
 of)
 Blinking tic . . . 136
 Blistering, albuminuria from . . . 14
 - - with cantharides . . . 14
 - - in pneumonia . . . 14
 Blisters (see Bullæ)
BLOOD PER ANUM
 - - anæmia from . . . 32
 - - from aneurysm . . . 76
 - - from angiodystasia . . . 81
 - - arsenic . . . 78

Blood per anum, contd.
 — carcinoma 77, 78, 129, 172, 330, 354, 455, 585, 620, 666
 — in chronic nephritis . . . 76
 — cirrhosis . . . 655
 — from colitis . . . 77, 78
 — duodenal ulcer . . . 53, 75
 — dysentery . . . 76
 — edema of pancreas . . . 76
 — fistula . . . 78
 — gastric ulcer . . . 78
 — in Henoch's purpura . . . 76
 — from intussusception . . . 78, 130
 — with invagination of rectum . . . 129
 — in leukaemia . . . 76
 — occult . . . 81
 — from prostatic haemorrhage . . . 76
 — papilloma recti . . . 79
 — polyps . . . 78
 — prostatic amp . . . 79
 — prostatic carcinoma . . . 79
 — prostatic poisoning . . . 747
 — in purpura hemorrhagica . . . 76
 — from rectal polypus . . . 78
 — thread-worms . . . 79
 — tuberculous bowel . . . 657, 666
 — typhoid fever . . . 76
 — ulcerative colitis 172, 459
 — venereal ulcer of rectum . . . 79
 — venous menstruation and . . . 79
 — casts in urine . . . 46

Blood changes in aplastic anemia . . . 24
 — with bilharzia haematobia . . . 26
 — in chlorosis . . . 26
 — in botriosephalus litatus . . . 26
 — in chlorosis . . . 56

Blood changes in chlorosis 274
 — cyanosis from . . . 157
 — with fibrinosis . . . 26

Blood changes in filariasis . . . 28

Blood changes after hemorrhage . . . 33

Blood changes in Hodgkin's disease . . . 37, 64, 569
 — with hydatid disease . . . 26
 — in lymphadenoma . . . 64

Blood changes in lymphatic leukaemia . . . 65
 — in malaria . . . 274, 637

Blood changes in mixed leukaemia . . . 26

Blood changes, parasitic . . . 26

Blood changes in pernicious anemia . . . 22, 24
 — in pernicious anemia . . . 37
 — in splenic anemia . . . 635

Blood changes in spleno-medullary leukaemia 24
 — in splenomegaly . . . 635
 — with trichin spiralis . . . 26
 — in typhoid fever . . . 656

Chairs of Leyden crystals in . . . 192
 — count, in ankylostomiasis . . . 26, 521
 — cysts of lymph-gland enlargement . . . 376
 — diagnosing carcinoma of stomach . . . 271, 317
 — in leukaemia . . . 273, 632
 — in pernicious anemia . . . 274, 634, 770
 — in splenomegaly . . . 635
 — in typhoid fever . . . 656

— essential in splenomegaly cases . . . 634
 — in malaria . . . 273, 568
 — morbus cordis . . . 533
 — peripheral neuritis . . . 64
 — culture, in diagnosing cause of obscure pyrexia . . . 63, 572
 — in malignant endocarditis . . . 34, 209, 566
 — in meningitis . . . 566
 — in pneumonia . . . 555
 — in septicaemia . . . 555, 567, 597, 637
 — in typhoid fever . . . 554, 656

Blood-stains, contd.
 — Malta fever . . . 597
 — in pneumonia . . . 597
 — in pyaemia . . . 597
 — in septicaemia . . . 597
 — in typhoid fever . . . 597

Blood culture, various organisms recovered on . . . 597
 — in abscess in sarcoma . . . 673
 — in diseases, albuminuria with . . . 16
 — in anuria . . . 193
 — in arsenic . . . 717
 — in haematemesis in . . . 266, 273
 — in haemoptysis from . . . 287
 — in infarct of kidney in . . . 7
 — in lymph-gland enlargement in . . . 106
 — in pleuritic effusion in . . . 106

Blood diseases with positive blood pictures . . . 261
 — in pyogenic pyaemia from . . . 555, 556
 — in rigors in . . . 596
 — in spinal cord changes from . . . 640
 — in splenic enlargement in . . . 106
 — in tenderness in . . . 706
 — in thrombotic infarcts in . . . 8, 640
 — in embryos in, in trichinosis . . . 729
 — examination, in diagnosing anaemia . . . 187
 — in chlorosis . . . 274
 — in purpura hemorrhagica . . . 273
 — in extravasation, haemoglobinuria after . . . 284
 — in faldopain tubes distended with (see Hamatoecia) . . . 284
 — in malaria embryos in 28, 109, 226
 — in ulcers, in diagnosing eosinophilia . . . 218
 — in relapsing fever . . . 536
 — in fixing and staining of . . . 21
 — in lymphatic leukaemia (Plate I) . . . 28
 — in malaria diagnosed from . . . 353
 — in parasites in 225, 536, 567
 — in method of making (Fig. 2) . . . 21
 — in pernicious anemia (Plate III) . . . 24
 — in spleno-medullary leukaemia (Plate II) . . . 26
 — in sporochlax obmeroni in . . . 536, 596, 637
 — in guinea-pig test for . . . 10, 75
 — in count, of, cyanosis from . . . 161
 — loss, anemia due to . . . 118
 — in coma from . . . 118
 — in microscope in detecting . . . 75
 — in mucus in stools (see Stools, Blood and Mucus in)

— from nipple . . . 181
 — nose (see Epistaxis)
 — occult, in stools, from ankylostomiasis . . . 81
 — — from carcinoma . . . 125, 126
 — — of pancreas . . . 194
 — — duodenal ulcer . . . 191, 126
 — — in gastric carcinoma . . . 126, 317
 — — in ulcer . . . 191, 126
 — — in pancreatitis . . . 191, 194

Blood, occult, test for 81, 171
 — in count, from gastric carcinoma . . . 630, 767
 — — in ulcer . . . 767
 — — in parasites . . . 27
 — in malaria (see Malaria pigment, carried down by phosphates) . . . 9
 — in per rectum (see Blood per Anum)
 — specific gravity of, in colic . . . 554
 — — in diabetes insipidus . . . 557
 — — in infusion and . . . 554

Blood, specific gravity of, measurement of . . . 534
 — — normal . . . 554, 557
 — — spectroscopic in detecting . . . 75

Blood, contd.
 — swallowed, in metastases from . . . 265
 — in trypanosomes in . . . 28, 236
 — in typhoid bacilli in . . . 561
 — in urea in, in uraemia . . . 85
 — in uterus distended with (see Hamatoecia)
 — in water in excess in, in chlorosis . . . 56

BLOOD-PRESSURE, ABNORMAL . . . 81
 — in acute variations of . . . 84
 — in digital estimation of labile . . . 81
 — in high, accentuated aortic second sound with 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000

Blood-pressure, high, contd.
 — in retinal hemorrhages with . . . 212
 — in retinitis with . . . 145
 — in splenomegaly polycythemia . . . 271, 633
 — in splenomegaly in diagnosis of . . . 485
 — in thrombosis with 212, 487
 — in uraemia . . . 85, 146, 315
 — in vertigo from . . . 752
 — in instrument needed for measuring . . . 81
 — in low, with acute abdominal pain . . . 137
 — in Addison's disease 33, 82, 296, 526, 752, 765, 770
 — in anuria . . . 296
 — in ashenic states . . . 82
 — in cigarette smoking . . . 81

Blood-pressure, low, conditions causing . . . 82
 — in Graves's disease . . . 82
 — in lead pipe from . . . 226
 — in heart disease . . . 226
 — in vertigo from . . . 752
 — need for instrument in measuring . . . 1

Blood-spitting, various causes of (and see Haemoptysis) . . . 285

BLOODY EFFUSION IN CHEST . . . 192
 — in Rotch's paper, stained by washed urine . . . 324
 — in blowing nose, pain on, from frontal sinus empyema . . . 189
 — in blows, death from . . . 166
 — in Babler lips, congenital . . . 628
 — in from lymphangitis . . . 674

Blue brain, general account of . . . 163
 — in eyes, psoriasis and . . . 693
 — in line of the gums in phlebotomy 34, 65, 119, 121, 131, 125, 505
 — in pell, psoriasis from . . . 535
 — in sclerotics with brittle bones . . . 242
 — in Bismuth (see Cyanosis)

Blushing, absence of, from sympathetic paralysis . . . 217
 — in from emotion . . . 241
 — in flushing distinguished . . . 241
 — in from coldness . . . 752

Boeck, in multiple benign sarcoid . . . 165
 — in boiler makers, deafness in . . . 166
 — in nose in the head in . . . 496

Boiling test for albumin . . . 4
Boiling test for albumin, precautions in . . . 424
 — in body, aching in perineum from . . . 474
 — in ankylostomiasis . . . 521
 — in arthritis from . . . 339
 — in ear affected by . . . 293
 — in cow-pox . . . 249
 — in erythema from . . . 289
 — in low stools from (see Green stools from Boer)

— in from dysentery . . . 269
 — in meningitis from . . . 520
 — in on scrotum . . . 625
 — in stiff neck from . . . 647
 — in thrombosis of mucinate vein from . . . 751
 — in Bone, absence of . . . 672

Bone, acute infections of 668
 — in atrophy, in tubes . . . 349
 — in bending of, in osteitis deformans . . . 670
 — in carcinoma of (see Carcinoma of Bone)
 — in cysts of (see Cysts)

Bone, chronic infections of 668
 — in 669, 670, 671, 672
 — in completion, tests for 161, 165
 — in congenital syphilis of . . . 669
 — in delayed by growth (Fig. 624) . . . 152
 — in erosion, by aneurysm . . . 134, 183, 526, 634, 693, 713, 770

Bone erosion, contd.
 - in Kaposi's disease .. 732
 - by rodent ulcer .. 735
 - fibroma of .. 671
 - gumma of .. 348
 - hyaloid of .. 673
 - impacted in oesophagus 495
 - inhaled, gangrene of lung
 from .. 290
 - inosinate, sarcoma of 428
 - in kidney tumours .. 356
 - narrow affections, albuminuria from .. 16, 17
 - - osteophyllia from .. 219
 - hypertrophy, in pericystic anamnia .. 467
 - splenomegaly poly-cythaemia and .. 534
 - necrosis of (see Necrosis)
 - new growth of, muscle atrophy with .. 61
 - rarefaction, in hip dis- ease .. 363
 - - rheumatoid arthritis (Fig. 156) 343, 344
 - of skull .. 152
 - sarcoma of, (see Sarcoma)
 - syphilis of, skilogram showing .. 669
Bone, syphilitic affections of 669
 - swelling on (see Swelling on a Bone)
 - thickened, in osteitis defor- mans .. 670
Bone, tuberculous abscess of 669
 - disease of (see Tubercu- culosis of Bone)
 - tumour of (see Swelling on a Bone)
Bones, bending of, from
 - moliities ossium .. 242
 - from rickets .. 242
 - brittle, in syringomyelia 257
 - brittleness of (see Fragil- itas Ossium)
 - chloroma affecting .. 265
 - curved, in rickets 145, 6 5
 - enlarged, in pulmonary osteoarthropathy .. 352
 - haemorrhage over, in scurvy .. 38
 - malignant disease of, al- bumose from .. 16
 - nasal, necrosis of, from syphilis .. 210
 - overgrowth of, in leontiasis ossia .. 670
 - of skull, rarefaction of .. 152
 - swelling on, from jaws 403
 - tender (see Tenderness in Bones)
 - in rickets .. 145
 - - soury rickets .. 38
 - thickening of, in acromeg- ally .. 406
 - in leontiasis ossia .. 406
 - noises in the head from 406
 - in osteitis deformans 406
 - osteoporosis .. 406
 - from syphilis .. 406
Bones, tumours affecting 670, 671, 672
 - of, in chloroma .. 34
 - roots, bulge from .. 26
 - ill-fitted, limping from 262
 - metastatic neuralgia and .. 439
 - pain in foot from .. 362
 - - paronychia from .. 400
 - tight, tubes from .. 113
 Boracic acid (see Acid, Boric)
BORBORYGMI .. 82
 - absent, in peritonitis .. 82, 388
 - with aerophagy .. 82
 - from asphyxia .. 82
 - in distinguishing colic .. 593
 - from peritonitis .. 82
 - with flatulence .. 82
 - from heart failure .. 82
 - hunger .. 82
 - in hysteria .. 82
 - over ileocecal valve .. 82
 - with intestinal colic .. 125
 - of obstruction .. 131, 388
 - intestinal putrefaction .. 82

Borborygmi, contd.
 - peristalsis and .. 82
 - stethoscope in detecting .. 82
 - in women .. 82
 Bordet-Gengou bacillus .. 645
 Bone and (see Acid, Boric)
 Boric epithelioma .. 684
Bothriophthalmus latus 519
 - albuminuria from .. 13
 - - anaemia from .. 33, 113
Bothriophthalmus latus, blood changes with .. 26
 - - euclyxia from .. 99
 - - eosinophilia from .. 219
 - - head of (Fig. 215) .. 519
 - - oedema of legs from .. 413, 115
 - - severe anaemia from 13, 521
Böttger's test, for sugar .. 262
 Bottle nose, in chronic al- cohohism .. 51
 Bougie, in curing cardio- spasm .. 455
 - in diagnosing foreign body in oesophagus .. 267
 - - oesophagus obstruction .. 267
 - - stenosis .. 125
 - - stricture .. 470
 - - urethral calculus .. 395
 - - stricture .. 394
 - - urethral .. 41
 - in diagnosing stone in ureter .. 455
 - wax-tipped, in diagnosing ureteric calculus .. 472
 Bovine cough with laryn- geal paralysis 494, 195
 - heart .. 207
 Bow legs, from achondro- plasia .. 187
 - from rickets .. 186
 Bowlers, subacromial bur- stitis in .. 476
 Boxing, enlarged heart from .. 214
 Brachyets, acute .. 475, 477
 Brachial (see Artery, Brachial)
Brachial neuralgia 151, 442
Brachial neuritis, general account of .. 443
 - plexus, affected by aneurysm .. 63
 - - cervical rib .. 63, 551
 - - new growth .. 63
 - - weight carrying .. 163
 - - compressed by thyroid gland enlargement .. 722
 - - diaphragm of .. 507
 - - lesions, Raynaud's dis- ease simulated by .. 165
 - - nodal .. 62
 Brachialis anticus, nerve supply of .. 504
 - - root innervation of .. 509
 Brachycephaly .. 237
 Bradshaw, myelopathic albuminuria of .. 17
BRADYCARDIA .. 82
 - from aortic stenosis .. 208
 - apparent, in mitral steu- sis .. 82
 - from cerebral lesions 83, 84
 - - digitalis causing .. 81, 704
 - from drugs .. 84
 - - fatty heart .. 212
 - - fibroid heart .. 213
 - in heart block .. 83
 - jaundice causing .. 84, 329
 - in myxoedema .. 84
 - - physiological .. 82
 - - sodium salicylate causing 84
 - in Stokes-Adams disease .. 83, 146
 - - strophilants causing .. 84
 - - from tuberculous mening- itis .. 81
 - - in uraemia .. 83
BRAOYPNŒA 83
Bradyonæa, list of causes of .. 84, 85
 Brain, abscess of (see Abs- cess, Cerebral)
 - aneurysm of (see Aneurys- m, Cerebral)
Brain, blue general account of .. 103

Brain, contd.
 - carcinoma of .. 301
 - concussion of (see Con- cussion)
 - congenital anomalies of 146
 - contusion, hyperpyrexia from .. 509
 - - cyst of carbon monoxide .. 291
 - embolism of (see Embol- ism, Cerebral)
 - fug, specks before eyes from .. 41
 - - fatigue from .. 766
 - - gumma of 291, 301, 302, 308
 - - hæmorrhage in (see Hæmorrhage, Cerebral)
 - injury, atrophy of testis from .. 66, 67
 - - falling out of beard after .. 67
 - - after .. 67
 - not tinged by jaundice .. 324
 - sarcoma of .. 391
 - syphilis of (see Syphilis, Cerebral)
Brain-stem lesions, effects of 610
 - thrombosis of (see Throm- bosis, Cerebral)
 - tumour of (see Cerebral Tumour)
 - wear, tubes and .. 515

 - second ary in left supra-clavicular gland ... 630
 - simulating carcinoma equina tumour ... 65
 - stragury from ... 419
 - ureters obstructed by ... 419

Carcinoma, contd.
 - palate, cervical glands
 - affected by ... 379, 380
 - foul taste from ... 795
 - microscope in diagnosis ... 588
 - ing. ... 613
 - sore throat from ... 613
 - pancreas, aneurysm from ... 661
 - ascites from ... 49
 - bile pigment in urine
 - from ... 101
 - Cannon's reaction
 - with ... 51, 52, 190, 630
 - carcinoma of duode-
 -num simultaneous ... 661
 - diagnosis from pan-
 -creatic ... 239
 - dilatation of stomach
 - from ... 174
 - fat in faeces with ... 101, 239, 330
 - gall-bladder enlarged
 - with ... 51, 254, 256, 330, 451, 630
 - glycosuria with ... 51, 330
 - iodine co-efficient of
 - urine in ... 100
 - jaundice with ... 239, 244, 326, 330, 451, 630, 661, 662
 - liver tumour simulated
 - by ... 330
 - malignant peritonitis
 - from ... 49
 - occult blood with ... 101
 - pain in hypochochlorium
 - from ... 451
 - proenteritis with ... 100
 - portal glands enlarged
 - from ... 329
 - pulsation of ... 51
 - transmitted by ... 330
 - second ary in left supra-clavicular gland ... 380
 - liver ... 252
 - stereobulb absent with
 - stomach growth simul-
 - lated by ... 330
 - swelling in hypochochlorium
 - from ... 629
 - undigested muscle in
 - faeces with ... 101
 - wasting from ... 661
 - parotid gland ... 695

Carcinoma of penis, general account of
 619
 - impotence from ... 342
 - inguinal glands, sec-
 - ondary to ... 381
 - pain in ... 473
 - ulceration due to ... 617

Carcinoma of perineum
 620
 - achong in perineum
 - from ... 474
 - inguinal glands invad-
 - ed from ... 621
 - peritonium ... 17, 49, 657
 - pharynx, cervical glands
 - affected by ... 379, 380
 - sore throat from ... 613
 - prostate, achong in peri-
 - neum from ... 474
 - age incidence of ... 394
 - calculus simulating ... 470

Carcinoma of prostate, characters of
 470
 - haematuria from ... 281
 - internal metastation
 - from ... 294
 - not uncommon ... 277
 - pain in penis from ... 469, 470, 471
 - rectal examination in
 - diagnosing ... 470, 587
 - retention of urine from ... 649
 - secondary in cranial
 - bones ... 711
 - spine ... 714
 - stragury from ... 649
 - symptoms like those of
 - adenocarcinoma en-
 - largement ... 470
 - priory (see Carcinoma of
 - Stomach)
 - rectum, age incidence of
 - from ... 78, 129, 585
 - albumaturia from ... 7

Carcinoma of rectum, contd.
 - ascites from ... 49
 - backache from ... 469
 - bearing-down pain in
 - bladder invaded by ... 298, 283, 394, 575,
 - 582, 649
 - blood per anum from ... 78, 129
 - and mucus stools
 - from ... 453, 585
 - caechexia from ... 78
 - carcinoma ceci simul-
 - lated by ... 459
 - constipation from ... 78, 129, 453, 585
 - diarrhoea from ... 78
 - difficulty in defecation
 - from ... 78
 - distention of caecum ... 189
 - destruction from venere-
 - al ulcer ... 79
 - dyschezia from ... 129
 - emaciation from ... 585
 - faecal urine from ... 283
 - faeces per urethrum
 - with ... 582
 - flatus per urethrum ... 582
 - with ... 582
 - frequent micturition
 - from ... 394

Carcinoma of rectum, general account of
 585
 - glands infected from ... 585
 - hamaturia from 7, 275, 283
 - impacted faeces simul-
 - lating ... 718
 - incontinence of faeces
 - with ... 313
 - intestinal obstruction
 - from ... 459
 - jaundice from ... 326
 - latent ... 7
 - leucocytes in urine ... 7
 - loss of strength from ... 129
 - weight from ... 129
 - malignant peritonitis
 - from ... 49
 - microscope in dia-
 - gnosing ... 585
 - mucus in stools from ... 129
 - odema of legs from ... 7
 - pain in back from ... 585
 - on distention with ... 585
 - in iliac fossa from ... 452, 453, 459
 - penis from ... 471, 473
 - over scrum from ... 78
 - down thighs from ... 78
 - periproctal abscess,
 - from ... 719
 - piles from ... 581
 - polypos simulating ... 585
 - portal glands enlarged
 - from ... 329
 - proctoscope in dia-
 - gnosing ... 129
 - pyuria from ... 375
 - rectal examination in
 - from ... 78, 129, 130, 453
 - renal tube casts with
 - ribbon-like faeces from ... 7
 - sacral plexus invaded
 - by ... 113
 - secondary in left supra-clavicular gland ... 380
 - in liver ... 252, 585
 - sense of fullness from ... 129
 - sigmoidoscope in dia-
 - gnosing ... 78, 129, 129, 585

Carcinoma of rectum, signs of
 129
 - simulating acute ne-
 - phritis ... 67
 - early equina tumour ... 3
 - speculum in detecting ... 78
 - stragury from ... 649
 - structure from ... 585
 - talipes from ... 113
 - testis from ... 718
 - thrombosis from ... 585
 - ulceration of ... 587
 - unsatisfactory defecation
 - with ... 129
 - wasting from ... 78
 - without symptoms ... 326

Carcinoma, contd.
 - of rib, tenderness from ... 707
 - scaly ... 374
 - serotum ... 626

Carcinoma of scrotum, general account of
 624
 - sigmoid colon, tumour
 - and x-rays in dia-
 - gnosing ... 459
 - bladder invaded by ... 582
 - opened by ... 238, 575
 - blood in stools from ... 666
 - and mucus from ... 453
 - caechexia from ... 666
 - carcinoma ceci simul-
 - lated by ... 459
 - colloid change in ... 676
 - constriction from ... 473
 - distention of caecum ... 189
 - diverticulitis simul-
 - lating ... 676
 - explosive diarrhoea
 - from ... 313

Carcinoma of sigmoid colon, general account of
 453, 676
 - haemorrhage from ... 508
 - impacted faeces simul-
 - lating ... 453
 - obstruction
 - from ... 459, 666, 676
 - operation in dia-
 - gnosing ... 676
 - pain in iliac fossa
 - from ... 452-454, 459
 - palpable tumour with ... 473
 - pyuria from ... 375
 - sigmoidoscopic meth-
 - od ... 453, 676
 - specific constipation
 - simulating ... 473
 - swelling in left iliac
 - fossa from ... 666
 - tumours from ... 666
 - tuberculous sigmoid
 - simulating ... 666

Carcinoma of skin, general account of
 730
 - lupus simulating by ... 192
 - rhinoscleroma simul-
 - lating ... 733
 - syphilitic distinguished
 - from ... 192
 - from syphilitic ... 728
 - from x-rays ... 223
 - of spinal cord, malinger-
 - ing simulated by ... 472
 - pain in the chest
 - from ... 472
 - of spine, interscapular
 - pain from ... 461
 - kyphosis from ... 154
 - malingering simulated
 - by ... 467
 - secondary to breast
 - gland ... 454, 648
 - spleen, excessive tenderness
 - of ... 632

Carcinoma of splenic flexure, general account of
 630
 - skiagraph showing ... 425
 - stragury, tenderness from ... 297
 - stomach, abdominal tu-
 - mour with ... 270, 271
 - acetonaemia from ... 4
 - age incidence of ... 269, 316
 - albuminuria with ... 46
 - anaemia in ... 270, 271, 630
 - aneurysm in dia-
 - gnosing ... 271
 - aneurysm simulated by
 - (Fig. 288) ... 694
 - anoxia from ... 270
 - nervous simulated
 - by ... 467
 - ascites from ... 51, 329
 - bile duct obstructed by ... 330
 - blood clots with ... 317
 - examination in ... 271
 - in gastric contents
 - with ... 317
 - oedema from ... 270
 - carcinoma of duo-
 - denum simulating ... 661
 - osophagus simul-
 - lating ... 165
 - pancreas simulating ... 370

- Carcinoma of stomach, contd.*
- of the fundus and vomit . . . 269
 - colour index in . . . 271
 - x-ray simulating . . . 653
 - deposits in . . . round
 - dependent from . . . 656
 - at umbilicus from . . . 656
 - diffuse, difficulty of diagnosing . . . 107
 - in rubber bottle
 - stomach from . . . 107
 - multiple serous effusions from . . . 107
 - secondary in liver . . . 274
 - serous effusions from . . . 274
 - skin on of . . . 270
 - without symptoms . . . 243
 - dilated stomach from . . . 174, 271, 316, 653, 678, 767
 - disintegration for meat due to . . . 43, 316
 - distinguished from . . . ulcer by x rays . . . 174
 - dyspepsia from . . . 316
 - simulated by . . . 270, 769
 - dysphagia from . . . 135
 - epigastric pain from . . . 270
 - tumour with . . . 317
 - fragments of growth in vomit . . . 766
- Carcinoma of stomach, gastric HCl in 33, 316, 270, 436, 630, 653, 766, 767**
- gastritis simulated by . . . 270
 - in left supraclavicular space . . . 271
- Carcinoma of stomach, general account of 269, 316, 317, 630**
- Lemnasteriosis from . . . 269
 - heartburn from . . . 297
 - hiccough from . . . 598
 - hysterical vomiting simulated by . . . 467
 - in blue fossa . . . 678
 - interscapular pain from . . . 461, 462
 - jaundice from . . . 329, 330
 - lactic acid with . . . 767
 - laparotomy in diagnosing . . . 174, 271
 - Oppler-Bass bacilli in . . . 317, 653, 769
 - leuk . . . 531
 - leukocytosis from . . . 630

- Cataract, anterior polar, from ophthalmia neonatorum . . . 759**
- ulcer of cornea . . . 753
 - black spots before eyes from . . . 72

Cataract, condt.
 - blindness never complete from 761
 - congenital, nystagmus from 407
 - in diabetics 261
 - diplopiæ from 175
 - extraction, erythropia after 592
 - multiple images from 175
 - ophthalmoscope in diagnosing 175
Catarra of bile-ducts, chyl-coloured stools from 326
 - jaundice from 326
 - cervical, backache from 646
 - sterility from 646
 - of shoulder, pain in 174
 - in sub-ascensu from 642
 - from aneurysm 642
 - from abscess 642
 - common cold 642
 - epistaxis from 220
 - hay fever 642
 - itchy 642
 - in measles 642
 - in sneezing due to 643
Catarrh of small intestine, causes of 172
Catarrhs, conjunctivæ (see Conjunctivæ, Catarrhs)
Caterpillar hair, dermatitis from 555
 - pruritus from 540
Catheter, condt., for enlarged prostate 396
 - in diagnosing bladder distention 45, 665, 688
 - calculus in prostate 470, 473
Catheter, in diagnosing cause of pyuria 575
 - ureteral structure 591
 - in obtaining urine cultures 218, 455
 - ureteral, in diagnosing stone in ureter 455
 - in urethra, discharge due to 181
Catheterization, anuria after 42, 396
 - death after 396
 - epididymo-orchitis from 478
 - rigor after 391, 395
Cats, fever from bite of 595
Catle, anthrax from 549
 - terna medullæ cervicis and caudæ equinæ, tumour of 619
 - peripheral neuritis simulated by 545
 - lesions, acute bedsores from 258
 - gangrene from 255
 - relaxed sphincter with 314
 - sarcoma of 62
 - tumour of, anaesthesia from 62
Cauda equina, tumour of, general account of 62
 - muscle wasting from 61, 62
 - pain in the back from 62, 545
 - leg from 62
 - paralyzed leg from 62
 - one leg first from 545
 - paraplegia from 544, 545
 - pelvic tumour simulating 615
 - peripheral neuritis simulated by 615
 - R. D. from 61, 62
 - rectal examination in 63
 - sacro-coccygeal joint disease simulating 63
 - serotica simulated by 62, 439
 - vaginal examination of 63
Cautie potash (see Potash, Cautie)
 - soda, in acetone test 16
 - in biuret test 16
 - estimating acidity 329
 - examining for chloride fibres 86, 642

Cautie soda, condt.
 - Nyländer's test 262
 - in producing hæmatin 284
Cauterization, for ulcers
 - serpiginous 734
Cavernous lacerating, over
 - fibrous ligum 168, 246
 - sinus (see sinus, cavernous)
Cavitation, in phthisis 643
Cayenne pepper deposit in urine 741
Cellist's cramp 151
Cellulitis, from abraded toe 410
 - bacteriological diagnosis of 413
 - of calf, talipes from 114
 - carbuncle simulating 539
 - in cutaneous wounds 240
 - erythema from 222
 - goat simulated by 410
 - hæmorrhagic with 410
 - of neck, from actinomycetosis 685
 - stridor from 651
 - œdema from 110, 415, 415
 - orbital, distinguished from cavernous sinus thrombosis 230
 - epithelium from 229
 - tubercle simulating 230
Cellulitis, pelvic, notes on 659
 - pelvic swelling due to 688
 - pyæmia with 410
 - red streaks in 410
 - from septic finger 229
 - sinus thrombosis from 229
Cellulose, acetate of, in aeroplane varnish 334
Central canal of spinal cord 62
Centre, chloro-kinaesthetic (Fig 296) 624
 - glosso-kinaesthetic (Fig. 296) 624
 - for vomiting 564
Centres in brain, for speech (Fig. 296) 624
 - micturition 297
 - reflex, in cord (Fig. 211) 548
Cerebellar artery, posterior, effects of lesions of 58
 - atrophy, after specific fevers 729
 - tremor from 729
 - hæmorrhage 538, 768
 - peduncle lesion, tremor from 729
 - tracts, role in co-ordination 55
 - tumour, ankle-clonus from 547
 - ataxy from 58, 547, 592
 - Babinski's sign with 68
 - bradycardia from 84
 - cerebellar abscess simulating 547
 - disseminated sclerosis simulating 547
 - falling to one side from 547
 - head-ache with 547
 - hesitant voice from 547
 - hypothermia with 311
 - intention tremor from 547
 - knee-jerk increased from 547
 - lateral sclerosis from 68
 - nystagmus with 107, 517, 592
 - obesity from 408, 410
 - optic atrophy from 592
 - paræsthesia with 547, 592
 - paraplegia from 544
 - retracted head from 589, 592
 - scanning speech from 547
 - sphincter troubles from 547
 - tendon reflexes exaggerated with 592
 - vertigo from 552
 - vomiting with 547
Cerebellum, abscess of (see Abscess, Cerebellar)
 - centre for equilibrium 751
 - epithelium of, ataxy from 58
Cerebellum, lesions of, causing ataxy 58, 59

Cerebrum, convulsions, from
 - exit with 58
 - nystagmus from 59
 - speech changes from 59
 - vertigo from 58
 - rooting from disease of 59
 - role in co-ordination 251
Cerebral abscess (see Abscess, Cerebral)
 - aneurysm (see Aneurysm, Cerebral)
 - arteries, atheroma of 1, 406
Cerebral disease, general signs of organic 295
Cerebral dwarfism 188
 - embolism (see Embolism, Cerebral)
 - hæmorrhage (see Hæmorrhage, Cerebral)
 - tumour, hypertrophy of cerebro-spinal fluid with 504
 - peduncles, ataxy from lesions of 58
 - softening, albuminuria with 435
 - from arterial degeneration 108
 - caisson stroke 108
 - Chyves-Jakes fever 102 from 108
 - deep reflexes increased from 725
 - diplopiæ from 547
 - from embolism 108, 545
 - endarteritis 545
 - general paralysis 108
 - glycosuria with 435
 - hyperæmia from 509
 - hæmorrhage 545
 - large cerebral artery 495
 - mental failure from 725
 - paralytic agitated simulating 725
 - period from 544
 - paraplegia from 589
 - sis from 589
 - rigidity from 725
 - round an abscess 296
 - a tumour 296
 - sphincter trouble from 725
 - from syphilis 108, 545
 - thrombosis 545
 - weakness from 725
 - syphilis (see Syphilis, Cerebral)
 - thrombosis (see Thrombosis, Cerebral)
 - tumour, aphasia from 626
 - arteriosclerosis simulating 295
 - atrophy of muscles from 447
 - aura with 68
 - Babinski's sign with 68
 - binocular homopteria from 502
 - bradycardia from 84, 741
 - bradyopia from 81
 - Chyves-Jakes hæmorrhage from 108
 - choked disc from 596
 - coma from 117, 444
 - first sign of 448
 - convulsions with 68, 144, 146, 447
 - diabetes insipidus from 557
Cerebral tumour, distinction from abscess 84
 - dreamy state from 68
 - desquama simulated by 345
 - edo and flow of knee-jerk with 279
 - goldiness from 292, 294
 - glycosuria from 294
 - hæmorrhage into 591, 596
 - head-ache from 147, 264, 295, 392, 396, 315, 429, 592, 595
 - 557, 626, 768
 - micturid. from 294
 - hemianopsia from 592
 - hemiplegia from 68, 392, 706
 - hyperæmia from 295
 - hyperæmia from 299
 - hyperæmia with 311

Cerebellum, condt.
 - ataxy simulated by 727
 - in anuria from 321, 322
 - Jacksonian epilepsy from 337, 359
 - knee-jerk lost with 596
 - latent 596
 - lead poisoning simulating 419
 - lumbar puncture in diagnosing 525
 - lymphocytes in cerebro-spinal fluid in 205
 - myoclonic simulating 38
 - noises in the head from 410
 - obesity with 410
 - optic neuritis from 147, 264, 545, 429, 592, 595, 597, 626, 711
 - pain in the face from 447
 - foot from 68
 - pot dyes from 147, 215
 - paresis from 711
 - simulator of from 418
 - photophobia from 525
 - pupil small with 552
 - without signs of pressure 592
 - simulating cerebral hæmorrhage 206
 - tremor 429
 - softening round 206
 - taste loss from 396
 - tenderness of scalp from 719, 711
 - tremor from 721, 727
 - the double-barrel simulating 447
 - tinnitus from 725
 - uræmia simulating 85
 - vertigo from 752
 - vomiting from 117, 264, 292, 396, 515, 429, 592, 595, 597, 626, 711, 765, 768
 - visual aura with 68
 - you see Vomiting, Cerebral
Cerebral vomiting 81, 295, 315, 767
Cerebritis (see Encephalitis, Cerebral)
 - cerebral fever (see Meningitis, Cerebral)
 - fluid, albumin traces 421
Cerebrospinal fluid, bacteriological examination of 305
 - albumin, in diagnosis 367
 - in diagnosing meningitis 599
Cerebrospinal fluid, from ear 119, 421
 - Lichtheim's solution reduced by 178
Cerebrospinal fluid, general characters of 304, 305
 - in general paralysis 129, 245, 296
 - lymphocytes in 446, 429, 544
 - in general paralysis 245, 296
 - tubes 449
 - meningitis 541
 - meningococci in 599
 - from nose, due to fracture of base 149, 178
 - polymorphonuclear 541
 - rate of flow of 294
 - reducing power of 294
 - not tinged by jaundice 592
 - trypanosoms in 28
 - tubercle bacilli in 599
 - urea in, in uræmia 85
 - Wassermann reaction in 116, 120, 395
 - xantho-protein reaction in 304

Children, scurvy in 72, 556
 — — severity mature in . . . 188
 — — stoma arthralgia in . . . 545
 — — — splenic purpura in . . . 132
 — — spinal caries in . . . 715
 — — spleen enlarged in 272, 634
 — — — palpable normally in 634
 — — splenomegaly erythrosis of 532

Children, Still's disease in 35, 378
 — — syphilitic arthritis in . . . 348
 — — — liver in . . . 372
 — — syphilitic bruit over mammillary in . . . 91
 — — — tubercle points in . . . 110
 — — — tachyarrhythmia in, from exanthems bronchial glands in . . . 85
 — — — tetany in . . . 7, 151

Children, thermometry in, notes on . . . 573
 — — tuberculous, anorexia in 43
 — — tuberculous, cervical glands in . . . 580
 — — — dactylitis in . . . 668
 — — — ear disease in . . . 122
 — — — haematuria in . . . 590
 — — — peritonitis in . . . 47, 48

Children, unexplained pyrexia in 571
 — — — articular in . . . 489
 — — — vomiting in fever of 761, 765
 — — — from worms in . . . 767
 — — — Werdnig-Hoffmann paralysis in . . . 135
 — — — water in tissues of . . . 381
 — — — Child, acute nephritis from 281
 — — — — after . . . 132
 — — — — in infant in . . . 467
 — — — — pain in the limbs in 463
 — — — — tremor from . . . 727
 — — — — urticaria in . . . 594

CHILLS 594
 — — (and see Rigors)
Chimney-sweep's cancer 621
 — — — chin, one affecting . . . 489
 — — — blow on, ear mured by . . . 421
 — — — dropping of, in nyctars . . . 255
 — — — — heavy, in acromioclavicular . . . 257
 — — — — irritation, hæmorrhage from 307
 — — — — swelling, in microcephaly 188
 — — — — syphilis affecting . . . 558
 — — — — sphuloderma of . . . 490

China, distoma pulmonale . . . 292
 — — — lung fluke in . . . 645
Chloasma, in phthisis 527
 — — — — pigmentation in . . . 527
 — — — — time, vesicular simu- lating . . . 250
 — — — — uterinum . . . 99, 527
 — — — — from vesicities . . . 527

Chloral, breadpoan from 84
 — — — — Chlores Stokes' breath- ing from . . . 108
 — — — — coma from . . . 118
 — — — — erythema from . . . 222
 — — — — hyperthermia from . . . 311
 — — — — purpura from . . . 555
 — — — — reduction by urine after 261
Chloralamide, erythema from . . . 222
Chlorate of potash (see Potassium Chlorate)
Chloride of barium, in bile- test . . . 714
 — — — — carbureta in . . . 747
Chloride of calcium (see Calcium Chloride)
 — — — — sodium, thirst from . . . 720
 — — — — sulphur, acute yellow atrophy from . . . 337
 — — — — — in urine from 325, 334, 337
 — — — — — in lymphatic fluid 376
 — — — — — phosphaturia and . . . 525

Chlorides, contd.
 — — in urine, absent in pneu- monia . . . 160
 — — — — defect in pneumonia 335
 — — — — diminished in nephritis 10
 — — — — in phosphorus poison- ing . . . 356
Chlorine, ergyza from . . . 178
 — — — — sore throat from . . . 613
 — — — — stridor from . . . 650

Chloroform and benzine, specific gravity mea- surement with . . . 534
 — — — — hydrolytic from . . . 81
 — — — — cold from . . . 118
 — — — — glycerone acid from 264
 — — — — haemohæmaturia from . . . 284
 — — — — headache from . . . 295
 — — — — in Indian test . . . 514, 745
 — — — — methylene blue and . . . 747

Chloroform poisoning, de- layed . . . 4
 — — — — tetany from . . . 151
 — — — — reduction by urine after 261
 — — — — in tetanus . . . 730
 — — — — urticaria from . . . 725

Chloroma 39, 556
 — — — — age, incidence of . . . 338
 — — — — carcinoma in . . . 32, 39
 — — — — blood changes negative in 556
 — — — — bone swellings in 29, 295, 556
 — — — — green tumours in 39, 556
Cholebrim glands enlarg- ed in . . . 556
 — — — — lymph glands enlarged in . . . 205, 556
 — — — — lymphocytes in cerebro- spinal fluid in . . . 305
 — — — — purpura in . . . 352
 — — — — related to leukæmia . . . 556
 — — — — lymphosarcoma . . . 39
 — — — — salivary glands enlarged in . . . 556
 — — — — simulating lymphatic leukæmia . . . 205
 — — — — spleen enlarged in . . . 295
 — — — — spontaneous fracture from . . . 242

Chlorosis, age, incidence of 36
 — — — — albuminuria rare in . . . 37
 — — — — — in infancy in 18, 37, 274
 — — — — — in infancy in . . . 22
 — — — — blood changes in 56, 274
 — — — — brittle or fragile in . . . 299
 — — — — cachexia, chlorotica . . . 39
 — — — — — scrotonium for . . . 39
 — — — — colour index in . . . 26
 — — — — constipation in . . . 37, 125
 — — — — cured by marriage . . . 271
 — — — — — dyspnoea in . . . 271
 — — — — — epistaxis in . . . 221
 — — — — — flushing in . . . 211
 — — — — — gastric ulcer in . . . 271
 — — — — — gastrostaxis in . . . 271

Chlorosis, general account of 36, 274
 — — — — hæmatemesis in 299, 274
 — — — — hæmic bruits in . . . 37, 39, 299
 — — — — heart impulse displaced from . . . 299
 — — — — iron in . . . 36
 — — — — noises in the head with 106
 — — — — nourishment good in . . . 274
 — — — — occupation and . . . 36
 — — — — oedema in 37, 274, 413, 415
 — — — — palpitation in . . . 271, 484
 — — — — — pleurisy in . . . 36
 — — — — pulmonary systolic bruit in . . . 91, 299
 — — — — rest in bed in . . . 36
 — — — — sclerotic blush in . . . 274
 — — — — sex, incidence of . . . 26
 — — — — skin greenish in . . . 274
 — — — — therapeutics in diagnosis . . . 26
 — — — — — uterine menstruation and . . . 274
 — — — — — (and see Anæmia)
Choleliths and milk pus, from hepatic abscess 257
 — — — — — excrete from . . . 424
Choked disc (see Neuritis, Optic)
Cholæmia, in cirrhosis . . . 332
 — — — — — coma from . . . 117, 321
 — — — — — convulsions from . . . 324
 — — — — — death from . . . 324

Cholera, contd.
 — — delirium from . . . 324
 — — — — head ache from . . . 296
 — — — — from ptarmine . . . 324
 — — — — stupor from . . . 324

Cholenteric, abscesses of
 — — — — liver from . . . 332
 — — — — albuminuria with . . . 16
 — — — — from carcinoma 326, 333, 662
 — — — — emphyema from . . . 106
 — — — — of gall-bladder . . . 335
 — — — — gall-stones 264, 326, 333, 397
 — — — — — umbilic from 326, 332, 360
 — — — — — tenocystitis with . . . 369
 — — — — — liver abscess from 333, 369
 — — — — — pain in the back from . . . 746
 — — — — — pleurisy from . . . 196
 — — — — — rigors from 326, 333

— — — — — septicæmia from . . . 637
 — — — — — tender liver with 333, 369
 — — — — — in typhoid fever . . . 333
 — — — — — uræmia with . . . 101

Cholecystitis, diodenal ul- cer simulated by . . . 150
 — — — — — exploration in diagnosis 150
 — — — — — indigestion simulated by 316
 — — — — — pain in hypochondrium . . . 150
 — — — — — — shoulder from . . . 473
 — — — — — plantoma tumour simu- lating . . . 659
 — — — — — pleurisy simulating . . . 132
 — — — — — pyrexia from . . . 150
 — — — — — rigors from . . . 150, 595
 — — — — — suppurative from gall- stones . . . 597
 — — — — — — rigors from . . . 597

Cholelithiasis (see Gall- stones)
Cholelith, albuminuria in . . . 13
 — — — — — anuria in . . . 42
 — — — — — blood impregnated in 161
 — — — — — Chlores Stokes' breath- ing in . . . 108
 — — — — — coma in . . . 147
 — — — — — — comma bacilli in . . . 717
 — — — — — cramps after . . . 152
 — — — — — cyanosis in . . . 161
 — — — — — gangrene from . . . 255
 — — — — — general wasting from . . . 39
 — — — — — hæmatemesis in 263, 274
 — — — — — hyperpyrexia in . . . 314
 — — — — — indigestion from . . . 314
 — — — — — leucocytosis in . . . 560
 — — — — — in hæmia, cyanosis from 157
 — — — — — menorrhagia from . . . 386
 — — — — — nephritis from . . . 9

Cholera nostras 717
 — — — — — pain in the limbs in 463
 — — — — — polyæthæmia in . . . 523
 — — — — — purpura in . . . 553
 — — — — — pus in stools from . . . 557
 — — — — — re-water stools in 273, 717
 — — — — — — rare in . . . 325
 — — — — — severe hæmaturia in . . . 325
 — — — — — simulated by trichinosis 484
 — — — — — tonsillitis in . . . 717
 — — — — — thyroid gland enlarged in 722
 — — — — — uræmia in . . . 655
 — — — — — Vibrio in motions in (Fig. 124) . . . 275

Cholesterin crystals (Fig. 124) . . . 254
 — — — — — in hydrocele . . . 695
 — — — — — in mucus . . . 254
Cholesterol in ascitic fluid 50
Cholesterol, in cerebrospinal fluid . . . 305
 — — — — — — perleche . . . 395
 — — — — — — potassium chloride crystals 395
Choluria . . . 741
 — — — — — from fistula between bile- duct and urinary tract 744
 — — — — — (and see Jaundice)

Chondroma, of breast . . . 686
 — — — — — band . . . 671
 — — — — — — pain, pain in iliac fossa from . . . 151, 460
 — — — — — — pain in . . . 671
 — — — — — — of tuberculous . . . 678
 — — — — — — abscess over . . . 671
Chorda tympani, paralysis of (see Paralysis of Chorda Tympani)
CHOROE . . . 134
 — — — — — from fracture of penis . . . 108
 — — — — — — smorrhœa . . . 108, 617

- Chloroform* 108
 from renal 175
 from pain from 175
 Chloroform, acute incidence of 133
 arsenic in 66, 717
 ataxia distinguished from 133
 Babinski's sign in 69
 - chronic 134
 - degenerative 134
 - duration of 133

Congenital heart disease, contd.

Congenital heart disease, heart large from 31, 215

Congenital heart disease, notes on 720

- palpitation from 484
- patent septum ventriculorum 111, 533
- phthisis and 588
- polythaemia with 215, 533
- pulmonary stenosis 533
- prognosis in 457
- rarer types of 111

Congenital heart disease, symptoms of 215

- systolic apical murmur from 89
- thrills with 157, 720
- trysts in 91

Congenital hernia 682

- hypertrophy of cervix 529
- hypoplasia of bowel 123
- phthisis 400
- lymphangioma circumscriptum 756
- microcephalia 698
- macroglossia 698
- malformation, E. epididym from 304
- meningocoele from 310
- of pelvic organs, dysmorphism from 192

Congenital malformations, of rectum (Figs. 219)

- 2521 586
- spuria lobuli from 540
- of uterus, detection of menorrhagiae 694
- myxosarcoma 388
- narrowness of anal canal 129

Congenital obliteration of bile ducts 139

- obstruction of duodenum from 130
- biliary ducts 220
- ascites 110
- optic nerve blindness 544
- perforation of palate 588
- persistence of pupillary membrane 551
- ptosis 542
- pulmonary regurgitation 93
- stenosis (see Pulmonary stenosis)

Congenital pyloric stenosis 384

- plastic pyloric, kyploplastic 155

Congenital syphilis (see Syphilis, Congenital)

Congenital systolic bruits 90, 91

Congenital talipes, general account of 112

- tremor 721, 725

Conjunctival test for free HCl 320

Connective, bright, in Graves's disease 256

Deposits in, in Gaultier's disease 634

- in eyes of 754
- in meso- in glioma 255

Ochromosis, of (Plate XXVIII) 746

- in pernicious anaemia 324
- pigmental, in ochromosis 746
- serous of 754
- yellow, from porph. acid 529

Conjunctivitis, acute (Plate XI) 250

- angular 251
- blinding the from 136
- diptheritic 251, 558, 724
- diptheroid of 254
- epithelial 229
- of eyelids of sex in 251
- follicular (Plate XI) 250, 251

Conjunctivitis, general account of 231

- gonorrhoeal 251, 724

Conjunctivitis, iritis, and glaucoma compared 232

- by laceration from 251
- membranous 251
- obstructed, lachrymal duct mistaken for 229

Conjunctivitis, contd.

- pain from 231, 445, 446
- phlyctenular (Plate XI) 239, 251
- ulcer with 734
- photophobia from 271, 524
- ptosis from 544
- rainbow vision from 562
- staphylococci causing 251
- ulcer of cornea with 231, 733
- serous of, myeloid 763
- Connective tissue, undigested, in faces 104, 179, 172

Consciousness, double, hysterical 20

- loss of (see Coma)
- vague dreamy state of, with cerebral tumour 68

CONSTIPATION 121

- abdominal swelling from 121

Constipation, acute, causes of 129, 130, 131

Constipation, acute, distinction from intestinal obstruction 129

- from embolism of pancreas 76
- faces in rectum in 129
- from haemorrhage into pancreas 76
- rectal examination in 129
- from acute congestion of liver 334
- paracanth 131, 664
- peritonitis 131
- yellow atrophy 333
- adhesions 124
- agargar from 124
- anamia from 32
- in anamia girls 125, 112
- from anal ulcer 128
- with anaemia nervosa 43
- from aperients 121
- appendicitis 124, 126, 131, 665, 677
- with ascites 127
- from asthma 128
- belladonna relieving 124
- with biliary colic 131
- in cachectic states 123
- from carcinoma 77, 78, 126, 330, 385, 650
- in catarrhal proctitis 329
- charcoal test for 121
- in chlorosis 37, 125
- in chronic peritonitis 47
- colic with 145, 122
- from colitis 121
- colonic ascension from 654
- from congenital obliterations of bile-ducts 329
- cumulative 121
- dating from infancy 123

Constipation, from deficient intestinal motor activity 123

- from deficient sensibility 124
- definition of 121
- from disease of duodenum 124
- of bladder 121
- of genital organs 124
- stomach 124
- disregard of call to evacuate 128
- obstruction of colon from 656
- diverticula from 125, 453
- from diverticulitis 125
- emphysema 128
- with enterospasm 178
- enuresis from 248
- luminal 125
- from fatty bowel 123
- in fever 123
- flatulence causing 123
- flatus from 246
- food breath from 87
- fragmentary 121
- from gastritis 267
- from greasy colon 123
- habitual (Plate XI) 122
- from haemorrhage into pancreas 264
- from hardness of faeces 128
- headache from 256

Constipation, contd.

- in Henoch's purpura 76
- Hirschsprung's disease 133, 390
- with hypertrophic stenosis of pylorus 766
- in hypochondriasis 124
- from hypoplasia of bowel muscle 123
- from hysteria 123
- from ilio-caecal kink 157
- mesenteric, from carcinoma 130
- in melaemia from 114
- in infants 128
- from inflamed piles 128
- inhibitory, rays in diagnosis 124
- from insanity 124
- in oedema from 77, 321
- intestinal, aperients in relieving 122
- diet in relieving 122
- dyscholia distinguished from 121

Constipation, intestinal, general account of 122

- palpable scybala in 121
- from intestinal fermentation 241
- obstruction 241, 246, 388, 522, 592, 597
- intussusception 127, 678
- invagination of rectum 129
- kink of colon 126
- large abdominal tumour 127
- with lead colic 131
- from lead poisoning (Figs. 54) 34, 124
- after leaving duodenum 126
- ulcer 126
- gastric ulcer 126
- lessening effect of purgatives in 122
- in Malta fever 126
- megalitis 128
- menorrhagia from 386, 387
- with mesenteric embolism 131
- thrombotic 131
- in microbismiosis, colitis (Figs. 52) 124
- mucous colitis 116
- mucous in stools from 398
- in myelitis 128
- from nervous depression 124
- in neurasthenia 121
- noises in the head from 106
- with obesity 127
- from oesophageal obstructions 123
- in old age 125
- opening relieving 124
- opening by finger in rectum 128
- from pain in abdomen 124
- pancreatitis 264, 594, 767
- pericolic abscess 663
- with peritonitis 126, 592
- petroleum for 125
- photophobia from 525
- pigmentations from 528
- after pregnancy 126
- pseudo-Berberis with 121
- from purpura 123
- from pyloric obstruction 121
- with renal colic 154
- in rickets 145
- from shock 123, 145
- soap in overcoming 124
- from splenic induration 121
- spasm of splenic artery 128
- spastic, abdominal pain from 245
- absconded caecum with 124

Constipation, spastic, general account of 124

- in mesenteric colitis with 125
- pain in left iliac fossa from 152
- sense of fullness from 245
- simulating appendicitis 124
- bowel tumour 124
- carcinoma colic 155
- rays in diagnosing 124, 245

Constipation, contd.

- scybala palpable in 124
- with spinal cord lesions 243
- from strangulated hernia 682
- Constipation, symptomatic** 131
- in talipes dorsalis 128
- from tea-drinking 128
- from too high water 128
- too little food 123
- toxicant from 106
- with tropical liver 369
- from tuberculous peritonitis 657
- with twisted ovarian cyst 131
- types of 121
- in typhoid fever 364, 595
- with undue abdominal aortic pulsation 543
- vertical, headache from 294
- with visceropostosis 127
- with vomiting, in Henoch's purpura 76
- from worry 124

Constipation, x-rays and barium in diagnosing 122

- in yellow fever 256

Contracturas, lamstrans, elongated in 156

- lachrymation in 156

CONTRACTURES, ATHE-

- TOTIC, etc. 131
- catopodal, in tetany 739

Contractures, choreiform 133

- contractures distinct from 131
- cramps distinguished 131

Contractures, fibrillar 131

Contractures, spasmodic 136

Contractures, spasmodic, causes of 126

Contractures, tetanic 137

- Contracture, Volkmann's, 111, 506
- nerve paralysis simulating 506

CONTRACTURES 138

Contractures, active 139

- atrophic and 137
- simulated by 352
- in brachial monoplegia 502
- after a burn (Figs. 60) 142, 143
- contractions distinct from 151
- cramps simulating 139
- in diplegia 139

Contractures, from disease 141

- after enteritis 141
- facial 140 (Figs. 198-200) 192, 194
- in Frodoch's disease 140
- from hemiparalysis 140

Contractures, hysterical 141

- from list of sclerosis 141

Contractures, list of causes of 138, 139

- from lower motor lesions 251
- massage in preventing 141
- movement in preventing 141
- from nerve injury 141
- neuritis 140
- neuritis and 142
- of palmar flexor 142
- of polymyositis 140, 146
- from prolonged rest 141
- spasm 142
- tetanus 142

Contractures, spastic 139

- from lesion injury 143
- Confusion of limb, genuine of lung from 260
- spinal cord, paraplegia from 538
- arhythmia in 545
- cough during 149
- cramps in 152
- by paresis during 309
- hypothermia in 311
- knee-jerk exaggerated in 358
- oedema of legs in 411, 415
- polyuria in 555, 556
- paraplegia in 558
- shortness of breath in 88
- slow pulse in 548
- tachycardia in 701
- tremor in 721, 725
- vertigo from 752

- CONVULSIONS** 143
 - in acute yellow atrophy 333
 - albuminuria from 144
 - from alcohol 144, 145, 146
 - aphasia after 626
 - in apoplexy 144, 147, 148
 - from arachnoid hemorrhage 146
 - asphyxia 144, 146
Convulsions, associated with coma 144
 - from atropine 144
 - bloody saliva in 143
 - from brain lesions 85
 - cerebellar abscess 146
 - cerebral abscess 146, 147
 - - aneurysm 146
 - - disease 295
 - - syphilis 144, 146
 - - tumour 146, 147
 - cerebritis 146
 - cholera 224
 - congenital heart 144
 - cyanosis in 143
 - in disseminated sclerosis 144, 144
 - from drugs 144, 145
 - ear disease 144
 - in eclampsia 146
 - from emotion 144
 - encephalitis 129, 502, 511
 - enlarged thymus 144, 145
 - in epilepsy 144, 146, 146
 - 85, 137, 144, 146, 148
Convulsions, epileptic
 - epileptiform in eclampsia 594
 - from cerebral tumour 68
Convulsions, epileptiform, conditions causing 146
 - - in general paralysis 129, 305
 - - rigors simulated by 594
 - - in saturnine encephalopathy 119
 - - Stokes-Adams disease 85
 - - uraemia 594
 - with fatty heart 212
 - from fevers 144
 - fright 144
 - fungating endocarditis 74
 - general paralysis 144, 146, 243
 - heart block 486
 - - disease 144, 146
 - hydrocephalus 145, 146
 - hydrophobia 750
 - hyperpyrexia after 309, 310
 - hypothermia after 573
Convulsions in hysteria 144, 147, 510, 417, 729
 - due to increased intracranial pressure 590
 - idiocy 144, 146
Convulsions, infantile 144
 - injury during 143
 - from intracranial new growth 144
 - irritating food 144
 - Jacksonian epilepsy 137, 147
 - jaw clenching in 143
Convulsions, localized, causes of 144
 - loss of consciousness in 133
 - in lung disease 146
Convulsions in malingers 157, 144, 147, 599
 - from muscles 144
 - meningeal hemorrhage 146
 - meningitis 129, 138, 144, 145, 146, 147, 307, 511, 515
 - morphia 144
 - mouth foaming in 143
 - from nasal disease 144
 - nephritis 42, 144
 - at onset of fevers 534
 - optic neuritis and 146
 - from otitis media 292
 - oxygen in checking 146
 - from phlebotomy 144
 - phosphorus poisoning 326
 - pneumonia 34, 119, 146, 147
 - pleurisy 144
 - polyomyelitis 110, 509
 - porphyria 146
 - in pregnancy 137, 144, 146
 - pyrexia in 144, 574
 - from renal calculus 144
 - rickets 144, 145, 229
 - rigors and 145
- Convulsions, contd.*
 - from santonin 144
 - in saturnine encephalopathy 119, 144
 - scarlet fever 144
 - after severe hemorrhage from sinus thrombosis 120
 - status lymphaticus 144
 - stertor in 143
 - in Stokes-Adams disease 144, 146, 186
 - from strychnine 138, 144, 147, 730
 - subdural hemorrhage 146
 - - syphilis 144
 - - tetanus 144, 145
 - - in tetanus 138, 729
 - tuberculous meningitis 566
Convulsions, unilateral, general account of 147
 - from uraemia 49, 85, 137, 144, 146, 417
 - after urinary operations 44
 - from vesical calculus 114
 - whooping-cough 144, 145
 - worms 144
Co-ordination, mechanism of 55
Copaiba, erythema from 222, 381
 - resin, polyuria from 535
 - purpura from 535
 - rash, small-pox simulated by 563
 - - syphilis simulated 384
 - urticaria from 771
 - white ring in urine from 5
 Copper, foul taste from 795
 - green sweat from 655
 - salts, pyralism from 542
 - reduction by glucose 261
 - sulphate in biuret test 16
 - in estimating sugar 265
 - - Fehling's test 261
 - - Fyess's test 261
Coronary-arteries, nerve supply of 504
 - root innervation of 509
 - for bovinum 297
Cor, spermatic (see Spermatic Cord)
 - spinal (see Spinal Cord)
Corns, limping from 362
 - pain in foot from 362
 - perforating ulcer under 736
 - suppurating under 736
Cornua, anaesthetic, in glaucoma 235, 761
 - injected vessels round, in glaucoma 761
 - opacity of, defective vision from 761
 - from iritis 72
 - from keratitis 72, 733
 - - ophthalmia 761
 - - monitiorium 759
 - - after ulcer 733
 - perforation of, from ophthalmia neonatorum 759
 - - from ulcer 733
Cornua, rodent ulcer of 734
 - stertor in glaucoma 232, 732
 - tuberculous ulcer of 734
 - ulceration of (see Elevation of the Cornua)
Cornual reflex in facial paralysis 112
Cornet player's cramp 151
Cornwall, ankylostomum in 520
Corona venosa 190
Coronary artery (see Artery, Coronary)
Corpora quadrigemina, lesion of, from iron 729
 - - tumour of, pupil reacting to light but not to accommodation in 551
Corpus luteum, hemorrhage from (see Hemorrhage from Corpus Luteum)
 - - cyst, hemorrhagic, pain in pelvis from 468
 - - stratum, lesions of, pyrexia from 511
- Corpuscles, basophile (see Basophile Cells)**
 - eosinophile (see Eosinophile Cells)
 - hyaline (see Lymphocytes, Large)
 - red (see Red Corpuscles)
 - white (see Leucocytes)
Corrosive sublimate test for bile 170
 - - - - - urobilin 170
Corrosives, abdominal pain from 268
 - acute gastritis from 267
 - albuminuria from 268
 - collapse from 268
 - dysphagia from 268
 - hamatemesis from 265
 - haematuria from 268
 - oesophagostenosis from 266
 - pain in epigastrium from 267
 - - mouth from 267
 - - pyralism after 542
 - rapid feeble pulse from 268
 - sore throat from 643
 - taste loss from 795
 - tongue swollen from 698
 - vomiting from 267, 765, 766
Corsets, liver forwarding from 567
Corti, organ of, deafness from changes in 166
Coryza, acute, in influenza 465
 - - pain in the limbs in 463, 464
 - - from arsenic 61

 - pemphigus 601
 - pityriasis rubra pilaris 488, 604
 - purigo 489
 - from pustules 558
 - in scrofuloderma 559
 - scorbuloa 602
 - syccosis 559, 600
 - on syphilides 560
Crusts, in syphilis 601
 - from vesicles 755
 Crutell, musculospiral paralysis from 65, 504
 Crum in children, from cold 425
 - - - - - oedema from 115, 415
 Cryoscopy of cerebrospinal fluid 204
Cryptomenorrhoea 17
 Cryptomonera (*see* Testis, Jotopae)
 Crystals, ammonio-magnesian 524
 - calcium oxalate (*Eq.*, 184) 425
 - in urine 9, 218, 268
CRYSTALS, CHARCOT-LEYDEN 102, 155
 - cholesterin (*Eq.*, 124) 254
 - choline peroxide 205
 - - - - - platiniochloride 205
 - colbin-hal 524
 - cystin (*Eq.*, 72) 164
 - dumb-bell 125, 741
 - envelope 425
 - fatty, in stools 104, 170, 172
 - hydrochlor 749
 - knife-tester 524
 - bicin (*Eq.*, 147) 524
 - phenyl thiocarbazon (*Eq.*, 127) 262
 - - - - - melting point of 262
 - lactosazone, melting point of 262

Crypsals, phenol, contd.
 - - pentosazone, melting point of 262
 - roseite 744
 - on skin, in ulcers 655
 - thorn-spine 740
 - triple phosphate (*Eq.*, 224) 524
 - tyrosin (*Eq.*, 118) 543
 - urate 740
 - - of sodium 344
 - uric acid (*Eq.*, 302) 741
 - - - - - in Bright's disease 9
 - in urine, from vesical calculus 580
 - - - - - whitestone 741
 Cubebis, erythema from 222
 Cud-cheking (*see* Mycystis)
 Curious, lesion of, hemianopsia from 301
 Cup, physio-logical (Plate XXI) 116
 Curettage, anaesthesia needed for 390
 - - in diagnosing carcinoma after 530
 - - - - - scab vaginitis 532
 - - - - - dysmenorrhoea cured by 192
 - - - - - endometriosis cured by 192
 - - - - - sterility curable by 646
 Curcums, in diagnosing stagnation in stomach 317
 - - - - - testing gastric motility 320
CURSCHMANN'S SPIRALS 153
CURVATURE, SPINAL
 (*see* Spine, Curvature)
 Cut, pneumothorax from 532
 - tenderness from 707
 - - - - - exsufflator, following 275
 - - - - - from hemipithia 275
 - - - - - septicaemia from 597
 Cut-throat, stenosis after 650
 - - - - - stridor after 650
 - ulceration of larynx after 287, 292
 Cyanosis, from abductor paralysis 158
 - acetabulae 157
 - acute, from aneurysm opening into pulmonary artery 92
 - - - - - superior vena cava 92
 - - - - - pneumothorax 159
 - - - - - tabes 159
 - from aneurysm 159, 298
 - angina hudsoni 158

 - simulated by caseous bronchial gland .. 157
 - sore throat in .. 64, 613
 - spleen enlarged in .. 632, 637
 - stomatitis from .. 542
 - stridor from .. 610
 - submaxillary glands inflamed from .. 379
 - tachycardia after .. 65, 702, 704
 - throat swabbing in .. 419
 - and tonsillitis, relative pyrexias of .. 571
 - toxæmia in .. 211
 - typhoid fever simulated by .. 627
 - ulcer of cornea from .. 731
 - ulceration of larynx from .. 287, 292
 - vocal neuritis after .. 706
 - - paralysis after .. 65
- Diphtheria, Vincent's angina simulating** .. 614
- weak first sound in .. 211
 - of wound .. 737
- Diphtheria, wrist-drop from** (*Fig. 23*) .. 65
- Diphtheritic antitoxin, purpura from* .. 553
- Diplegia, from bilateral cerebral softening* .. 515
- cerebral, atetosis from .. 132, 729
 - embolism .. 133
 - dysarthria in .. 627
 - facial paralysis in .. 493

Diplopia, vertical, contd.
 - intention tremor in 724, 729
 mental backwardness with 729
 optic atrophy with 729, 729
 papillo-macular with 729
 - sensor-gait with 729, 729
 - spherometer trouble with 729

Diplegia, congenital cerebral, general account of 132
 - contractures in 139
 - from porencephalia 139
 spastic infantile 132, 139
 tremor from 727

Diplophagia of Morax
 Asenfeld, conjunctivitis from 231

Diplophoria, intracardiac
 - meningitis (see Meningitis)
 - pneumonia (Pfeil)

DIPLDIPLOIA 614
 - from absence of orbit 174

Diplopia, binocular, general account of 175, 177
 crossed (Fig. 82) 176
 caused by glasses 175
 - in discomitant strabismus 196
 - from hamorrhage into orbit 177
 - homonymous (Fig. 81) 176
 - from low error of refraction 175

Diplopia, monocular, general account of 175
 - from orbital growth 177

Diplopia from paralysis of eye muscles (Fig. 83) 177
 poly-scoliosis 175
 from strabismus 177, 619
 vertigo from 752
 (and see Strabismus)

Dipping 41 371

Dirt, in cranium from 385
 - typhus fever and 325
 - eating 43
 - disease 99

Dise, checked (see Neuritis, Optic)

Discharge from the ear (see Otorrhagia)

Discharge from ophthalmia 561

DISCHARGE, NASAL 178
 - from bacterial disease 179, 180, 162, 658
 bacillus leprae in 383
 - bacteriologic examination 178

Discharge, nasal, various causes of 178, 179, 180
 - in children 179, 559

DISCHARGE FROM THE NIPPLE 181
 blood-stained, from
 - duct carcinoma 687
 bloody 181
 milk, at puberty 686
 - soon after birth 686
 milky 686
 in Paget's disease 730
 purulent 181, 685

DISCHARGE, URETHRAL 181
 bacteria in 67
 - bacterial diagnosis 181
 - due to carcinoma 181
 - from chanere 181

Discharge, urethral, endoscope in investigating 183
 - due to foreign body 181
 in clot 182, 183

Discharge, urethral, in gonorrhoea 182, 381, 469
 - from zoot 181
 - due to herpes 181
 - inguinal glands enlarged from 381

Discharge, urethral, method of investigating 183
 chlostridial 181
 - due to papilloma 181
 - from polypos 181
 - syphilitic disease 629
 - rheumatism 181
 - due to soft sores 181
 - from stricture 183

Discharge, urethral, contd.
 - due to syphilis 181
 - with testicular abscess 622
 - due to tubercle 181
 - without micro-organisms 181

DISCHARGE, VAGINAL 185
 blood-stained, from
 - carcinoma 186
 - from endometritis 185
 - fibroid 186
 - hydratiform mole 186
 - polyp 186
 cervical erosions 185
 endocervicitis 185
 endometritis 185, 391
 - from carcinoma 185, 391
 chorion epithelioma 391
 - fibroid 186
 - pessaries 185, 186
 - pyometra 186, 392

Discharge, vaginal, gonorrhoeal 185
 - in peripheral fever 596
 - pyosalpinx with 678
 - diplozo-oophoritis and liberation of peritoneum 620
 - white 185
 - yellow 185

Discharges, madura foot from 756

Dislocation of hip, congenital 156
 - abdomen prominent from 251
 - lordosis in 251
 - walking gait from 251
 - of jaw, pyramidal from 512
 lens 175
 ophthalmoscope method 475
 papil irregular from 551
 shallow anterior chamber from 175
 tremor of iris from 175
 of spleen 629, 679, 641

Diseases, proper names associated with (see end of Index)

Disorientation in alcoholism 29

Disparateness 175

Disparation 175

Disposition, change of, in general paralysis 129

Dissecting-room, sore, protractor gland enlarged from 381
 - finger affected by 214

Disseminated sclerosis, abdominal reflex absent in 592
 - alopecia in 17
 amyloidosis in 728
 ankle-clonus in 397, 517
 aphasia in 118
 ataxic in 57, 251, 397, 517
 - Babinski sign in 68, 118, 397, 728
 black spots before eyes from 72
 central scotoma in 517, 769
 cerebellar tumour simulated by 517
 - coma from 117, 141
 contracted visual fields in 517, 728
 - convulsions in 144, 148
 - diplopia in 146
 - dysarthria in 627
 erythrodysplasia with 111
 extensor plantar reflex 592, 517
 - lines of in 231
 - fatigability in 148
 - gait in 728

Disseminated sclerosis, general account of 728
 - girdle pain in 259
 - sensation in 609
 - headache in 291, 295
 - hemiparesis in 609
 - hemiplegia in 397, 297
 - lipspas in 552
 - hysteria simulated by 727
 - simulating 728

Disseminated sclerosis, contd.
 - impaired articulation in 148
 - intention tremor in 148
 - knee-jerk increased in 397, 196, 517, 724, 728
 - mercury poisoning simulated by 726
 - monoplegia in 592
 - neuritis in 609
 - neurasthenia simulated by 316
 - neuritis simulated by 517, 518
 - numbness in 609
 - nystagmus in 148, 198, 426, 592, 517, 728, 760
 - ocular paralysis in 760
 - optic atrophy in 148
 - optic atrophy, 196, 502, 517, 760
 - neuritis rare in 517
 - optimum in 118
 - pallor of optic disc in 728, 760
 - parasthesia in 517
 - paralysis of a commensal diplopia in 760
 - one leg in 496
 - paralytic from 502, 511
 - penile erection absent 315
 - precipitate detestation in 314
 - pseudo-nystagmus with 197

Disseminated sclerosis, sensory changes in 609

Disseminated sclerosis, signs of 148
 - spasticity in 397, 592
 - speech in 397, 517, 728
 - sphincter trouble in 148, 196, 502, 517, 728

Disseminated sclerosis, symptoms of 307
 tremor in 721
 - variations in symptoms 517
 - voice hoarse in 517
 - vomiting in 295
 - writers' cramp simulated by 151

Dissolution, sense of in atrophy 153
 - hysterical 153

Distention, abdominal (see Abdominal Distention)

Distoma hepaticum 325, 328
 pulmonale 287, 292, 645

Disuse, contractures from 139, 141
 - muscle-wasting from 59
 - 602, 555, 554, 771
 from acetamide 26
 - aspirin 224, 113, 771
 - atoxyl 222, 224
 - atropine 222, 642
 - belladonna 692
 - bromide 296, 298, 222, 559, 560, 563, 771, 771
 butylchloral hydrate 222, 555
 - caustic of soda 222, 221
 - chloral 222, 555
 - chloral hydrate 222
 - chlorate of potash 557
 - copal 222, 281, 333, 565, 771
 - ephedrine 555, 771
 - one dyptus, sulphur from 239
 - iodine 98, 559, 560, 563, 771
 - jurepures from 756
 - papules from 98, 560, 561
 - acute simulated by 559
 - necromyolysis with 559
 - sulphuric simula- 565
 - sulphuric simulating 569
 - uricaria from 771
 - vesicles due to 757
 - iodoforn 222, 222
 - purpura from 555

Dogs (Dog), adrophobia from 138, 197, 730

Dogs, effect of tolylene- 337
 - damping on 337
 - jaundice in 658
 - from melanosis in 658

Dome-shaped dullness, from hepatic disease 291

Dorsalis pedis artery, cessation of pulsation in 54

Double-consciousness, hysterical 29

Double vision (see Diplopia)

Douches, astrincent, sterilized from 336
 - non-sterilized from 336

Douglas's pouch, malignant deposits in 587
 - livid in 19

- swelling in (see Pelvic Tumour; Swelling, Pelvic; and Swelling in Douglas's Pouch)

Drugging, in chest, from chronic mediastinitis 155
 - from hydrocele 181
 - sensation, from hepatopneumonia 368
 - in hypochondrium from carcinoma of liver 375
 - of urine (see Urine, Drugging)

Drugging, myalgia from 167
 - stiff neck from 129

Drawing up of legs (see Legs, Drawing up of)

Dreamy state, from cerebral tumour 68

Drizzling of saliva, in babies 542
 - in bulbar paralysis 542, 589
 - in facial paralysis 495
 (and see Trismus)

- of urine (see Urine, Drizzling)

Drinking, diabeto-nephritis simulated by 537
 - polyuria from 554, 555, 556
 - secret 555
 - neuritis from 66

Drop-leaf (see Frost-drop)

Drop-wax (see Frost-drop)

Drop-wax, from cramp 159

Drowsiness, in acute yellow atrophy 276
 - from cerebral disease 225
 - encephalitis 332
 - diabetes 85, 764
 - meningitis 594
 - phos-phorus poisoning 326
 - uraemia 49, 226

Drug rash 26, 553, 554, 602, 555, 771, 771
 from acetamide 26
 - aspirin 224, 113, 771
 - atoxyl 222, 224
 - atropine 222, 642
 - belladonna 692
 - bromide 296, 298, 222, 559, 560, 563, 771, 771
 butylchloral hydrate 222, 555
 - caustic of soda 222, 221
 - chloral 222, 555
 - chloral hydrate 222
 - chlorate of potash 557
 - copal 222, 281, 333, 565, 771
 - ephedrine 555, 771
 - one dyptus, sulphur from 239
 - iodine 98, 559, 560, 563, 771
 - jurepures from 756
 - papules from 98, 560, 561
 - acute simulated by 559
 - necromyolysis with 559
 - sulphuric simula- 565
 - sulphuric simulating 569
 - uricaria from 771
 - vesicles due to 757
 - iodoforn 222, 222
 - purpura from 555

Dyspareunia 193
 - causes of 193, 194
 - kraurosis vulvae 193, 194, 701
 - sterility from 616

Dyspepsia (and see Indigestion)
 - from acylia 318
 - acute abdominal pain 319
 - pylorism from 543
 - from alcohol 319
 - anxiety 337
 - appendicular 297, 316
Dyspepsia, asthenic 319
 - from atony 319
 - bleeding gums from 72
 - brain lesions simulating 315
 - carcinoma of stomach simulating 270
Dyspepsia, from carcinoma of stomach 316
 - cardiac tendril after 328

Dyspepsia, changes in stools with 171
 - chronic, from gastric ulcer 658
 - with carborosis 371
 - cough from 118
 - from defective teeth 319
 - deficient exercise 319
 - diarrhoea from 171
 - from emotion 319
 - flatulent 319
 - heartburn from 297
 - foul breath from 87

Dyspepsia, functional, general account of 318, 319
 - from gall-stones 297, 316
 - gastralgia 319
 - gastritis simulated by 317
 - zouty 319, 333
 - from grief 337
 - hasty meals 319
 - headache from 296
 - heart disease simulated by 435, 435, 709
 - from hyperasthenia of stomach 319
 - hyperchlorhydria 318

Dyspepsia, hypersthenic 319
 - hysteria simulating 315
 - insomnia from 321
 - liver congestion with 369
 - loss of appetite from 43
 - weight from 769
 - myocardial affections simulating 181
 - nervous, ovaria and 425
 - from neurasthenia 466
 - with nutmeg liver 268
 - from oral sepsis 319

Dyspepsia, organic, differential diagnosis of 316, 317, 318
 - from over-fatigue 319
 - over-work 319
 - ovaria and 281, 424
 - pain in the back from 428
 - chest from 709
 - round heart from 435
 - palpitation from 455, 485
 - pelvic lesion simulated by 468
 - phlogia from 525
 - presordial pain from 433
 - pregnancy simulating 315
 - from pyloric spasm 319
 - pyorrhoea 71
 - roseola from 241
 - scurf 319
 - from shock 319

Dyspepsia, simulated by fatty heart 485
 - simulating dysmenorrhoea 433
 - tabes simulating 315
 - from tea 319, 321
 - tenderness in chest from 709
 - from tetrachlorethane 331
 - tinitus from 723
 - from tobacco 319
 - tongue swollen in 638
 - tooth-indentured from ulcer of tongue from 758, 749
 - from unsuitable food 319
 - vomit from 353
 - from worry 319

DYSPHAGIA 194
 - from aneurysm 195, 434
 - from bilateral facial paralysis 543
 - in bulbar paralysis 135, 197, 589, 543, 627
 - from carcinoma 195, 199, 206, 455, 617
 - cervical atheritis 617
 - esophageal stenosis 435
 - cleft palate 198
 - corrosives 268
 - dermatitis herpetiformis 74
 - after diphtheria 196, 545
 - erythema bullosum 74, 198
 - general paralysis 195
 - hydrophobia 138, 543
 - hysterical 196, 197
 - from idiopathic dilatation of oesophagus 198
 - after irritants 198
 - larynx lesion 198, 199
 - lead poisoning 197
Dysphagia lusoria 196
 - from necrosis 75
 - mumps 198, 617
 - myxo-stoma gravis 197, 543

Dysphagia due to nerve causes 196

Dysphagia from oesophageal obstruction 194, 195, 196

Dysphagia from pain on swallowing 198
 - polyneuritis 543
 - of hypoglossal nerve 543
 - pharyngitis 74, 198
 - pharyngeal stenosis 198
 - post-pharyngeal abscess 198
 - pouch of oesophagus 196, 763
 - pylorism from 543
 - from quinsy 198
 - sore throat 198, 615
 - spasm of oesophagus 435
 - spasmodic, in hydrophobia 197
 - from stomatitis 74, 198
 - syphilis, certain 197, 199
 - thyroid gland enlargements 722
 - tongue lesions 198
 - tubercle of larynx 199

DYSPLASIA 199
 - from aductor paralysis 158
 - acute, from aneurysm opening into pulmonary artery 92
 - - - - - superior vena cava 92
 - - - - - aortic rupture 210
 - bronchitis 420
 - bronchopneumonia 420
 - haemorrhage into thyroid 721
 - irritation of caecum-gland into trachea 420
 - laryngeal paralysis 495
 - pneumothorax 159
 - tubes 159
 - tooth-plate in larynx 495
 - from alkalis 95
 - from aneurysm 92, 159
 - angina Ludovici 438
 - aortic reorganization 297
 - asthma 722
 - athlete's leg 214
 - with aorta 42
 - from bronchitis 322
 - bronchopneumonia 590
 - capillary bronchitis 590
 - cardiac, asthma simulated by 555
 - in chlorosis 274
 - chronic, mastoiditis 455
 - chronic, nephritis 722
 - from congenital heart 215, 217, 720
 - diphtheria 157
 - emphysema 322
 - with fatty heart 212, 213
 - fibroid heart 213
 - lung 216
 - zouty 158, 722
 - Graves's disease 722
 - haemorrhage into intrathoracic sacroma 159
 - mediastinum 159
 - thymus 159
 - thyroid 158

Dyspareunia, aetiology
 - heart disease 522
 - with leucorrhoea 568
 - hydrophobia 138
 - hydro-pneumothorax 632
 - insomnia from 722
 - from laryngeal obstruction 590
 - fibrous thyroiditis 158
 - medullated new growth 424
 - neutral reorganization 210
 - myocardial changes 300
 - myosarthritis 212
 - osteitis deformans 670
 - over-strain of heart 214
 - phthisis 322
 - pneumothorax 432
 - polycythaemia and 533
 - from post-pharyngeal dilatation 198, 616
 - pulmonary embolism 159, 289
 - Riedel's disease 158
 - renal, asthma simulated by 535
 - retracted head from 590
 - spasmodic, from asthma 420
 - from thyroid gland enlargement 722
 - from uraemia 40, 236
 - (and see Breath, Shortness of, and Orthopnoea)

DYSTONIA 199
 - from cystic kidneys 402

Dystocia, list of causes of 199
 - Dystrophy, muscular (see Myopathy)

Dystrophia adipogenitalis (Fop. 176) 499

EAR, Arnold's nerve of 118
 - bulb affecting 293

Ear, cerebrospinal fluid from 119, 421
 - chills affecting 293
 - component parts of 463
 - condylomata 422
 - dermoid cyst of 293
 - diphtheria of 422
 - discharge from (see Otorrhoea)
 - oozing of 206, 422
 - cough from 118
 - epithelioma of 578, 422
 - erysipelas affecting 293
 - foreign body in, (see Foreign Body in Ear)
 - furuncle in 422
 - haemorrhage from (see Haemorrhage from Ear)
 - into middle 466
 - herpes affecting 293
 - with facial palsy 495

Ear lesions, noises in the head from 406
 - vertiginous from 408
 - over-strain from 408
 - liquor otitum escaping from 421
 - lobules, absent, in progeria 191
 - lupus affecting 422
 - polypus (see Polypus of Ear)
 - pulsation detected by 208, 697
 - recent ulcer affecting 422
 - serous cyst of 293
 - of stapes in 422
 - swelling of, from furuncle 422

Ear, syphilis of internal 752
 - from 295
 - urate of sodium in 744
 - wax in, rough from 148
 - deafness from 161, 165
 - ear of corn, indurated, gangrene of lime from 260

EARACHE 202

Earache, various causes of 202, 203
 - Ears, atrophy of, from liposarcoma 603
 - blue, blue brain and 254
 - orange, in rotinism 136
 - cyanosis of 136

Ears, aetiology
 - haematoma of, in progeria 243
 - large, in monolism 248
 - pitcher-shaped, in monolism 258
 - Raynaud's disease affecting 293, 256, 639
 - sclerotic, in arterio-sclerosis 311
 - thick, in myxo-stoma 254
 - Eason's reaction, in haemoglobinuria 285
 - Eating of dirt 47
 - excessive, urine acid 742
 - Lapsal, sense of fullness after 243
 - Eberth's bacillus (see Bacillus Typhosus)
 - Echinodermos, from arthritis 117
 - Echinococcus 552
 - Echinococcus (see Hydatid)

ECCLAMPSIA, general account of 146
 - convulsions in 157, 146
 - rigors simulated by 594
 - Ecthyma 690
 - impetigo and 557, 558
 - pustules in 537
 - Ectopic gestation, left peritoneum 587

Ectopic gestation, notes on 690
 - abdominal pain from 393
 - acute abdominal pain from 194, 593
 - fluctuating due to 420
 - bimanual examination in detecting 468
 - blood per vaginam with 593
 - collapse from 393
 - coma from 418
 - lantous from 393
 - internal bleeding from 393
 - - - - - 293, 593, 720
 - leucorrhoea from 594
 - metastasis from 392
 - pain in hypochondrium from 451
 - - - - - the pelvis from 668, 688
 - pallor from 593
 - pelvic swelling with 393, 688
 - rigidity from 129, 593
 - ruptured 129, 593
 - simulating dysmenorrhoea 193
 - - - - - peritonitis 593
 - swelling in Baugle's pouch from 587
 - tenesmus from 718
 - tubal mole from 393
 - uterine bleeding due to 393
 - vomiting from 593
 - Ecthyma 690
 - Ectromelias 188

Ectropion 220
 - Eozymia, indolent with 644
 - - - - - indolent 644
 - - - - - tubercular, in region 193
 - affected by 401, 600
 - burning in 558
 - - - - - chromopolypus simulating 756
 - - - - - cysts in 558, 600, 692, 753

ECZEMA, dermatitis distinguished from 755
 - ear affected by 148, 202, 203, 422
 - - - - - eczema marginatum distinguished from 250
 - - - - - eczema polymericum 219
 - - - - - erythema from 222, 692
 - - - - - erythema simulating 251
 - - - - - fungus distinguished from 247
 - - - - - itches affected by 239, 249
 - - - - - lichenitis from 249
 - - - - - molluscum from 692
 - - - - - papules in 487

ECZEMA, general account of 754, 755
 - from glycosuria 290
 - - - - - granulosum rubra and diste 674
 - - - - - impetiginosum, cutaneous diphtheria simulating 558

- Urticaria, contd.*
 - itching in 491, 510, 558, 564,
 719, 756
 - lesions in dermatosis 488
 - lichen urticatus simulat-
 ing 756
 - lips affected by 265, 600
 - maceratum, bathing-
 drawers area affected 401
 - morbilli's itch and 250
 - osseous distinguished
 from 250
 - epidermophyton caus-
 ing 250
 - erythema simulating
 microscope in diagnosis
 250
**Eczema marginatum, parts
 affected by 250**
 - seborrhoeic distinguished
 from 250
 - umbilica simulating 755
 - varicose fungoides simulat-
 ing 751
 - vesicles affected by 250, 399
 - vesiculation after 487
 - vesicles from 562
 - from otitis media 422
 - otorrhoea from 422
 - Page's disease simulat-
 ing 750
 - papular 600
 - blood-crusts in 487
 - itching in 487, 488
**Eczema, papular, lichen
 planus distinguished
 from 487**
 - strobiliform simulat-
 ing 488
 - vesicles in 488
 - papules in 487
 - pityriasis rubra after 604
 - - papular simulating 604
 - prurigo distinguished
 from 490
**Eczema, psoriasis distin-
 guished from 603**
 - pustular 557, 560
 - impetigo simulating 568
 - ringworm simulating 249
 - rubrum 755
 - scales simulating 600
 - scales in 600
 - scales in 488, 601, 602, 603
 - seborrhoeic 600, 602, 603
 - congenital syphilis dis-
 tinguished from 401
 - of fish area 242
**Eczema, seborrhoeic, of in-
 fants 401**
 - parts affected by 401
 - scaldiness in 242
 - small-pox simulated by
 staining of skin from 602
 - syphilis simulating 491, 560
 - tenderness of scalp from 710
 - tinea crinita distin-
 guished from 249
 - of umbilicus 483
 - vesicular simulating 250
 - vesicles in 487, 488, 600,
 755, 754
 - due to wax in ear 422
 - weeping in 600
 - white-science, urinary 4, 5
**EFFUSION IN CHEST,
 BLOODY 102**
**EFFUSION IN CHEST,
 SEROUS 104**
 - (and see Pleural
 Effusion; and
 Pleuritic Effusion)
 - pericardial (see Pericardial
 Effusion)
 - pleural albuminous after 15
EGG-SHELL CRACKLING 150
 - from aneurysm 633
 - from aortic aneurysm 152, 633
 - of 400
 - of aortic aneurysm in 521
 - of aorta in 79, 282
 - of ribs in 370
 - of rising fever in 596
 - of rheumatism in 634
**EHRLICH, DIAZO REAC-
 TION OF 173**
- Ejaculatory ducts, gonorrhoeal
 infection of 182**
 - elastic fibres in sputum
 (see sputum, Elastic
 Fibres in)
Elbow, osteo-arthritis of 547
 - pneumococcal arthritis of 539
 - position in tetany 2
 - tuberculous disease of 247
**Elbow-jerks, increased, in
 brachial monoplegia 502**
 - hemiplegia 505
**Elbow-joint, disease, arm
 atrophy from 361**
**Elbows, psoriasis affecting
 489, 491, 602, 603**
 - pityriasis rubra pilaris
 affecting 489
 - rheumatic nodules on 732
 - seborrhoeic eczema affect-
 ing 401
 - small-pox affecting 561
 - xanthelasma of 562
**Electric blindness, crys-
 tallosis in 762**
 - cataracts, disease from 255
 - light, eye-strain from 476
 - steel groovers, subaro-
 chnoid bursts in 416
 - welders, photophobia
 in 521
**Electrical reactions in myo-
 asthenia gravis 581**
**Electrical reactions, normal
 582, 583**
 - in Raynaud's disease,
 etc. 584
 - in Tetany 584
 - in Thomsen's disease 581
 - (and see Reaction of
 Degeneration)
 - treatment of functional
 aphonia 495
**Electricity, insomnia re-
 lieved by 525**
 - in lowering high blood-
 pressure 523
**Electrocardiogram, in diag-
 nosing angina pec-
 toris 476**
 - aneurysm fibrillation 486
 - 91, 485, (Fig. 196) 486
 - heart-block 486
 - heartburn 297
 - myocardial changes 45, 485
 - paroxysmal tachy-
 cardia 518, (Fig. 289) 703
 - Stokes-Adams' dis-
 ease 486
 - between stomach and
 heart lesions 709
 - of heart-block (Figs. 37,
 38) 83
 - heart cases 544
 - showing extrasystoles
 (Fig. 251) 544
**Electrolysis of water-pipes,
 plumbism from 65**
**Elephantiasis, atrophy of
 testis from 66**
**Elephantiasis, blood changes
 in 28**
 - chylous ascites with 50
 - chyloids from 28, 50
 - from filariasis 28, 109, 111,
 701, 737
 - geographical distribution
 412
 - impotence from 512
 - from lymphatic obstruc-
 tion 411
**Elephantiasis, pseudo-
 serous 695**
 - syphilis simulating 701
**Embolism, cerebral, acute
 rheumatism and 119**
 - acute incidence of 119, 147
 - aphasia from 626
 - apoplexy from 147
 - atelectasis after 152, 153
 - in children 133
 - brachial monoplegia
 from 501
 - Babinski's sign with 68
 - cerebral softening from
 108, 515
 - Cheyne-Stokes breath-
 ing from 108
- Embolism, cerebral, contd.**
 - coma from 118, 119, 610
 - diplegia from 304, 610
 - from endocarditis 147
 - epilepsy after 133
 - fungating endocarditis
 and 34, 119, 505, 504, 610
**Embolism, cerebral, hæ-
 morrhage after 640**
 - headache from 291, 295
 - heart fruits and 119
 - from heart disease 133, 515
 - hæmiparesis from 504, 592
 - hemiparesis from 68,
 135, 258, 305, 304, 640
 - from intracardiac
 thrombosis 147
 - meningeal defect after 133
 - from mitral stenosis
 303, 504
 - spastic paraplegia after 152
 - speech defect after 133
 - from thrombi 233
 - tremor from 133
 - unilateral paresis from 118
 - of cord, in infective endo-
 carditis 517
 - in fungating endocarditis 8
 - gangrene from 255
 - from heart disease 258
 - infarction from 8
 - of kidney from 7
 - from intracardiac throm-
 bus 258
 - mesenteric, in fungating
 endocarditis 34, 589, 640
 - metastases from 131
 - from heart disease 131
 - intestinal obstruction
 simulated by 289
 - laparotomy in diagnos-
 ing 289
 - melæna from 131
 - meteosism from 289
 - peritonitis from 289
 - simulated by 594
 - peripheral, in fungating
 endocarditis 640
 - pulmonary, bronchial
 breathing from 290
 - after childbirth 290
 - from clot in heart 289
 - cyanosis from 159, 289
 - dyspnoea from 159, 289
 - gangrene of lung from
 259, 644
 - hæmoptysis from 159,
 289, 290
 - infarct from 160
 - from infective endo-
 carditis 159, 290
 - rales from 290
 - sudden death from
 159, 290
 - from venous thrombus
 159, 290
 - in pyæmia 28, 506
 - (and see Infarct of Lung)
 - of radial artery, in fungat-
 ing endocarditis 551
 - renal, in fungating endo-
 carditis 7, 640
 - hæmaturia from 283
 - infarction from 283
 - pain in loin in 283
**Embolism, retinal, appear-
 ances after 416**
 - (Plate XX) 418
 - black spots before eyes
 from 72
 - blindness from 762
 - in fungating endocar-
 ditis 54
 - of spleen, in fungating
 endocarditis 34, 632, 640
**Embolism of spleen, general
 account of 640**
- Embolism of spleen, contd.**
 - pain in chest from 640
 - spleen enlarged from 632
 - sudden pain from 288
 - unequal pulses from 559
Embryoma of kidney 556
 - acute in loin from 278
 - colic from 278
 - hæmaturia from 275, 278
 - renal enlargement from 278
Embryoma of testis 480, 695
 - Emetics, vomiting from 605
 - Emmetine, disappearance of
 amebæ after 77
**Emissary vein (see Vein,
 Emissary)**
**Emission, no-turnal, albumi-
 nuria after 15**
 - or oxaluria and 424
**Emotion, acute yellow
 atrophy after 333**
 - angina pectoris from 434
 - flushing from 211
 - convulsions from 111
 - diarrhoea from 173
 - dyspepsia from 337
 - jaundice from 325, 337
 - menorrhagia from 386
 - palpitation from 481, 486
 - pyralorrhoea from 543
 - tremor from 724, 525
 - uncontrolled, facial par-
 alysis and 495
 - uncontrolled, in pseudo-
 bulbar palsy 627
**Empysema, albuminuric
 217**
 - ascites from 46, 217
 - from asthma 153
 - asthma, distinguished
 from by eosinophilia
 219
 - simulated by 535
 - back pressure from 16, 217
 - barrel-shaped chest in
 167, 266
**Empysema and bron-
 chitis 160**
 - bronchitis with 14, 16,
 153, 167, 217
 - bulging above and below
 clavicles in 168
 - carbon dullness dimin-
 ished in 167, 206
 - chest changes with 14
 - expansion slight in 167
 - Cheyne-Stokes breathing
 from 108
 - clubbed fingers from 111
 - compensatory, with 6-
 broad lung 216
 - constipation from 128
 - cyanosis from 161
 - deficient vesicular mur-
 mur in 160
 - dyspnoea from 222
 - epistaxis from 290
 - expiration prolonged in
 167
**Empysema and fatty heart,
 difficulty of distinguish-
 ing 485**
 - flatulence with 241
 - hæmoptysis from 289
 - heart failure from 14, 16,
 108, 161, 118
 - impulse impalpable in 167
 - obscured by 217, 297
 - sounds hard to hear in
 hyper-resonance from 89
 - melastic skin with 69
 - insomnia from 321, 322
 - intercostal spaces wide in
 167
 - liver dullness diminished
 in 167, 266, 268
 - enlarged from 217
 - mitral stenosis mistaken
 for 217
 - menorrhagia from 286, 287
 - neck short in 167
 - oedema of legs from 217
 - in old people 85
 - orthopnoea from 325, 418
 - outline of chest in (Fig.
 80) 167
 - over-distended chest in 169
 - pain in chest from 432
 - ribs in 165
 - palpitation from 181, 185

Emphysema, cont'd.

Emphysema, physical signs
 of 217
 - pneumothorax from 531
 - polyvethaloma from 532, 533
 - resonance in re-erect m. 167
 - ribs, everted from 566
 - right ventricle, enlarged
 from 215, 217, 239
 - rupture of ribs from 531
 - shortness of breath from
 89, 89
 - shoulders, spare and
 high in 167
 - small respiratory expansion
 in 160

Emphysema, subcutaneous, various causes of
 - crepitus from 150, 153

EMPHYSEMA, SURGICAL

- of abdomen 656, 656
 - from fractured rib 532
 - gas-producing m. 656
 - wounds 656
 - cystic breast with 217
 - telangiectases round
 wrist from 250
 - tenderness of chest in 208
 - tightness in chest from 132
 - tricuspid regurgitation
 from 217
 - vesicular murmur diminished in 167
 - violent coughing bouts
 from 289
 - winter bronchitis with 160
 - cough from 44
 Emphysematous, in tetanus 138

EMPYEMA

Empyema, abnormal sites of
 of 86, 103, 643

absence of breath sounds
 with 103
 - voice sounds with 103
 adhesions round 532
 albuminuria with 16
 anaemia with 32, 34

Empyema of atrium of

Highmore 180, 462
 - subacute smells
 from 612
 - from appendicitis 103,
 104, 106
 - ascending nephritis 106
 - axillary abscess from 666
 - bacillus coli communis
 causing 104
 - pyocyanus causing 104
 - bronchial breathing over 103
 - bronchocyst after 292
 - from bronchopneumonia 103, 160
 - bursting through lung 287

Empyema, causes of

- chest bulged on one side
 by 168
 - shrunken from 153,
 154, 168
 - from cholera 106
 - clubbing of fingers from 111
 - crackling rales over 103
 - diaphragm depressed by 658

Empyema, difficulties in

locating 643
 - from diaphragm split 103, 106
 - elastic fibres in sputum
 due to 260
 - with few signs 291
 - fibroid lung after 292
 - fetal bronchitis simu-
 lated by 643
 - foul breath from 86
 - sputum from 260, 643
 - taste from 705
 - from fractured rib 104

Empyema of frontal sinus

(and see sinus, front.)
 - gall-bladder, albuminuria
 with 16
 - from carcinoma 326
 - cholangitis from 333
 - from cholangitis 326
 - from gall-bladder stones
 from 104, 106

Empyema of gall-bladder, cont'd.

- gall-bladder, enlarged
 by 255
 - from gall-stones 326
 - from leucocytes from 254, 360
 - operation for 254
 - from typhoid fever 254, 333
 - gangrene of lung simu-
 lated by 290, 643
 - from gastric ulcer 106,
 106, 106
 - gumma of liver 106
 - haemoptysis from 287, 291
 - from hepatic abscess 104,
 106, 370
 - hydrated cyst of liver 106
 - induratum from 345, 745
 - from infarction of lung 106
 - injury 104
 - lardaceous disease from 8, 655
 - latent 106
 - leucocytosis with 350, 361
 - lobar pneumonia 106
 - after measles 297
 - needling in diagnosis 35,
 103, 160
 - nephritis from 9
 - from new growth of liver 106
 - after operations 106
 - osteoarthropathy from 352
 - from otitis media 106
 - pain in the chest from 120, 131, 432
 - pathis of infection in 104
 - from pelvic peritonitis 106
 - perinephric abscess 104
 - perinephritis 106
 - periodic pur. expectora-
 tion from 291
 - from peritonitis 106
 - phthisis 104

Empyema, without physical

signs 86, 643
 - after pleurisy 106
 - pneumococcal 105, 104, 106
 - after pneumonia 35, 104,
 (Fig. 71) 169, 201,
 574, 597, 643
 - pneumothorax from 531
 - pointing 168, 169, 222
 - polymorphonuclear cells
 and 35, 361
 - prolonged pyrexia from 563, 567
 - from pylophlebitis 106
 - pysoptysis 106
 - pyrexia of 574
 - early of peritonitis from 106
 - from renal calculus 106
 - retraction of chest after 169
 - rib-resection in 106
 - rigor from 595, 597

Empyema, ruptured into

(lung 86, 168, 291, 551,
 582, 643, 705
 - after scarlet fever 597
 - scrofulosis from 155
 - septicaemia from 567, 637
 - simulated by abscess in
 the liver 106
 - lung abscess 106
 - subdiaphragmatic abs-
 cess 106
 - simulating bronchiectasis 86
 - sinus from 655
 - staphylococcal causing 104
 - stretch from 230
 - streptococcus causing 104
 - from subpharyngeal
 abscess 103, 104, 370, 658
 - sudden abundant expres-
 sion of 86
 - tenderness of spine from 715
 - from tuberculous kidney 106
 - typhoid toxin causing 104
 Eucyphalitis, age incidence
 of 129, 192
 - ataxic from 58
 - attheros after 122
 - brachial monoplegia from 592
 - coma from 117, 591
 - convulsions with 129,
 146, 592, 511
 - heclahe with 129, 592, 525

Eucyphalitis, cont'd.

- hemiplegia from 303, 304
 - lumbar puncture in dia-
 gnosing 525
 - meninges simulated by 511
 - optic neuritis from 129, 525
 - paraplegia from 152, 510
 - photophobia from 525
 - post-mortem diagnosis 129, 525
 - proctitis from 129
 - pupil small with 552
 - pyrexia from 592, 511
 - retracted heel from 589
 - relation to polymyositis 152
 - simulating meningitis
 129, 591
 - sinus thrombosis 129, 511
 - vomiting with 129, 592,
 511, 525

Eucyphalitis, eucyphalitis

- from 229
 Eucyphalitis, fulminating 51
 Eucyphalitis, of metastatic
 carpal (Fig. 282) 671
 - sarcoma simulated by
 (Fig. 282) 671
 - simulating 672

Endocarditis, cerebral, hemiplegia from

- from 305, 304
 - from syphilis 304
 - from thrombosis from 304
 - cerebral softening from 515
 - gangrene from 255, 258
 - hemiplegia from 517
 - syphilis 515
 - heclahe from 291
 - spinal, albumina from 17
 Endocarditis, abscess of
 - pyrexia with 89
 - acute, from acute rheu-
 matism, 90, 296, 195,
 209, 211, 283, 161, 641

Endocarditis, acute, bruit:

from 209
 - cardiac impulse dis-
 placed from 211
 - in children 211
 - systolic diastole after 209
 - regurgitation from 95
 - systolic bruit from 92
Endocarditis, acute, of
aortic valve 209
 - aortic diastolic bruit
 from 95
 - systolic bruit from 2,
 89, 90, 211
 - obliteration of valves
 after 214
 - in children 211
 - acute, from chorea 30, 299, 211
 - from erysipelas 90

Endocarditis, acute, general

account of 211
 - mitral-stroke bruit
 from 2, 36, 587
 - mitral regurgitation
 from 211
 - stenosis after 211
 - myocarditis with 212
 - palpitation from 211
 - from pneumonia 30
 - precordial pain from 211
 - from purpural fever 30
 - rephalitis of first
 sound from 211
 - from scarlet fever 209, 209, 211
 - sepsis of a valves after 244
 - from septicaemia 90
 - in tonsillitis 211
 - age incidence of 37
 - aortic disease from 299
 - cerebral embolism from 147
 - fungating, acute abdom-
 inal pain in 76

Endocarditis, fungating,

acute aneurysms in 640
 - aortic 8
 - age incidence of 394
 - albuminuria in 354, 563
 - alternative names for 555
 - ana in from 7, 21, 31, 640
 - aneurysm from 34
 - of hepatic artery 51, 551
 - of 51, 551
 - aortic regurgitation
 from 93, 209

Endocarditis, fungating, cont'd.

- aortic systolic limit 89
 - ascites in 7, 51
 - axillary aneurysm from 967
 - blood cultures in 209, 566
 - bruits in 566
 - without bruit 8, 566, 640
 - a case of 7
 - cerebral abscess from 562
 - haemorrhage from 640
 - cloughs Stokes breath-
 ing in 148

Endocarditis, fungating,

chief signs of 34
 - coma in 117, 640
 - convulsions from 34
 - disappearance of pulse
 in 551
 - embolism in 8, 51
 - of spleen in 34
 - of brain in 31, 119,
 205, 591
 - cord in 54, 587
 - intestine in 54, 299
 - kidney in 7, 8, 24, 285
 - lung in 59, 290
 - pancreas in 76
 - radial artery in 574
 - spleen in 34
 - tetanus in 54, 632
 - fingers, clubbed in
 (Fig. 270) 640
 - zosteriform 54

Endocarditis, fungating,

general notes on 640
 - zosteriform 217, 574
 - thromboses in 295
 - haematuria from 7, 8, 34,
 285
 - hemiplegia from 288
 - hemorrhages with 54
 - hemorrhagic erosions
 in 209
 - heart block from 536
 - hemiplegia from 566, 304,
 511
 - hypopycnyosis 509
 - influenza simulating 564
 - intestinal obstruction
 simulated in 76, 589
 - lambohy with 534
 - leukocytosis with 34
 - liver enlarged in (Fig.
 270) 640
 - meningitis from 597
 - simulated by 597
 - mitral regurgitation
 ens in 209
 - mitral regurgitation
 from 211
 - of months' duration 567

Endocarditis, fungating,

multiple emboli in 640
 - nephritis from 283
 - neuritis in 64
 - neuroretinitis in 7
 - oslenia of ankles from 7
 - face from 7
 - obscure pyrexia from 574
 - optic neuritis with 34
 - pain in the back from 8
 - perilysis from 54, 201,
 591, 640
 - peripheral neuritis from 64
 - peritonitis in 34
 - peritonitis from 589
 - petechiae in 563
 - phlebitis in 34
 - pneumococcal 209, 567
 - from pneumonia 283
 - prolonged pyrexia from 563
 - pulmonary, nonob-
 scure from 217
 - of pulmonary valve 215
 - purpura with 34, 559,
 (Fig. 226), 555
 - pyrexia from 7, 54,
 563, 567
 - without pyrexia 211
 - renal tube casts in 7
 - retinal hemorrhages in 7
 - riors in 54, 595, 596
 - serum treatment 34
 - shortness of breath
 from 7

Epi-staxis, oculi.
 - in chronic alcoholism . . . 51
 - in nephritis 11, 76, 221, 266
 - in erythema 11, 220, 266, 635
 - common site of ulcer causing . . . 221
 - concealed . . . 221
 - in fatal eclamptic jaundice . . . 332
 - fullness in head relieved by . . . 221
 - hæmorrhages from 265, 266
 - in hæmophilia . . . 221, 273
 - Herod's purpura . . . 76
 - Hodgkin's disease . . . 274
 - internal carotid erosion . . . 121
 - in leukaemia . . . 25, 221
 - relapsing fever . . . 336
 - scarlet fever . . . 220, 221, 273
 - simulating hæmorrhages . . . 221
 - hæmoptysis . . . 221
 - in small-pox . . . 273
 - spectrum in diagnosing cause of . . . 221
 - in splenomegaly poly-erythema . . . 633
 - transient relieved by . . . 221
 - in typhoid fever 76, 221, 636
 - vicarious menstruation and . . . 221

Epithelial casts 6
 - cells, similitude of renal, ureteral, and vesical . . . 575
 - renal, in dysuria . . . 109
 - in urine . . . 3, 10
 - in acute nephritis . . . 11
 - from bacteriuria . . . 70
 - from calculus . . . 117

Epitheloma (see Carcinoma)
 - adenoid cysticum . . . 733
 - destruction from rodent ulcer . . . 179

Epithelioma, general notes on 730, 731

Epi-tracheal glands (see Lymphatic glands, Epit-racheal)

Equis, bleeding gums from 72

Epulis, fibrous 671, 684
 - malignant . . . 672
 - microscopic in diagnosing . . . 71
 - pyramidal from . . . 512

Equilibrium, mechanism of maintenance of 751

Erb, on electrical reactions in tetany 581
 - myopathy of . . . 135

Erb's palsy, general account of 507
 - seen in tetany . . . 3, 132
 - Erb's tonic, bidental (see Frigoris)

Erythema, dead fingers in . . . 162
 - in erythromelalgia simu-lated by . . . 259
 - gangrene from . . . 255, 259
 - purpura from . . . 553
 - Raynaud's disease simu-lated by . . . 259
 - from rye . . . 259
 - tetany from . . . 131

Erosion of bone by aneurysm 131, 183, 516,
 - 693, 713, 770
 - in Kaposi's disease . . . 732
 - by rodent ulcer . . . 735
 - covered, backache from 168
 - in carcinoma simulating 391
 - character of discharge from . . . 185
 - in metrorrhagia from . . . 310
 - in metastasis from . . . 392
 - in tubercle simulating . . . 391
 - hæmorrhage . . . 265, 269, 272
 - Erosion, in Jacquet's erythema . . . 101

Error of refraction (see Refraction, Error of)

Eructatio nervosa 240, 316

Erethations, acid, from dys-pepsia 319
 - from acute dilatation of stomach . . . 173
 - explosive, after soda-water, etc. . . . 588
 - from gastritis . . . 267

Erethations, oculi
 - with intestinal colic . . . 125
 - rapidly repeated, aëro-phagy indicated by . . . 245
 - Erysipelas, albuminuria in . . . 43
 - bacteriologal diagnosis 113
 - baldness from . . . 71
 - bathing-drawers' area . . . 101
 - affected by . . . 101
 - bulla in . . . 96, 98, 674
 - diathesis-reaction in . . . 173
 - dilatation of heart in . . . 214
 - of ear . . . 203
 - endocarditis with . . . 30
 - erythema in . . . 223
 - simplex simulating . . . 227
 - of toe . . . 674
 - gangrene from . . . 255
 - hyperpyrexia in . . . 309
 - leucocytosis with . . . 360
 - lupus erythematosus . . . 710
 - simulating . . . 590
 - neutrophils from . . . 590
 - oedema from . . . 113, 115,
 - pyrexia in . . . 98, 567, 568
 - rigor in . . . 591, 595, 674
 - from a scratch . . . 568
 - simulated in angioneu-rotic oedema . . . 226
 - in Meigs' disease . . . 226
 - sloughing from . . . 674
 - spleen enlarged in . . . 632, 637
 - streptococci in . . . 98
 - streak from . . . 651
 - temperature chart in (Fig. 245) . . . 568
 - tenderness of scalp from 710
 - toxæmia in . . . 214
 - urticaria simulating . . . 771
 - weak first sound in . . . 214

ERYTHEMA 222
 - acute tubercle . . . 562
 - in acute rheumatism . . . 228
 - in angioneurotic oedema . . . 226
 - from arsenic . . . 224
 - articular . . . 227
 - from ataxyl . . . 224
 - bromides . . . 98
 - bullous, acute oedema of tongue from . . . 698
 - bleeding gums with . . . 72
 - bulla in . . . 96, 98
 - colon affected by . . . 71
 - dys-phagia from . . . 198
 - eosinophils in . . . 39, 219

Erythema bullosum, general account of 98
 - mouth affected by . . . 74
 - pyrexia in . . . 71
 - vagina affected by . . . 71
 - in cerebrospinal meningitis . . . 225, 591

Erythema, classified causes of 222, 223
 - from copula . . . 284
 - in dengue . . . 225, 166
 - dermatitis herpetiformis . . . 222
 - in German measles . . . 98
 - gonorrhœa . . . 96
 - in herpes . . . 774
 - from herpes progenitalis . . . 618
 - lyphathal disease . . . 222
 - ab igne . . . 226
 - in impetigo . . . 558
 - induration . . . 223

Erythema induratum scrofulosorum 404
 - tuberculous and . . . 738
 - ulcer of leg from . . . 738
 - from nodules . . . 98
 - iris, bulla in . . . 96, 98
 - eosinophils in . . . 219

Erythema iris, general account of 98
 - vesicles in . . . 756
 - in iritis, bathing-draw-ers area affected by . . . 401
 - itching in . . . 510

Erythema, Jacquet's infan-tile 400
 - from jelly fish . . . 224

Erythema keratodes 404, 405
 - due to knot-stress . . . 224
 - of legs, in girls, from standing . . . 401

Erythema in leprosy 225, 383
 - in melaria . . . 225
 - nodules . . . 228
 - Meigs' disease . . . 226
 - multiforme . . . 223
 - in acute rheumatism . . . 105

Erythema multiforme, general account of 489
 - vesicles of . . . 189
 - ports affected by 489, 562
 - pyrexia supra after 604
 - prurigo simplex simu-lating . . . 489
 - scales in . . . 600
 - small-pox simulated . . . 562
 - streptococci simulating 489
 - erythema simulating . . . 489
 - vesicles in . . . 227, 756
 - from measles in . . . 224
 - nodules in acute rheu-matism . . . 105, 228, 614
 - age and sex incidence 104
 - Bazin's disease distri-buted from . . . 104
 - bilateral character . . . 104
 - duration of . . . 104

Erythema nodosum, general account of 404
 - leprosy simulating 103, 104
 - lipping from . . . 562
 - multiple swellings with 668
 - osteomyelitis simulated by . . . 104, 668
 - pairs in joints in . . . 104
 - pyrexia in . . . 104
 - skins affected by . . . 668
 - successive crops of . . . 104
 - no alteration with . . . 104
 - papulation . . . 189
 - from parasites . . . 226
 - with peliosis rheumatica 556
 - in pellagra . . . 162, 226
 - (Pfeil's A) . . . 228
 - from polyneuritis . . . 464
 - ptomaine poisoning . . . 224
 - rheumatism . . . 223
 - in rubeola fever . . . 598
 - rheumatic . . . 14, 227
 - from rhus-toxicodendron . . . 224
 - salvarsin . . . 221

Erythema scarlatiforme, general account of 223, 227
 - scales in . . . 602
 - in scarlet fever . . . 614
 - from searants . . . 224
 - in seborrhœic dermatitis . . . 101
 - from serum injections . . . 223
 - simplex . . . 223
 - erysipelas simulating . . . 227

Erythema simplex, general account of 227, 228
 - leprosy simulating . . . 383
 - scales in . . . 602
 - scarlet fever simulated . . . 227
 - in small-pox . . . 561
 - from sodium cacodylate . . . 224
 - solar . . . 222
 - from strawberries . . . 225
 - tape-worm . . . 226
 - toxæmia . . . 226
 - trade . . . 224
 - trypanosomiasis . . . 226
 - vasiform, of infants . . . 101
 - vesicular, perleche with . . . 266
 - vesiculous . . . 756
 - from weaver-fish . . . 224
 - r-rays . . . 223

Erythraemia 534
 - erythrasma, bathing-draw-ers area affected by . . . 401

Erythrasma, general account of 251
 - erythrocythæmia . . . 534

Erythromelalgia, age incidence of 111
 - in apparently healthy persons . . . 111
 - cold relieving . . . 111
 - in dis-sensitized sclerosis 111
 - erythema simulating . . . 223
 - itching of feet in . . . 111
 - gangrene from . . . 255, 256
 - in rate in . . . 111

Erythromelalgia, general account of 441
 - influence of posture on . . . 111

Erythromelalgia, intermit-tent claudication differ-entiated from 441
 - oedema of feet in . . . 111
 - pain in the feet in . . . 111
 - the limbs from . . . 256

Erythromelalgia, Raynaud's disease differentiated from 441
 - sex incidence of . . . 111
 - in symphyseal . . . 111
 - tubes dorsalis . . . 111

Erythropsia 762
 - Lesson of vanilla, demo-nstrating from . . . 755

Essential albuminuria . . . 15
 - hæmaturia . . . 275

Essential hæmaturia, general account of 281
 - leucocytosis from . . . 500
 - lithæmic, nephritis and 701
 - vaginal swelling from . . . 699

Estimation of alkalinity by silver nitrate 746

Estimation of sucra 263

Estimation of total acidity of gastric contents . . . 320

Ether, blood pigment dis-solved by 81
 - hæmoglobinuria from . . . 284
 - hæmolytic from . . . 285
 - leucopenia from . . . 171
 - in occult blood test . . . 171
 - peripheral neuritis from 64
 - thrombus from . . . 725

Ethionol, air cells (see Stimus, Ethionol)

Encyphosis, sore fingers from 229
 - Emmels, obesity in . . . 409

Enstachian tube, adeno-id, obstructed, deafness from 165
 - in epiphysis . . . 166
 - Encephaloma (see Fever), Acute 223

Exercise, ammonia and . . . 187
 - deficient, bulimous and 526
 - obesity from . . . 108, 185
 - urea acid and . . . 712
 - effect on albumuria . . . 15

aortic regurgitant
 - burnt . . . 185
 - pulserate . . . 88
 - renal calculus . . . 394
 - hæmaturia after . . . 280
 - intermittent claudication of . . . 111
 - irregular heart made regular by . . . 88
 - palpitations and . . . 187
 - pulserate and 185, 186, 104
 - pyrexia from . . . 571
 - rheumatism relieved by 166
 - uric acid amount and . . . 574
 - violent, epistaxis from . . . 220

Exen-sibility, in Graves's disease 215, 722
 - of muscles, increased in . . . 152

Excitation, irascible, in tetany 119
 - in myxoedema . . . 119

Excitement, arrhythmia of heart and 545
 - diarrhoea from . . . 173
 - after epaleptic fit . . . 145
 - insomnia from . . . 320
 - nightmare from . . . 102
 - paroxysmal hæmoglobinuria from . . . 285
 - precordial pain from . . . 151
 - rye-rapid from 519, 702, 714
 - pyrexia from . . . 575

- Excoriation of lip, in nasal diphtheria . . . 179
 - nose, in nasal diphtheria . . . 178
 Eversion, angina pectoris caused by 316, 433, 434
 - brachial neuritis increased by . . . 442
 - excessive, hemoglobinuria after . . . 284
 - in epistaxium increased by . . . 436
 - precordial pain on . . . 433
 Exhaustion, with hepatosis . . . 368
 - hypothermia from 571, 573
 - impotence from . . . 313
 - insomnia from . . . 321, 322
Exhaustion during labour, signs of . . . 201
 - in malaria . . . 30
 - myasthenia . . . 235
 - nervous, localized convulsions from . . . 144
 - twitching from . . . 136
 - from polyorrhometis . . . 107
 Exophthalmic goitre (see Graves's Disease) . . . 229
EXOPHTHALMOS . . . 229
 - from aneurysm . . . 229, 230
 - cavernous sinus thrombosis . . . 597
 - distended nasal sinus 229, 230
 - encephaloid . . . 229
 - epiphora from . . . 229
 - from exostosis . . . 229
 - in Graves's disease 215, 229, 229, 236, 486, 702, 722, 726, 731
 - from gumma . . . 229
 - intermittent, from varicose veins . . . 230
 - from meningoid . . . 229
 - myopathy . . . 235
 - new growth . . . 229
 - orbital cellulitis . . . 229
 - pulsating, from aneurysm from thrombosed cavernous sinus . . . 229
 - tubercle in orbit . . . 229
 - tumour of orbit . . . 229
 - ulcer of cornea from . . . 734
 - unilateral, from exostosis . . . 671
 Exostosis, from arthritis . . . 113
 - bursts over . . . 670
 - cartilage cap on . . . 670
 - family history of . . . 693
 - of femur (*Fig.* 281) 670, 692
 - ivory, exophthalmos from . . . 671
 - of frontal bone 201, 250
 - skull . . . 671
 - multiple hereditary . . . 671
 - orbital, exophthalmos from . . . 229
 - x-rays in diagnosis 201, 671
 Expiration, prolonged, in emphysema . . . 167, 217
 - plethys . . . 288
 Exploratory sounding of chest (see Needle) . . .
 Explosives, high, acute yellow atrophy from 334
 Exposure, hypothermia from . . . 311, 571
 Extensor brevis dexterior, nerve supply of . . . 498
 - pollicis, nerve supply . . . 505
 - carpi radialis brevis, nerve supply of . . . 505
 - - - - - longior, nerve supply . . . 505
 - ulnaris, nerve supply of . . . 505
 - communis dexterior, nerve supply of 499, 505
 - - - - - role in claw-hand . . . 499
 - hallucis, nerve supply of 499
 - indicis, nerve supply of . . . 505
 - longus dexterior, nerve supply of . . . 498
 - - - - - hallucis, hypercontracted in Friedreich's disease . . . 110
 - - - - - pollicis, nerve supply of 505
 - minimi digiti, nerve supply of . . . 505
 - ossis metacarpi pollicis, escape in plumbic wrist-drop . . . 65
 - - - - - nerve supply of . . . 505
 Extensor, *contd.*
 - plantar reflex (see Plantar Reflex)
 - proprius hallucis, nerve supply of . . . 498
External auditory meatus, lesions of . . . 422
 - cutaneous nerve, pain in . . . 429
 - plantar nerve . . . 498
 - popliteal nerve (see Nerve, External Popliteal)
 - rectus, paralysis of 176, 177, 495
 Extract, pancreatic . . . 191
 Extracranial chamber (*Fig.* 23) 73, 210, 379, 381, 613, 739
 Extrasystoles, arrhythmia from . . . 515
 - angular, in mitral stenosis . . . 517
 - auscultatory phenomenon with . . . 517
 - from coronary sclerosis . . . 517
 - curve showing (*Fig.* 231) 514
 - dropped beat from . . . 517
Extrastyles, general account of . . . 547
 - heart-block simulated by . . . 516, 517
 - irregular pulse from . . . 519
 - Mackenzie on . . . 517
Extrastyles, need for graphic tracings in diagnosis . . . 547
 - from nervousness . . . 547
 - polygraph tracing of (*Fig.* 234) . . . 547
 - pulse with . . . 547
 - pulsus biseminus from . . . 547, 559
 - slow pulse from . . . 548
 Extra-uterine gestation (see Ectopic Gestation)
 Extravasation, urethral, scrotal fistula from . . . 621
 - of urine, after injury 278, 370
Extroversion of bladder 539, 540
EYES, ACUTE INFLAMMATION OF . . . 231
 - - - of (*Plates XI, XII*) . . . 239, 232
 - almond-shaped, in Mongolism . . . 238
EYES, BLACK SPECKS BEFORE . . . 71
 - blue, post-nasal and . . . 603
 - burning, from error of refraction . . . 295
Eye, choroid coloboma of 415
 - closing of, ataxy exhibited on . . . 56, 57
Eye, congenital crescents in 415
 - conjugate deviation of 118
 - deformed, by exostosis 204
 - difficulty in closing in myopathy . . . 235
 - discharge from . . . 761
 - displaced, in hydrophthalmos . . . 205
 - embolism of (see Embolism, Retinal)
 - feeding of ret. m., from conjunctivitis . . . 231
 - foreign body in (see Foreign Body in Eye)
 - herpes of, pain from . . . 415
 - infarction of (see Embolism, Retinal)
 - inflamed, from conjunctivitis . . . 231
 - - - - - glaucoma . . . 231
 - - - - - iritis . . . 231
 - injury of, photophobia from . . . 524
 - - - - - pupil irregular after . . . 551
 - melanotic sarcoma of, (see Sarcoma)
Eye, myopic crescent in 416
 - nerve connections of (*Fig.* 138) . . . 309
 - oblique, in Mongolism . . . 237
 - ochromosis of (*Plate XXXIII*) . . . 746
 - opaque in, in congenital syphilis . . . 233
Eye, opaque nerve fibres in 416
 - *contd.*
 - pain in (see Pain in the Eye; and Photophobia)
Eye, physiological cup of 415
 - pricking, from error of refraction . . . 295
Eye, rodent ulcer of . . . 734
 - running at (see Coryza)
 - sarcoma of . . . 252
 - shifty, of drug-taker . . . 234
 - ulceration of (see Ulceration of the Cornea)
 - watering, from error of refraction . . . 295
 Eyeball, fixed, from abscess in orbit . . . 177
 - - - - - growth in orbit . . . 177
 - - - - - haemorrhage into orbit . . . 177
EBEYALL, RETRACTION OF THE . . . 217
 - Eyebrows, defective, in myxedema . . . 234, 409
 - eczema seborrhoeicum of 491
 - overhanging . . . 203
 - syccosis affecting . . . 558
 Eyelashes, pediculosis pubis affecting . . . 401
 - syccosis affecting . . . 558
 Eyelids, absence of hair on . . . 71
 - angioneurotic oedema of . . . 412
 - - - - - *Fig.* 178)
 - change of . . . 379
 - chromistrosis of . . . 654
 - drooping, in myasthenia . . . 235
 - epithelioma of . . . 378
 - oedema of (see Edema)
 - pigmentation of, in Graves's disease 215, 226
 - puffy, in myxedema . . . 231
 - quivering, in hysteria . . . 137
 - - - - - malinizing . . . 137
 - red, from cavernous sinus thrombosis . . . 229
 - - - - - chronic conjunctivitis . . . 229
 - - - - - retrofled, in Graves's disease . . . 751
 - - - - - stitching together of, in treatment . . . 721
Eyelids, xanthelasma of 324
 - xanthoma of . . . 732
 Eyestrom, from astigmatism . . . 524
 - close work . . . 524
 - error of refraction 416, 525
Eyestrain, general account of . . . 446
 - glaucoma from . . . 292
 - headache from . . . 291, 296
 - from hypermetropia . . . 524
 - occupations causing . . . 524
 - pain in the eyes from . . . 446
 - photophobia from . . . 524
 Eye-tension, diminished, from paralysis of cervical sympathetic, increased in glaucoma . . . 232, 233, 55
FACE (and see Facies)
 - absence of hair on . . . 71
 - acne affecting . . . 489, 569
 - actinomycosis affecting 736
 - angioneurotic oedema of (*Fig.* 178) . . . 412
 - asymmetry of, from facial paralysis . . . 193
 - - - - - with torticollis . . . 142
 - atelectosis of 131, 132, 133, 495
 - atrophy of, from seventh nerve paralysis . . . 63
 - bleeding nuclei of (*Plate XXXII*) . . . 292
 - bloodless, from asphyxia . . . 413
 - bones of, enlarged, in leontiasis ossia . . . 670
 - chromistrosis of . . . 655
 - encephalomyelomy of (*Plate XXXI*) . . . 694
 - colloid edema of . . . 733
 - contracture of (*Figs.* 198-200) . . . 492
 - - - - - from Bell's palsy 110, 494
 - cramps in, in tetanus . . . 131
 - cyanosis (see Cyanosis)
 - dysidrosis of . . . 755
 - endothelioma invading 180
 - enlarged, in acromegaly 685
 - epilepsy confined to . . . 145
 - epithelioma of . . . 673
 - erysipelas of . . . 674
 - erythema multiforme affecting . . . 489
 - flushing of . . . 673
 - flush area of . . . 241
 - flushed, in diabetes . . . 264
 - - - - - yellow fever . . . 273
 - flushing of (see Flushing)
 - gumma of . . . 541
 - habit tic of . . . 135
 - haematoid of . . . 655
 - healed gumma of (*Fig.* 227) . . . 541
 - hemiatrophy of . . . 61, 194
 - Henoch's purpura affecting (*Fig.* 157) . . . 345
 - herpes of . . . 753
 - hysterical spasm of . . . 494
 - impetigo affecting . . . 569
 - leprosy erythema of . . . 383
 - lichen scrophulorum of . . . 488
Face, lupus of . . . 735
 - - - - - erythematous affecting . . . 217, 692
 - - - - - meningeal projecting tubercle (*Fig.* 102) 230
 - - - - - miliaria of . . . 755
 - - - - - multiple benign scaroid affecting . . . 105
 - - - - - myxolonus of . . . 137
 - - - - - myopathy of . . . 514
 - - - - - ochromosis of (*Plate XXXIII*) . . . 746
 - - - - - oedema of (see Edema)
 - - - - - pain in (see Pain in the Face)
 - - - - - paralysis of (see Paralysis, Facial)
Face, pellagra affecting (*Plate XI*) . . . 226
 - - - - - pemphigus neonatorum affecting . . . 491
 - - - - - pigmentation of (and see Pigmentation of the Skin) . . . 527
 - - - - - pityriasis rosea affecting 604
 - - - - - prurigo affecting . . . 489
 - - - - - puffiness of, in nephritis 42
 - - - - - rigidity of, in epilepsy . . . 729
 - - - - - meningitis . . . 729
Face, rodent ulcer of 735, 758
 - - - - - rodent affecting 241, 189
 - - - - - scarring of, ectropion from . . . 229
 - - - - - scleroderma affecting . . . 599
 - - - - - sebaceous cyst of . . . 732
 - - - - - seborrhoea affecting . . . 692
 - - - - - sensory areas of (*Figs.* 188, 189, 191) . . . 448
 - - - - - small, in anastoplasia . . . 187
 - - - - - small-pox affecting 561, 737
 - - - - - subcutaneous emphysema of . . . 203
 - - - - - swelling of (and see Edema)
 - - - - - (Edema) . . . 673
 - - - - - from vena cava obstruction . . . 158, 159
 - - - - - syccosis affecting . . . 558
Face, syphilis of 209, 283, 735
 - - - - - syringomyelia affecting . . . 698, 699
 - - - - - ties affecting . . . 136
 - - - - - timea vesicular on . . . 259
 - - - - - tremor of, in general paralysis . . . 116
 - - - - - tumours affecting . . . 673
 - - - - - ulceration of . . . 755
Face, unilateral sweating of 654
 - - - - - varicella of . . . 671
 - - - - - yacunia affecting 736, 737
 Facial nerve paralysis (see Paralysis, Facial)
FACIES, ABNORMALITIES OF . . . 233
Facies in achondroplasia (*Fig.* 117) . . . 237
Facies of acromegaly 204, 685
 - - - - - (*Fig.* 116) 237, 685

- Facies, contd.*
 - bloated from aneurysm 159
 - from asphyxia 113
 - vena cava superior obstruction 158
 - in cataplexy 189
 - chronic alcoholic 253
 - in edema 114
- Facies, congenital syphilitic** 235
 - congested from nitrate resorption 240
- Facies of cretinism** (Figs. 88) 234
 - expressions, in paralytic agnitas 503
 - in familial alcoholic jaundice 631
 - in (Plate XVIII) 332
- Facies in familial lenticular degeneration** 238
 - fatuously placid, in muscular sclerosis 234
- Facies in Graves's disease** (Figs. 113) 236
 - hyperaemic, from peritonitis 388, 593
 - in leontiasis ossea 291
 - nitrate stenosis (Plate 114) 71
- Facies in Mongolian idiosy** (Figs. 118, 119) 237
- Facies, myasthenic** 235
- Facies, myopathic** (Figs. 109, 110) 235
- Facies, myxodematous** (Figs. 107, 108) 234
 - in ochromosis (Plate XXVIII) 716
- Facies of paralysis agnitas** (Figs. 114, 236) 236
 - perichthosom, in scarlet fever 228
 - in pellagra (Plate IX) 226
 - pigmented, with uterine lesions 39
 - rat-like, in microcephaly 188
 - in rarer sarcomas 598
 - rubicund, from alcohol 35
 - sallow, pigmented, in chlorosis 54
 - sallow, in congenital syphilis 100
 - in seventh nerve paralysis 191
- Facies in splenomegaly polycythemia** (Plate XVII) 634
 - square, in acromegaly 237
 - starfish, in pseudo-bulbar palsy 627
 - in strychnine poisoning 598
 - tetanic 598
- Faces of vomiting** (see Vomiting, Faces)
- Faces (and see Stools)**
 - abdominal swelling from 677
 - accumulation of, in colon 657
 - movable kidney simulated by 603
 - emaciated in diagnosing 654
- Faces, accumulated, notes on** 631
 - obstruction from 621
 - pain in hypochondrium 620
 - acid, from ferment from 641
 - pancreatic disease 101
 - alkaline, with gall-stone obstruction from 104
 - putrefaction 246
 - analysis of, Combridge's reaction and 101
 - bilharzia ova in 79
 - blood and mucus in (see Stools, Blood and Mucus in)
- bulbar, from fermentation 246
 - clay-coloured 224, 326
 - in colon, swelling in hypochondrium from 629
 - dry, hard, from deficient water intake 121, 125
 - in diabetes 121, 125
 - in hot weather 125
 - obstruction due to 125
 - oemia in diagnosing tumour due to 677
- Faces, small*
 - examination of, in dental ulcer 35
 - fat, in chronic paracystitis 264
 - jaundice 324
 - lats 101
fatty 239
 - diabetes, from post-cretinism 328
 - flakes in 328
 - gall-stone in 116, 327
 - hard, dyscholeza from 128
 - inoperable, age incidence of 172
 - carcinoma simulated by 156, 718
 - diarrhoea from 172
 - emaciated in diagnosing 718
 - felt per rectum 172
 - intestinal obstruction from 126
 - pain in left iliac fossa from 152
 - rectal examination in diagnosing 718
 - swelling in right iliac fossa from 665
 - tenacious from 718
 - incontinence of (see Incontinence of Faeces)
- keratin particles in 520
 - lead in 73, 119
 - meat fibres in, in chronic pancreatitis 264
 - in organisms in, in putrefaction 246
- Faeces, microscopical examination of** 519
 - in paucity of 191
 - mucus and blood in (see Stools, Blood and Mucus in)
- muscle fibres in, from intestinal putrefaction 211
 - pancreatic disease 328
 - occult blood in 126
 - with carcinoma of the pancreas 101
 - duodenal ulcer 104
 - gastric ulcer 104
 - peptic ulcers 104
 - offensive, in jaundice 324
 - ova in 226, 321
 - of ankylostomum in 81
 - islets in 328
 - in distum in 328
 - polypoid (tumour) colon parasites in 521
- FAECES PASSED PER URETHRAM** 238
 - from spermatozoa 382
 - secretory stimulation 238
- Faeces passed per urethram, list of causes of** 238
 - pneumothorax with 539
 - ribon-like, from carcinoma recti 78
- Faeces, simulating kidney** 354
 - enlarged liver 67
 - spleen 631
 - small in amount, yet normal 121
 - starfish cells, from erythrastric fermentation 241
 - stercorula absent from, in carcinoma of pancreas 104
 - trypsin activity of 328
 - tubercle bacilli in 76, 285, 158
 - tumours simulated by 354
 - uric acid in 713
 - vegetable cells in 520
 - resin in, with fermentation 246
- Faunting, after flushing** 241
 - attacks, in Addison's disease 526
- Faithfulness, in angina pectoris** 435
 - from aortic regurgitation 297
 - arsenic 268
 - extra-uterine gestation 293
 - fatty heart 212
 - haematemesis 268
 - hepatoptosis 368
- Faunus, contd.*
 - movable kidney 115
 - paronychia trichosporia 704
 - presiding haematemesis 286
 - from snake-bite 537
 - Falls, shivering from 196
 - of head, fractured space from 648
 - shoulder, Erb's palsy from 597
 - subconjunctival burrs from 436
- Fallopian canal, lesion in** 474
 - tubal distension, palsy 688
 - swelling due to 688
 - suppuration in (see Fallopian Tube)
- tubes, absent, sterility from 646
 - distended, dyscholeza from 129
 - false images 176
- Familial acholic jaundice** (Plate XVIII) 332, 634
 - spleen enlarged in 631
 - in uraemic idiosy 731
 - ataxic tremor 724, 727, 728
 - constipation 123
 - jaundice 325
- Familial lenticular degeneration** 238
 - metastasis 388
 - over-weight 100
 - tremor 724, 725

 - gout 514
 - haemophilia 53, 73, 536
 - Hirsch's cirrhosis 332
 - heart disease 114
 - Huntington's chorea 171
 - Meigs's disease 114
 - myopathy 599, 512
 - polydactylous 136
 - post-nicturnal 232
 - pharynx 104, 768
 - pseudo-hyperparathyroidism 513
 - Quincke's disease 111
 - retinitis pigmentosa 660
 - splenomegaly cirrhosis 637
 - Toombs's prostatic atrophy 117, 512, 543
- Famine, relapsing fever and typhus fever** 339, 457
- Faradic current, in muscle testing** 385
- Fars, ophthalmological notation of** 749
 - Fasting 794
 - Fat boy of Bokham 469
 - boys, hyperphrotonia and 469
 - primary lesions and 469
 - disappearance of pellets and 469
 - diarrhoea, at first for 469
 - in eyes 504
 - in tongue 504
 - from pancreatic disease 116, 172, 294, 328
 - spondyl and mis-spondyl 101
 - globules in isotope fluid 59
 - laves 101
 - tubercles 6
 - indigestion, stools with 171
 - necrosis, in acute pancreatitis 351, 389, 661
 - pancreatic 594, 767
 - subcutaneous, delirium in rales 236
- Fat-pads, above clavicles in retrosternum** 234
 - in myxoedema 231
 - litzschally, undine, in neuro-thymia 715
 - Fatigue, dyspepsia from 349
- Fatigue, contd.*
 - fibrillar contractions from 134
 - haemoglobinuria from 284
 - insomnia from 322
 - localized convulsions from 144
 - specks before eyes in 71
 - tremor from 724, 727, 727
 - twitching from 126
- Fatness, myocardial changes associated with** 14
 - in primary pulmonary (and see Obesity)
- fatty cysts 6
 - change, heart large from 54
 - crystals, in stools 170
 - from pancreas disease 172
 - degeneration of heart (see Heart, Fat)
- liver in phosphorus poisoning 73, 337
 - infiltration, ascites from of bowel, constipation from 123
- Fatty liver, general account of** 374
- FATTY STOOLS** 239
 - from carcinoma of duodenum 239
 - pancreas 54, 239
 - chronic pancreatitis 239
 - jaundice 239
 - superposition of heart 53
 - uterus (see Lipoma)
- tumour, diverticuli, haemorrhoids affecting 74
 - epithelioma of 579, 612
 - pythium bullosum of 74
 - tumour of 613
- Faeces, inflamed, general account of** 615
 - sore throat from 613
 - mucous patches on, in syphilis 618
 - pemphigus affecting 71
 - red in scarlet fever 228
 - tuberculous 613
- Faces, acholic Schauderian** 246
 - causing 246
 - dyspepsia, areolar distum 217
 - pushed from 217
 - biliousness from 71
 - crusts in 609
 - diagnosis, observed by treatment 217
 - oemia, retrosternal from 217
- Favus, general account of** (Figs. 125) 246, 247
 - hair changes from 247
 - honey-comb appearance in 246
 - lupus erythematosus simulating 247
 - trichine 247
 - microscopic in diagnosing 247
 - mucous smell of 246
 - mucous membrane affected by 246
 - mycelium in 247
 - nails affected by 247, 250, 259
 - preference for scalp 246
 - ringworm distinguished from 249
 - scabrous distinguished from 247
 - staining points 247
 - spores in 247
 - sulphur dress of 246
 - tenderness of scalp from 170
 - hair, amorphous from 18
- Febra, enteric and** 164
 - gastro-intestinal aspects of 164
- Febriola, general account of** 573
 - measles and 164
 - pain in hypochondrium 164
 - pneumonia and 164
 - pulmonary tuberculosis 164
 - rheumatism and 164
 - scarlet fever and 164
 - sore throat and 164
- Feet, acroparasthesia of** 141
 - atrophic of 111
 - blue, with talipes 112
 - broad, in myxoedema 119

FINGERS, DEAD 162
 from articular osses 162, 163
 atheroma 162, 163
 blue from 162, 163
 carbonyl of soda 163
 cervical ribs 162
 cold 162
 emolument 162
 hemorrhoidal anal 162
 from occupation 162
 in pellagra 162
 swimmers 162
 washerwomen 163
 from weight-carrier 143
 osteochondroma of *(Fig. 155)* 143
 enlarged, in acromioclavicular pulmonary osteoarthropathy 111
 erythema nodosum of 105
 erythematous lesions of 239
Fingers, gangrene of *(Plat. VIII)* 255
 in Raynaud's disease 162
 cyanogenetic 257
 gangrenous arthritis of 340
 Heberden's nodes on *(Fig. 155)* 343
 necrosis of, in Raynaud's disease *(Fig. 126)* 257
 nodular nodules 191
 numbness of, in acromioclavicular 144
 occupation of 144
 alveolar *(Fig. 160)* 247, 195
 spinal abscesses of 249
 systemic tubercular phlebitis 189
 erythema nodosum 28
 erythema toxicum 2
 alveolar osteoarthropathy of *(Fig. 161)* 247
 alveolar abscesses of 239
 avascular disease affects 162, 256, 257, 699
 bacillary fever affecting 357
 epiphyseal from 440
 epiphyseal gland disease from 280
 shies of 563, 755
FINGERS, SDRE 239
 contained callosities of 580
 from 580
 spindle, in acute rheumatoid arthritis *(Fig. 153)* 342
 common affections of 240
 xiphoid abscess 249
 xiphoid, from tubercular arthritis 668
 xiphoid, in myxedema 499
 three middle epiphyses in a hand 187
 tumor of, in Graves' disease 707, 770
 tubercular (see *Disabilities, Tubercular*)
 deviation of 163, 210
 alveolar abscesses of 239
 osteoarthritis of 324
 gangrene, left ventricular 206
 left hand 224
 gangrenous 28
 gangrene after 673, 771
 gangrene, not caused by 267
 gangrene, pythemic from 542
 gangrene, gangrene of hand from 259
 gangrene perforated by 267
 gangrene 584
 gangrene swollen from 698
 gangrene, erythematous 224
 gangrene, anal, gangrene in 471
 gangrene from 193
 gangrene from 193
 gangrene, on distal part from 585
 gangrene in penis from 471, 473
 gangrene examination in 194
 gangrene in diagnosis 194
 gangrene from 718
 gangrene, syphilitic 739

anal, anal 78
 carcinoma from 194
 between labesinal fold 744
 urinary tract 744
 bronchoesophageal 259
 gastrocolic, lead vomiting from 766
 genital sterility from 646
Fistula, rectovaginal 585
 rectovesical 585
 alter childbirth 238
 pemphig, from 621
 non 530
 paraproctitis from 570
 septal 476, 621
 from rectal suppuration 621
 structure 621
 syphilitic basis 624
 tubercle bacilli from 479
 from tuberculous 618, 621
 urethral excystation 621
 umbilical 45
 from pneumococci 634
 peritonsils 634
 tuberculous peritonitis 43, 48, 631, 656
 urethral, behind in perineum from 474
Fistula, urethral, general account of 620
 in an epiphysis 184
Fistula, urinary, general account of 397
 vesical, cystoscopic 509
 diaphragmatic 145
 vesical 145
Fits, definition of kind of 123
 convulsions 123
 location of system 758
Fixing fluid for histological specimens 393, 391
 fluid, fixative 393
 fluid, from 316, 349
 flashes of light, from 241
 fluid, hanging from 241
 fluid, nasal, after anal 139
 pain from 138
 in ticks *(Fig. 87)* 136
FLATULENCE 240
 ante abdominal pain from 495
 in acute peritonitis 241, 269
 chronic 316
 chronic dyspepsia 319
 chronic 447
 diaphragm and crura 447
 diaphragm with 82
 food with 124
 with emphysema 241
 food accumulation with 241
 with gastritis 241
Flatulence, gastric, general account of 241, 246
 from gastritis 267
 in heart disease 241
 heart disease pain simulated by 433, 437, 709
 mesenteric from 431
 inter-epiphysal from 464, 462
Flatulence, intestinal, general account of 241, 246
 loss of weight from 769
 mesenteric anal 288
 pain in chest from 769
 epigastric from 437
 heart from 432, 435
 in left hypochondrium from 430
 in shoulder from 471
 palpitation from 435, 485
 pelvic lesion simulated by 482
 with polyserous kidneys 42
 with pyloric obstruction 244
 simulating dysmenorrhoea 493
 tenderness in chest from 799
 from tetrahydrothione 334
Flatus, absent with intussusception 129
 in acute proctitis 451
 from atrophy 246

Flatus, contd.
 anorexia 246
 constipation 246
 terms of stool 246
 fullness, relieved by passage of 245
 from heart failure 246
 passage of, culture checked by 427
 from putrefaction 246
 Flavour 706
 Flashes, itching in 549
 purpura from 555
 Flexor, brachii, digitorum, nerve supply of 498
 fullness, nerve supply 498
 mamma digiti, nerve supply of 498, 504
 pollicis, nerve supply 504
 carpi radialis, nerve supply of 504
 ulnaris, nerve supply 504
 carpi ulnaris, nerve supply of 509
 in ulnar paralysis 440
 longus digitorum, nerve supply of 498
 indicis, nerve supply 498
 pollicis, nerve supply 504
 profundus digitorum, nerve supply of 504
 sublimis digitorum, nerve supply of 504
 Flexors digitorum, role in claw-hand 369
 and disease 28, 29
Flint's marasmus 95, 277
 Flows, purpura-haemorrhagic 224
 Fluke, liver 35, 328
 lung 287, 292, 645
 fluid, serous 45
 albumen of 48, 79
 foetorial 48
 bloody 49
Fluid, ascitic, characters of 48
Fluid, ascitic, chylous, characters of 50
 increased turbidity 54
 increased viscosity 54
 increased fluidity 54
 blood in 49
 blood in, booklets in 49, 181, 576
 hydrocele 181
 loss of in cholera 164
 masses from 157, 164
 from chylous 729
 glycerine 164
 excessive, in chylous effusion 84
 systemic fluid from 259
 infection by 334
 infection of the blood from 164
 from peritonitis 729
 polyserous from 562, 563
 from severe diarrhoea 563
 containing 729
 sweating 729
 in typhus 164
 from vomiting 729
 in yellow fever 164
 ovarian 45
Fluid, pleuritic, characters of 102, 104
 spermatozoa 181
 fibrous in, in detritus 77
 alteration of color 77
 fibrousness in, urethral test 225
(Plat. XXXV) 748
 fluid, milk, with streptococci 36, 183, 764
 in myxedema 58, 469
(Fig. 104) 231, 469
FLUSHING 241
 in urea 241
 from alcohol 241
 flushing distinguished from 241
 in brachial neuritis 442
 chlorosis 241
 in chloruretic 241
 in erythromelalgia 441
 of face in malaria 29
 fainter after 241
 from iodine inhalation 241

Flushing, contd.
 general debility 241
 goldsmiths, after 241
 in Graves' disease 246
 with hysterical pyrexia 310
 from indigestion 241
 in lactation 241
 local, from visceral distension 458
 in menorrhoea 241
 in measles after 241
 in miasmata after 241
 in polipitation after 241
 in polydipsia acutata 727
 in prostatic after 241
 in pneumonia 241
 rosacea 241
 sense of suffocation after 241
 in the duodenum 447
 in tinitus after 241
 tremor after 241
 vomiting after 241
 in whooping cough 154
 flushing, in prostatic 793
 from test for bile 743
 foaming at mouth in convulsions 116
 epilepsy 145
 indigestion 117
 local heart, with pregnancy 689
 sounds, proving pregnancy 49
 with hydrops amni 19
 movements, with hydrops amni 45
 prostatic 689
 local, brachii (see from chronic, brachii)
 labor of, breathless 40
 brachii, tenderness of the 40
 forms, local, albumen of 40
 from 46
 local, loss of discharge from 478
 local, in condyloma 405
 local, in condyloma 405
Followed, condyloma 239, 241
(Plat. VI) 239, 241
 followed, case, Tom-dillo 71
 followed, desquamation 249
 followed, depressed, local 474, 584
 followed, in ticks 145, 625
Food, a case of containing iron of 718
 food taste from 707
 food taste, vomiting due to 565
 in typhus 157
 formation through 100
 food, in case of formation of food of 581
 between teeth, food taste from 707
Food, minute, coloration of 744
Food, Charcot's point in 349
 claw 409, 499
 epithelioid 581
 flat (see *Flat-foot*)
 from body in 362
Foot, gangrene of *(Plat. VIII)* 258
 in aneurysm of 758
 pain in (see *Foot in the Foot*)
 pallor of, from intermittent claudication 441
 perforated a shaver of 257, 265, 735, *(Fig. 265)* 736
 small pony, affecting 564
 alteration of (see *Foot in the Foot*)
 foot drop 56, 115
 food, others, cramps in 240
 swollen, in foot 244
 nodules on skin of 667
 tenderness of spine in 745
 for men, system, entery, venous thrombosis 229
 oval, peduncle 157
Forceps at delivery, paraplegia from 549, 541
 hemiplegia from 113
Fordyce's disease, general account of 363, 366

- forearms, erythema multiforme affecting . . . 489
 - nodosum from . . . 491
 - local fatness of, in Dermoid's disease . . . 410
 - paralysis of, Volkman's (Fig. 58) . . . 141
 - septic, epitrochlear gland enlarged from . . . 580
 Forehead, acute affecting . . . 489
 - bulging, in anhydroplasia . . . 187
 - - - rickets . . . 187
 - carcinoma of . . . 179
 - cheriopatholya on . . . 97
 - chromatosis of . . . 634
 - cerebral aneurysm of (Figs. YAAT) . . . 694
 - congenital syphilitic eruption on . . . 400
 - - - downy, in Alcoholism . . . 258
 - herpes of . . . 754
FOREHEAD, ENLARGEMENT OF THE 203, 204
 - hematoma of . . . 205
 - punctation of . . . 527
 - prominent, in congenital syphilis (Fig. 106) 251, 255
 - - - sloping, in microcephaly . . . 490
 - - - syphilitic of . . . 490
 - - - wrinkled, in acromegaly . . . 257
 - - - in tabes (Fig. 115) . . . 256
FOREIGN BODY IN AIR-PASSAGE,
 asthma simulated by . . . 555
 - - - loud breath from . . . 87
 - - - aorta perforated by . . . 267
 - - - in bronchus, bronchiectasis from . . . 292
 - - - engorged of lung from . . . 259, 260, 652
 - - - hamptysis from . . . 287
 - - - pyopneumothorax from . . . 652
 - - - simulating diphtheria . . . 457
 - - - stridor from . . . 650
 - - - cyanosis from . . . 157
 - - - in ear, deafness from . . . 165
 - - - - - eardrum from . . . 292
 - - - otorrhoea from . . . 422
 - - - speculum in detecting . . . 422
 - - - tympanus from . . . 722, 723
 - - - vertigo from . . . 732
 - - - in eye, blinking from . . . 156
 - - - pain from . . . 415
 - - - photophobia from . . . 524
 - - - ulcer of cornea from . . . 733
 - - - fatal hematoma from . . . 267
 - - - in foot, lumping from . . . 262
 - - - pain in foot from . . . 262
 - - - in gums, ptialism from . . . 542
 - - - hematoma from . . . 271
 - - - in knee, lumping from . . . 562
 - - - larynx . . . 149, 157
 - - - death from (Fig. 94) . . . 195
 - - - foul breath from . . . 87
 - - - laryngeal obstruction by . . . 118, 419
 - - - meningitis simulated by . . . 590
 - - - orthopnea from 118, 419
 - - - simulated by alveolar paralysis . . . 158
 - - - in nose, discharge from . . . 179
 - - - epistaxis from . . . 220
 - - - foul breath from . . . 87
 - - - cesophageal stenosis from . . . 194
 - - - in oesophagus, benign in diagnosis . . . 267
 - - - hematoma from . . . 265
 - - - oesophagoscopy in diagnosis . . . 196, 267
 - - - perforation by . . . 267
 - - - pyopneumothorax from . . . 652
 - - - straws in diagnosis . . . 267
Foreign body in rectum 584
 - - - abscess due to . . . 584
 - - - from anus from . . . 78
 - - - in urethra . . . 181, 184
Formalin fixing fluid 391, 701
 - formation . . . 540
 - formula, distoma pulmonale in . . . 292
 - Foul air, headache from . . . 295
FOUL BREATH 86
 - Lournar, on chamber from . . . 751
FOURTH DISEASE, general account of 228, 229
 - Fovis, blood of, used by malingers from . . . 286
 Fox, follicle, on vacciform erythema of infants . . . 401
 - - Tilbury, impetigo contagiosa of . . . 401
 Fracture, badly united, olecranon from . . . 411
 - - - of base of skull, blood-tinged . . . 762
 - - - cerebrospinal fluid from ear due to . . . 119
 - - - - - nose due to 119, 178
 - - - deafness from . . . 466
 - - - diabetes insipidus from . . . 537
 - - - epistaxis from . . . 220
 - - - hemorrhage from . . . 121
 - - - ear due to 119, 121
 - - - nose due to . . . 119
 - - - tunnus from . . . 523
 - - - vertigo after . . . 752
 - - - basis of skull, hemiparesis from . . . 202
 - - - talus from . . . 96, 97
 - - - callus after . . . 667
 - - - compound, talipes from . . . 114
 - - - crepitus from . . . 152
 - - - Dupuytren's, talipes . . . 114
 - - - of femur, oedema of legs after . . . 414
 - - - sciatic nerve paralysis from . . . 499
 - - - of fibula . . . 562
 - - - green-stalk, callus first evidence of . . . 667
 - - - of tibia, lumping from . . . 263
 - - - of tibia . . . 262
 - - - lumping from . . . 362, 263
 - - - from mollities ossium . . . 242
 - - - from rickets . . . 212
 - - - of humerus, paralysis of innervating nerve from . . . 594
 - - - jaw . . . 683
 - - - ptialism from . . . 542
 - - - muscle atrophy with . . . 61
 - - - from muscular effort . . . 242
 - - - abducting nerve, muscle wasting from . . . 61
 - - - - K.D. from . . . 61
Fracture, pain long after 476
 - - of pelvis, sciatic nerve paralysis from . . . 499
 - - - rupture of bladder from . . . 278
 - - - urethra injured by . . . 470
 - - - penis . . . 408
 - - - Fort's, talipes from . . . 114
 - - - of ribs, crepitus with . . . 207
 - - - emphysema from . . . 104
 - - - hamptysis from . . . 282
 - - - rarity of pneumothorax from . . . 552
 - - - surgical emphysema from . . . 295, 552
 - - - tenderness from . . . 207
 - - - x-rays in diagnosing . . . 707
Fracture of sacrum, anæsthesia from (Fig. 259) 608
 - - skull, decalyptra from . . . 81
 - - - cerebrospinal fluid from ear after . . . 121
 - - - coma from . . . 118
 - - - hyperæmia from . . . 599
 - - - unilateral paresis from . . . 118
 - - - spine, acute bed-sores from . . . 258
 - - - aliochæra from . . . 17
 - - - from diving . . . 242
 - - - fall on head . . . 648
 - - - vertebral points from 131, 436
 - - - from lumbar . . . 510
 - - - hyperæmia from . . . 210
 - - - from muscular effort . . . 242
 - - - myelitis from . . . 510
 - - - pain in neck from . . . 448
 - - - paralysis of bladder from . . . 598
Fracture of spine, contd.
 - - paraplegia from . . . 243, 538
 - - - paraplegia from . . . 538
 - - - spontaneous, from . . . 243
 - - - transverse myelitis from . . . 516
 - - - urine dribbling after . . . 398
FRACTURE, SPONTANEOUS . . . 242
 - - from carcinoma . . . 242, 672
 - - - caries . . . 242, 243
 - - - chloroma . . . 242
 - - - fragilis ossium . . . 242
 - - - general paralysis . . . 242, 243
 - - - hydatid . . . 673
 - - - new growth . . . 243
 - - - sarcoma . . . 242
 - - - in scurvy-rickets . . . 670
 - - - syringomyelia . . . 257
 - - - of vertebra . . . 715
 - - - x-rays in diagnosing . . . 152
Fracture-dislocation, spinal, aliochæra from 17
Fracture-dislocation of spine, anæsthesia from 608
 - - knee-jerks lost after . . . 538
Frænum, linguæ, abraded, by violent coughing . . . 289
 - - - ulcer of, in whooping-cough . . . 739
 - - - penis, perforated, by soft sore . . . 618
Frænititis ossium, blue sclerotics with . . . 242
 - - - duri-sm with . . . 187
Fræpititis ossium, general account of 242
 - - - osteomalacia and . . . 187
Fragility of red cells, enlarged spleen and . . . 634
 - - - in familial acholuric jaundice . . . 522
 - - - mode of testing . . . 634
Frambæsia . . . 495
France, ringworm of 247
Fræckles, in acute rheumatoid arthritis . . . 342
 - - - Kaposi's disease . . . 731
 - - - von Recklinghausen's disease . . . 719
 - - - xeroderma pigmentosum simulating . . . 383
Freezing-point depression of acute fluid . . . 61
Fresh air, deficiency of, rickets from . . . 145
Friction, auricular 548
 - - bulle from . . . 96, 97
Friction-sounds, in pericarditis . . . 433
 - - - peripneumonitis . . . 450
 - - - pleurisy . . . 450
 - - - pleuropneumonitis . . . 433
 - - - (and see Ribb)
Fried fish, cod from . . . 117
Friedlander's bacillus, see Bacillus Friedlanderii
Friedreich's ataxy, age incidence of 60, 113, 140, 513
 - - - no ankle-clonus in . . . 512
 - - - ataxy in 57, 113, 140, 291
 - - - Babinski's sign in . . . 68
 - - - choreiform movements in . . . 513
 - - - contractures in . . . 138, 140
 - - - familial nature . . . 140
 - - - family history in . . . 512
Friedreich's ataxy, general account of 140, 512
 - - - bulle erythra in . . . 135
 - - - in . . . 512, 513
 - - - hypertrophy of extensor longus hallucis in . . . 140
 - - - incoordination in . . . 251
 - - - intention-tremor in . . . 728
 - - - knee-jerk absent in . . . 513
 - - - in . . . 115, 512, 513
 - - - kyphosis in . . . 140
 - - - main bolt in . . . 140
 - - - muscular atrophy in . . . 140
 - - - myoclonic simulation of . . . 61
 - - - myxædem in 113, 140, 512
 - - - optic atrophy in . . . 512
 - - - paraplegia from . . . 510, 512
 - - - phthisis in . . . 513
Friedreich's ataxy, contd.
 - - - pneumonia in . . . 513
 - - - posterior column changes in . . . 57
 - - - pseudobulbarism in . . . 497
 - - - pupils normal in . . . 512
 - - - rigidity in . . . 139
 - - - scoliosis from 140, 151, 512
 - - - no sensory disturbance in . . . 512
 - - - in . . . 512
 - - - sex incidence of . . . 140
 - - - simulating infantile paralysis . . . 69
 - - - speech in 113, 140, 513, 627
 - - - no splinter trouble in . . . 512
 - - - talipes in 60, 113, 140, 512
 - - - tremor in 140, 512, 727, 728
Fright, acute yellow atrophy after . . . 333
 - - - chorea after . . . 133
 - - - convulsions from . . . 144
 - - - diabetes insipidus from . . . 537
 - - - menorrhagia from . . . 386
 - - - palpitation from . . . 184, 186
 - - - patulous tachycardia from . . . 705
 - - - pupil dilated by . . . 534
Froelich's syndrome 150
Froelich's, in erythema (Fig. 103) 253, 254
Frontal bone, exostosis of . . . 239, 671
 - - - tumours of . . . 294
 - - - lobe lesion, acropylia from . . . 626
 - - - speech centre in . . . 624
Frontal lobe tumour, signs of 727
 - - - ridges, enlarged, in acromegaly . . . 257
 - - - sinus disease (see Sinus, Frontal)
 - - - veins, engorged, in cavernous sinus thrombosis 229
Fronto-bulle, bulle from 96, 97
 - - - fingers affected by 239, 240
 - - - gangrene from . . . 255
 - - - hamatolobium from . . . 284
 - - - Raynaud's disease simulating . . . 162
 - - - vesicles from . . . 757
Front, colic from . . . 117
 - - - diarrhoea from . . . 171, 717
 - - - nightmare from . . . 462
Fruit-stone in bronchus, hamptysis from . . . 287
Fucelin stain . . . 641
Fucus vesiculosus, weight reduction by . . . 770
Fulness in chest, from mediastinal new growth 434
 - - - epigastrium, from gastritis . . . 317
 - - - gastric, from atony . . . 244
Fulness, gastric, general account of 243
 - - - from hypertonus . . . 244
 - - - leather-bottle stomach . . . 244
 - - - rapid eating . . . 243
 - - - in head, from high blood-pressure . . . 296
 - - - - - plethoria . . . 221
 - - - intestinal, from excess of gas . . . 245
FULLNESS, SENSE OF 432
 - - - from acute congestion of liver . . . 334
 - - - aerophagy due to . . . 245
 - - - from æsthetic dyspepsia . . . 519
 - - - in hypochondrium, from carcinoma of liver . . . 373
 - - - rectum, from carcinoma . . . 129
 - - - - - piles . . . 78
 - - - - - rectal polypus . . . 78
Functional albuminuria 15, 537
 - - - nerve, death from . . . 699
 - - - disease, death from . . . 699
 - - - disease, trouble (see Hydræmia and Neurosis)
Functioning ovaries (see Endocarditis, Lungarini)
Fungiform papillæ, prominent, in scarlet fever 227

- of testis ... 482
- from thrombosis ... 258
- from bandaging ... 258
- of toes, in diabetes ... 240
- from embolism ... 24
- in tubes ... 257
- gangrene's itch ... 540
- of nose, foul breath from ... 86
- taste from ... 705
- Gas in abdominal cavity** 652, 653, 656
- carbon monoxide poisoning from ... 114
- peritonitis (see Pneumothorax)
- in pleural cavity (see Pneumothorax)
- in workers, carcinoma of scrotum and ... 621
- Gases, indication of, haemoglobinuria from** 284
- irritant, corvix from ... 178
- in urethra from ... 157
- poisonous, head ache from 295

Gasserian ganglion, excision of, necrosis of
 - cornua from ... 734
 - herpes of ... 447
 Gastralgia, dyspepsia from 319
 - epigastric tenderness from ... 437
 - pain in epigastrium from 319, 436
 - after food from ... 437
 - in young women ... 437
 Gastroecstasis (see Dilatation of Stomach)
 Gastric carcinoma (see Carcinoma of Stomach)
 contents, arsenic in ... 78
 - blood in, from carcinoma of stomach ... 317
Gastric contents, in carcinoma of stomach ... 270
Gastric contents, in dilatation of stomach ... 766
Gastric contents, estimation of total acidity of 320
 - HCl (see under Acid, Hydrochloric)
 - lactic acid (see under Acid, Lactic)
Gastric contents, methods of analysing ... 319, 320
 - micro-organisms in ... 267
 - mucus in ... 320
 - occult blood in ... 630, 767
 - Oppler-Boas factor in 320
Gastric contents, organic acids in ... 320
 - poison in 78, 85, 108, 117
 - sarcina in 115, 211, 320
 - streptococci in ... 419
 - unduly acid, with gastric ulcer ... 437
 - yeasts in 241, 318, 320, 766
 - (and see Vomit)
 Gastric crises (see Crises, Gastric)
 Gastric diarrhea ... 172
Gastric flatulence, general account of ... 240
 - fullness, (see Fullness, Gastric)
 - juice, absent, in gastritis 317
Gastric juice, absence of HCl from ... 33
 - acidity diminished, in gastritis ... 317
 - analyses, in diagnosing gastroecstasis ... 171
 - diarrhea ... 170
 - changes, with carcinoma of stomach ... 316
 - pyloric stenosis ... 318
Gastric juice, characters in chronic gastritis 43, 317
 - unduly acid, with
 - duodenal ulcer ... 75
 - gastric ulcer ... 75
 - (and see under Gastric Contents)
Gastric peristalsis, visible 521
 - sarcoma (see Sarcoma of Stomach)
 - ulcer, abdominal tenderness with ... 115
 - absence of omentum from ... 661
 - ascloimia from ... 1
 - acute ascites from ... 47
 - peritonitis from ... 392
 - adhesions from ... 174
 - age incidence of 36, 268
 - albumosuria with ... 16
 - anaemia with ... 36, 269
 - blood per anum from 75
 - in vomit from ... 767
 - carcinoma from 316, 653
 - in chlorosis ... 271
 - chronic dyspepsia from 658
 - neutral fibrosis of 171
 - coffee-ground vomit from ... 268
Gastric ulcer, diagnosis from anæmic vomiting 36
 - distention from duodenal ... 75
 - carcinoma by rays 174
 - emphysem from 101, 106

Gastric ulcer, contd.
 - epigastric hyperæsthesia from ... 269
 - pain with ... 36, 266
 - excess of acid with ... 437
 - females affected by ... 75
Gastric ulcer, gall-stone distinguished from ... 437
 - metastasis from 174, 653
Gastric ulcer, general account of 36, 268
 - peritonitis from 36, 388
 - hæmatemesis from 56, 75, 265, 266, 268, 269, 317, 437
 - hemorrhagic erosions and ... 269
 - HCl in ... 767
 - heart-burn from ... 297
 - hyperacidity with ... 75
 - indurium in ... 101
 - inflammatory matting round ... 174
 - intersepalular pain from ... 461, 462
 - laparotomy in diagnosing from carcinoma 174
 - leaking ... 531
 - constipation after ... 126
 - local peritonitis from 174
 - rigidity over ... 592
 - spot of tenderness from ... 317, 437
 - loss of weight from ... 769
 - melæna from 75, 268, 269
 - occult blood in faeces with ... 101, 126, 767
 - œdema of legs after 114
 - pain in the back from 269, 428, 437, 716
 - chest from ... 709
 - pain due to ... 767
 - in the epigastrium from 268, 456, 462
 - after food from 269, 317, 437
 - left hypochondrium from ... 450
 - hypogastrium from 662
 - shoulder from ... 471
 - pancreatic artery opened by 268
 - pancreatitis from 100, 101
 - perforation of 47, 658
 - acute abdominal pain from ... 193
 - pancreatitis simulating ... 380
 - collapse from ... 436
 - pain in epigastrium from ... 456
 - laparotomy for ... 456
 - pneumoperitonæum from ... 652
 - shock from ... 436
 - pleurisy from ... 106
 - pneumothorax from ... 531
 - profuse hæmatemesis from ... 266
 - ptysis from ... 543
 - pyloric stenosis from 174, 269, 297, 317, 653
 - in servants ... 36
 - sex incidence of 36, 268, 457
 - simulated by anaemia 768
 - carcinoma ... 269
 - erisipelas ... 269, 272
 - duodenal ulcer 36, 271
 - dysmenorrhœa ... 195
 - gastric ulcer ... 272
 - gastrostaxis 36, 76, 266, 268, 271
 - heart disease 456, 709
 - leaking pyloric lesion 468
 - tubes ... 315
 - undue abdominal "aortic" pulsation 543
 - simulating carcinoma 174
 - enlarged gall-bladder 368
 - splenic artery opened by ... 268
 - subcutaneous emphysema from ... 203
 - subdiaphragmatic abscess from 103, 451, 531, 652, 658
 - sudden pallor from ... 268

Gastro-intestinal disorder, febriena representing 464
 - headache from ... 296
 - insomnia from ... 321
 - from round-worms ... 520
 - in rickets ... 145
 - rigor from ... 595
 - tetany from ... 3
 - secretions, not tinged by ... 324
 Gastroptosis, asthenic dyspepsia with ... 319
 - with gastric atony ... 241
 - movable kidney with ... 318
 - x-rays in diagnosing (Fig. 144) 318
 Gastroscope, in diagnosing acute gastritis ... 267
 - carcinoma of stomach ... 270, 271
Gastrostaxis ... 36
 - age and sex incidence of ... 270
 - in chlorosis ... 267
 - gastric ulcer simulated by ... 76, 266
 - simulating ... 268, 274
 - hæmatemesis from 265, 266
 - from hemorrhagic erosions ... 269
 Gaucher's disease, conjunctiva in ... 634
 - familial ichthyiform face and ... 634
 - family history and ... 633
 - special cells in ... 634
 - spleen enlarged in ... 631
 - splenic anaemia and ... 633
 - von Jaksch's disease and ... 634
 Gauze packing, pain in pelvis after ... 468
 Gellé's test ... 165
 Gemelli, nerve supply of 498
General paralysis of the insane, anomia in ... 612
 - aphasia in ... 621
 - Arzyl Robertson pupil in ... 551
 - bedriddenness from ... 59, 212
 - bleeding gums in ... 72
 - cerebral softening from ... 108
 - cerebrospinal fluid in ... 120, 243
 - Choyne - Stokes breathing from ... 108
 - coma in 117, 120, 144, 266
 - congestive attacks of 624
 - convulsions in 120, 141, 146, 243
 - deep reflexes in ... 146
 - defective writing, etc., in ... 120
 - dementia from ... 19
 - dysarthria in ... 627
 - dysphagia in ... 197
 - epileptiform seizure in ... 395
General paralysis of the insane, general account of ... 120
 - gangliose glands in ... 216
 - grinding of teeth in 243
 - hæmatoma in ... 243
 - headache from ... 294
 - hearing of voices in 465
 - hemiplegia in 393, 395, 624
 - insomnia from ... 322
 - irritability in ... 323
 - judgement defective in ... 146
 - knee-jerks unequal in 558
 - laryngeal paralysis in 495
 - leucocytes in cerebrospinal fluid in ... 395
 - lumbar puncture in 243
 - lymphocytes in cerebrospinal fluid in ... 395, 396
 - memory defective in 146
 - mental and moral changes in ... 726
 - mental work and ... 245

General paralysis of Insulin ... 518
 -- paralytic ... 518, 519
 -- post mortem ... 518
 -- sent in ... 513
 -- perforating ulcer of foot in ... 755
 -- plumbism simulating ... 119, 727
 -- pupal changes in ... 116
 -- pupils unequal in ... 170, 552
 -- simulating cerebral hemorrhage ... 120, 395
 -- sores in ... 72
 -- spasmodic twitches in ... 136
 -- speech blurred in ... 116, 726
 -- spout vomas fracture in ... 212, 623
 -- stammering from ... 248
 -- syphilis and ... 213, 195
 -- tottering gait in ... 726
 -- tremor in ... 116, 724, 726, 727
 -- Wassermann reaction in ... 120, 245
 -- wasting in ... 59
 -- weakness of muscles ... 116
 -- worry and ... 213
 -- writers' or map simulating by ... 151
 Geniculate branch of obturator nerve ... 363
 Genital organs, soft hard ... 70
 -- condyloma around ... 49
 -- elephantiasis of ... 20
 -- external, glands draining ... 679
Genital organs, herpes of ... 753, 754
 -- Jacquet's syndrome of ... 101
 -- myoma cutis of ... 752
 -- oedema of, in neutro-nephritis ... 9
 -- prostatic, hyper-nephroma and (*Fig.* 175, p. 108), 109, 650
 -- scabs of ... 555
 -- syphilides affecting ... 750
 -- syphilitic papules around ... 49
 -- region, how affecting ... 540
 Genitourinary region, ery-thrasma of ... 251
 Genital, heartburn relieved by ... 297
 -- taste of ... 706
 Geographical distribution of ankylomyositis ... 51, 521
 -- beriberi ... 63
 -- bilharzia ... 79, 282
 -- cholera major ... 154
 -- dengue ... 466
 -- distoma pulmonis ... 292
 -- eczema maceratum ... 250
 -- elephantiasis ... 28
 -- epidemic gangrene ... 259
 -- trichinosis ... 164
 -- hepatic abscess ... 291
 -- leishmaniasis ... 291, 638
 -- impetigo herpetiformis ... 38
 -- kala-azar ... 29, 633
 -- lung fluke ... 635
 -- malaria ... 632
 -- Malta fever ... 556
 -- Mediterranean fever ... 556
 -- molluscum ... 212
 -- mycetozoa ... 736
 -- onchium tropicæ ... 645
 -- primary alcoholism of ... 53
 -- relapsing fever ... 356, 596
 -- sleeping sickness ... 28
 -- yellow fever ... 273, 536
 German measles, albumin-uria ... 13
 -- diagnosis from scarlet fever ... 62
 -- enlarged posterior con-jugal glands in ... 562
 -- erythema in ... 223, 228
 -- fourth disease simu-lating ... 229
 -- lymphatic glands in ... 228, 376, 377, 378, 562

Genzyme mouse, could ... 562
 -- metastis in ... 562
 -- from ... 377
 -- occipital glands en-larged in ... 377, 378
 -- rash of ... 378
 -- razor rare in ... 595
 -- scales in ... 602
 -- scarlet fever distri-buted from ... 377
 -- simulated by ... 248
 -- sore throat in ... 613
 German primary alcohol-ism ... 53
 Gestation, ectopic (see Fetopie gestation)
 Giant cells in tuberculosis ... 103
 Giddiness (and see Vertigo) in ... 115
 -- arteriosclerosis ... 11
 -- from cerebral abscess ... 302, 596
 -- tumour ... 241
 -- after flushing ... 590
 -- due to increased intra-cranial pressure ... 590
 -- in nephritis ... 42
 -- pellagra ... 225
 -- preceding haematemesis ... 286
 -- from snake-bite ... 357
 -- in uremia ... 49
 -- Weil's disease ... 356
 Gienza's stain, for spiro-chætæ ... 701
 Gigantism, and acromegaly with gigantism (*Plate II, Fig. 1, 2*) ... 22
 Gingsher, heartburn relieved by ... 297
 Ginzher, reumatism through nose ... 588
 Givargitis, blood-spitting due to ... 285
 -- septic, purpura and ... 557
 -- suppurative (see Pyococ-cus Alveolaris)
 -- from syphilis ... 73
 -- tuberculous ... 72, 71
 Girdle, sore of, cyst from ... 181
GIRDLE PAIN ... 260
 -- from arthritis ... 171
 -- from condromyositis ... 299, 516, 713
 -- in disseminated scler-osis ... 260
 -- from fractured spine ... 471, 476
 -- hematomyelitis ... 110
 -- in myelitis ... 260
 -- from new growth in spine ... 711
 -- in cystic paraplegia ... 260
 -- from spinal injury ... 715
 -- syphilitic spinal meningitis ... 260
 -- in tabes ... 260, 456
 -- with transverse myelitis ... 140, 476
 -- sensation, disseminated sclerotic ... 609
 -- in diabetes ... 116, 609
 Glial parietal meningitis ... 28
 Glands, arthritis with ... 340
 -- bacillæ (see Bacillus) ... 340
 -- Malloxy ... 340
 -- bacteriology in ... 579
 -- causing ... 579
 -- bullæ in ... 36, 97
 -- horses and ... 97
 -- of leg ... 737
 -- lungs affected in ... 97
 -- nasal discharge in ... 179
 -- occupation meningitis ... 179
 -- pyrexia in ... 97
 -- razor in ... 595
Glanders, skin lesions of ... 559
 Glands, penis, distro-phy ... 171
 -- epithelium of ... 171
 Glandoma (*Plate XI*) ... 270
 -- age incidence of ... 232
 -- anterior chamber shal-low ... 272, 762
 -- atropine diastroph in ... 233
 -- blindness from ... 273, 762

Glandoma, could ... 272
 -- chiasmatically involved in ... 272
 -- from close work ... 272
 -- commutative injected in ... 272
 -- corner anæsthetic in ... 272
 -- stony in ... 272, 762
 -- emp. distinction from physiological ... 115
 -- from diastroph error ... 272
Glaucoma, disc of ... 417
 -- disc in (*Plate XX*) ... 418
 -- halos round lights from ... 272
 -- headache from ... 272, 291, 295, 712
 -- hyperæcrosis from ... 272
 -- in hypermetropes ... 272
 -- inflammatory ... 272
 -- iris discoloured in ... 272
 -- injected in ... 272
 -- from iris ... 761
Glaucoma, iritis, and con-junctivitis compared ... 232
 -- Ebermation from ... 231
 -- migraine simulated by ... 233
 -- oedema of eyelids in ... 233
 -- optic disc white and eye ... 272
 -- rotated in ... 272
 -- pain from ... 272
 -- in the ears from ... 272
 -- eye from ... 272, 145, 525
 -- face from ... 149
 -- head from ... 272
 -- teeth from ... 272
 -- photophobia from ... 271, 524, 525
 -- pre-hypertension increased by ... 272
 -- pupil dilated in ... 272, 762
 -- and fixed in ... 272
 -- vision from ... 272, 762
 -- eye in absence of ... 272
 -- sarkoidic-like simulated by ... 272
Glaucoma, iritis, and con-junctivitis compared ... 761
 -- tenderness of eyeball in ... 272
 -- scalp from ... 713
 -- tension of eyeball in-closed in ... 272, 273, 551
 -- unequal pupils from ... 552
 -- visual field contracted in ... 760, 552
 Vomiting from ... 272
 Glyceric phosphorus in ... 117
 Gleet, arthritis from ... 540
 -- syphilitic with ... 637
Gleet, general account of ... 182, 183
 -- ætiology in ... 181
 -- marriage in relation to ... 184
 Gleyer's disease ... 659
 Glioma of brain, hemi-anopsia from ... 201
 -- ocula optica ... 62
 Gliosis, spinal, pain in ... 443
 -- in syringomyelia ... 110
 Globulin and albumin, relative proportions in urine ... 4
 -- in ascitic fluid ... 18, 50
 -- cerebrospinal fluid ... 305
 Globus hystericus ... 187, 465, 651
 -- aphonia and ... 495
 -- in hysteria ... 141
 -- morion, tuberculous ... 637
 -- minor, syphilitic, zono-coccal ... 637
 Glosso-lipidosis, hypertro-phic form ... 28
 Glossoitis, chronic, origin ... 758
 -- oral and ... 758
 -- leukoplakia and ... 698
 -- smoking and ... 758
 -- syphilitic and ... 748
 -- dysphagia from ... 498
 -- tongue swollen from ... 698
 Glossokineticæ, centre ... 621
 Glosso-platyedæ, nerve paralytic ... 706
 Glottis, œdema of ... 171
 Glandia of Larynx ... 270
 Glove anæsthesia, in hy-po-pharynx ... 171, 165
 -- from peripheral neuritis ... 56
 -- in syringomyelia ... 609
 -- and striking anæsthesia (*Fig.* 256) ... 609

Glucose, quantitative esti-mation of ... 263
 Glandia of Larynx ... 270
 -- superior ... 498
 -- region, condylomata on ... 709
 Glycerin, atrophy of, from lip joint disease ... 61
 -- in camp of, in travellers ... 151
 -- nerve supply of ... 499
 -- pseudohypertrophy of ... 743
 Glycerin, maximum, nerve supply of ... 498
 -- minimum, nerve supply of ... 498
 Glycerin, hæmoglobinuria from ... 284
 Glycerin, relation to neph-roses ... 4
GLYCOSURIA ... 260
 -- and albuminuria, associ-ated with ... 12
 -- albuminuria in ... 261
 -- from alcoholism ... 85, 264
 -- aluminuria ... 264
 -- diabetes and ... 264
 -- alkaptonicæ simulating ... 746
 -- Combes's reaction and ... 100
 -- errors in tests for ... 742
 -- estimation by fermenta-tion ... 265
 -- fermentation test for ... 742
 -- goat and ... 713
 -- in Graves's disease ... 264
 -- Larynx paralysed with ... 198
 -- obesity preceding ... 198
 -- with pancreas lesion ... 61
 -- (*Fig.* 291, 290, 187, 661)
 -- peripheral neuritis from ... 265
 -- phenylhydrazine test for ... 745
 -- in pituitary infarction ... 260
 -- potassium from ... 260
 -- in pregnancy ... 264
Glycosuria, prognosis with ... 3
Glycosuria, significance of ... 263, 264
 -- in starvation ... 264
Glycosuria, symptoms of ... 260
 -- temporary, in absolute ... 264
 -- from cerebral hæmorrhage ... 261
 -- tumour ... 264
 -- head injury ... 264
 -- pneumonia ... 264
Glycosuria, tests for ... 261
 -- in ... 742
 -- and see Diastroph)
 Glycuron and (see Acyl-glycuron)
 Glander's test for bile ... 743
 Goat, babe, swelling of face from ... 674
 -- vesicles from ... 722
 Goat's milk, Molluscum ... 722
 -- fever from ... 106, 565
 Goat, debility concerning ... 261
 Goutie, asthma simulated by ... 525
 -- catarrhs from ... 158
 -- dyspnoea from ... 158
 -- exophthalm (see Graves's) ... 158
 -- hæmorrhage into ... 158
 -- paronychia ... 722
 -- in rheumatism with ... 722
 -- simulating Graves's disease ... 722
 -- tachycardia with ... 722
 -- suppurative ... 158
Gouties, varieties of (see Phlogi Goutie)
 Gouty, diabetes in ... 228
 Gouty, subconjugal hær-morrhage in ... 476
 Gonococcal arthritis (see Gonococci (*Plate AXVIII*)) ... 644
 -- acute asydetic ... 47
 -- arrangement in pairs ... 591
 -- in arthritic fluid ... 549
 -- in ascitic fluid ... 19
 -- bacterium from ... 709

- Gonococcus, characters of** 182

Hæmolytic simulating 529

Hæmocytemeter 21

Hæmoglobin, above normal, in morbus cordis 533

free in urine in nephritis reduced, spectrum of (For. 31) 80

Hæmoglobinometer, Hall-dine-Gowers' 21

HÆMOGLOBINURIA 284

black urine from 745

colour of urine in 284

Esso's reaction in 285

experimental 284

hematophorinuria simulating 744

hematuria simulated by

Hæmoglobinuria, list of causes of 284

Hæmoglobinuria, paroxysmal 284

urine test for 285

spectroscope in diagnosis 285

apthæ and 285

urine dark brown in various druses causing 284

Wassermann reaction in 285

Hæmolytic, hæmoglobinuria evidence of 284

Hæmophilia, anæmia from 33

Hæmophilia, arthritis in, general account of 350

bleeding gums in 72, 273
 from scratches in 536

blood changes not pathognomonic in 273

epistaxis from 221, 273

excessive bleeding from cuts in 273

— after tooth extraction in 273

family history in 33, 74, 556

Grandfather in 273

hæmatemesis in 266, 273

hæmatoma in 273

hæmorrhage into ankle 302

— hip joint in 273

— joints in 273

— knee from 302

hæmoptysis in 287

hæmorrhagic otitis in 421

limping from 302, 303

menorrhagia from 386, 387

metrorrhagia from 390, 392

pain in foot from 302

purpura in 553

— sex incidence of 273, 556

— stromatosis in 542

Hæmoptumoid, from bullæ wound, 652

needling in diagnosing 530, 651

— suspension with 285

HÆMOPTYSIS 285

anæmia from 32

from aneurysm 119, 290, 291, 292

aortic disease 212

back pressure 641

bronchial cysts after 641

from bronchiectasis 291

bronchitis 119, 290, 291

bronchopneumonia 289

canceroma of lung 212

chronic nephritis 212

coma from 118

from congestion of lungs 212

cough and 286

from distoma pulmonare 292

embolism of lung 159, 289, 290

emphysema 289

emphysema 291

epistaxis simulating 221

intermittent hæmaturia 332

fatal 287, 291

in phthisis 288

from fibroid lung 216

frequency at night 286

from fungating endocarditis 288

gangrene of lung 259

hæmatemesis from 265, 266

Hæmoptysis, hæmatemesis distinguished from 285

from hepatic abscess 291

high blood-pressure 212

hydatid of lung 291

infarction of lung 106, 212, 290

injury to chest 289

larvætic 119

Hæmoptysis, list of causes of 286, 287

from lobar pneumonia 289

lung-blake 645

malnutrition of 286

growth 131

inner's phthisis 288

nutritive regeneration 210

stenosis 119, 288, 289

new growth 119, 290, 291

new growth 119, 290, 291

noises in the head after 106

obscure of legs after 113

at onset of pneumothorax 531

from phthisis 149, 159, 288

stroma of lung 290

stimulated by bacillus prodigiosus 287, 474

tooth-brush injury 73

tooth-plate injury 73

Hæmorrhage, contd.

in splenicæmic polyæthæmia 633

tickling in throat preceding 286

tubercle bacilli and 275

from violent coughing 289

whooching-sound 289

Hæmorrhage, anæmia from 32

into ankle 332

anæmia, convulsions from 116

beneath skin (see Purpura)

blood changes after 33

into carcinoma 371

in liver 375

cerebral, priapism from 378

vomiting from 368

cerebral, absolute rest for 118

accentuated aortic second sound with 303

age incidence of 81

albuminuria with 119, 303, 515

aphasia from 626

apoplexy from 147, 302

arterial changes with 84, 119

arterio-sclerosis and 12, 147, 303

athetosis from 132

Babinski's sign with 68

brachial monoplegia from 501

brachycaecia from 81

brachypnea from 81

Cheyne-Stokes breathing from 108

cerebral softening from 315

tumour simulating 306

coma from 118, 261, 303

diplegia from 515

distinction from abscess and tumour 81

after embolism 610

Hæmorrhage, cerebral, general account of 119

general paralysis simulating 120, 305

glycosuria from 264

granular kidneys with 12, 81, 119, 305

headache from 294, 295

heart sounds with 119, 305

hemiparesis from 301, 302

hemiparesis from 302

hemiparesis from 118, 302

hemiplegia from 68, 119, 258, 303

high blood-pressure with 84, 119, 117, 303, 515

in Horder's disease 274

hypertæxia with 84, 119, 306, 309

hypertension of cerebrospinal fluid with 304

hypothermia with 311

intermittent claudication simulating 306

Jacksonian epilepsy 137

from labour 132

large heart with 119, 117

lead poisoning simulating 119

optic neuritis with 84

paralysis from 132, 514

pyrexia from 85, 306, 309

rapid onset 84

retinitis and 119, 515

septic changes and 515

systemic brain with 119

tube casts and 119

uræmia simulating 85

vertigo preceding 752

vomiting due to 765, 768

in young persons 304

and see Apoplexy

and cerebral tumour 303, 306

collapse from 311

convulsions from 120

Hæmorrhage, contd.

into the cord from injury 515

multiple, priapism from 538

paraplegia from 514

schlem spontaneous 515

from corpus luteum 688

— cyst, pain in pelvis 468

duodenal, coma from 118

noises in the head after 406

Hæmorrhage from ear, causes of 421

from fractured base 119, 421

goitre 158

Graafian follicle 193

from troin, from malignant glands 679

HÆMORRHAGE FROM GUMS 72

in yellow fever 336

Hæmorrhage into hip-joint 363

hypothermia after 311

internal, after abdominal injury 503

from duodenal ulcer 120, 720

leaking aneurysm 120, 720

ruptured tubal gestation 120, 363, 363, 490, 720

in typhoid fever 120, 574

intestinal, from colitis 663

into intestinal wall in Henoch's purpura 556, 767

intrathoracic sarcoma 159

jaundice and 324

into joints 273, 350, 362, 363

Hæmorrhage into knee-joint 362

leucocytosis after 560

from lungs, see Hæmoptysis

in lymphatic leukæmia 556

into mediastinum 159

into neck, laryngeal paralysis from 496

meningeal, atelectasis from 132

brachypnea from 81

coma from 118

convulsions from 116

from head injury 118

hemiplegia from 113

from labour 152

non-malignant from 113

spasmodic paraplegia from 152

tripharynx from 118

mesenteric, in Henoch's purpura 767

into middle ear, in Bright's disease 166

deafness from 166

in leukæmia 166

pernicious anæmia 166

from the mouth, from internal carotid erosion 421

in splenicæmic polyæthæmia 633

(and see Bleeding Gums)

invisous membranes, in blood diseases 596

in pseudo-leukæmia 37

septic-rickeys 670

septic states 260

from nose (see Epistaxis)

occult (see Blood, occult)

indefinite of legs after 413, 415

into optic thalamus, hypertæxia from 509

Hæmorrhage into orbit 177

into pancreas, acute abdominal pain from 76

blood per anam from 76

cellulose from 76, 264

constipation from 76, 264

in fat persons 76

glycosuria from 264

intestinal obstruction simulated by 76, 264

laparotomy diagnosis 76

in pain in abdomen, from 264

peritæphal 553

peritæphal, from injury 667

in septic 28, 72, 99

Heart, contd.
HEART, ENLARGED 206
 — *with adherent pericardium*, 14, 51, 213
 — *from alcoholism*, 54,
 210, 214
 — *in aneurysm*, 208
 — *in aortic stenosis*, 92, 208
 — *in arteriosclerosis*, 1, 2,
 11, 54, 212
 — *in athletes*, 214
 — *in Bright's disease*, 46
 — *in bronchiectasis from*, 292
 — *in cerebral hamorrhage and*, 119, 117
 — *in chest bulged by*, 169
 — *from chronic lung disease*, 54
 — *in chronic nephritis*, 1, 2, 10, 11, 42, 54, 55, 76, 106, 109, 274, 297, 408
 — *in chloruria with*, 109
 — *in epigastric pulsation with*, 206
 — *from fatty change*, 51, 212
 — *in fibroid change*, 54
 — *in lung from*, 292
 — *in Graves' disease*, 215
 — *from hard work*, 54, 214
 — *in hiccup from*, 308
 — *with high blood-pressure*, 298, 485
 — *in impulse displaced*, 206, 298
 — *in heaving with*, 206
 — *in left ventricle, with arteriosclerosis*, 588
 — *in granular kidney*, 588
 — *in high blood-pressure*, 588
 — *in re-duced first sound with*, 588
 — *in from mitral regurgitation*, 89, 210
 — *with myocardial affection*, 11
 — *in from myocarditis*, 212
 — *in orthopnea from*, 118, 429
 — *with patent interventricular septum*, 215
Heart enlarged, physical signs of, 206
 — *in produced first sound with*, 2
 — *in re-duced first sound with*, 588
 — *in from rheumatic myocardial changes*, 54
 — *in skolar resonance from*, 611
 — *in splenomegaly polythaemia*, 633
 — *in uraemia*, 116
 — *in failure, acute dilatation of stomach in*, 173
 — *in produced adherent pericardium*, 46
Heart failure, albuminuria from, 14, 55, 55
 — *from aortic disease*, 46
 — *in arteriosclerosis*, 1, 11, 46, 55, 161
 — *in ascites with*, 55, 105, 694
 — *in barbituric acid from*, 82
 — *in Bright's disease*, 46, 105
 — *from bronchiectasis*, 161
 — *in bronchitis*, 46, 161
 — *in and emphysema*, 161
 — *in bulbar*, 95, 97
 — *in cases due to different causes ultimately alike*, 53
Heart failure, causes of 2, 46
 — *Cheve's-Stokes breathing from*, 108
 — *in cough from*, 118
Heart failure, cyanosis from 157, 161
Heart failure, diagnosis between chief causes of 14
 — *from emphysema*, 46, 161
 — *in enlarged liver with*, 53
 — *in from fatty heart*, 53
 — *in fibroid lung*, 46, 161
 — *in flatus from*, 246
 — *in gall-stones simulated*, 436
 — *in gastric ulcer simulated*, 436
Heart, contd.
Heart failure, general account of, 52, 53
 — *from granular kidney*, 1, 11, 46, 161
 — *high blood-pressure*, 1, 16, 55, 81, 161
 — *hypothermia with*, 311
 — *in jaundice from*, 325
Heart failure, list of causes of, 418
 — *in liver enlarged from*, 47
 — *in lividity with*, 694
Heart failure from lunn conditions, 14, 46
 — *in disease*, 161
 — *in mesocarditis from*, 286, 287
 — *in from mitral disease*, 46,
 53, 55
 — *in myocardial affections*, 46, 52
 — *in nephritis*, 55
Heart failure from nephritis, points in distinguishing 11
 — *in nutmeg liver with*, 694
 — *in asclema from*, 415
 — *in of limbs and arms from*, 413
 — *in legs with*, 52, 195, 413, 415, 694
 — *in orthopnea with*, 105, 420, 694
 — *in pain in the back from*, 136
 — *in epigastrium from*, 190

 — *in mitral regurgitation from*, 89, 211
 — *in from obesity*, 89, 212
 — *in orthopnea from*, 118
Heart, fatty, palpitation from, 181, 485
 — *in pernicious anemia*, 55, 587
 — *in in phosphorus poisoning*, 53, 73, 212, 337

- Heart, fatty, contd.*
 -- from phthisis . . . 212
 -- pulse irregular from . . . 212
 -- slow from . . . 212
 -- weak with . . . 213
 -- shortness of breath from . . . 53, 88
Heart, fatty, symptoms of 14
 -- syncope attacks from . . . 212, 215
 -- tachycardia from . . . 204
 -- from typhoid fever . . . 212
 -- wasting diseases . . . 212
 -- weak cardiac sounds . . . 212
 -- with . . . 213
 -- fibroid, from alcohol . . . 210
 -- aneurysm of heart from 213
 -- mitral perforation from . . . 53, 215
 -- aortic regurgitation with . . . 53
 -- apical systolic bruit in . . . 89
 -- ascites from . . . 46
 -- back pressure from . . . 46
 -- Chaynes strokes from . . . 108
 -- angina from . . . 108
 -- fatty heart simulating . . . 55
Heart, fibroid, general account of . . . 213
 -- heartburn simulating . . . 207
 -- heart failure from . . . 46, 108, 118
 -- heart large from . . . 54
 -- mitral regurgitation from . . . 89, 211
 -- orthopnea from . . . 118
 -- pain in the back from . . . 74
 -- palpitation from . . . 81
 -- shortness of breath from . . . 88
Heart, fibroid, symptoms of 14
 -- from syphilis . . . 53
 -- tachycardia from . . . 204
 -- fetal . . . 19, 45, 689
Heart impulse, accentuated first sound at . . . 2
 -- diffuse, from dilatation . . . 206
 -- pericarditis . . . 215
 -- diminished, in emphysema . . . 167, 217
HEART IMPULSE, DISPLACED 207
 -- from acute endocarditis . . . 211
 -- with adherent pericardium . . . 215
 -- in aortic disease . . . 207
 -- regurgitation . . . 94
 -- by ascites . . . 44
 -- fibroid lung . . . 168, 206, 216, 291
 -- with Flint's bruit . . . 393
 -- heart enlargement . . . 206
Heart, list of causes of 297, 298
 -- in mitral regurgitation . . . 89, 210
 -- stenosis . . . 216
 -- over-strain of heart . . . 211
 -- patent interventricular septum . . . 215
 -- pericarditis . . . 215
 -- by pleural effusion . . . 298
 -- pleuritic effusion . . . 268
 -- pneumothorax . . . 168, 206
 -- when right ventricle enlarged . . . 215
 -- (and see Heart, displaced)
 -- feeble, from fatty heart . . . 212, 213
 -- myocarditis . . . 212
 -- over-strain of heart . . . 214
 -- heaving, from hypertrophy . . . 206
 -- inappreciable in emphysema . . . 167
 -- increased, in pericarditis . . . 215
 -- indistinguishable in emphysema . . . 215
 -- from pericardial effusion . . . 297
 -- in mitral stenosis . . . 216
 -- normal site of . . . 297
 -- obscured by emphysema . . . 206, 217
Heart muscle, contd.
 -- site of . . . 206
 -- wavy, with adherent pericardium . . . 215
Heart, irregular, contd.
 -- (Pulse, irregular) . . . 545
 -- from absinthia . . . 186
 -- alcohol . . . 186
 -- coffee . . . 186
 -- in mitral stenosis . . . 2, 30
 -- from myocardial changes . . . 88
 -- rounded, regular, by exercise . . . 88
 -- from smoking . . . 186
 -- tea . . . 186
Heart, nerve segments corresponding to 708
 -- pericardium in determining size of . . . 206
 -- polyplex of . . . 750
 -- primary alcoholic 14, 46, 55, 118
 -- heart failure from 118
 -- orthopnea from . . . 118
 -- palpitation from . . . 181
 -- rupture of . . . 215
 -- sarcoma of, heart block from . . . 83
Heart, sensory nerves of 433
HEART SOUNDS, ACCENTUATED 1
 -- accentuated second, from high blood-pressure . . . 81, 298
 -- in arteriosclerosis 11, 90
 -- cerebral hemorrhage and . . . 119, 303
 -- first, accentuated, in mitral stenosis . . . 216
 -- from nervousness . . . 2
 -- like second, from myocardial changes . . . 88
 -- prolonged, in chronic nephritis . . . 108
 -- from hypertrophy . . . 208
 -- reduplicated, from over-strain of heart 211
 -- slipping, in mitral stenosis . . . 2, 95, 288, 185
 -- weak, in diphtheria . . . 211
 -- ex-crescendo . . . 211
 -- fatty heart . . . 215
 -- scarlet fever . . . 214
 -- typhoid fever . . . 214
 -- typhus . . . 211
 -- fetal, proving pregnancy . . . 19, 45, 689
 -- hard to hear, in emphysema . . . 167, 217
 -- inaudible second, in mitral stenosis . . . 95
 -- limp first, in arteriosclerosis . . . 11
 -- in interstitial nephritis . . . 10, 11, 90, 106, 108
 -- limp first, cerebral hemorrhage and . . . 119
 -- in chronic nephritis . . . 10
 -- prolonged first, with cardiac hypertrophy . . . 2
 -- in chronic nephritis . . . 11
 -- from high blood-pressure . . . 81
 -- at impulse . . . 1
 -- pulmonary sound, accentuated in mitral stenosis . . . 95, 288, 289
Heart sounds, reduplicated 2
 -- from high blood-pressure . . . 208
 -- second, in mitral stenosis . . . 95, 288, 288
 -- reduplication of (see Reduplication)
 -- weak first, from myocarditis . . . 212
 -- stopping and going on with a jerk . . . 547
 -- systolic of, heart block from . . . 83
 -- thrombus in . . . 152, 147, 289
 -- thumping of, from atheroma . . . 486
 -- epilepsy . . . 186
 -- on getting into bed . . . 186
Heart, thumping of, contd.
 -- from smoking . . . 186
 -- vagus branches to . . . 118
HEARTBURN 296
Heartburn, causes of 296 297
Heartburn, characters of pain of 297
 -- drugs relieving . . . 297
 -- electrocardiograph in diagnosing . . . 297
 -- in health . . . 296
 -- heart disease simulating . . . 297
 -- by . . . 297
 -- palpitation with . . . 297
 -- pyrosis with . . . 436
 -- vomits with . . . 436
Heart cramps 151
 -- erythema from . . . 222
 -- erginine from . . . 255
Heart regulation, notes on 571
 -- sense lost, in Brown-Sequard paralysis . . . 197
 -- from cerebellar artery lesions . . . 58
 -- in symphysectomy . . . 63, 97
 -- stroke, alcoholism simulating . . . 310
 -- vomia in . . . 118, 119, 310
 -- hyperpyrexia from . . . 129, 209, 310
 -- occupation in diagnosis of . . . 113
 -- opium poisoning simulating . . . 310
 -- post-mortem examination in diagnosis . . . 129
 -- prognosis in . . . 129
Heartiness in alcoholism 425
 -- from chronic pericarditis . . . 425
 -- sense of, in liver region from hepatocystitis . . . 568
Heberden's nodes 216, 405
Hela, prurigo form of 489
Hedraeae crystals 740
Heel, bedsores over 257
 -- Jaquez's erythema of . . . 101
 -- pain in (see Pain in Heel)
 -- rubbed, limping from . . . 362
 -- small, comical, in talipes . . . 312
Hen's sign of pregnancy 393
Heller's test 9
 -- for albumin . . . 15
 -- Helmut, for gall-stones . . . 650
Helmitol, stranguary from 649
Hemeralopia 763
Hemianesthesia, in disseminated sclerosis 609
Hemianesthesia, general account of 610
 -- hemiplegic and . . . 202, 506, 610
 -- in hysteria . . . 53, 141, 166, 610
 -- spinal injury . . . 206
 -- 206
HEMIANOPSIA 300, 301, 302
 -- (see Anomalous, of the eye)
 -- abeyia with . . . 625
 -- after apoplexy . . . 302
 -- from cerebral embolism . . . 302
 -- hemianesthesia with . . . 640
 -- hemianesthesia with . . . 302
 -- hemiplegia with . . . 302
 -- from intermittent closure . . . 302
Hemianopsia, lesions causing 301
 -- in metastatic . . . 201, 202, 359
 -- from occipital lesions . . . 292
 -- in one eye . . . 501
 -- from optic tract lesion . . . 291
Hemianopsia, pupil reactions and 302, 552
 -- squinted, in metastatic . . . 501
 -- varieties of . . . 501
 -- from visual cortex lesion . . . 299
Hemiparesis 58
Hemiparesis, hemiplegia with 501
Hemiparesis of face 61, 62
 -- (See Face, 292, p. 194)
Hemiparesis 153, 506
 -- hemiplegia from . . . 501
Hemiparesis in metastatic 500
Hemiparesis 654
Hemiparesis 654
Hemiparesis, from cerebral hemorrhage 192
Hemiparesis 68
HEMIPLEGIA 302
Adult hemiplegia 500
Adult hemiplegia 500
Hemiplegia, age incidence of 303, 304
 -- cerebral with . . . 303, 304
 -- multiple sclerosis . . . 39, 149, 303
Hemiplegia, aphasia with 626
 -- ataxia after . . . 626
 -- ataxia after . . . 139, 141
 -- bedsores in . . . 207
 -- from arterio-sclerosis . . . 507
 -- cerebral abscess . . . 68, 206

 — leucocytosis in . . . 260
 — localized convulsions
 from . . . 144
Hydrophobia, notes on . . . 730
 — parapneumonia from . . . 338
 — paralysis from . . . 338
 — respiratory pain in . . . 138
 — retracted head in . . . 589
 — rare in . . . 395
 — simulating tetanus . . . 138
 — temperature not high in . . . 20
 — trismus from . . . 730
Hydropericardium,
 churning sounds with . . . 652
 — succussion in chest from . . . 652
Hydropericardium, ex-
 ploring needle in dia-
 gnosing . . . 530
Hydropneumothorax, gene-
 ral account of . . . 651, 652
Hydrops amnii . . . 11, 45
Hydroquinone, acetic acid,
 alkalpotassa and . . . 746
Hydroquinone, pelvic swelling
 due to . . . 688
Hydrothorax, from back
 pressure . . . 242
 — chronic nephritis . . . 242
 — high blood-pressure . . . 242
 — mitral regurgitation . . . 211
 — orthopnea from . . . 418
 — and see Chest, Serous
 Effusion in; and
 Pleural Effusion
Hydroxyamine sulphate,
 in estimating sugar . . . 263
Hysteria, cystic, of axilla
Hysteria, closed, sterility
 from . . . 645, 646
 — bilateral, dyspareunia
 from . . . 195, 194
 — vaginismus from . . . 195
 — impertigo, menorrhagia . . . 193
 — monoplegia, dyspareunia
 from . . . 193
 — hysterical, delirium from 169
Hypertalpia, with double
 ulcer . . . 75
 — gastric ulcer . . . 75
 — of urine, frequent mictu-
 rition from . . . 391
HYPERCALCIS . . . 308
 — with facial paralysis . . . 493
 — from Fallopiun canal le-
 sion . . . 294
 — in fevers . . . 166
Hypercalcaemia, list of causes
 of . . . 30d, 309
 — in micturine . . . 166
 — otitis media . . . 166
Hypocaulcaemia, anaesthet (see
 Hypocaulcaemia)
Hypocaulcaemia in blood
 diseases . . . 610
 — brachial neuralgia . . . 412
 — Brown-Séquard paralysis . . . 497
Hyperaesthesia of chest . . . 700
 — from conformed scleroses
 of cord . . . 610
 — epigastric, from gastric
 ulcer . . . 269
Hyperaesthesia, general ac-
 count of . . . 610
 — from haematomyelia . . . 110
 — herpes zoster . . . 610
 — in typhoid area, from ear
 disease . . . 419
 — from hysteria . . . 468, 610
 — in neurasthenia . . . 610
 — from neuritis . . . 110
 — new growth in spine . . . 714
 — in peripheral neuritis . . . 410, 465
 — in periculous anaemia . . . 610
 — with pythiasis . . . 451
 — referred pain . . . 428
 — from spinal caries . . . 610
 — of stomach . . . 319
 — in talcs . . . 409, 610
 — with transverse myelitis . . . 110
 — from tumour of spinal
 meninges . . . 610
Hyperaesthesia vesicae . . . 398
Hyperaesthesia, anaesthesia
 with . . . 606
 — in anaemia pectoris . . . 708
Hyperalgia of chest . . . 708
 — in nerve regeneration . . . 607
 — peripheral neuritis . . . 606, 607
Hyperchlorhydria, acute . . . 42
 — increased in . . . 318
 — dyspepsia from . . . 318
 — pain in epigastrum from . . . 436
 — relieved by food in . . . 437
Hyperidrosis . . . 654
 — in brachial neuralgia . . . 412
 — exsuffled nail and . . . 490
Hypermyopia of uterus . . . 616
 — amenorrhoea from . . . 616
 — sterility from . . . 645, 646
Hyperparotitis, from arse-
 nic . . . 34, 61, 75
Hyperpneumonia, anaemia
 from . . . 35
Hyperpneumonia, astigma-
 tism with . . . 417
 — crescent with . . . 415
 — eye-strain from . . . 416, 524
 — glaucoma and . . . 232
 — headache from . . . 712
 — from minor degrees of . . . 446
 — morning headache from 294
Hypermetropia, optic disc in 417
 — (Plate XA) . . . 418
 — pain in the eye from . . . 416
 — photophobia from . . . 524
 — progressive, from tu-
 mour of optic nerve . . . 230
 — pupil small with . . . 551
 — strabismus from . . . 649
 — tenderness of scalp from 712
Hypermetropia . . . 19
Hyperophthalmia, colic from 356
Hyperophthalmia, general
 account of . . . 356
 — haematuria from . . . 356
 — of kidney, achiluz in loun
 from . . . 378
 — colic from . . . 378
 — haematuria from . . . 278
 — renal enlargement from 278
 — slow growth of . . . 278
 — kidney enlarged by . . . 355
Hyperophthalmia, *cond.*
 — obesity from . . . 408, 409
 — precocious genitalia with
 (Fig. 175) . . . 408, 409
 — pubic hair with . . . 351,
 (Fig. 174) 408, 409, 630
 — spleen simulated by . . . 662
 Hyperpnea (see Blood-
 Pressure, High)
Hyperplasia, large-celled,
 in Hodgkin's disease 379
HYPERPYREXIA . . . 309
Hyperpyrexia, from brain
 lesions . . . 574
 — with cerebral haemor-
 rhage . . . 84, 306
 — definition of . . . 309
 — delirium with . . . 169
 — from head injury . . . 574
 — in heat-stroke . . . 120
Hyperpyrexia, hysteria and 310
 — from intracranial lesions 311
Hyperpyrexia, list of causes 309
 — in malaria . . . 20
 — malingering of . . . 310
Hyperpyrexia, notes on . . . 574
 — from pontine haemor-
 rhage . . . 119, 311
 — in rheumatic fever . . . 169, 574
 — septicaemias . . . 374
 — typhoid fever . . . 574
 — uraemia . . . 374
 — Hyper-resonance of chest,
 from emphysema . . . 89, 217
 — over sound lung when
 other thorax . . . 168
 — with pneumothorax 432, 530
Hyper-resonance in thorax 611
Hypertrismus, sense of full-
 ness from . . . 211
Hypertrismus pulmonary
 osteo-arthropathy (see
 Pulmonary Osteo-
 arthropathy)
Hypertrismus of
 pylorus . . . 766
Hypnotics, delirium from 169
Hypochlorhydria, dyspep-
 sia from . . . 518
Hypochlorite of calcium,
 in indican test . . . 314
Hypochondriasis, blue brain
 and . . . 163
 — constipation from . . . 124
 — hyperaemia in . . . 308
 — insomnia from . . . 322
 — ospitium in . . . 325
 — oxaluria and . . . 124
 — pruritus from . . . 540
 — with undue abdominal
 aortic pulsation . . . 545
Hypochondrium, left, organs
 contained in . . . 660
 — pain in (see Pain in the
 Hypochondrium)
Hypochondrium, right, or-
 gans contained in . . . 660
 — swelling in (see Swelling
 in Hypochondrium)
Hypoclysis, scolic . . . 319
Hypogastric, organs con-
 tained in . . . 660
 — pain in (see Pain in
 Hypogastrum)
 — swelling in (see Swell-
 ing in Hypogastrum)
Hypoglossal nerve, para-
 lysis of . . . 65, 135, 545
 — hypomnesia . . . 19
 — in alcoholism . . . 20
 — epilepsy . . . 20
Hypoparism . . . 410
 — ecchyma from . . . 108
Hypopygon ulcer . . . 754
 — from fifth nerve paraly-
 sis . . . 754
 — with iris . . . 232
 — from tubercular sac-
 cularization . . . 220
 — ulcer of cornea 231,
 (Plate XII) 232, 753
Hypoplasia, urine-stream
 changes from . . . 394
Hypoplasia muscles, atro-
 phy of (see under
 Atrophy)
 — root innervation of . . . 509
HYPOthermia . . . 310
 — in alcoholism . . . 310
 — Anglo-Bulians . . . 312
 — with anaemia . . . 312
 — cerebral abscess . . . 502, 574
 — in children . . . 573
 — after convulsions . . . 573
 — in cretinism . . . 234
 — definition of . . . 310
 — from exhaustion . . . 571, 573
 — exposure . . . 571
 — heart failure . . . 571
 — intense pain . . . 513
Hypothermia, list of causes
 of . . . 311
 — in milkman (see Milk)
 (Fig. 143) . . . 312
 — in marasmus . . . 573
 — mitral stenosis (Fig. 142) 311
 — morning, in fevers . . . 311
 — tuberculous . . . 312
 — in myxoedema . . . 255
 — neurasthenia . . . 466
 — from opium poisoning . . . 119, 310
 — snake-bite . . . 337
 — summer diarrhoea . . . 573
 — in uraemia . . . 40
Hypothyroidism . . . 58
 — at myxoedema . . . 409
 — obesity from . . . 408
Hypothyroidism, therapeu-
 tic test of . . . 409
Hypotonia of muscles, in
 tabes dorsalis . . . 236
Hypoxanthin, uric acid
 from . . . 742
Hysteria, abdominal dis-
 tention from . . . 418
 — absence of fatigues in . . . 417
 — administration of poisons
 from . . . 718
 — anhidrosis in . . . 728, 559
 — amputation in . . . 411
 — anaesthesia in . . . 134, 468,
 498, 503, 716
 — anaesthetic in diagnosing
 . . . 114, 142, 351, 390
 — ankle-clonus in . . . 141
 — no ankle-clonus in . . . 307
 — ankle-jerk exaggerated in . . . 497
 — anorexia due to . . . 43
 — anaemia in . . . 612
 — anuria from . . . 10, 42
Hysteria, aphonia in . . . 628, 651
 — arthritis simulated in . . . 350
 — ascites simulated by . . . 390
 — asthma simulated by . . . 555
 — ataxia from . . . 59
 — Babinski's sign absent in . . . 141
 — baldness in . . . 610
 — barborghum in . . . 82
 — in a boy . . . 59
Hysteria, brachial mono-
 plegia in, general ac-
 count . . . 503
 — bradypnea in . . . 84, 85
 — bulbo in . . . 165, 465, 97
 — carcinoma of stomach
 — simulating . . . 467
 — cerebral tumour simu-
 lating . . . 727
 — Charcot's spasmogenic
 zones in . . . 707
 — chorea and . . . 744
 — clonus in . . . 141, 465
 — constipation due to . . . 43, 128
 — contracted visual fields in . . . 728, 759
 — contractures in . . . 134, 139, 141
 — disappearance under
 anaesthetics . . . 141
 — persistence during sleep 141
 — coma in . . . 118, 144
 — convulsions in . . . 114, 729
Hysteria, convulsive fits in 147
 — cough from . . . 119
 — craving for sympathy in . . . 716
 — deafness in . . . 166
 — deep reflexes increased in . . . 154
 — delirium in . . . 310
 — disseminated scleroses
 — simulated by . . . 728
 — simulating by . . . 727
 — simulating by . . . 728
 — double consciousness and . . . 20

Hysteria, cont.
 - dyspepsia simulated by . . . 315
 - dysphagia in . . . 196, 197
 - emaciation due to . . . 43
 - epilepsy simulated by . . . 137
 - exaggeration of symptoms in . . . 716
 - flushings in . . . 310
 - full turgor from . . . 705

Hysteria, general signs of
 - globus hystericus in . . . 165, 166
 - globus hysterics in 141, 197, 165, 195, 651
 - headache from 296, 310, 712
 - hemianaesthesia from 59,
 141, 466, 610
 - hemiparesis in . . . 654
 - hemiplegia from 59,
 307, 497, 503

Hysteria, hiccough in
Hysteria and high temperatures
 - hysterics simulated by . . . 141
 - hyperaesthesia in . . . 309
 - hyperaesthesia in 168, 610
 - of breast in . . . 611
 - of ovary in . . . 611
 - hyperpyrexia from . . . 309
 - insomnia from . . . 321, 325
 - intention tremor in 724, 728
 - knee-jerks in 307, 308,
 468, 497
 - knee-joint disease simulated by . . . 141
 - laparotomy mis-take in . . . 390
 - hysterics test in . . . 297
 - heat-anaesthesia in . . . 44
 - localized convulsions from . . . 144
 - loss of hearing in . . . 640
 - smell in . . . 640
 - taste in . . . 640, 705
 - nalmizing distinguished from . . . 350
 - memory defects in . . . 20
 - metemorphosis in . . . 330
 - little muscle atrophy in . . . 351
 - muscle wasting in . . . 305
 - nictropnea in . . . 136
 - neurasthenia simulating . . . 746
 - neurosis distinguished from . . . 487
 - noses in the head in . . . 406
 - oesophagismus in . . . 135
 - ophthalmia in . . . 138, 147
 - orthopnea from . . . 418
 - ovarian-cyst simulated by 320
 - disease simulated by 168
 - pain from . . . 458
 - pain in the breast from 450
 - a joint in . . . 450
 - the limbs from 165, 165
 - muscles in . . . 144
 - palata reflex absent in . . . 168
 - palpitation from 184, 186
 - parasthesia in . . . 144

Hysteria, paralysis in 141, 134
 - aetians simulating 503

Hysteria, paralysis of one leg from 497
 - paraplegia from 39, 197
 - paraplegia in . . . 165
 - paraplegia in . . . 705
 - little paraplegia in . . . 117
 - phantom tumour in . . . 590
 - phosphenes in . . . 522
 - photophobia in . . . 525, 526
 - plantar reflex in . . . 69, 398
 - - flexor in . . . 307, 197
 - polymorphous convulsions in . . . 117
 - polyuria from . . . 555, 719
 - pruritus from . . . 540
 - ptosis from . . . 143
 - ptosis from . . . 542, 543
 - paralytic from . . . 544
 - quivering eyeballs in . . . 137
 - reflexes in . . . 502
 - regularization of food through nose from . . . 589
 - restlessness in . . . 310
 - retention of urine in . . . 396
 - retracted head in . . . 589
 - rigors simulated in . . . 594
 - risus sardonicus in . . . 598
 - scissors from . . . 135
 - screaming in . . . 137

Hysteria, cont.
 - sex incidence of . . . 465
 - simulating new growth 112
 - - pregnancy . . . 142, 590
 - - Snedden's type in detecting 760
 - - spasms of face from . . . 494
 - - spasmodic twitches in 136
 - - spinal cord action of field of vision in . . . 759
 - - stocking and glove anaesthesia in . . . 165
 - - strabismus in . . . 649
 - - stridor from . . . 651
 - - strychnine poisoning - simulated by 447, 598, 729
 - - subjective smells in . . . 642
 - - suggestion treatment in . . . 508, 187, 526
 - - tachypnoea in . . . 85
 - - talipes from . . . 144, 144
 - - tenderness in . . . 531, 707
 - - tremor in . . . 120
 - - of scalp from . . . 712

Hysteria, tenderness of spine from 745
 - in muscles in . . . 141
 - tetanic spasms in . . . 438
 - tetanus simulated by . . . 117, 729, 730
 - - simulating . . . 138
 - - tetany in . . . 152
 - - thirst in . . . 141
 - - thoracitis from . . . 719
 - - thorax due to . . . 136
 - - tremor in . . . 134, 724, 727
 - - trismus in . . . 158, 147
 - - simulated by . . . 729
 - - typhoid-spore simulating 715
 - - with morbid abdominal aortic pulsation . . . 543
 - - urgent desire to micturate in . . . 398
 - - variability of symptoms in . . . 759
 - - vomiting from 345, 657, 768
 - - wrist-drop in . . . 350
 - - (and see Neurosis)

Hystero-epilepsy 137
 - retracted head in . . . 589

ICEDIVA, bed-room from 258
 - of liver from 278
 - of food, general disease in 658
 - lethargy, amnesia with 654
 - fingers - affected by . . . 240
 - hysteria . . . 188
 - ketosis-plans one form . . . 188
 - - onychophagia with . . . 480
 - - tongue indurated - simulated . . . 250
 - ketosis craves of children . . . 225, 326, 329
 - (and see Jaundice)

Ideas of grandeur, in
 - general paralysis 120, 247
Idiocy, anaerotic family 761
 - coma in . . . 144
 - congenital blindness with 344
 - - convulsions with 144, 446
 - - epilepsy simulating . . . 544
 - - kypnosis in . . . 155
 - - microcephaly and . . . 188
Idiocy, Mongolian 237, 238
 - - faces of (*Figs.* 118, 119) . . . 237
 - - thyroid treatment in - distinguishing from . . . 258
 - - of cretinism . . . 510
 - - paraplegia from . . . 510
 - - speech defect in . . . 624, 628
 - - tongue swollen in . . . 237, 628

Idiosyncrasy 628
 - idiopathic dilatation of colon (see Hirsch-Sprung's Disease)
 - - oesophagus, vomiting due to . . . 763
Idiots, slobbering in 543
 - bowels, kink 267, 154, 157
 - - valve, sounds of food poisoning . . . 82
 - - tuberculous of . . . 458
Idiom, congenital obstinacy of 130

Idiom, congenital obstinacy of
 - abscess (see Abscess, Idiom)
 - artery, aneurysm of 152, 151, 160, 587, 678
 - - crest, bed-room over . . . 257
 - - loss, swelling in (see Lymphatic Glands, Idiom; Swelling in Idiom)

Idiom, slobbering in 543
Idiosyncrasy 628
 - - of face, loss from 452, 454
 - - carcinoma of, pain in the fossa from . . . 451, 460
 - - tumour of, pain in the fossa from . . . 459
Idiosyncrasy, list of 146
Idiosyncrasy, slobbering in 543
Idiosyncrasy, aneurysm of 152
 - - aortic aneurysm from . . . 188
 - - microcephaly and . . . 188
 - - monodelmia . . . 190
Idiosyncrasy, aspiration pneumonia after 260
 - - gangrene of lung from . . . 260, 644
Impacted wisdom tooth, simulating tetanus in 158
Impetigo, bacillus coli causing 558
 - - pyocyanus causing . . . 558
 - - bullae in 96, 98, 101, 562
 - - bullae in . . . 558
 - - erysipelas . . . 104, 558
Impetigo contagiosa, bullae in 96, 98
 - - honey like crusts in . . . 98
 - - crusts in 98, 562, 755
 - - cutaneous - diptheria - simulating . . . 558
 - - erythema and . . . 557, 558
 - - erythema in . . . 558
 - - of face and hands . . . 560
 - - no fever in . . . 562
 - - tetanus - general account 558
 - - variola . . . 558
 - - herpes simulating . . . 754
 - - herpeticiformis in Austria 98
 - - pregnancy . . . 98
 - - leprosy - slight with . . . 560
 - - lips seldom attacked by . . . 754
 - - occipital 2nd root enlarged from . . . 578
 - - papules in . . . 555
 - - parts affected by . . . 562
 - - pemphigus-like type in infants . . . 97
 - - perleche with . . . 566
 - - pustular - erysipelas - simulating . . . 558
 - - pustules in . . . 557, 558, 560
 - - ringworm simulating . . . 249
Imoetigo, scabs of 600
 - - from scabs alone . . . 710
 - - small-pox simulating by 562
 - - staphylococci causing . . . 558
 - - streptococci causing . . . 558
 - - syphilis simulating . . . 560
 - - vesicles in . . . 558, 562, 755

Impaction, cyst, vulva of 700
IMPOTENCE 312
 - debility of . . . 312
Impotence, functional temporary 313
Impotence, list of causes of 312, 313
 - - acute, prostatic prostatic 538
 - - sterility distinct from . . . 312
Impulse on conjunctiva (see Conjunctiva, Impulse on)
Impaction, from frontal lobe tumour 727

Impotence, from frontal lobe tumour 727
Impaction, sterility from 646

INCONTINENCE OF FÆCES 313

- due to increased intracranial pressure . . . 590
 - - from lateral sclerosis . . . 517
 - - in tabes . . . 578
 - - urine, cystitis from . . . 578
 - - - from dis-tinction of micturition centres . . . 398
 - - distended bladder . . . 45
 - - - emesis distinct from . . . 218
 - - due to increased intracranial pressure . . . 590
 - - - from myelitis . . . 578
 - - retention simulating . . . 395
 - - - from retroverted gravid uterus . . . 689
 - - - simulating paralysis . . . 218
 - - in tabes . . . 578

Impo-oxidation (and see Ataxy)

- from peripheral neuritis 165
 - in tabes . . . 609
India, ankylo-tonium in 81, 521
 - - kalazar in . . . 633
 - - mycetozoa in . . . 736
 - - relapsing fever in 556, 596
Indian hook method for speochea pallida 701
India rubber bottle stomach (see Catarrh of Stomach, Diffuse)
 - carbon bisulphide in dissolving . . . 65
 - - workers in, paralysis in 65
Indian, milder from 314
 - - Moon's test and . . . 262
 - - source of . . . 314

Indican, tests for 314 745

(*Plate XXXI*)
 748
INDICANURIA 314
 - - appendicitis and . . . 351
 - - black urine from . . . 745

- brown ring with nitric acid due to . . . 5, 314
Indicanuria, causes of 314, 315
 - from diuresis of liver . . . 101
 - - emphysema . . . 745
 - - gastric ulcer . . . 101
 - - in healthy persons . . . 215
 - - intestinal catarrh . . . 194
 - - - putrefaction . . . 101, 746
 - - melanuria simulated by . . . 715, 746

Indicanuria, notes on 745

- from yellow fever . . . 745
 - - mustard with gall-stones . . . 172

INDIGESTION (and see Dyspepsia) 315

- an-sallowing - small ring 316
 - - aneurysm - small ring 316
 - - angina pectoris simulated by . . . 316
 - - - cases, stools with . . . 171
 - - of children, appendixitis and . . . 316
 - - cholecy-stitis - simulating . . . 316
 - - chronic, anuria from . . . 329
 - - diarrhoea from . . . 172
 - - - from dilatation of the stomach . . . 217
 - - - distended uterus . . . 217
 - - - fat, stools with . . . 171
 - - - flushing from . . . 244
 - - - in infants . . . 321
 - - - in women from . . . 321
 - - - inters-apertur from from . . . 161, 162
 - - - intestinal obstruction - simulating . . . 316
 - - - - aneurysm - simulating . . . 316
 - - - - oedema and phosphorina alternating in . . . 423, 424
 - - - pain in shoulder from . . . 174
 - - - from pancreatic lesions . . . 101, 661
 - - - phthisis - simulating . . . 215
 - - - pleurisy - simulating . . . 216
 - - - from pyloric obstruction . . . 123
 - - - small intestines - simulating . . . 316
 - - - sugar, stools with . . . 171
 - - - in women simulating . . . 315

- Indigo, *Indigo indrum* .. 311
 Indigo Blue .. 745
 — epilepsy treated by .. 747
 — mercuric bism subim-
 lating .. 747
 Indigo-red .. 745
 Indol .. 314
 — indacema and .. 745
 Indoxyl-carbonic acid,
 blue-urine from .. 747
 Indoxyl sulphate 314, 745
 Inertia, uterine, dystocia
 from .. 290
 Infantile hemiplegia (see
 Hemiplegia, Infantile)
 — paralysis (see Paralysis,
 Infantile)
 — uterus (see Uterus, In-
 fantile)
 Infantism with achondro-
 plasia .. (Fig. 86) 187
 — anamniotic (Fig. 91) 190
 — ateloid and (Fig. 92) 190
 — from cretinism (Fig. 88) 189
 — and dwarfism distin-
 guished .. 188
**Infantism, general account
 of** .. 188-91
 — *cretinism* with .. 188
 — *Hertor* on .. 189
 — improved by pancreatic
 extract .. 191
 — pituitary (Fig. 89) 189,
 190, 410
 — with splenomegaly .. 189
 — thymic .. 189
 — thyroid .. 190
 Infants, ascoturia in .. 4
 — acute arthritis of .. 344
Infants, acute colitis in .. 78
 — nephritis simulated in .. 413
 — amount of sleep for .. 320
 — builder of osseous .. 665
 — blood per annum in .. 746
 — bullous impetigo in .. 401
 — carpaloid spasm in .. 452
 — caseous bronchial glands in .. 385
 — Cheyne-Stokes breathing
 in .. 407
 — coli bacilluria in .. 569
 — colic in .. 117, 324
Infants, convulsions of .. 131
 — *eromatoid* in .. 132
Infants, cyclical vomiting of 384
Infants, diarrhoea in .. 171
 — diarrhoea and vomiting in .. 4
 — drawing up of legs in .. 321
 — dribbling of saliva in .. 542
 — epilepsy in .. 145
 — epiphysitis in .. 663
 — general oedema in .. 413
 — haemoglobinuria in .. 284
 — hemiplegia in .. 301
 — hemiplegia in .. 305, 304
 — Hirschsprung's disease
 in .. 130
**Infants, hypertrophic steno-
 sis of pylorus in** .. 765,
 766
 — induration in .. 321
Infants, isosmia in .. 321
 — intestinal obstruction in .. 130
 — intussusception in .. 78,
 130, 717
 — Jaquet's erythema in .. 409
Infants, jaundice in .. 329
 — knee-jerk diminished in .. 358
 — hyper-protrusion in .. 366
 — marasmus in .. 384
 — milk flow from nipple in .. 680
 — normal pyloric palpable .. 151
 — penphagus in .. 97
 — plantar reflex extensor
 in .. 69, 319
 — post-pharyngeal abscess in 647
 — prolapso in .. 358
 — pupils small in .. 351
 — pyloric spasm in .. 660
 — rarity of phthisis in .. 385
 — reorganization of food in 761
 — rheumatic fever un-
 known in .. 311
 — rigid abdomen in .. 325
 — scales of face in .. 351
 — sero-uric in .. 321
 — sewing-machine in .. 670
Infants, comb.
**Infants, seborrhœic eczema
 of** .. 401
 — epastic paraplegia in .. 152
 — summer diarrhoea in 533, 717
 — syphilitic fingers in .. 239
 — tetany in .. 151
 — umbilical hernia in .. 483
 — vacciniform erythema of 401
 — vaginal hemorrhage in 292
 — water in tissues of .. 284
 — Wehring-Holtmann para-
 lysis of .. 135
 Infarction of brain (see
 Embolism, Cerebral)
 — intestine (see Mesenteric
 Embolism; Embolism,
 Renal; and Kidney,
 Infant of)
 — lung, after appendicitis 106
 — from embolism 160, 290
 — empyema from .. 106
 — gangrene of lung from 632
 — hamoptysis from 106,
 287, 289, 290
 — impaired note over .. 160
 — from infective endo-
 carditis .. 290
 — lateral sinus throm-
 bosis .. 106
 — leukemia .. 290
 — mitral stenosis .. 289
 — after operations .. 106
 — from otitis media .. 106
 — phthisis simulated by 106
 — pleurisy from .. 106
 — pyopneumothorax
 from .. 652
 — rub over .. 160
 — vesicular murmur defi-
 cient over .. 160
 — (and see Embolism,
 Pulmonary)
 — retina (see Embolism,
 Retinal)
 — spleen (and see Spleen,
 Embolism of)
**Infarct of spleen, general
 account of** .. 640
 — *hicough* from .. 308
 — rub over 31, 629, 640
 — thrombotic, in blood
 diseases .. 640
 Infective endocarditis (see
 Endocarditis, Purgate-
 192)
 Inferior cerebellar artery,
 thrombosis of .. 58, 610
 — dental nerve .. 162
 — gluteal nerve .. 498
 — laryngeal nerve .. 148
 — oblique muscle, paraly-
 sis of .. (Fig. 53) 177
 — rectus, paralysis of (Fig.
 54) 177
 — *vena cava* (see Vena
 Cava Inferior)
**Inflation of stomach, tech-
 nique** .. 214
Inflammation of .. 319
 — diagnosis 174, 214,
 317, 318, 330, 639,
 655, 660
 Influenza, abdominal pain in 465
 — albuminuria in .. 13
 — anuria after .. 612
 — arthritis of .. 319
 — atrophy of testis from .. 66
 — bacilli (see Bacillus In-
 fluenzae)
**Influenza, bacteriological
 diagnosis of** 178, 164,
 465, 643
 — bacterial neuralgia and 465
 — bronchitis in .. 465
 — bronchopneumonia from .. 289, 290
 — cardiac bruits in .. 364
 — chill in .. 639
 — conditions wrongly la-
 belled .. 638
 — corviza in .. 465
 — corviza .. 378
 — cough after .. 183, 349
 — deafness from .. 166
 — delirium with .. 169
 — dengue simulating .. 466
 — depression in .. 465
 Influenza, *contd.*
**Influenza, often diagnosed
 when not present** 64,
 416, 465, 572
 — diphtheria simulating .. 389
 — duration of .. 639
 — epidemics of .. 639
 — epiglottitis from .. 66
 — epiglottino-orethritis from 478
 — epistaxis from .. 229
 — febricula representing .. 465
 — gastro-enteritis in .. 563
 — gastro-intestinal sym-
 ptoms in .. 165
**Influenza, general account
 of** 465, 564, 638, 639
 — haemorrhagic otitis in .. 424
 — heart-block from .. 346
 — jaundice in .. 465
 — leucocytosis rare in 360, 419
 — liver abscess simulating 370
 — malignant endocarditis
 simulating .. 564
 — meningitis in .. 599
 — menorrhagia from .. 386
 — neuritis from .. 149
 — orchitis from .. 66, 478
 — otitis media in .. 364
 — pain at back of eyes in .. 416, 564
 — in head in .. 564
 — buds in .. 465, 496
 — humbar region in .. 534
 — pancreatitis in .. 190
 — peripheral neuritis from
 61, 64, 465, 466
 — Pfeiffer's bacillus in 465, 564
 — photophobia in .. 525
 — pneumonia in .. 465, 563
 — prolonged pyrexia from 363
 — prostration in .. 465, 639
 — ruses in .. 594, 595
 — retrobulbar neuritis from 416
 — simulated by paraty-
 phoid .. 565
 — softening of cord from .. 547
 — spleen enlarged in .. 632
 — spindlyitis deformans
 from .. 711
 — stoky rales at bases from 290
 — sudden onset of .. 639
 — sweating in .. 639
 — tachycardia from 703, 704
 — tinea after .. 115
 — temperature chart of ..
 prolonged (Fig. 210) 564
 — things simulating .. 572
 — thrombosis of cerebral
 veins after .. 115
 — tubercle and .. 564
 — typhoid fever simulated
 by .. 639
 — — simulating .. 564, 565
 — viral neuritis after .. 703
 — *lufaspiatus*, nerve supply
 of .. 594
 — paralysis of .. 596
 — postdiphtheritic of .. 513
 — R.D. in .. 596
 — wasting of, in phthisis .. 61
 Infundibulum, swelling at,
 from splenic sinus
 disease .. 251
 Infusion, oedema from 112, 115
 — in replacing lost fluid .. 551
 — specific gravity of blood
 and .. 554
 Inguinal abscess (see Abs-
 cess, Inguinal)
 — canal, testis in .. 66, 482
 — glands (see Lymphatic
 Glands, Inguinal)
 — hernia (see Hernia, In-
 guinal)
 — lymph glands (see Lym-
 phatic Glands, In-
 guinal)
**Inguinal region, left, organs
 contained in** .. 660
**Inguinal region, right, or-
 gans contained in** .. 660
 — swelling in (see Swell-
 ing, Inguinal)
 Injury, abdominal, acute
 dilatation of stomach
 from .. 173
 — *chytrina* from .. 199
 — collapse from .. 593
 — internal bleeding after 593
 — laceration of muscle
 with .. 593
 — laparotomy after .. 593
Injury, abdominal, notes on 593
 — peritonitis after .. 593
 — simulated after .. 593
 — pulse small and fre-
 quent after .. 593
 — rigidity after .. 593
 — shock from .. 765
 — skin cold and clammy
 after .. 593
 — vomiting from .. 765
 — receptaculum chyli
 ruptured by .. 199
 — abscess of liver from .. 369
 — alopecia from .. 17
 — anuria from .. 40, 42
 — appendicitis simulated
 after .. 457
 — arthritis from .. 476
 — axillary aneurysm from 667
 — to back, fracture of spine
 from .. 310
 — hyperpyrexia from .. 310
 — myelitis from .. 310
 — neurofibroma after .. 715
 — strangury from .. 649
 — at birth, hemiplegia
 from .. 303, 304
 — to bladder, hæmaturia
 from .. 275
 — strangury from .. 649
 — bleeding gums from .. 72
 — blood spitting from .. 265
 — bony swelling due to .. 667
 — of brachial plexus, effects
 of .. 596
 — breast pain from .. 139
 — bridge of nose fallen in .. 179
 — to cervical spine, hemi-
 plegia from .. 303
 — of chest, hæmopneumo-
 thorax from .. 652
 — hæmoptysis from 286, 289
 — hydro-pneumothorax
 from .. 652
 — pneumothorax from
 531, 532
 — chyloous ascites from .. 59
 — chytrina from .. 59
 — claw-foot from .. 199
 — contractures from 138, 143
 — during convulsions .. 146
 — deafness from .. 163
 — diaphragmatic hernia
 from .. 652
 — to ear, noises in the head
 from .. 406
 — ectropion from .. 229
 — empyema from .. 104
 — epiglottitis from .. 66
 — epiglottino-orethritis from 478
 — epistaxis from .. 229
 — eye, photophobia from 524
 — pupil irregular after .. 551
 — fibrositis from .. 475
 — of foot, limping from .. 362
 — gangrene from .. 255, 256
 — gastric pains from .. 151
 — hæmatemesis from .. 271
 — hæmatocœle after 481, 482
 — hæmatoma from .. 791
 — of penis from .. 475
 — scald from .. 205
 — hæmorrhage into cord
 from .. 515
 — from ear due to .. 421
 — to head, brachyptosis from 84
 — coma in .. 118, 264
 — — causing and not
 caused by .. 118
 — concussion from .. 118
 — depressed fracture from 118
 — fractured base from .. 118
 — glycosuria from .. 264
 — headache from .. 296
 — hypercæmia from .. 304
 — hyperpyrexia from .. 574
 — Jacksonian epilepsy
 from .. 147
 — memory defects from 20

- Injury, cont.*
- to hook, meningeal .. 118
 - hemorrhage from .. 118
 - memory defects from .. 29
 - neurasthenia after .. 715
 - hip-joint, sciatic nerve paralysis from .. 199
 - hydrocele from .. 481
 - hypopygia after .. 300
 - hypothermia after .. 311
 - insomnia from .. 321
 - Jacksonian epilepsy from .. 137
 - of jaw, effects of .. 683
 - of kidney, abscess from .. 576
 - of larynx from .. 275, 278
 - of renal endothoracic from .. 278
 - of knee, shock from .. 765
 - of vomiting from .. 765
 - lung, congestion from .. 260
 - subcutaneous emphysema from .. 203
 - to mouth, ptosis from .. 512
 - necrosis from .. 309
 - necrosis from .. 175
 - necrosis of nasal bones .. 179
 - of nose from .. 179
 - oedema of testis after .. 481
 - of nerve, contusion from .. 148, 141
 - R.D. from .. 61, 63
 - muscular atrophy from .. 61, 63
- Injury, neurasthenia from 715**
- neurasthenia after .. 408
 - operation camp from .. 151
 - oxygen from .. 400
 - ophthalmoplegia interna .. 552
 - of orbitis from .. 66, 178, 180
 - ossification of tibia from .. 671
 - pachymeningitis from .. 51
 - pain in the back from .. 128
 - pleuro-pneumonia .. 454, 457
 - of shoulder from .. 171
 - paralysis of sciatic nerve from .. 113, 199
 - to pelvis, limping from .. 363
 - perforation of pylorus from .. 373
 - pericarditis from .. 373
 - pericarditis from .. 193
 - periosteal abscess from .. 668
 - peritonitis from .. 707
 - pneumococcal arthritis after .. 339
 - purpura from .. 573
 - retrovesical fistula from .. 238
 - sarcoma from .. 180
 - of sciatic nerve, clipes from .. 115
 - septicaemia from .. 594
 - spinal thrombosis from .. 317
 - to spine, difficulty in mastication after .. 395
- Injury to spine, effects of 715**
- hemianaesthesia from .. 306
 - hemiplegia from .. 306
 - incontinence of feces from .. 314
 - paraplegia from .. 113, 314
 - paraplegia from .. 338
 - sciatic nerve paralysis from .. 113
 - of talipes from .. 113
 - testis atrophy after .. 336
 - transverse myelitis from .. 389, 516
 - spleen, enlargement of spleen from .. 632, 641
 - pain in left hypochondrium from .. 641
 - rupture of spleen from .. 641
 - twisted hilum from .. 641
 - testis atrophy from .. 647, 648
 - subcutaneous emphysema from .. 476
 - tenderness from .. 707, 710
 - of spine from .. 715
 - testis atrophy after .. 67, 315
 - neurasthenia after .. 715
 - shock from .. 765
 - of vomiting from .. 765
 - to thigh, limping from .. 363
 - thoracic duct, chyloous effusion due to .. 196
- Injury, cont.*
- tilted, arrested growth from .. 114
 - overgrowth from .. 114
 - tongue swollen from .. 698
 - torso testis from .. 696
- Injury, transverse myelitis and 165**
- tubercular arthritis after .. 348
 - tympanic membrane ruptured by .. 121
 - ulceration of bladder after .. 580
 - of larynx from .. 158, 190, 287, 292
 - of leg from .. 737
 - of perineum from .. 619, 620
 - of rectum due to .. 685
 - to urethra, adhesion of perineum from .. 171
 - discharge due to .. 181
 - extravasation of urine from .. 278, 279
 - haematuria from .. 275, 278
 - inability to micturate after .. 278
 - pain in penis from .. 169, 170
 - vaginal closure from .. 17, 18
 - discharge from .. 185
- Innervation of arm muscles 504, 509**
- Innervation of leg muscles 498, 493**
- Immobility, artery, anastomosis of .. (Fog. 184) 435**
- Immobility, home, strychnia of, serotica simulated by .. 438**
- vein, obstructed by .. 438
 - mediastinal glands .. 381
 - growth .. 419
 - thrombosed .. 751
- Immobility, game, sport (see Animal Immobility)**
- Insanity, from alcohol .. 116**
- anaemia from .. 18
 - attheros associated with .. 142
 - chorea followed by .. 141
 - congenital diplegia and .. 152
 - constipation from .. 121
 - delirium in .. 169
 - emesis and .. 248
 - epilepsy and .. 115
 - explosive sounds in head in .. 727
 - foreign body in nose in .. 179
 - hearing of voices in .. 405, 723
 - Huntington's chorea and .. 174
 - insomnia from .. 321, 322
 - from insomnia .. 322
 - loss of appetite in .. 45
 - in myxoedema .. 48
- Insanity, noises in head in 40**
- barotonia in .. 739
 - from pellagra .. 225
 - porverted appetite in .. 43
 - subjective smells in .. 612, 613
- Insset bites, swelling of**
- face from .. 674
 - cheeks from .. 771
 - in ear, earache from .. 202
- Insset's crawling, sensation of .. 510**
- INSOMNIA .. 320**
- from alcoholism .. 322, 326
 - anaemia .. 325
 - aneurysm .. 320
 - arteriosclerosis .. 323
 - cerebral syphilis .. 116, 322
- Insomnia, chief causes at various ages 321, 322**
- Insomnia of children 321**
- to chronic hepatitis .. 311
 - from cirrhosis .. 323
- Insomnia, list of causes of 320, 321**
- malnutrition of .. 325
 - plumbism .. 34
 - squabs before eyes from .. 74
 - in tabes .. 650
- Insomnia, treatment of 322, 323**
- Instrumentation, abscess of testis from .. 622**
- effect on urethritis .. 184
 - epididymitis from .. 697
 - epididymo-orchitis from .. 178
 - hematocysts from .. 271
- Instrumentation, cont.*
- prostatic abscess from .. 581, 620
 - urethritis from .. 182
 - Insular sclerosis (see Disseminated Sclerosis)
 - Intellect, dull, in myxoedema .. 53, 234, 409, 537
- Intention tremor, general account of .. 317, 728**
- (and see Tremor)
 - Intercostal artery, nephro- and pulmonary .. 111
 - muscle, overstrain of .. 131, 132
 - paralysis of .. 518
 - nerves (see Nerve, Intercostal)

 - by pelvic adhesions .. 130
 - from peritonitis .. 125
 - perforated band .. 388
 - peritonitis from .. 388, 593

Intestinal obstruction, contd.

Intestinal obstruction, peritonitis distinguished from .. 388
 -- simulated by .. 354
 -- paralytic in .. 129
 -- no pyrexia with .. 115
 -- rectal examination in .. 129, 130, 459
 -- sacculation of colon from .. 663
 -- shock with .. 131
 -- sigmoidoscope in diagnosing cause of .. 241, 246, 459
 -- simulated by embolism of pancreas .. 76
 -- hemorrhage into .. 76
 -- pancreas .. 76, 264
 -- Henoch's purpura .. 76
 -- mesenteric embolism .. 289
 -- thrombosis .. 289
 -- sordes in .. 86
 -- swelling in iliac fossa from .. 459
 -- from tuberculosis of bowel .. 666
 -- tuberculous peritonitis .. 130, 657
 -- ulceration .. 125

Intestinal obstruction, visible peristalsis with **130, 241, 316, 388, 522, 661, 663**
 -- from volvulus .. 130, 388, 459
 -- vomiting with .. 115, 131, 315, 436, 522, 675, 765, 767
 -- wind with .. 241
 -- x-rays and bi-muth in diagnosing cause of .. 241, 316, 459
 -- putrefaction (see Putrefaction)

Intestinal sand .. 599
 -- status, presentation from .. 528
 -- toxæmia, infantilis from .. 115
 -- noises in the head from .. 406
 -- œdema from .. 445

Intestine, aneurysm ruptured into .. 76, 129
 -- carcinoma of (see Carcinoma of Colon)
 -- casts of .. 115, 116, (*Fig.* 172), 398, 539, 549
 -- contracted, felt by hand .. 115
 -- embolism of (see Embolism, Mesenteric)
 -- hypertrophy of, from carcinoma of bowel .. 77
 -- hypoplasia of muscle of .. 123
 -- idiopathic dilatation of (see Hirschsprung's Disease)
 -- lardaceous (see Lardaceous Disease)
 -- large (see Colon)
 -- liver abscess ruptured into .. 370
 -- mucous cast of (*Fig.* 172) .. 298, 399
 -- paralysis of .. 289, 425
 -- stenosis of .. 125
 -- tuberculous of (see Tuberculosis of Bowel)
 -- visible coils of .. 44
 (and see Peristalsis, Visible)

Intestines, deficient motor activity of **123**
 -- gas in liver dullness .. 366
 -- diminished by .. 366
 -- lymphoid structures in, enlarged in lymphatic .. 582
 -- matted, from chronic peritonitis .. 47
 -- tuberculous peritonitis .. 48
 -- putrefactive changes in, melanæmia from .. 101

Intracranial lesions, acetabular from .. 4
 -- pressure, increased, brachyplexia from .. 84, 518
 -- brachyplexia from .. 84
 -- old, and flow of knee-jerk with .. 359

Intracranial pressure, contd.

-- increased, headache from .. 84
 -- hypothermia with .. 511
 -- knee-jerk lost with .. 359
 -- optic neuritis with .. 84

Intracranial pressure, increased, symptoms due to .. 590
 -- vertigo from .. 84
 -- vomiting from .. 84

Intrathoracic tumour, bulging due to .. 168
 -- chest bulged on one side by .. 168
 -- arm muscle from .. 107
 -- brachial plexus from .. 63
 -- rected by .. 63
 -- cough from .. 150
 -- pain in shoulder from .. 474
 -- x-rays in diagnosing .. 63, 150
 (and see under Mediastinum)

Introduction to Surgery, illustrations from **142, 234, 389, 661, 665, 737**

Intubation, ulceration of .. 287, 292

Intussusception, abdominal tumour from **78, 115, 127, 129, 659, 665, 662, 678**
 -- age incidence of .. 717
 -- blood per anum from .. 78
 -- and mucus from .. 78, 127, 130, 585, 663, 678
 -- in children .. 583, 678
 -- chronic .. 678
 -- colic from .. 127
 -- simulated by .. 115
 -- collapse from .. 78
 -- constipation from .. 127, 678
 -- drawing up of legs from .. 78

Intussusception, general account of .. 78
 -- Henoch's purpura simulating .. 76, 556
 -- from Henoch's purpura .. 767
 -- hyperæsthetic swelling from .. 665
 -- indicanuria from .. 315
 -- in infants .. 78, 130
 -- intestinal obstruction from .. 130, 288, 585, 678, 717
 -- kidney simulated by .. 678
 -- mucus stools from .. 298
 -- operation in diagnosing .. 717
 -- polypos simulating .. 717
 -- prolapse simulating .. 717
 -- protruding per anum .. 717
 -- pulse-rate increased in .. 78
 -- rectal examination of .. 78, 116, 127, 130, 585, 717
 -- screaming from .. 78
 -- simulated by simple coils .. 78
 -- spasmodic pain from .. 663
 -- tenesmus from .. 663, 717
 -- vomiting from .. 663, 678
 -- invagination of rectum .. 129

Inversion of uterus .. 539
 -- simulating prolapse .. 539
 -- vulval swelling from .. 700

Iodide, acute from .. 98
 -- for actinomycosis .. 458
 -- anastoma from .. 612
 -- atrophy of testis from .. 66
 -- bleeding gums from .. 72, 73
 -- bullæ from .. 96, 98
 -- coils simulated by .. 178
 -- food in .. 72
 -- cyanosis from .. 139
 -- in diagnosing syphilis .. 560, 691
 -- gumma .. 230, 615, 619
 -- nature of ulcer of .. 279
 -- tongue .. 279
 -- syphilis .. 405, 480, 588, 622, 735, 738, 739
 -- eruption, syphilis simulating .. 560
 -- erythema from .. 98, 222
 -- food in .. 72
 -- anastoma reaction from .. 98
 -- gumma of liver and .. 253
 -- laryngeal obstruction from .. 418

Iodide, contd.

-- nasal catarrh from .. 612
 -- discharge from .. 178
 -- nodules due to .. 94
 -- noises in the head from .. 403
 -- œdema from .. 410, 413, 415
 -- of face from .. 613
 -- larynx from .. 159, 418, 659
 -- orthopnea from .. 118
 -- peculiarities of sweat after .. 655
 -- photophobia from .. 525
 -- pyralism from .. 542
 -- purpura from .. 553
 -- pustules from .. 98, 560, 563
 -- none simulated by .. 559
 -- from, no comedones with .. 559
 -- rash, small-pox simulated by .. 565
 -- skin eruptions from .. 98
 -- stridor from .. 650
 -- syphilitic bone pains relieved by .. 669
 -- pyrexia checked by .. 568
 -- taste loss from .. 705
 -- transmitted to infant from mother .. 98
 -- in uræmia .. 75
 -- uræmia from .. 771
 -- vesicles due to .. 757
 -- iodine, bullæ from .. 97
 -- in Cammidge's reaction .. 100
 -- co-efficient of urine .. 100
 -- dermatitis from .. 755
 -- scales from .. 692
 -- starch grain stained by .. 170
 -- test for bile pigment .. 713

Iodized serum, in examining for proseriforms .. 730

Iodoform capsules in testing for pancreatic disease .. 191
 -- erythema from .. 222
 -- purpura from .. 553
 -- test for acetone .. 3

Ipecauanha, disappearance of amœba after .. 77
 -- Iridocyclitis .. 733

Iridodialysis, pupil irregular from .. 551

Iris, adhesions of, from
 -- tritis .. 232
 -- from ulcer of cornea .. 733
 -- endothelium .. 733
 -- discoloured in glaucoma .. 232
 -- green, with tritis .. 232
 -- injected, in glaucoma .. 232
 -- prolapse of .. 733
 -- tremor of, from di-cated lens .. 175
Iritis, acute (*Plate XI*) .. 230
 -- adhesions after .. 551
 -- atropine in diagnosing .. 232
 -- treatment of .. 233
 -- black spots before eyes from .. 72
 -- blindness from .. 72
 -- cherry vesels injected in .. 232
 -- corneal opacities from .. 72
Iritis, general account of .. 232
 -- glaucoma from .. 761

Iritis, glaucoma, and conjunctivitis, compared **232**
 -- headache from .. 291, 295, 712
 -- hyperæmia from .. 508
 -- hypopyon with .. 232
 -- iris discoloured with .. 232
 -- keratitis punctata with .. 232
 -- lacrymation from .. 231
 -- pain from .. 231
 -- in eye from .. 415
 -- face from .. 419
 -- photophobia from .. 231, 524
 -- pupil changes with .. 232
 -- irregular after .. 551
 -- from syphilis .. 403
 -- synechia from .. 72, 232
 -- tenderness of scalp from .. 712
 -- turbid aqueous with .. 232
 -- from ulceration of cornea .. 733
 -- unopac pupils from .. 553
Iron, blue sweat from .. 635
 -- in chlorosis .. 36
 -- headache from .. 295
 -- relieved by .. 296
 -- in intestinal sand .. 599

Iron, contd.

-- ptychiorrhœ, adæquon .. 746
 -- and in Biak's test .. 746
 -- carboluria and .. 170
 -- in diætic acid test .. 170
 -- in urine and .. 745
 -- melanuria and .. 745
 -- salicylates and .. 170
 -- thirst from .. 720
 -- in Uffelmann's test .. 320
 -- phosphate, white precipitate of .. 170
 -- sulphate, black motions from .. 75, 385

Iron-touers, cramps in .. 130
 -- irritation in diagnosing .. posterior urethritis .. 579
 -- testing for urethritis .. 581

Irritable bladder **393, 424, 742**
 -- stranguy in .. 619

Irritable breast of Astley Cooper .. 431
 -- larynx .. 160
 -- spine .. 715

IRRITABILITY .. 323
 -- in acromegaly .. 323
 -- alcoholism .. 323
 -- from local ventilation .. 323
 -- in chloria .. 143
 -- diabetes .. 323
 -- epilepsy .. 323
 -- general paralysis .. 323
 -- Graves's disease .. 323
 -- jaundice .. 323
 -- leukæmia .. 323
 -- melanoholia .. 323
 -- from meningitis .. 315, 323
 -- mental deficiency and .. 323
 -- in nephritis .. 623
 -- in neurasthenia .. 325, 715
 -- phlebotomy .. 323
 -- rickets .. 145
 -- from tea .. 321
 -- with tropical liver .. 369

Irritant poisons, acute gastritis from .. 267
 -- pyralism after .. 542

Irritant poisons, symptoms caused by .. 336
 -- hæmatemesis from .. 265, 268
 -- pain in epigastrium from .. 706
 -- pigmentation from .. 327
 -- saw-throat from .. 613
 -- tongue swollen from .. 698
 -- vegetable, sore fingers from .. 239
 -- vomiting from .. 705, 765

Ischæmic paralysis (*Fig.* 58) **113**
 (and see Volkman's Paralysis)

Ischioanal abscess (see Abscess, Ischioanal)

Ischia, examination of, per rectum .. 584
 -- Ischia, maluria in .. 632
 -- pellogia in .. 540
 -- Ichi, carpenter's .. 540

Itch, dhubie's .. 250
 -- gardener's .. 540
 -- grower's, from sugar .. 540
 (and see Scabies)

Itching in aphthætion
 -- dermatitis .. 540
 -- from bug-bites .. 540
 -- in chlorophonyx .. 77, 540
 -- chilblains .. 540
 -- dermatitis gestationis .. 540
 -- herpetic .. 98, 540, 710
 -- drug-fishes .. 384
 -- in œzema .. 488, 491, 540, 588, 560, 710, 734, 756
 -- erythema .. 540
 -- from fleas-bites .. 540
 -- in herpes gestationis .. 96
 -- with inflammatory papules .. 487
 -- from jelly-fish stings .. 224, 540
 -- in lichenization .. 491, 540
 -- Helen urticaria .. 540, 756
 -- with medicinal poisons .. 540
 -- from mesquite-bites .. 540
 -- in mouth, from Forsyæ's disease .. 366
 -- in mycosis fungoides .. 540
 -- of nose, snuffing the .. 136

- Kidney, renal*
 local swelling of . . . 13
 of the albuminuria from . . . 357
 of the . . . 40, 42
 of arteriosclerosis with . . . 42
 of vesicæ rare with . . . 42
 (Haynes-Stokes) breathing
 apparatus with . . . 108
 flatulence with . . . 42
- Kidneys, cystic, general account of** . . . 12, 42
 of hæmaturia with . . . 42
 of headache with . . . 42
 of inter-stestinal obstruction . . . 12
 of kidney enlarged in . . . 355
 of oedema rare with . . . 42
 of ovarian cyst simulated by . . . 354
- Kidneys, cystic, physical signs of** . . . 354
 of polyuria from . . . 556, 557
 of pyelonephritis with . . . 511
 of renal tumours with . . . 42
 of simulating chronic nephritis . . . 42
 of spleen simulated by . . . 662
 of tube casts from . . . 557
 of uræmia with . . . 42, 108
 of urine changes with . . . 42, 357
 of a variety of Bright's disease . . . 6
 of vomiting with . . . 42
 of cysts of kidney enlarged from . . . 352
 of displaced in a vasculoprosis . . . 126
 of embolism of (see Embolism, Renal)
 of embryoma of (see Embryoma of Kidney)
- KIDNEY, ENLARGEMENT OF** . . . 352
 of by abscess . . . 352
 of albuminuria with . . . 51, 330
 of aneurysm mistaken for . . . 631
 of appendix lesion simulated . . . 354
 of bile-duct obstructed by from bladder growth . . . 330
 of from calculus . . . 41, 451
 of by carcinoma . . . 355
 of carcinoma coli simulated . . . 351
 of in compensation for the other . . . 355
 of contralateral acting from . . . 355
 of dilatation of stomach from . . . 174
- Kidney, enlarged, distinction from other tumours** . . . 353, 354
 of dullness in loin with . . . 253
 of trees simulating . . . 354
 of gall-bladder simulating . . . 353
 of hæmatoma mistaken for . . . 631
 of hæmaturia with . . . 51, 330
 of hyponephrosis . . . 280, 352, 355, 356, 556, 575
 of from injury . . . 278
 of inter-stimulation simulated . . . 678
 of tumour from . . . 330
- Kidney, enlarged, large spleen distinguished from** . . . 629
 of liver simulating . . . 51, 330, 353
 of mes-enteric tumour simulated . . . 354
 of movement with respiration . . . 629
 of by new growth . . . 278, 352
 of omental tumour simulated . . . 354
 of pancreas tumour simulated . . . 354
 of pelvic tumours simulated . . . 353
 of perinephric lesions simulated . . . 353
- Kidney, enlarged, physical signs of** . . . 352, 629
 of by poly-cystic disease . . . 12, 42, 280, 1252, 355, 357
- Kidney, enlarged, contd.*
 of from pyælitic . . . 451
 of hydrography in di . . . 354
 of from pyelonephritis . . . 354, 576
 of pyonephrosis . . . 352, 355, 356, 536, 577
 of pyuria with . . . 51, 330
 of spleen simulating . . . 353, 661
 of suprarenal tumour simulated . . . 331, 354, 650
 of by tuberculosis . . . 282, 352, 355, 579
 of varicose with . . . 352
 of from vesical growth . . . 277
 of fatty, in phosphorus poisoning . . . 337
 of floating, Kiehl's lobe simulated . . . 367
 of granular (see Granular Kidney)
 of growth in, varicose with . . . 356
 of hydrated cyst of . . . 357
 of hypernephroma of (see Hypernephroma of Kidney)
 of in due fossa . . . 676
 of infant of, abscess from . . . 76
 of albuminuria due to . . . 7
 of in blood diseases . . . 7
- Kidney, infarct of, causes** . . . 8
 of from embolism . . . 7
 of in fungating endocarditis . . . 7, 34
 of hæmaturia from . . . 275, 283
 of renal tube casts due to . . . 7
- Kidney, infarct of, symptoms of** . . . 8
 of from thrombosis . . . 7
 of (and see Embolism, Renal)
 of injury of (see Injury of Kidney)
 of lardaceous (see Lardaceous Disease)
 of lesions, bladder lesions simulated by . . . 575
 of increased frequency of micturition with . . . 575
 of liver swelling with . . . 367
 of movable, acting in loin from . . . 280
 of albuminuria from . . . 7, 460
 of appendicitis simulated by . . . 160, 665
 of bile-duct kinked by . . . 331
 of biliary colic simulated by . . . 150, 151
 of blue brain and . . . 163
 of carcinoma of colon simulated . . . 663
- Kidney, movable, characters of** . . . 663
 of chronic nephritis from . . . 7
 of colic from . . . 280, 394
 of collapse from . . . 115
 of constipation with . . . 127
 of Deitl's crisis from . . . 115, 280, 665, 765
 of duodenum dragged on . . . 280
 of kinked by . . . 331
 of enteropositis with . . . 331
 of faces in bowel simulated . . . 663
 of fatness from . . . 115
 of frequent micturition from . . . 280, 394
 of gall-bladder simulating . . . 663
 of gastro-intestinal symptoms from . . . 280
 of gastroptosis with . . . 318
- Kidney, movable, general account of** . . . 280
 of hæmaturia from . . . 115, 275, 280, 460
 of hydrated simulating . . . 663
 of hypernephrosis from . . . 115, 356, 665
 of in due fossa . . . 115, 356, 678
 of intermittent hydro-nephrosis from . . . 451
 of fundus from . . . 331
 of micro-cyst simulated . . . 254
- Kidney, movable, contd.*
 of hæmaturia from . . . 115
 of masses in the head with . . . 406
 of omental mass simulated . . . 663
 of ovarian cyst simulating . . . 353
 of tumour simulating . . . 663
 of pain in iliac fossa from . . . 451, 460
 of loin from . . . 460
 of palpation in diagnosing . . . 253
 of polyuria from . . . 665
 of no pyrexia with . . . 460
 of renal tube casts due to . . . 7
 of right's lobe simulated . . . 252, 663
 of simulating enlarged gall-bladder . . . 252, 253
 of swelling in right iliac fossa from . . . 665
 of torsion of . . . 394
 of with undue abdominal aortic pulsation . . . 543
 of urethral kinking from . . . 7
 of vomiting from . . . 765
 of without symptoms . . . 280
 of neuræmia of, simulating . . . 426
 of new growth of, albuminuria from . . . 7
 of cystoscope in diagnosing . . . 7
 of kidney enlarged from . . . 352
 of tube casts from . . . 7
- 8 Kidney, new growth of, urine changes from** . . . 7
 of varicose . . . 278
 of pain over (see under Pain)
- Kidney, palpitation, technique of** . . . 277
 of palpation of . . . 275, 278
 of pelvic, carcinoma coli opening . . . 550
 of poly-cystic, age incidence of . . . 280
 of arterio-sclerosis with . . . 357
- Kidney, polycystic, general account of** . . . 280, 357
 of hæmaturia from . . . 275, 280
 of hypernephrosis distinguished from . . . 280
 of kidney enlarged in . . . 355
 of urine changes with . . . 357
 of right, normally palpable . . . 663
 of sarcoma of (see Sarcoma of Kidney)
 of scarred, from ascending nephritis . . . 8
 of sickening sensation on palpating . . . 253, 331
 of single, good health with . . . 40
 of stone in (see Calculus, Renal)
 of tuberculous (see Tuberculosis of Kidney)
- Kink of colon, constipation of** . . . 126
 of of duodenum, with movable kidney . . . 331
 of ileo-cæcal, appendicitis simulated by . . . 457
 of constipation from . . . 457
 of heartburn from . . . 297
 of pain in iliac fossa from . . . 454, 457
 of x-rays and bismuth in diagnosing . . . 157
 of of ureter, from movable kidney . . . 7
- Kirkland's disease, cervical glands enlarged from** . . . 379, 615
- Kirkland's disease, general account of** . . . 615, 616
 of temperature chart in . . . 615
 of Klebs-Loeffler bacillus (see Bacillus Lymphitica)
- Klumpke's palsy** . . . 507
 of hæmatomelethra simulated . . . 509
 of knee-elbow position in abdominal examination . . . 693
 of detecting ascites . . . 411
 of knee, housemaid's . . . 46
 of sub-ocromial bursitis allied to . . . 476
 of injury, shock from . . . 765
- Knee-jerk, contd.*
 of vomiting from . . . 765
- KNEE-JERK, ABNORMALITIES OF** . . . 357
 of absence of one, in tabes . . . 515
 of in chorea . . . 359, 503
 of diminished, in anterior cruritis . . . 439
 of from bronchopneumonia . . . 358
 of epileptic diarrhoea . . . 358
 of in infants . . . 358
 of club and bow of, with cerebral tumour . . . 559
 of increased, abdominal reflexes and . . . 358
 of in myotrophic lateral sclerosis . . . 62, 517
 of with ankle-clonus . . . 39, 358
 of blue brain and . . . 163
 of with brachial monoplegia . . . 502
 of from cerebellar abscess . . . 517
 of in tumour . . . 517
 of in congenital scoliosis . . . 358
 of in disseminated sclerosis . . . 307, 496, 517
 of with extensor plantar reflex . . . 39
 of functional nerve trouble . . . 39
 of from general ill-health . . . 358
 of in hemiplegia . . . 39
 of hysteria . . . 307, 308, 468, 497, 518
 of lateral sclerosis . . . 517
 of neurasthenia . . . 558, 466
 of from new growth in spine . . . 711
 of in the head with . . . 406
 of in paraplegia . . . 109
 of patellar clonus with . . . 358
 of in phthisis . . . 358
 of phalar reflexes and . . . 358
 of with pyramidal tract lesions . . . 39, 358
 of in renal disease . . . 358
 of in spastic paraplegia . . . 512
 of syringomyelia . . . 508
 of from transverse myelitis . . . 62
 of after typhoid fever . . . 343
 of with undue abdominal aortic pulsation . . . 558
 of lost, from anterior crural nerve lesion . . . 498
 of cerebral tumour . . . 359
 of in diabetes . . . 65, 264, 359
 of after diptheria . . . 359
 of from fracture-dislocation . . . 358
 of in Friedreich's ataxy . . . 115, 512, 513
 of increased intracranial pressure . . . 519
 of myelitis . . . 358
 of myopathy . . . 358
 of peripheral neuritis . . . 358, 410
 of pneumonia . . . 359
 of sick children . . . 510
 of tabes . . . 126, 315, 358, 429, 453, 466, 514, 650, 719, 768
 of from transverse myelitis . . . 62
- Knee-jerk, method of testing** . . . 357
 of myasthenia gravis . . . 359
 of unequal, in general paralysis . . . 358
 of from gross intracranial lesion . . . 118
 of in hemiplegia . . . 305, 358
 of polyneuritis acuta . . . 359
 of tabes . . . 359, 515, 650
- Knee-joint, Charcot's disease of** . . . (See Dislocation of Joint)
 of disease, rickets simulated . . . 564
 of of small curies and . . . 516
 of thumb atrophy from . . . 61, 363
 of with tuberculous peritonitis . . . 48
 of flexed, from popliteal abscess . . . 692
 of forcible extension of contracted, senate nerve paralysis from . . . 113

<i>Knee-joint, contd.</i>									
- foreflex-extension of con-									
- tracted, talipes from	113								
- forearm body in	362

- flushing in	241								
- galactorrhœa in	686								
- mastitis in	685								
- mastoma in	631								
- milk flow from nipple	during	181							
- no pregnancy during	35								
- swelling of breasts in	685								
- tetany during	151								
Lacteæ and Eosin, Eosinæ	261								
- Lambert's Herpes test for	262								
- limbata's test reduced by	261								
- osipus salt reduction by	261								
- osipus crystals from	261, 262								
- picric acid test and	262								
Lamæny, metallic tinkling	of, with pneumothorax	168							
Lavulose, ferment stion with	yeast	263							
Lalling	628								
Lameness (see Lamency)									
Lamnia, embrosi	415, 416								
Lambroxy, Herpes test for	261								
- limbata's test reduced by	262								
- osipus salt reduction by	261								
- osipus crystals from	261, 262								
- picric acid test and	262								
Lamæny, metallic tinkling	of, with pneumothorax	168							
Lavulose, ferment stion with	yeast	263							

Larynx, obstruction of, food.
 from a pharyngeal stricture
 — valve . . . 157, 429
 — larynx . . . 157
Larynx, obstruction of, list of causes of 418, 659, 651
 — orthopnea from 418, 419
 — from post-pharyngeal abscess . . . 157, 419
 — retracted head from . . . 589
 — stridor with 157, 419,
 — sneaking in with 590, 650
 — tracheotomy for 419, 590
 — up-and-down movements of larynx in 169, 419, 429, 590
 — oedema of (see Oedema of Larynx)
 — papilloma of, asthma simulated by . . . 535
 — paralysis of (see Paralysis, Laryngeal)
 — pneumonia of, haemoptysis from . . . 287
 — spasm of . . . 752
 — syphilis of . . . 199
 — toothplate impacted in (*Fig. 94*) . . . 195
 — ulceration of (see Ulceration of Larynx)
 — vagus supply of . . . 148
Laszette, in diabetes . . . 260
 — after epileptic fit . . . 143
 — from serum injection . . . 554
 — in typhoid fever . . . 646
Latent uræmia, general account of . . . 40
Lateral sclerosis, age incidence of . . . 140
 — autotrophic (see Autotrophic Lateral Sclerosis)
 — anæmia with . . . 140
 — anæsthesia with . . . 140
 — Babinski's sign with 68, 140
 — some causes of . . . 68
 — contractures from 138, 140
 — drawing up of legs with 119
Lateral sclerosis, primary, general account of
 — paraplegia from 140, 314
 — retention of urine in . . . 308
 — rachitis in . . . 139
 — resulting seat from . . . 259
 — splinter troubles with 140
 — in strychnine . . . 62
 — sinus erosion, in otitis media . . . 421
 — thrombosis of (see Thrombosis of Cerebral Sinus)
Lateralopulsion in paralysis acetaræ . . . 725
Latussums dorsæ, atrophy of . . . 513
 — nerve supply of . . . 505
 — root innervation of . . . 509
Laughing, reorganization of food through nose from 588
Laughter, explosive, from double hemiplegia . . . 231
 — from . . . 307
Lavage of bladder, boric acid for . . . 575
 — in pyæmia . . . 575
 — stomach, in diagnosing dilatation . . . 317
 — gastrostomy . . . 174
 — hour-glass contraction . . . 318
 — in testing motility . . . 329
 — for opium poisoning . . . 219
Lead acetate in Cammidge's reaction . . . 100
 — test for cystin . . . 161
 — amblyopia from . . . 759
 — ammonium sulphide test for . . . 65
 — chromate in Cammidge's reaction . . . 100
 — central oedema from . . . 759
 — delirium from . . . 169
 — edæ, renal colic simulating . . . 151
 — edæness from . . . 466
 — food taste from . . . 705

Lead, contd.
 — mefilla oblongata de-generation from . . . 197
 — poisoning, abdominal cramps in . . . 181
 — abortion from . . . 34
 — acute nana from 119, 147
 — albuminuria from . . . 34
 — amenorrhœa from . . . 18
 — anæmia from . . . 32, 34
 — anuria from . . . 40, 41
 — from beer . . . 117
 — bleeding gums from . . . 72
 — blue line on gums in 34,
 — 65, 119, 124, 131, 425, 505
 — brittle de diabite in . . . 723
 — cerebral . . . 99
 — cerebral hemorrhage simulated by . . . 119
 — tumour simulated by 119
 — symptoms from 146, 147
 — colic from 34, 117,
 — 126, 131, 425, 505
 — simulated by . . . 115
 — coma from . . . 118, 119
 — constipation due to . . . 34, (*Fig. 51*) 124, 131
 — convulsions from 34,
 — 146, 147
 — cramps from . . . 84
 — dementia from . . . 119
 — from electrolysis of water-pipes . . . 65
 — epigastric pain in 34, 68
 — epilepsy from . . . 34
 — epileptiform convulsions from . . . 119
 — faces analysed and . . . 65
 — fatty liver from . . . 53
 — food-poison from . . . 113
Lead poisoning, general account of . . . 34
 — general paralysis simulated by 119, 727
 — gout from . . . 34
 — granular kidney from 34
 — from hair-wash . . . 65
 — headache from 34, 117, 295
 — infantism from . . . 189
 — insomnia from . . . 34
 — irritability from . . . 323
 — lead in faeces in 75, 119
 — in urine in 34, 75,
 — 119, 147
 — leucopenia with . . . 364
 — mania from . . . 34
 — mania in . . . 34
 — neuritis from . . . 110
 — noses in the head from 106
 — of external papillæ nerve in . . . 199
 — occupation and 117, 147
 — ophthalmoplegia from 34
 — optic atrophy from . . . 529
 — neuritis from 34, 119, 559
 — pain in the limbs from 166
 — at umbilicus in . . . 184
 — paralysis from . . . 726
 — of sixth nerve from 34
 — penile erection absent from . . . 313
Lead poisoning, peripheral neuritis from 31, 61, 65, 113, 113, 165, 166, 505
 — parietal basophilæ in 23
 — retrolateral neuritis . . . 416
 — neurine encephalo-pathy from . . . 119
 — sight impaired in . . . 34
 — source obscure . . . 65
 — tetany from . . . 151
 — tremor from . . . 724, 726
 — urine analysis and . . . 65
 — vomiting from . . . 34
 — from water . . . 147
 — wrist-drop in 34, 63, 505
 — in screening radium . . . 223
 — sulphide from cystin . . . 161
Lead's nitrate, ankylostoma mmm in . . . 529
Lead-workers, plumbism in 117
 — leather-bottle stomach . . . 244
 — Leathier in acetate fluid . . . 59
 — phosphates from . . . 522
Lead-lute, purpura from 553
Lead's, foul taste from 705

Legal's test for acetone . . . 3
Leg muscles, innervation of 498, 499
 — Volkmann's contracture of . . . 114
Legs, bent, in osteitis deformans . . . 155
 — low . . . 186, 187
 — burn of, talipes from . . . 114
 — cramps in, from peripheral neuritis . . . 463
Legs, determination of length of . . . 153
 — diplegia affecting . . . 132
 — drawing up, from appendicitis . . . 677
 — — calcaneal . . . 117, 125
 — — hamatomyelia . . . 149
 — — in infants . . . 117, 321
 — — from mitesuspension 78
 — — lateral sclerosis . . . 140
 — — peritonitis . . . 425
 — — transverse myelitis 110
 — elephantiasis of . . . 153
 — epithelioma of . . . 381
 — erythema multiforme affecting . . . 489
 — — nodosum of (see Gangrene) gangrene of (see Gangrene) glands draining . . . 679
 — ulceration of, talipes from 114
 — local fatness of, in Dermom's disease . . . 110
 — lupus of . . . 758
 — multiple benign spread affecting . . . 165
 — myxotoma of . . . 755
 — oedema of (see Oedema) pain in (see Pain in the Leg; and Pain in the Extremity, Lower)
 — paralysis of (see under Paralysis of one Leg)
 — pigmented scars on, from syphilis . . . 209
 — position in tetany 2, 151
 — short, from achondroplasia . . . 187
 — — in dwarfs . . . 186
 — — from rickets (*Fig. 186*)
 — swollen, inflamed (ganglionic glands from) . . . 381
 — stiffness of, in Thompson's disease . . . 584
 — strychnine affecting 698
 — swollen, in myxœdema 537
 — ulcer of (see Ulceration of the Leg)
 — unduly curved, in rickets 655
 — unsquid, scabies from 153
Leishman-Donovan bodies (Plate XXVIII, Fig. 1) . . . 611
 — in kala-azar . . . 632
 — in splenic puncture for 633
 — Leishman's stain 21, 28, 31, 363
 — lemon-yellow skin, in pernicious anæmia . . . 569
Lemonade, polyuria from 554, 555
 — in diagnosing eczema . . . 188
 — dislocation, diplopia from . . . 175, 551
 — in ophthalmoscope . . . 175
 — — pupil irregular from . . . 551
 — shallow anterior chamber from . . . 175
 — tremor of iris from . . . 175
Lenticular degeneration, familial, facies in . . . 278
Lentigo, macules in 382
Leontiasis ossea, bone changes in . . . 685
 — chrom thickening of bones from . . . 496
 — cranial and Face bones enlarged in . . . 670
 — forehead enlarged in 204
 — shallow anterior chamber from . . . 175
 — tremor of iris from . . . 175
Lenticular degeneration, familial, facies in . . . 278
Lentigo, macules in 382
Leontiasis ossea, bone changes in . . . 685
 — chrom thickening of bones from . . . 496
 — cranial and Face bones enlarged in . . . 670
 — forehead enlarged in 204
 — shallow anterior chamber from . . . 175
 — tremor of iris from . . . 175
Leontiasis ossea, general account of . . . 204
 — increasing sizes of foot with . . . 201, 670
 — — noses in the head from 106
 — — osseous deformans related to . . . 204

Leontiasis ossea, contd.
 — osteoporosis and . . . 204
 — — Page's disease related to . . . 204
 — — from syphilis . . . 204
Lepidophyton, ringworm from . . . 259
Leprosy, anæsthesia in 383, 404, 529
 — in nasal discharge in . . . 583
Leprosy, bullæ in 601
 — centralization in . . . 101
 — crusts in . . . 604
 — distinction from leucoderma . . . 524
 — erythema in 222, 225, 584
 — — nodosum simulated by . . . 403, 404
 — simplex simulated by 383
 — fingers affected by 239, 240
 — forehead enlarged in . . . 201
 — guærene from . . . 255, 257
Leprosy, general account of 403
 — leontiasis from . . . 287
 — lipous nodules mimicked by . . . 403, 404
 — macules in . . . 583, 403
 — mucous membranes affected by . . . 104
 — necrosis in . . . 61
 — nodular 403, (*Fig. 173*) 404
 — in Norwegian (*Fig. 173*) 404, 505
 — pins in joints in . . . 494
 — perforating ulcer of foot in of . . . 735
 — peripheral neuritis from 41, 43, (*Fig. 206*) 505
 — pigmentation in 259, 528
 — rosacea mimicked by . . . 403
Leprosy, skin eruptions of 383
 — sabutaneous nodules in 63
 — scars mimicked by . . . 103
 — syphilis simulated by . . . 405, 404
 — simulating . . . 63
 — syringomyelia simulating . . . 403
 — telangiectases in . . . 403
 — thin vascular simulating . . . 250
 — ulceration in 63, 257,
 — of larynx from 404, 601
 — — of larynx from 158, 499, 287, 292
 — nose from . . . 229
 — Wassermann's test positive in . . . 494
Leptothrix bacillus, septi-cæmia from . . . 557
Leucæm, in acute yellow atrophy 273, 335, 765
 — crystals (*Fig. 147*) . . . 533
Leucætic count, differential (see Differential Leucocyte Count)
Leucocytes, abnormal forms of (Plate IV), 22, 23
 — in ascitic fluid . . . 18
 — blood, in children . . . 350
 — — daily variations of . . . 569
 — in pregnancy . . . 569
Leucocytes, in cerebrospinal fluid . . . 305
 — behind cornea, in iritis 252
 — eosinophile (see Eosinophile Cells)
 — gonococci in 182, 185, 591
 — in leukaemia . . . 21
 — meningococci in . . . 591
 — in morbus cordis . . . 573
 — micrococcus . . . 212
 — normal numbers of . . . 22
 — polymorphonuclear (see Polymorphonuclear Cells)
 — in pustules . . . 557
 — relative numbers of . . . 23
 — in stools . . . 557
 — tube casts . . . 6
 — urine . . . 742
 — — in acute nephritis . . . 14
 — — from bacilluria 455, 770
 — — carcinoma recti . . . 7
 — — (and see Pyuria)
 — in uterine casts . . . 195

- Leucocytosis, subd*
 - vaginal discharge 185
 - varieties of normal 22
- LEUCOCYTOSIS** 359
 - from acute peritonitis 363
 - from abscess 369

Lymphadenoma, lymphosarcoma and 571, 635
 - Meulien's syndrome . . . 695
 - nucleocytes in . . . 23
 - occipital glands enlarged in . . . 378
 - orthipnea in . . . 419
 - pleuritic effusion in . . . 406
 - portal glands enlarged by . . . 45, 51, 325, 529
 - purpura in . . . 571
 - pyrexia in . . . 670
 - salivary glands enlarged by . . . 695
 - simulating meningitis . . . 51
 - spleen enlarged in . . . 711
 - tenderness of . . . 529, 670
 - tubercular glands simulated by . . . 378
 - vocal cord paralysis from . . . 375
Lymphadenoma circumscriptum 756
 - of cord, hernia simulated by . . . 682
 - lymphangitis, bladder by . . . 674
 - from dissection wound . . . 240
 - erythema from . . . 222
 - of penis . . . 472
 Lymphatic glands, of hepatic, enlarged, of hepatic, with thoracic glands . . . 308
 - in Hodgkin's disease . . . 674
 - in . . . 51
 - in lymphadenoma . . . 51
Lymphatic glands, axillary, anatomy of 666
Lymphatic glands, axillary, enlarged 380
 - from carcinoma . . . 280, 683, 687
Lymphatic glands, axillary, enlarged, general account of 656, 667

<p>enlarged, in German measles .. 228 - from herpes .. 431 - Hodgkin's disease (<i>Fig. 168</i>) .. 377, 569, 675 - leukæmia .. 51 - below serofulo- sorum with .. 188 - in lymphadenoma 51, 280 - lymphatic leukæ- mia .. 25 - from mastitis .. 688 - prurigo .. 490 - from septic absorp- tion .. 380 - tubercle .. 378, 380 - tuberculo-lympho- sorum in arm from .. 443 - tubercular, caseous, age incidences of .. 385</p> <p>Lymphatic glands, bron- chial, caseous, brady- pnoea from .. 84, 85 - - - bromelactase? from .. 292 - - - seen with the bron- choscope (<i>Fig.</i> 68) .. 158 - bronchitis stenosis from .. 292, 381, 704 (<i>Fig. 64</i>) .. 149 - in children .. 85 - cough from .. 149 - difficulty in dia- gnosing .. 385 - atelect lung from general tubercu- losis from .. 385 - hæmoptysis from larynx from 307, 308 irruption into bron- chus 381, 420, into trachea .. 418 - metastasis from .. 385 - from milk .. 385 - obstructing .. 385 trachea .. 157 - orthopnea from 418 - pleuric nerve irri- tation by .. 308 - simulating dipht- heria .. 157 - tubercula from 85 - vagus nerve irri- tation by .. 308 - rates in diagno- sing .. 85, 149 - serous hæmo- pnevis from .. 287</p> <p>Lymphatic glands, bron- chial, enlarged .. 381 - bronchitis ob- structed by .. 376 - in Hodgkin's dis- ease .. 569 - in lymphatism .. 382 - cystic, fruit over mucous from 91 - x-rays in detect- ing .. 376 - inflamed, cough from 149 - cord, enlarged from epithelioma .. 758 - caseous, milk causing 308, 379, 385 - periodic fever from 308 - pyæmia from .. 704 - redolent from with x-rays in diagnosing 85, 149, 308, 459, 704 - cervical, carcinoma- tous .. 196</p> <p>Lymphatic glands, cervical, enlarged .. 379 - from food .. 647 - erous tooth .. 647 - caseous thiorac glands with .. 308</p> <p>Lymphatic glands, cervical, enlarged, epithelioma- tous .. 380 - in German measles 228 - Hodgkin's disease .. 376, (<i>Fig. 168</i>) 377, 569, 675</p>	<p>Lymphatic glands, con- d. - cervical, enlarged, inflammatory .. 379 - - - in Kerkel's dis- ease .. 379, 615 - - - below serofulo- sorum with .. 488 - - - in leukæmia .. 51 - - - lymphadenoma 51, 379 - - - lymphatic leukæ- mia .. 25 - - - lymphosarcoma .. 379 - - - mumps simulated by .. 617 - - - from otitis media 379 - - - pediculosis 379, 647 - - - septic neers .. 740 - - - scab with .. 378, 379, 617</p> <p>Lymphatic glands, cervical, enlarged, sources of infection causing .. 617 - - - spinal axes and 516 - - - stiff-neck from .. 617 - - - from tonsillitis 617</p> <p>Lymphatic glands, cervical, enlarged, tuberculous 379, 378 - - - with tuberculous peritonitis .. 48 - - - inflamed, dysphagia from .. 617 - - - sore throat from .. 617, 617 - - - torticollis from .. 112 - - - lymphadenomatos, orthopnea from 418, 419 - - - trachea obstructed by .. 418 - - - malignant, ortho- pnea from 418, 419 - - - stridor from .. 651 - - - tracheo-obstructed from .. 418 - - - cord, par- alysis from .. 495 - - - œdema of .. 380 - - - tuberculous, laryn- geal paralysis from 495 - - - ulceration of .. 379 - - - ulceration of malig- nant .. 380</p> <p>LYMPHATIC GLAND EN- LARGEMENT .. 376 - - - gland-cell inflamma- tion .. 376 - - - in chloroma 295, 556 - - - generally, in German measles .. 228 - - - in plague .. 378 - - - Stoll's disease 35, 378 - - - syphilis 240, 491, 618 - - - tuberculous .. 378 - - - in Hodgkin's disease 37, 55, 61</p> <p>Lymphatic gland enlarge- ment, localized .. 378 - - - leukæmia 55, 61, 570 - - - lymphadenoma .. 61 - - - lymphatic leukæmia 556 - - - multiple benign sar- coma .. 405 - - - mycosis fungoides pleuritic effusion with .. 106 - - - syphilis and .. 569 - - - from tumor carcinoma 219</p> <p>Lymphatic glands, epi- trochlear, enlarged .. 380 - - - with orbitis .. 35 - - - from dental chan- cre .. 381 - - - in Hodgkin's dis- ease (<i>Fig. 168</i>) 377 - - - rheumatoid arth- ritis .. 515, 378 - - - from septic ab- sorption .. 380</p> <p>Lymphatic glands, femoral, anatomy of .. 679 Lymphatic glands, femoral, enlarged .. 381, 675 - - - from bites .. 679 - - - epitheliomatous .. 679, 708</p>	<p>Lymphatic glands, con- d. - femoral, enlarged, from pediculosis .. 679 - - - syphilite .. 679 - - - from trachea .. 679 - - - tuberculous .. 679 - - - hernia simulated by 679, 680 - - - suppurating .. 679</p> <p>Lymphatic glands, general- ized enlargement of, list of causes of .. 376 Lymphatic glands, Hodg- kin's, characters of .. 377 Lymphatic glands, Hodg- kin's, distinguished from tubercle .. 380 - - - iliac, calcareous, simu- lating stone in ureter 155 - - - connections of .. 679 - - - enlarged .. 676 - - - appendicitis simu- lated by 159, 677 - - - malignant 581, 180 - - - swelling in right iliac fossa from 665 - - - tuberculous .. 677 - - - inflamed, causes of 459 - - - pain in iliac fossa from 452, 451, 459 - - - pyæmia from .. 459 - - - rectal examination for .. 459 - - - swelling in iliac fossa from .. 459</p> <p>Lymphatic glands, iliac, tuberculous .. 459 - - - operation in dia- gnosing .. 459 - - - tuberculous can- cer simulated by .. 459 - - - von Pirquet's re- action with .. 459 - - - x-rays in dia- gnosing .. 459 - - - inflamed, abscess from 381 - - - pain over .. 381 - - - pyæmia from .. 381 - - - reddening of skin over .. 381</p> <p>Lymphatic glands, inguinal, anatomy of .. 679 Lymphatic glands, inguinal, enlarged .. 381 - - - by carcinoma 181, 385 - - - with chancre 618, 700 - - - from epithelioma 619, 621, 695, 700</p> <p>Lymphatic glands, inguinal, enlarged, general ac- count of .. 679 - - - in German measles 228 - - - from herpes 451, 754 - - - in Hodgkin's dis- ease .. 569, 635 - - - leukæmia 51, 679 - - - lymphadenoma 51, 679 - - - lymphatic leu- kæmia .. 25 - - - melanotic sar- coma .. 381 - - - prurigo .. 490 - - - from sarcoma .. 680 - - - serotal chancre .. 621 - - - septic absorption 381 - - - in sleeping sickness 617 - - - from soft sores .. 617 - - - syphilis .. 184, 377 - - - trypanosomiasis 378 - - - tuberculous .. 378 - - - inflamed, lumping from .. 563 - - - from soft sore .. 619 - - - suppurating .. 680 - - - lumbar, enlarged, from carcinoma 180, 585, 696 - - - in stool, inflamed .. 203</p> <p>Lymphatic glands, medi- astinal, caseous, notes on .. 704 - - - phrenic nerve irri- tation by .. 208 - - - trichocystia from 705, 704</p>	<p>Lymphatic glands, con- d. - mediastinal, caseous, vagus nerve irri- tation by 308, 703, 704 - - - x-rays in dia- gnosing .. 704</p> <p>Lymphatic glands, Medi- astinal, enlarged .. 381 - - - in Hodgkin's dis- ease .. 569 - - - pressure signs from 381 - - - simulating aneur- ysm .. 781 - - - mediastinitis .. 581 - - - new growth .. 581 - - - x-rays in dia- gnosing 581 - - - malignant, vocal cord paralysis from .. 495 - - - sarcoma of .. 751 - - - mesenteric, caseous .. 18 - - - adhesions from .. 130 - - - bands from .. 159 - - - intestinal obstruc- tion from .. 159</p> <p>Lymphatic glands, mes- enteric, enlarged .. 381 - - - in lymphatism .. 382 - - - tuberculous 381, 677</p> <p>Lymphatic glands, occipital, enlarged .. 378 - - - in German measles 228, 377, 378 - - - in syphilis 377, 378 - - - pelvic, enlarged, from carcinoma of bladder 472, 579, 580 - - - recti .. 585 - - - malignant .. 381 - - - rectal examination in detecting 381, 472 - - - from testis growth 626 - - - obstructed, chyluria from .. 28 - - - popliteal, enlarged .. 692 - - - from septic absorp- tion .. 382 - - - suppurating .. 692 - - - portal, enlarged, ascites from 15, 51, 329 - - - bile-duct obstruc- ted by 51, 525 - - - carcinomatous 45, 51, 325, 329, 330, 331, 381</p> <p>Lymphatic glands, portal, enlarged, jaundice from .. 329, 329, 329, 330 - - - leukæmia 45, 51, 325, 330 - - - lymphadenomatos 45, 51, 329 - - - from lymphosar- coma .. 329 - - - malignant, ascites from .. 45, 50 - - - bile-duct ob- structed by 50 - - - jaundice from 50, 325 - - - portal vein ob- structed by 45, 50, 51 - - - sarcomatous .. 51 - - - tuberculous 45, 51, 329 - - - posterior cervical, en- larged in German measles .. 562 - - - mediastinal, second- ary deposits .. 193</p> <p>Lymphatic glands, pre- auricular, enlarged .. 378 - - - from chancre of eyelid .. 379 - - - epithelioma .. 378 - - - melanotic sarcoma 379 - - - rodent ulcer .. 378 - - - septic absorption 378 - - - sepsis .. 695 - - - syphilis .. 695 - - - tubercle .. 695 - - - puncture in diagnosis of trypanosomiasis 28 - - - retropharyngeal, secum- dary deposits in 7, 381, 749, 750</p>

 -- intercostal, overstrained,
 from bronchitis .. 432
 -- -- pain in chest from 132
 -- -- stretch from over-strain
 of .. 451
 -- laceration of abdominal
 593
**Muscle tone, mode of main-
 tenance** .. 55
**Muscles of arm, nerve
 supply of** .. 507
**Muscles of arm, root innerv-
 ation of** .. 509
 -- calcification of .. 143
 -- electrical reactions of
 normal .. 582, 583
 -- flabby, with fatty heart 212
 -- in rickets .. 714
 -- haemorrhagic knots in,
 in scurvy .. 556
 -- hyperaemia of, anaesthesia
 with .. 606
 -- hypotonia of, in tabes
 dorsalis .. 246
 -- injury of, contracture
 from .. 143
**Muscles of leg, innervation
 of** .. 498, 499
**Muscles of leg, spinal seg-
 ments associated with** 498
 -- ossification of .. 143
 -- pain in (see Pain in Muscles)
 -- parasites encysted in .. 729
 -- rupture of, purpura from 553
 -- slow relaxation of, in
 Thompson's disease .. 581
 -- swelling of, in myositis
 ossificans .. 143
 -- swollen, in trichinosis .. 464
 -- tenderness of (see Tenderness
 of Muscles)
 -- trichinella in .. 464
MUSCULAR ATROPHY .. 59
 -- progressive (see Pro-
 -- gressive muscular
 atrophy)
 -- dystrophy, primary (see
 Myopathy) .. 62, 68
Muscular rheumatism 438,
 441, 443, 467
 Musculo-cutaneous nerve 594
 Musculospiral nerve (see
 Nerve, Musculo-spiral)
 Mustomos, haemoglobin-
 uria from .. 281
 Mussels, urticaria from .. 771
 Mustard plasters, erythema
 from .. 222
 -- sore fingers from .. 239
 -- vomiting from .. 765
 Mutton (and see Speech,
 Loss of)
 -- aphasia distinguished .. 621
 -- in dementia .. 623
 -- melancholia .. 621
 -- Myalgia, cervical, head-
 -- ache simulated by .. 294
Myalgia, general account of
 -- intercostal, tenderness
 from .. 707
 -- pain in the chest from .. 136
 -- -- limbs in .. 493
 -- -- tenderness from 431, 706
 Myasthenia gravis, lullar
 paralysis simulating
 -- drooping of eyelids in 255
 -- -- of chin in .. 255
**Myasthenia gravis, dysar-
 thria in** .. 627
 -- desphagia from 197, 547
**Myasthenia gravis, electri-
 cal reactions in** .. 584
 -- exhaustion in .. 255
Myasthenia gravis, facies in
 (Figs. 111, 112) .. 235
 -- knee-jerk in .. 259
 -- muscles affected in .. 197
 -- nasal voice in .. 627
 -- ptosis in .. 541
 -- ptalism from .. 543
 -- rapid fatigue in .. 627
 -- regeneration of food 761
 -- risorius weak in .. 235
 -- sneering appearance in 235
 -- zygomatic muscles
 weak in .. 255
 Myelium in erythrasma .. 251
 -- favus .. 247
 -- ringworm .. 247
 -- tinea versicolor .. 259
Mycetozoa .. 736
**Mycosis fungoides, general
 account of** .. 731
 -- itching in .. 540
 Myelitis, acute bedsores from 258
 -- -- hyperaemia from .. 309
 -- -- from injury .. 310
 -- -- stranguary from .. 649
Myelitis, anaesthesia from 608
 -- compression, pain at um-
 -- bilicus from .. 484
 -- constipation in .. 128
 -- contractures after .. 158
 -- difficulty in micturition
 with .. 595
 -- gangrene from .. 255
 -- girdle pain in .. 260
 -- knee-jerk lost after .. 558
 -- paralysis of bladder in .. 398
 -- -- one leg from .. 496
 -- precipitate defecation
 from .. 314
 -- pupil reacting to light
 but not to accommoda-
 -- tion in .. 551
 -- retention of urine in 396, 398
 -- transverse, anaesthesia
 with .. 62, 140, 516
 -- -- with at anaesthesia .. 346
 -- -- from aneurysm .. 389
 -- -- ankle clonus from .. 62
 -- -- anterior crural
 -- changes in .. 62
 -- atrophy of muscles
 from .. 62
 -- cervical cord affected
 by .. 62
 -- -- from compression 389, 516
 -- -- cystitis from .. 578
 -- -- dorsal cord affected by
 -- drawing up of legs
 with .. 140
 -- -- extensor plantar reflex
 from .. 62, 68
**Myelitis, transverse, general
 account of** .. 62, 516
 -- girdle pain from 140, 436
 -- hyperaesthesia with .. 140
 -- incontinence of urine
 in .. 578
**Myelitis, transverse, injury
 and** .. 389, 516
 -- knee-jerk increased
 from .. 62
 -- -- lost from .. 62
 -- -- loss of reflexes from .. 515
 -- -- main-stiffness from .. 62
 -- -- pain from new growth .. 289
 -- -- pain and .. 516
 -- paraplegia from 514,
 515, 516
 -- priapism from .. 578
 -- R.D. from 61, 62, 515
 -- retention of urine in .. 578
 -- simulating amyotro-
 -- phic lateral sclerosis 62
 -- -- progressive muscular
 atrophy .. 62
 -- -- from softening .. 516
 -- -- spastic paraplegia from 62
 -- -- spirometer trouble from
 .. 62, 110
 -- -- from spinal curves .. 389
 -- -- thrombosis .. 389
 -- -- syphilis .. 389
 -- -- tympanites from .. 389
 -- -- wasting of muscles
 from .. 61, 515
 -- -- urine dribbling in .. 398
 Myelocytes (Plates II, IV)
 -- in aplastic anaemia .. 22, 26
 -- -- eosinophile (Plate II,
 -- Fig. N, p. 22) .. 23
**Myelocytes, general account
 of** .. 23
 -- in Hoelkin's disease 25,
 37, 61, 377, 635
 -- lymphadenoma .. 23
 -- lymphatic leukaemia .. 26
 -- lymphocytes simulating 23

Nerve, contd.

stiff (see Stiff Neck)
 swelling of, from aneurysm opening vena cava 159
 thyroid gland enlargement (see Thyroid Gland Enlargement)
 - from vena cava obstruction .. 158
 - sphylos roseola on .. 383
 - ties affecting .. 136
 - ulcer of, from tuberculous glands .. 379
 Neurobrosis of fibrils .. 690
 Necrosis of bone, abscess in heart from .. 596
 - acute, mistaken for acute rheumatism .. 338
 - anoma with .. 35
 - central, sarcoma simulated by .. 608
 - pyramis from .. 596
 - suppurative pericarditis from .. 596
 - of cartilage, in lupus 402, 735
 - ear bones, otorrhoea from .. 422
 - - polyp from .. 422
 - fat (see Fat Necrosis) .. 131
 - of femur, popliteal abscess from .. 692
Necrosis of jaw .. 683
 - stomatitis from .. 642
 - in leprosy .. 63
 - of nasal bones, anoma from .. 612
 - - bridge of nose fallen in from .. 179
 - - foul breath from .. 87
 - - from injury .. 179
 - - pus from nose due to .. 179
 - - from sphyllis 179, 210
 - - from periosteitis .. 698
 - of pubic bones, serosal swelling from .. 614
 - tibia, talipes from .. 114
 Necrospina .. 616, 647
 Nessel in foot .. 362
 - knee .. 362
 - rectum .. 584
 Nesselwomen, anaesthesia .. 414
 Needlework, cramps in arm from .. 446
 - eye-strain from .. 446
 - pain in the eyes from .. 446
 Needling of chest, in diarrhoeing emphysema 55, 103, 149
 - fluid in chest 104, 520
 - haemopneumothorax 530, 651
 - hepatic abscess .. 253
 - - subphrenic abscess 658
 - pyopneumothorax 651, 652
 - la nephritis from .. 286
 - subcutaneous emphysema from .. 293
 - of meningeae .. 220
 - of joint, in diagnosis .. 540
 Negro blood, pigmentation of mouth from .. 528
 Negroes, caecoxia in .. 99
 - dirt-eating in .. 99
 - perverted appetite in .. 99
 - pox in .. 99
 - pigmented mouth in .. 528
 - stomach disease of .. 99
 - white-tongue in .. 99
Neisser, gonococcus of 182
 Neisser's stain, for bacillus diphtheriae .. 157, 614
 Neosylvarium, erythema from .. 222, 224
 Nephritis, acute, acute dilatation of heart from 211
 - albuminuria in 42, 281
 - albumosuria with .. 16
 - anogenital .. oedema simulating (Figs. 178) 412
 - anuria in .. 42
 - Cheyne-Stokes breathing from .. 108
 - from chill .. 281
 - chronic parenchymatous nephritis after 108

Nephritis, contd.

Nephritis, acute, exacerbation of chronic 10
 - from exposure to cold .. 42
 - from ingesting endocarditis .. 7, 8, 283
Nephritis, acute, general account of .. 9
 - haematuria in 42, 275, 281
 - Henoch's purpura simulating .. 556
 - mercerial stomatitis in .. 542
 - nitral regurgitation from .. 211
 - oedema of 9, 281, 415
 - from liver simulating .. 412
 Nephritis, acute, without oedema 9, 11, 14, 281
 - puller in .. 42
 - pneumococcal 9, 42
 - polyuria after .. 535
 - puffiness of ankles in .. 42
 - face in .. 42
 - pyrexia in .. 42
 - in secondary sphyllis .. 642
 - simulated in aneurism .. 413
 - by carcinoma recti .. 413
 - in infants .. 413
Nephritis, acute, simulated by thrombosis of renal veins .. 7
Nephritis, acute, in scarlet fever .. 14, 12, 611
 - from a specific fever .. 281
 - streptococcal .. 9
Nephritis, acute suppurative, general account of .. 594
 - tube-casts in 42, 281
 - without tube-casts 10, 13
 - from typhoid fever 42
Nephritis, acute, universal oedema in .. 412
 - uraemia from .. 108
Nephritis, acute, unrecognized .. 9
Nephritis, acute, urine changes in 9, 10, 14, 42
Nephritis, acute, various causes of .. 9
 - vena caval thrombosis .. 549
 - amoebiasis from .. 18
 - anaemia with .. 104
 - anuria in .. 40
 - ascending, albuminuria from .. 15
 - causes of .. 7, 13
 - Cheyne-Stokes breathing from .. 108
 - emphysema from .. 106
 - hyperpnoea in .. 209
 - hemiplegia from .. 106
 - pleurisy from .. 106
 - uraemia from 108, 146
 - B. coli with .. 69
 - pyocyanic with .. 69
 - bacilli in .. 96
 - oedema with .. 99
 - chronic, acute supervening on .. 412
 - age incidence of .. 10
 - albuminuria with 76, 191, 212, 274, 298, 408
 - a first sign of .. 13
 - albuminuria, pyramis with 17, 212, 274, 408
 - anuria in 11, 34, 76, 274
 - anaemia with .. 42
 - anuria from .. 42
 - apical fruit in .. 11
 - arterio-sclerosis with .. 42
Nephritis, chronic ascending, general account of .. 8
 - ascites with .. 12, 212
 - blood per anura in .. 76
 - blood-pressure high in .. 14, 11, 42, 76, 408
 - des-obliteration in .. 11
 - cardiac impulse in .. 11
 - causes of .. 7
 - catarrh of small intestine from .. 172
 - chylous ascites from .. 106

Nephritis, chronic, contd.

- coma in .. 42
 - contractions in .. 42
 - Cheyne-Stokes breathing from .. 108
 - chylous fluid in chest from .. 106
 - diarrhoea from .. 172
Nephritis, chronic, effects of 42
 - enlarged heart with 10, 11, 42, 54, 109, 274, 408
 - epistaxis from 11, 76, 266
 - first symptom of .. 221
 - frequent micturition from .. 393
 - at night with .. 394
 - gastritis from .. 317
 - general oedema in .. 42
 - giddiness in .. 10
 - haematemesis in .. 271
 - haemoptysis from .. 212
 - haemorrhages in .. 11
 - headache in .. 11, 42
 - heart impulse displaced with .. 298
 - heart sounds with 10, 11
 - high-tension pulse in 274
 - hydrothorax from .. 212
 - hyperaetia in .. 309
 - hypothermia in .. 311
 - infantism from .. 191
 - infiltration of lungs from .. 212
 - inflammation of serous membranes in .. 11
 - insomnia in .. 11
Nephritis, chronic, interstitial (see Granular Kidney)
 - irritability in .. 325
 - left ventricle large in 76
 - liver enlarged from .. 212
 - nitral regurgitation from .. 298
 - morning headache from 291
 - nitrate liver from .. 268
 - obesity from .. 408
 - oedema of legs from .. 212
 - palpitations in .. 11
Nephritis, chronic parenchymatous, general account of .. 10, 408
 - polyuria in 42, 191, 298
 - radial artery thick and tortuous with .. 212
 - resulting from acute .. 10, 408
 - retinal changes with 11, 42
 - - haemorrhages with 212
 - - ringing aortic second sound with .. 408
 - shortness of breath in .. 11
 - simulated by polycaecitis kidneys .. 42
 - stridor in .. 42
 - thick tortuous arteries in .. 274
 - tumour from .. 724
 - tubal, anaemia in .. 323
 - coma in .. 11
Nephritis, chronic tubal, Rose Bradford type .. 11
 - uraemia in .. 11
 - tube casts with 76, 212, 274, 298
 - uraemia in .. 42, 108
Nephritis, chronic, urine changes in .. 10
 - weakness from .. 76
 - chylous ascites with .. 109
 - chyluria with .. 109
 - from cold and damp .. 10
 - convulsions from .. 144
 - Friedlander's bacillus with .. 69
 - gastritis with .. 43
 - haemoglobinuria in .. 284
 - high blood-pressure in .. 14
 - latent .. 9
 - loss of appetite with .. 9
 - myxodema simulating .. 38
 - oedema with .. 109, 413
 - pain in limbs in .. 463
 - pleural effusion from .. 104
 - pneumococcus with .. 69
Nephritis of pregnancy, general account of 6, 8, 9

Nephritis, contd.

- rice in .. 595
 - simulated by chronic .. 47
 - - peritonitis .. 234
 - - myxoedema .. 234
 - - from scarlet fever .. 617
 - - streptococcus with .. 69
 - - streptococcus with .. 69
Nephritis, tube casts with 6, 109, 420
 - tubercle bacilli with .. 69
 - unilateral .. 281
 - urate deposit uncommon with .. 741
Nephritis, varieties of 6, 9
 - vertigo from .. 732
 - in Weil's disease .. 336
Nerve, anterior crural, affections of .. 439
Nerve, anterior crural, distribution of .. 498
Nerve, anterior crural, paralysis of .. 498
 - spinal segments derived from .. 498
Nerve, anterior thoracic, muscles supplied by 504
 - spinal segments supplying .. 504
 - Arnold's .. 148
 - auditory, noises in ear due to lesion of .. 723
 - - tumour on, tremor with 729
 - cases, obscure, sphyllis at the root of .. 407
 - circumflex, affected by weight-carrying .. 163
Nerve, circumflex, muscles supplied by .. 505
 - neuritis of .. 477
 - paralysis of, arthritis simulating .. 506
 - spinal segments supplying .. 505
 - weight-carrying affecting .. 163
 - external cutaneous, pain in .. 439
Nerve, external plantar, distribution of .. 498
 - spinal segments derived from .. 498
Nerve, external popliteal, distribution of .. 498
 - neuritis of .. 499
Nerve, external popliteal, paralysis of .. 499
 - spinal segments derived from .. 498
 - in Tooth's palsy .. 513
 - fifth, hypertrophied in area of .. 654
 - neuralgia in .. 462
 - - pythiasis from .. 542
 - - neuritis of .. 543
 - - tumour of, anaesthesia from .. 711
 - - neuralgia pain from 711
 - - glossopharyngeal, paralysis of .. 706
 - - gamma of, muscle wasting from .. 61
 - - R.D. from .. 61
 - hypoglossal, paralysis of .. 63, 135, 543
 - impulses, motor, rate of discharge of .. 724
 - inferior dental, neuralgia in .. 462
Nerve, inferior neural, distribution of .. 498
 - spinal segments derived from .. 498
 - inferior laryngeal .. 148
 - intercostal, abscess irritating .. 432
 - - aneurysm irritating .. 432, 434
 - - callus involving .. 432
 - - herpes affecting .. 431
 - - new growth irritating 432
Nerve, intercostal, tender points on .. 707
 - internal cutaneous, neuralgia of .. 412
Nerve, internal plantar, distribution of .. 498

Nerve, spinal, of plantar, foot
 — spinal segments derived from ... 498
 — popliteal, derived from lesion of ... 469

Nerve, internal popliteal, distribution of ... 498
 — interosseus supplied by ... 469
 — lumbococcygeus supplied by ... 469

Nerve, internal popliteal, paralysis of ... 493
 — spinal segments derived from ... 498
 — ulnar nerve homologue of ... 469

Nerve, long thoracic, muscles supplied by ... 504

Nerve, long thoracic, paralysis of (*Fig. 207*) ... 505, 506
 — spinal segments supplied by ... 504

Nerve, median, muscles supplied by ... 504
 — paralysis of, ischaemic paralysis simulating ... 506
 — spinal segments supplied by ... 504

Nerve, musculocutaneous, muscles supplied by ... 504
 — spinal segments supplied by ... 504

Nerve, musculospiral, muscles supplied by ... 505
 — neuralgia of ... 442
 — paralysis of ... 504, 505
 — spinal segments supplied by ... 505
 — new growth on, muscle wasting from ... 44
 — R.D. from ... 44
 — roots derived from ... 498

Nerve, obturator, distribution of ... 498
 — genicular branch to knee ... 363
 — spinal segments derived from ... 498

Nerve, obturator, paralysis of ... 498
 — spinal segments derived from ... 498
 — optic, compression of, ... 562
 — fibrils from ... 562
 — conditions of (*Fig. 188*) ... 590
 — happens from axid lesion of ... 552
 — lesion of one, pupal changes from ... 552

Nerve, optic, opaque nerve fibres of (*Plate VII*) ... 416
 — tumour of, hypermetropic from ... 230
 — tropic due to ... 230
 — phrenic, ascending fibres in ... 432
 — compression of, no pain with ... 434
 — diaphragm supplied by ... 769
 — irritation of, by caseous glands ... 308
 — laceration from ... 307, 308
 — paralysis of ... 65
 — role in vomiting ... 764
 — roots derived from ... 769
 — twigs to liver and gall bladder ... 769

Nerve, posterior scapular, muscles supplied by ... 504
 — spinal segments supplied by ... 504
 — phrenic ... 493
 — pyramidal, spinal segments derived from ... 498
 — quadratus femoris, spinal segments derived from ... 498
 — recurrent laryngeal, compressed by thyroid gland enlargement ... 722
 — paralysis of (see Thyroid, Laryngeal)

Nerve regeneration, sensory recovery after ... 606
 — time required for ... 583

Nerve, oculi,
 — roots, serial, injury of, claw-toot from ... 469

Nerve, sciatic, distribution of ... 498
 — injury of, ripples from ... 498

Nerve, sciatic, paralysis of ... 499
 — spinal segments derived from ... 498
 — seventh, paralysis of (see Paralysis, Facial)

Nerve, subscapular, muscles supplied by ... 535
 — spinal segments supplied by ... 505

Nerve, superior gluteal, distribution of ... 498
 — spinal segments derived from ... 498

Nerve supply of heart ... 433

Nerve supply of the scalp (*Fig. 209*) ... 710

Nerve, suprascapular, muscles supplied by ... 504

Nerve, suprascapular, paralysis of ... 506
 — spinal segments supplied by ... 504
 — suprathoracic, paralysis of (see Paralysis of Third Nerve)

Nerve, ulnar, effects of division of ... 606
 — internal popliteal nerve homologue of ... 469

Nerve, ulnar, muscles supplied by ... 504
 — paralysis of (see Paralysis, ulnar)
 — spinal segments supplied by ... 504

Nerve vagus, branches of ... 418
 — compressed by thyroid gland enlargement ... 722
 — no pain with ... 434
 — irritation by aneurism ... 704
 — caseous glands ... 307, 308
 — laceration from ... 308
 — by mediastinal fibrosis ... 706
 — tachycardia from ... 733, 704
 — by thoracic new growth ... 704
 — laryngeal paralysis from changes in ... 495
 — neuritis of ... 703
 — paralysis of (see Paralysis of Twelfth Nerve)
 — role in cough ... 418
 — role in vomiting ... 764

Nerves, callus involving, muscular atrophy from
 — R.D. from ... 61, 63
 — electrical reactions of normal ... 583
 — injury of, contractures from ... 458, 441
 — muscular atrophy from ... 65
 — R.D. from ... 61, 63
 — olfactory, absence of ... 642
 — neuritis of ... 642
 — role in taste ... 762

Nerves, sensory, distribution of (*Fig. 256*) ... 605

Nerves, spinal, distribution of sensory divisions of ... 427
 — thickened, in von Recklinghausen's disease ... 732
 — Nervosus, accentuated first heart sound from ... 726
 — from alcohol ... 62
 — alcoholism simulated by extravasates from ... 547
 — in Graves's disease ... 226, 486, 766, 770
 — increased knee-jerk with ... 59
 — irregular heart from ... 349
 — palpitation from ... 481, 486
 — polyuria from ... 535
 — shortness of breath from ... 88
 — tachycardia from ... 728, 702, 704
 — tremor from ... 724, 725, 726

Neuralgia, abdominal ... 425, 426
Neuralgia, anterior crural ... 439
 — from antrum disease ... 480
 — brachial, alternating with oculo-motor ... 459
Neuralgia, brachial, general account of ... 442, 443
 — writer's cramp simulated by ... 451
Neuralgia, calcanean ... 439
 — cervicobrachial ... 477
 — pain in shoulder from ... 475
 — from decaying tooth ... 296, 448, 710
 — disseminated sclerosis ... 609
 — distinction from headache ... 246
 — scutche from ... 292
 — from ear lesions ... 710

Neuralgia, epileptiform ... 447

Neuralgia, from error of refraction ... 443
 — external oblique muscle ... 449
 — from eye lesions ... 710
 — from tooth ... 441

Neuralgia, facial, general account of ... 418
 — ptosis from ... 442
 — after herpes ... 431, 445, 754
 — bands from ... 465, 465
 — interstitial, cervicobrachial simulating ... 423, 459, 507

Neuralgia, intercostal, general account of ... 431
 — metastatic tumour simulating ... 431
 — new growth of spine simulating ... 707
 — pain on breathing with ... 431
 — in the epizostrium ... 436
 — hypochondrium from ... 459, 454
 — movement with ... 431
 — pleurisy simulating ... 707
 — pneumonia simulating ... 432, 707
 — spinal abscess simulating ... 707
 — cores simulated by ... 454
 — simulating ... 441
 — tender points with ... 431, 436, 450
 — tenderness from ... 706, 707
 — vertigo before digestion ... 436, 707
 — interstitial, oculo-simulated by ... 445

Neuralgia, intestinal, general account of ... 415
 — of kidney, simulating stone ... 426

Neuralgia, mammary ... 430

Neuralgia, metatarsal ... 439

Neuralgia minor, general account of ... 711, 712
 — after neuritis ... 431
 — obturator ... 459
 — in osteitis deformans ... 679
 — ovarian, appendicitis simulated by ... 665
 — pain in the chest from ... 439, 451
 — saw from ... 462
 — proximal headache and ... 294

Neuralgia, phrenic ... 431
 — cerebellar tumour ... 582
 — cerebral abscess ... 441
 — 147, 306, 307, 626
 — laryngeal ... 81
 — metastasis ... 81, 85, 146
 — meningitis ... 295, 309
 — tumour ... 81, 147, 306, 315, 429, 502, 537, 525, 626, 711
 — convulsions and ... 446
 — from encephalitis ... 129, 525
 — lung tissue endocarditis ... 44
 — headache with ... 768
 — hereditary ... 760
 — hypermetropic distended ... 447
 — meningitis ... 129, 507, 515, 525, 599, 599, 649

 - scotoma from 700, 762
 - from syphilis 446
 - waxing and waning slight with 445
 - sciatia 438
 - of supra-orbital nerve 506
 - tenderness of spine from 713
 - visual, after fever 763
 - tachycardia from 763
- Neurofibromata, rheumatic nodules simulated by 732*
- skin tumours from 732
 - in von Recklinghausen's disease 710
 - pain from 431
 - from 700
- Neuronata, of brachial plexus 443*
- Neurorhinitis, arthritis form of 250*
- Neuroromyositis, pain in the limbs from 463*
- Senator of 464
 - 398
- Neuroses of bladder 363**
- the brain and 363
- Neuroses, occupation, of arm 445**
- from peccorini 74
- Neuroses, contd.*
- vasomotor (see Vasomotor Neuroses) 13
 - Neurosis, abdominal distention from 418
 - anaesthesia in 418
 - ears simulating 477
 - chieftis and 365
 - diarrhoea from 173
 - disseminated sclerosis simulating 517, 518
 - earache from 202
 - of fifth nerve 543
 - hysteria distinguished from 487
 - lachrymation from 178
 - nasal discharge from 178
 - new growth of spine simulating 477
 - optic disc examinations in cases of suspected 120
 - orthopnea from 418
 - pain in the hand from 151
 - paraplegia from 514
 - in pregnancy 543
 - prolonged pyrexia from 363
 - pseudo-anemia from 434
- Neurosis, pyrexia and 570**
- nasal discharge from 518
 - salivation from 543
 - spasm of oesophagus from 435
 - vaginismus from 194
 - writer's cramp simulated 151
 - (and see Hy-tremia)
- Neutrophile myelocytes (see Myelocytes)*
- Newborn, abdominal distention from cystic kidneys in 12*
- haemoglobinuria in 284
 - intestinal obstruction in 129
 - jaundice of 325, 326, 329
 - malformed rectum in 129
 - nulary abscesses in 557
 - ophthalmia (see Ophthalmia Neonatorum)
 - peniphages in 401
 - prolonged pyrexia in 567
 - septicaemia in 567
 - tetanus in 730
 - umbilical inflammation in 567, 656
 - vaginal hemorrhage in 392
- New Zealand, hydrophobia in 291*
- Nicholson, on testis growth 696*
- Nicotina, tremor from 726*
- Night blindness (and see Vision, defects of) 731, 763**
- from retinitis pigmentosa 761
 - cramps 150
 - starts, from hip disease 363
 - sweats in Barlow's disease 651
 - phthisis 288, 476, 651
 - rickets 651
 - tetosis 321, 492
- NIGHTMARES 402**
- Night-workers, pallor in 21
 - Ninth nerve paralysis 706
 - Nipple, brown in pregnancy 430
 - cracked, pain in the breast from 429
- NIPPLE, DISCHARGE FROM 181, 680, 686, 687, 750**
- eczema of 750
 - epithelioma of 429
 - inflamed, pain in the breast from 429
 - Nipple, Paget's disease of 120
 - retracted, pain in the 630
 - pink normally 430
 - retracted by carcinoma 687
 - in Paget's disease 720
 - scabs of 755
 - secondary areola round, in pregnancy 420
 - Nitrate of silver (see Silver Nitrate)
 - Nitric acid (see Acid, Nitric)
 - Nitrate of amyl (see Amyl Nitrate)
 - sodium, in Camidge's reaction 100
 - in diazo-reaction 173
- Nitroglucine, angina abdominalis relieved by 115*
- - pectoris relieved by 476
- Nitroprusside test for acetone 3**
- for melanuria 746
 - (Plate XXVII) 748
 - Nits 378
 - Nocturnal emission 15, 421
 - noerures 621
 - Node on bone, after injury
 - periosteal, in typhoid fever 670

- angina of 220
 - bleeding from (see Epistaxis)
 - blowing, epistaxis from 220
 - subcutaneous emphysema from 203
 - bottle 51
 - bridge of, depressed in achondroplasia 187
 - congenital syphilis (Fig. 206) 234, 255
 - fallon in, from injury 173
 - in nasal bone necrosis 179
 - syphilis 179
 - from an hyposphema 251
 - and flat, in Monolism 237
 - bulbous dermatoses affecting 99

Nasa, cond.
 - cerebro-spinal fluid from 119, 178
 - chondrosis of, 655
 - crusts in, from atrophic rhinitis 179
 - deformed by exostosis 204
 - epithelia of 179
NOSE, DISCHARGE FROM 178
 - (and see Discharge, Nasal)
 - dry, from fifth nerve 612
 - epistaxis 229
 - emissary vein to 229
 - endothelium of 179, 180
 - enlarged, by rosacea 211
 - epithelium of 179, 339
 - excretion of, in nasal epithelia 178
 - fibrous of 229
 - foreign body in 87, 179, 229
 - gangrene of, from embolism 31
 - haemorrhage from (see Epistaxis)
 - inability to breathe through, from hypertrophic rhinitis 179
 - lesions of, causing epistaxis 220
 - lipkus of 179, 339
 - picking, epistaxis from 220
 - - from worms 519
 - pink 634
 - polyp in (see Polypus Nasal)
 - prosthesis, in micro-epithelia 388
 - pruritis of 510
 - Raynaud disease affecting 296, 699
 - red, with carboles 371
 - reorganization of food through (see Reorganization of Food through Nose)
 - rhinosclerosis of 753
 - rolfent ulcer of 179, 755
 - running at (see Discharge, Nasal)
 - seroma of 179
 - sepsis in, arthritis from 339
 - = food breath from 86
 - = meningitis from 590
 - syphilitic of 179
 - tuberculous of 179
Nuclear paralysis, facial 493
Nuclein, derivatives of 742
 - phosphates from 522
Nucleoprotein, albuminuria and 424
 - in cerebro-spinal fluid 305
 - nuclein 70
Nucleoprotein, reactions in urine 4, 5
 - ure acid from 742
 - in urine, with oxaluria 424
Numbness, as an aura of epilepsy 67
 - in disseminated sclerosis 699
 - of fingers, in aeropar- aesthesia 411
 - - occupation and 414
 - after flushing 211
 - in sensation 458
 - sense of, in paroxysmal tachycardia 703
 - from peripheral neuritis 465
 - in tabes 609
Numerical spasm 149, 644
Nursemaids, hypertrophy of breast in 685
 - scoldish in 154
Nurses, chamber of finger in 240
Nutmeg liver (see Liver, Nutmeg)
Nutmeg-carrot skin, in prurigo ferrox 190
 - xeroderma 188
Nyctalopia, causes of 763
Nycturia, remnant, adaptation and 746
Nylander's test for sugar 262
NYSTAGMUS 407
 - from albumin 197
 - neural irritation 408
 - anidlyopia with 759

Nystagmus, condt.
 - from anterior polar cataract 759
 - in blind persons 497
 - from cerebellar abscess 517
 - - lesions 59
 - - tumour 407, 408, 517, 592
 - chorobitis 759
 - colour blindness 497
 - congenital cataract 497
 - congenital opacity 759
 - disseminated sclerosis 118, 497, 498, 499, 502, 517, 518, 519, 520, 728, 760
 - Friedreich's disease 118, 140, 497, 513
 - lipkus with 552
 - after injury 498
 - from macular coloboma 759
 - in misers 497
 - ophthalmia 761
 - - neumatoma 407, 759
 - persistent hyaloid artery 759
 - after poisoning 408
 - from retinitis 759
 - in strabismic 119
 - in strychnine 498, 508
 - from unusual retinal pigment distribution 497
 - varieties of 497
 - vertigo with 498, 751
 - from working in dim light 497
OBESITY
 - (see Bermeier, Obesity)
OBESITY 408
 - abdominal distention from 48, 655, 656
 - amenorrhoea from 18
 - anaemia with 32
 - from cerebellar tumour 410
 - constipation with 127
 - with deficient ovarian activity 403, 646
 - in Deroin's disease 410
 - after epididymitis 409
 - in emphyse 409
 - fatty heart with 33, 90, 212
 - glycosuria and 269, 261
 - and hypertrophied 409
 - lack of exercise 185
 - life insurance and 498
Obesity, list of causes of 408
 - at menopause 499
 - mercurial parasthetic and 439
 - after orchitis 499
 - palpitation from 185
 - pancreatic apoplexy 76
 - from pituitary lesion 409
 - a psychogenic state 408
 - shortness of breath in 53
 - stimulating asites 44
 - sterility from 646
 - umbilical hernia and 185
Obstruction (see Constipation)
Obstruction, intestinal (see Intestinal Obstruction)
Obstruction to urine outflow, causes of 7
Obturator foramina, nerve supply of 498, 499
 - hernia (see Hernia, Obturator)
 - internal, nerve supply of 498
 - nerve 498
 - neuralgia 499, 459
Occipital lobe lesions, hemiparesis from 302, 552
 - = pupil reflex and 552
 - = tumour of, visual aura with 68
 - = lymph glands (see Lymphatic Glands, Occipital)
 - = rectum, flat in, Mondolin 190
Occipito-frontalis, eyelid raised by 542
Occlusio posteriori presentations, dystrophia from 291
Occiput, pain over, from otitis media 292
Occult blood (see Blood, Occult)

Occupation, aeroparasthesia and 411
 - astigmatism and 645
 - = yellow atrophy and 334
 - achlostromas and 81, 529
 - antrax and 559, 674
 - aortic disease from 299
 - arthritis from 476
 - aspergillus of lung and 645
 - = berg-hill and 411
 - bulla from 36
 - = caisson disease and 397
 - cerebral rals symptoms and 415
 - chamber of finger and 249
 - chronic pharyngitis from 613
 - chlorosis and 36
 - cow-pox and 249
 - = cramps and 150, 151
 - dead fingers from 162, 163
 - deafness and 166
 - dermatitis from 755
 - in diagnosing heart-stroke 119
 - drops in sweat and 653
 - Dupuytren's contracture and 412
 - = earache from 224
 - epistaxis from 224
 - epithelioma seroi and 461, 465
 - erythema from 222, 221
 - eye-strain from 146, 221
 - finger numbness and 414
 - glanders from 179, 645
 - hamman's knee and 476
 - = heling and 549
 - head poisoning and 117, 147
 - hot water, used by 296
 - microbism and 33, 73, 224
 - and phages and 299
Occupation neuroses 445, 476
 - tetonia from 724
 - = roses in the head from 401
 - = myositis and 407
 - = cystitis from 199
 - ossification of tendon from 671
 - pain in the eyes from 146
 - pallor due to 21
 - peripheral neuritis and 65
 - pharyngitis and 610
 - phosphorus poisoning 610
 - and 336

Edema, (cont.)
 of test and epididymus .. 274
 — with orchitis .. 371
 — in erythromelalgia .. 441
 — polyneuropathy .. 464
 — from fibrositis .. 470
 — general, in infants .. 473
 — fungating endothelitis .. 473
 — gastroenteritis .. 473
 — nephritis .. 9, 10
 — snake-bite .. 337
 of genital organs, in acute nephritis .. 9
 — bands, from angioneurotic oedema .. 415
 — heart failure .. 413
 — myxoedema simulating .. 38
 — from Kayser's disease .. 413
 — head, from vena caval obstruction .. 751
 — inner side of eyelids .. 251
 — from conjunctivitis .. 251
 — from iodides .. 419
 — jelly-fish stings .. 224
 — of labia, in nephritis .. 412
 — labium minus .. 701
Edema of larynx, acute bacterial .. 419, 616
 — in anæmia Ludovici .. 499
 — from Bright's disease .. 419
 — in .. 159, 129, 650
 — laryngeal obstruction .. 418
 — from .. 418
 — from laryngeal ulceration .. 419
 — orthopnea from .. 418
 — stridor from .. 650
 — suffocative, laryngeal paralysis simulating .. 495
 — leg (one) in Mayo's disease (Fig. 177) .. 411
 — from pelvic tumour .. 411
 — from pleurisy .. 414
 — rectal examination with .. 411
 — thrombosis .. 419, 749
 — vaginal examination with .. 411
 — legs, albuminuria with .. 412
 — from anæmia .. 413
 — angioneurotic oedema .. 414
 — ankylo-tonosis .. 51
 — from aortic regurgitation .. 207
 — with arteriosclerosis .. 11
 — ascites .. 52
 — from lock pressure .. 212
 — in beriberi .. 62, 411
 — Bright's disease .. 105, 412
 — cadaveric states .. 413
 — from œdema of kidney .. 790
 — recti .. 7
 — chlorosis .. 413
 — chronic nephritis .. 212
 — in convalescents .. 414
 — after diaphragm ulcer .. 414
 — from emphysema .. 217
 — after fractured femur .. 414
 — after gastric ulcer .. 411
 — with granular kidney .. 11
 — after hemorrhage .. 413
 — from heart failure .. 52, 105, 112, 413, 694
 — high blood-pressure .. 212
 — Hodgkin's disease .. 413
 — inferior vena-cava obstruction .. 414
 — leukæmia .. 415
Edema of legs, list of causes of .. 413
 — from malaria .. 413
 — in diaphragm emphysema .. 413
 — massage for .. 414
 — in Meigs's disease .. 414
 — from nitral regurgitation .. 210, 211
 — myxoedema changes .. 90, 500
 — myxoedema .. 411
 — nephritis .. 412, 413
 — with surface liver .. 353
 — in old people .. 411
 — torpid heart .. 411
 — peritoneal ascites .. 413
 — from portal obstruction .. 272

Edema of legs, contd.
 — pseudo-leukæmia .. 414
 — in Raynaud's disease .. 411
 — from renal growth .. 7
 — simulated by myxoedema .. 537
 — from splenic anæmia .. 413
 — starvation .. 413
 — syphilis .. 413
 — with triacridin regurgitation .. 92
 — tube casts with .. 112
 — from tuberculosis .. 413
 — after typhoid fever .. 411
 — varicose veins .. 410
 — vena-cava obstruction .. 719, 750
 — from leucure .. 410
 — liase abscesses from .. 365
 — over liver abscess .. 370
 — of lungs, in nephritis .. 9, 412
 — lungs, acute, in Bright's disease .. 420
 — from lymphatic obstruction .. 410
 — with mustard poultice .. 559
 — over in-stomach .. 597
 — in Meigs's disease .. 226
 — from meninges .. 410
 — of neck, from angina Ludovici .. 413
 — anthrax .. 413
 — cellulitis .. 413
 — erysipelas .. 413
Edema of neck, from vena cava obstruction 413, 751
 — with nephritis .. 109
 — from neuritic ligature .. 411
 — nutmeg liver with .. 368
 — of palms, in erythema keratodes .. 405
 — penis in nephritis .. 411
 — pleural effusion and .. 404
 — with polyseric kidneys .. 42
 — polyuria after .. 535, 536
 — of prepuce, from balanitis .. 617
 — from chancere .. 419
 — retina .. 416
 — scalp, in nephritis .. 412
 — from superior longitudinal sinus thrombosis .. 597
 — wound infection .. 410
 — xeroma, in nephritis .. 412
 — from peri-neurial abscess .. 697
 — from sweat prickles .. 224
 — of sides, in erythema keratodes .. 405
 — solid, from lymphatic obstruction .. 411
Edema, SYMMETRICAL 411
 — from thrombosis .. 410
Edema of tongue, acute, causes of .. 698
 — transient .. 411
 — of trunk, from renal growth .. 7
 — unilateral in tuberculo-peritonitis .. 412
Edema, universal .. 418
 — from aspartum .. 413
 — beer swilling .. 412
 — in Bright's disease .. 105
 — from drugs .. 413
 — infusion .. 412
Edema, universal, list of causes of .. 415
 — from snake-bite .. 413
 — from venous obstruction .. 413
 — of vulva, in anæmia .. 701
 — from water-fish prick .. 224
Œsophagismus .. 435
 — Œsophago-empne .. 195, 196
 — in diagnosing foreign body in œsophagus .. 267
 — Œsophagus, aneurysm opening into .. 267, 120, 265, 134
 — from .. (Fig. 95) 195
 — from impacted in .. 195
 — bullous dermatoses affecting .. 99
 — cardiac end of, site of .. 194
 — sensibility of .. 194
 — chicken-pox affecting .. 616

Œsophagus, contd.
 — epirational stenosis of .. 155
 — coin impacted in .. 195
 — epithelioma of (see Carcinoma of Œsophagus)
 — foreign body in 194, 195, 265, 267
 — hæmatemesis from affections of .. 265
 — idiopathic dilatation of (Fig. 98) 198, 763
 — opened by foreign body .. 265, 267
 — mediastinal new growth .. 265, 267
 — obstruction of, by abnormal subclavian artery .. 196
 — œsophagus from .. 4
 — œsophagus from .. 33
 — by aneurysm .. 195, 134
 — bougie in diagnosing .. 763
 — œsophagus from .. 33
 — by carcinoma .. 195
 — constipation from .. 123
 — after corrosives .. 194
 — from fibrous stricture .. 194
 — foreign body .. 194
 — leucopenia with .. 361
Œsophagus, obstruction of, list of causes of .. 763
 — œsophagus in diagnosing .. 195
 — pain in the chest from .. 159
 — œsophagus in diagnosing (Fig. 95) 195, 763
Œsophagus, obstruction of, general account of 194-6
 — from tooth-plate .. 194
 — pouch of vomiting due to .. 763
Œsophagus, pouches of 196
 — small-pox affecting .. 616
 — spasms of, dysphagia from .. 155
 — neuritic .. 135
 — pain in chest from .. 155
 — vagus branches to .. 148
 — varicose veins in, hæmatemesis from .. 265
 — Oidium albicans .. 71
 — in spurtum .. 615
 — tropicæ, in Ceylon .. 615
 — phthisis simulated by .. 615
 — in spurtum .. 645
 — Oil of cedar, erythema from .. 222
 — Oil, volatile, bullæ from .. 96
 — Oil (see also Age; and Age, Ludovici) .. 68
 — Olfactory aura .. 68
 — nerves (see Nerves, Olfactory) .. 612
 — Oligæmia, definition of .. 20
 — Oligæthæmia, cord changes from .. 69
 — definition .. 20
 — Oligochromæmia, definition .. 20
 — Oligospermia, sterility from .. 646, 647
 — Oliguria (see Anuria)
 — Oligo-spondo-cerebellar atrophy .. 727
 — Omentum, abscess of (see Abscess, Omental)
 — cyst of .. 661
 — fit necrosis in .. 767
 — in hernia .. 657, 682
 — hydatid cyst in .. 677, 658
 — lesions of, pelvic swelling due to .. 688
 — loaded with fat .. 15
 — matting of, from chronic peritonitis .. 171, 367
 — small-intestine and liver .. 48, 267
 — thickened by carcinoma .. 49
 — colon, growth stimulating .. 125
 — stomach, growth stimulating .. 125
 — tumour of, bile-duct obstruction by .. 331
 — umbilico from .. 331
 — kidney simulated by .. 331
 — malignant .. 331
 — movable, kidney simulated by .. 663
 — simulating enlarged liver .. 331

Omentum, contd.
 — spleen simulated by .. 664
 — tuberculous .. 331, 661
 — in umbilical hernia .. 483
 — Omphalo-mesenteric duct, cyst of .. 86
 — Omphalo-fœtal breath from .. 483
 — taste from .. 705
 — Onychia .. 400
 — Onychocryptosis .. 400
 — Onychocryptosis .. 400
Oncocystosis .. 249
 — Onychorhexis .. 400
 — Oophoritis, pain in iliac fossa from .. 452
 — pelvis from .. 468
Opaque nerve fibres, optic (Plate 31X) .. 416
 — Operation, abdominal, hæmatemesis from .. 266, 274
 — acetoneuria after .. 4
 — acute dilatation of stomach after .. 173
 — peritonitis after .. 592
 — for angions of tongue .. 699
 — anuria from .. 10, 42
 — in appendicitis .. 454
 — aspiration pneumonia after .. 259
 — atrophy of testis from .. 66
 — bronchopneumonia after .. 289
 — cervical closure after .. 18
 — coli bacilluria after .. 70
 — in coli bacilluria .. 455
 — diagnosing actinomycosis of liver .. 375
 — antral tumour .. 685
 — appendicitis .. 450
 — appendicular adhesions .. 458
 — breast tumour .. 131
 — calculus .. 687
 — carcinoma 317, 159, 686, 687
 — cause of, laces per urethrum .. 238
 — intestinal obstruction .. 211
 — cholecystitis .. 450
 — diaphragmatic hernia .. 652
 — duodenal ulcer .. 450
 — hæmatocele .. 181, 182
 — hydrocele of hernial sac .. 681
 — lipoma of cord .. 681
 — mucocœle .. 251
 — nature of pelvic swellings .. 694
 — new growth of testis .. 696
 — sub-mammary abscess .. 686
 — torsio testis .. 480, 696
 — tuberculous abscess of liver .. 375
 — breast .. 686
 — iliac glands .. 459
 — ureteral calculus .. 455
 — ureteritis .. 455
 — distinguishing empyema from abscess in the liver .. 103
 — from sub-diaphragmatic abscess .. 107
 — double pupil from .. 475
 — embolism of lung after .. 290
 — empyema after .. 196
 — for empyema of gall-bladder .. 254
 — entered cured by .. 178
 — epididymo-orchitis from .. 220
 — epistaxis from .. 220
 — in error, in tubes .. 220
 — erythema from .. 220
 — fistula after .. 220
 — hæmoptysis after .. 196
 — hypochloria after .. 211
 — infarction of lung after .. 196
 — infective parotitis after .. 694
 — in jaundice cases, fatal .. 555
 — neurasthenia after .. 715
 — œdema after .. 411
 — pain in pelvis after .. 468
 — paralysis of palate after .. 588, 588
 — pleurisy after .. 196
 — for pneumococcal arthritis .. 340

OTHER-HANONESS .. 17
Otitis, acute hæmorrhagic 421
 — media, from adenoids .. 202
 — — arthritis from .. 539
Otitis media, bacteriology of 422
 — from typhlogonoma .. 289
 — cerebellar abscess from .. 592
 — cerebral abscess from .. 592
 — 84, 306, 752
 — cervical glands enlarged from .. 379
 — chorda tympani purulosis from .. 706
Otitis media, complications of .. 84
 — convulsions with .. 202
 — deafness from 165, 423, 423
 — delirium with .. 202
 — earache from .. 202
 — e zema from .. 422
 — empyema from .. 106
 — granulata from 121, 423
 — hæmoptysis in .. 106
 — hæmorrhage from ear .. 421
 — headache from .. 202
 — hearing impaired with .. 202
 — hyperæsthesia acustica in .. 166
 — infarction of lungs from .. 106
 — in influenza .. 564
 — internal carotid artery eroded from .. 421
 — jugular vein thrombosis from .. 106
 — lateral sinus erosion in .. 421
 — — thrombosis from 84, 106, 159, 289, 567
 — mastoid abscess from .. 84
 — tenderness with .. 202
 — menbrana tympani perforated from .. 422
 — meningitis from .. 500
 — noises in the head from 406
 — optic neuritis from .. 202
 — otorrhœa due to .. 421
 — otoscope appearances of .. 202
 — pain in hyoid area from 449
 — — ear from 165, 422, 423
 — — over occiput from 202
 — — on opening mouth .. 202
 — — with .. 202
 — pleurisy from .. 106
 — pneumococcal .. 379
 — polypt from .. 421, 423
 — prolonged pyrexia from 567
 — pulmonary embolism from .. 159
 — pyrexia with .. 202
 — rigors from (*Fig.* 214) 567
 — after a scarlet fever 10, 617
 — screaming from .. 202
 — septicæmia from .. 567
 — simulating meningitis 202
 — suppurative meningitis from .. 84
 — swelling of meatus from 422
 — tenderness of scalp from .. 422
 — tinnitus from 165, 422, 423, 723
 — tuberculous .. 422
 — in typhoid fever .. 595
 — unilateral headache from .. 244
 — vertigo from 123, 752, 753
 — vomiting with .. 202, 765
Otorrhœa (see *Hæmorrhœa* from Ear) .. 421
OTORRHŒA .. 421
Otorrhœa, albuminous discharge in .. 421
 — arthritis from .. 379
 — cerebellar abscess from .. 517
 — from cerebral abscess .. 425
 — from epithelia of ear .. 422
 — epithelia of skin with .. 558
 — from ozæna .. 422
 — erythema .. 422
 — foreign body .. 422
 — furuncle .. 202, 422
 — mastoid abscess .. 427

Otorrhœa, contd.
 — necrosis of bone .. 422
 — noises in the head from 406
 — from otitis media 421, 422
 — parotid abscess .. 423
 — ritors from .. 597
 — from scarlet fever .. 227
 — sinus thrombosis from .. 597
 — from suppurating lymph gland .. 422
 — — sebaceous cyst .. 423
 — — temporomandibular joint .. 423
 — syphilis .. 422
 — tuberculous .. 422
 — from way in ear .. 421
Otosclerosis, deafness from .. 165, 753
 — noises in the head from 406
 — paracus Willisii with .. 165
 — tinnitus from .. 723, 753
 — vertigo from .. 753
Ova of ankylostomum (Figs) .. 28, 29, 80
 — in faeces .. 81
 — — ascaris, in faeces 328, (*Fig.* 217) 520
 — — bilharzia (*Fig.* 216) 79
 — — in faeces .. 79
 — — urine .. 282, 472, 581
 — — distoma in faeces .. 328
 — — in sputum .. 292
 — — in faeces .. 226
Ova in faeces, mode of examining for .. 519
 — in sputum .. 645
 — of tenia solem 519, (*Fig.* 216) 520
 — trichocephalus alsoar (*Fig.* 28) 80, 520, (*Fig.* 215) 521
Ovarian actively deficient, general account of 646
 — — excessive hæmorrhagia from .. 587
 — — obesity from 408, 409, 646
 — — cyst (see *Cyst, Ovarian*)
 — — secretion, menstruation and .. 18, 588
 — — tumour (see *Ovary, Tumour of*)
Ovaries, absent, sterility from .. 646
 — — defective, in ateliosis 191
 — — destruction of both, amenorrhœa from .. 18
 — — prolapsed tender, dyspareunia from .. 193, 194
 — — — levator ani spasm .. 193
 — — — vaginismus from .. 193
 — — thyroid relationship to 409
Ovaritis, appendicitis simulated by 456, 665, 678
 — — generally bilateral .. 457
 — — pain in iliac fossa from .. 156
 — — simulated by undue abdominal aortic pulsation .. 543
Ovary, affections of, effect on menstruation .. 19
 — — anæmia with .. 32
 — — appendicitis simulabed by .. 456, 665
 — — eosinophilia with .. 219
 — — pain in the back from 428
 — — ureteric calculus simulating .. 578
 — — carcinoma of (see *Carcinoma of Ovary*)
 — — cystic, felt per rectum 587
 — — fibroma of .. 689
 — — functionless, with incarcerated uterus .. 19
 — — hyperæsthetic, in hysteria 611
 — — impacted tumour of, backache from .. 468
 — — — pain in thigh from 468
 — — inflammation of (see *Ovaritis*)
 — — metastasis of .. 665
 — — new growth of, pelvic swelling due to .. 688
 — — — felt per rectum .. 587
 — — papilloma of .. 49
 — — prolapsed, pain in the pelvis from .. 468

Ovary, contd.
 — sclerosed, pain in the pelvis from .. 468
 — — sensory skin area of .. 468
 — — small cystic .. 193
 — — — dysmenorrhœa from 192
 — — tumour of (and see *Cyst, Ovarian*), albuminuria from .. 13
 — — amenorrhœa with .. 689
 — — anæmia from .. 35
 — — ascites from .. 331
 — — bearing-down pain from .. 427
 — — bilateral .. 19
 — — bile-duct compression by .. 331
 — — — dyschezia from .. 129
 — — — dystocia from .. 200
 — — enlarged spleen simulating .. 630
 — — jaundice from .. 331
Ovary, tumour of, kidney simulated by 353, 354, 663
 — — microscope in diagnosing .. 690
 — — pancreatic cyst simulating .. 688
 — — — rectal examination in diagnosing .. 331
 — — — secondary portal glands from .. 331
Ovary, tumour of, some signs of .. 630, 631
 — — sterility from .. 646
 — — swelling in hypochondrium from .. 629
 — — tenaculum in diagnosing .. 689
 — — twisted pedicle of, appendicitis simulated by .. 691
 — — — vaginal examination in diagnosing .. 331, 631
Over-eating, acute congestion of liver from .. 331
 — — obesity from .. 408
Over-exertion, acute dilatation of heart from 211, 211
 — — cramps from .. 150
 — — left ventricle enlarged from .. 206
 — — mitral regurgitation from 211
 — — ruptured aortic valve from .. 210
Over-strain, mental, impotence from .. 343
 — — pain in the limbs from .. 163
 — — — and stiffness from .. 164
 — — subacromial bursitis from 176
 — — tenderness of spine from 715
Over-study, nightmare from 102
Over-use, cramps from .. 151
Over-work, dyspepsia from 219
 — — evening headache from 294
 — — insomnia from .. 321
 — — malarial attack from .. 32
 — — neurasthenia from .. 406
 — — pain in the back from .. 428
 — — twitching from .. 156
Ovum (see *Ovary*)
Oxalate of calcium crystals (Fig. 181) .. 423
 — — in intestinal sand .. 599
 — — crystals in urine .. 9, 218
 — — ure acid with 424, 741, 742
Oxalates, amount passed normally .. 423
Oxalic acid (see *Acid, Oxalic*)
OXALURIA .. 423
 — — soluble in loin from .. 281
 — — — age incidence of .. 421
 — — calculus simulated by .. 281
Oxaluria, diet and .. 424
 — — dyspepsia with .. 281
 — — from endogenous sources 421
 — — frequent micturition from .. 394, 424
 — — after gooseberries .. 281
 — — in gouty persons .. 424
 — — hæmaturia from .. 275, 281
 — — hyperbionosis and .. 424
 — — irritable bladder from .. 424
 — — nervous dyspepsia and .. 421
 — — neurosthenia and .. 424
 — — nocturnal enuresis from 424

Oxaluria, contd.
 — — nocturnal micturition from .. 218
 — — nucleoprotein with .. 424
 — — after oxalic acid poisoning .. 268
 — — pain in testis from .. 483
 — — with pancreatic affections .. 10
 — — and phacælium alternating .. 424, 524
 — — powdered-wig phenomenon from .. 423
 — — priapism from .. 538
 — — renal calculus with .. 424
 — — after rhubarb .. 284
 — — spermatorrhœa and .. 424
 — — after tomatoes .. 281
 — — white precipitate in urine from .. 423
Oxybutyric acid (see *Acid, Oxybutyric*)
Oxygen, convulsions stopped by .. 146
Oxyhæmoglobin, hæmato-porphyrin simulating 744
 — — spectrum of (*Fig.* 30) .. 80
Oxyuris vermicularis .. 520
 — — anal irritation from .. 520
 — — — no blood changes with 26
 — — — blood in stools from .. 79
 — — — in children .. 520
 — — — eosinophilia rare from 219
 — — — not eosinophilia with .. 520
 — — gonorrhœa simulated 520
 — — grinding of teeth from 255
 — — priapism from .. 538
 — — valvular irritation from 520
Ozæna, from atrophic rhinitis .. 179
 — — foul breath from .. 87
 — — from hypertrophic rhinitis .. 179
 — — — syphilis in .. 79
Ozæna ether, in blood test 286
 — — — effervescence with pus 375
PACHYMEINGITIS,
 — cervical, claw-hand from .. 109, 110
 — — pain in arms from 110, 113, 441
 — — tenderness of spine from .. 411
 — — cervico-heral, pain in the shoulder from .. 477
 — — — simulating myofibrositis .. 477
 — — — neuritis .. 477
 — — — syphilitic .. 477
Pachymeningitis, chronic hypertrophic hæmorrhagic .. 515, 516
 — — headache from .. 294, 325
 — — hyperæcæsis in .. 308
 — — lumbar puncture in diagnosis .. 325
 — — noises in the head from .. 406

 433, 476, 535
 -- aortic incompetence
 433
 -- recumbentia ... 297

Pain in the arm, contd.

-- left, from heart disease
 445
 -- lumbar puncture in
 diagnosing cause of
 -- from mediastinal new
 growth ... 431
 -- neuromata ... 433
 -- occupation and ... 411

**Pain in the arm, from
 occupation neuroses** 445

-- pachymeningitis 119, 477
 -- peripheral neuritis ... 115
 -- testicular ... 445

Pain in the arm, radicular 444

-- skiamgram in diagnosing
 cause of ... 442
 -- from spinal curvcs ... 111
 -- ghosis ... 443
 -- tumour ... 443
 -- syringomyelia ... 508
 -- vertebral growth ... 111
 -- writer's cramp, etc. ... 445
 -- as an aur of epilepsy ... 47

PAIN IN THE BACK (and
 see Backache) 427

-- from abdominal aneu-
 rysm ... 437
 -- abscess ... 428
 -- acute rheumatism ... 427
 -- aneurysm 195, 271,
 290, 428, 429, 664, 711
 -- aortic incompetence ... 433
 -- appendicitis ... 428
 -- biliary colic ... 450
 -- bladder lesions ... 428
 -- carcinoma ... 385
 -- cauda equina tumour
 ... 62, 545
 -- debility ... 428
 -- duodenal ulcer ... 428
 -- dyspepsia ... 428
 -- fevers ... 427
 -- fibrositis ... 64
 -- gall-stone ... 428
 -- gastric ulcer 269, 428, 437
 -- herpes ... 428
 -- hyperaesthesia with ... 428
 -- from infective arthritis
 428
 -- kidney affections ... 428
 -- lumbar bluish with ... 428
 -- lumbago ... 428, 438
 -- malaria ... 30
 -- metasthatis ... 435
 -- meningitis ... 427
 -- myositis ... 64
 -- neurasthenia ... 715
 -- new growth ... 414

 -- over-work ... 428
 -- parietal calculus ... 426
 -- psychalgia ... 445
 -- renal lesions ... 428

Pain in the back, referred

-- from (*See*, 294) 716
 -- in relapsing fever 637
 -- from renal embolism 8
 -- scintilla ... 428
 -- serum infections ... 223
 -- skin lesions ... 428
 -- spinal curvcs 136, 364,
 428, 429, 516, 713
 -- growth ... 414
 -- stone in kidney ... 471
 -- typhoid spine ... 440
 -- uterine lesions ... 218
 -- vascular seminiferous
 lesions ... 428
 -- Wolf's disease ... 336
 -- crays in diagnosing
 cause of ... 428
 -- in yellow fever 273, 336
 -- at back of eye, in in-
 fluenza ... 361
 -- in back of right chest,
 from gall-stones 327
 -- from all-stones 327

PAIN, BEARING-DOWN 426

-- cysto-vesical in diag-
 nosing cause of ... 427
 -- from impacted fibrroids
 427
 -- ovarian tumours ... 427
 -- pelvic abscess ... 427
 -- disorders ... 426
 -- hamatocele ... 427
 -- pressure on bladder ... 426

Pain, haemorrhoidal, contd.

-- pressure on rectum ... 426
 -- rectal examination in
 diagnosing cause of
 -- from retrovertebral
 uterus ... 427
 -- sigmoidoscope in di-
 agnosing cause of ... 427
 -- tea-sinus with ... 426
 -- from uterine displace-
 ment ... 424
 -- vaginal examination in
 diagnosing cause of ... 427
 -- in leg toe, from exostosis
 671
 -- bladder, from calculus ... 742

 437
 -- phosphenic poisoning
 436
 -- pleurisy ... 436
 -- plumbism ... 51, 438
 -- rheumatism ... 126
 -- ruptured duodenal
 ulcer ... 436
 -- gastric ulcer ... 436
 -- small-pox ... 272
 -- spinal curvcs ... 436
 -- tubes ... 768

- Paralysis of palate, contd.*
- after removal of adenoids 589
 - stertor from 647
 - from syphilis 589
 - after tonsillectomy 589
 - unilateral, without speech defect 628
- Paralysis of pharynx, causes of** 588
- from glossopharyngeal nerve lesion 706
 - recumbent of food through nose from 688
 - pharynx nerve, from diptheria 585
 - pseudo-bulbar, age incidence of 589
 - no atrophy of tongue in 589
 - due to cortical softening 589
 - emotional expression uncontrolled in 627
 - facial paralysis in 493
 - palate affected in 588
 - pharynx affected in 588
 - recumbent of food through nose from 178, 588
 - spasticity in 627
 - starely fibres in 627
 - pseudo-hypertrophic (see Myopathy)
 - of pupil, complete 551
- Paralysis of sciatic nerve** 499
- from forcible extension of knee 113
 - fracture of femur 199
 - polio 199
 - gut with 499
 - from hip-joint injury 199
 - Hodgen splint 113
 - injury to lumbar spine 113
 - new growth 113
 - polyv lesions 499
 - splint 113
 - talipes from 113
 - from wound 113
- Paralysis of serratus manusus** 505, 506
- seventh nerve (see Paralysis, Facial)
 - shoulder, from poliomyelitis acuta 509
 - simulated by arthritis 501
 - of sixth nerve, diplopia from (Fib. 83) 177
 - effects of 176
 - with facial paralysis 193
 - from plumbism 41
 - spastic, of arm 502
 - one leg, from strychnine 110
 - of sphincter vesicae, incontinence from 218
 - spinal accessory 135, 142
 - from sialid 141
 - of stapedius 493
 - from Fallopiun canal lesion 494
 - stomach, acute dilatation of stomach from 173
 - superior oblique, diplopia from (Fib. 83) 177
 - rectus, diplopia from (Fib. 83) 177
- Paralysis, supranuclear** 492
- Paralysis of supracapular nerve** 506
- temporal muscle, from fifth nerve lesion 706
 - of third nerve (and see Ophthalmoplegia) and Strabismus) 510
 - from (Fib. 227, 228) 547
 - from mid-brain tumour 721
 - unequal pupils from 552
 - tongue, in bulbar paralysis 693, 589, 706
 - unilateral, without speech defect 628
 - trunk in Landry's paralysis 518
- Paralysis, contd.*
- twelfth nerve 63, 135, 543
 - ulnar, adductor pollicis affected in 110
 - claw-hand from 103, 110
 - flexor carpi ulnaris affected in 110
 - hypotliaric wasting from 110
 - ischaemic paralysis simulating 506
 - lumbricals affected in 110
 - progressive muscular atrophy distinguished from 61
 - sensory changes from 110
- Paralysis, unilateral, from gross intracranial lesion** 118
- of the corpus, death from 65
 - after diphteria 65
 - tachycardia from 65
 - vocal cord (see Paralysis, Laryngeal)
 - Volkmann's ischaemic 111, (Fib. 58) 141, 505
 - from spinal 61
- Paralysis, abscess, (see Abscess, Parametric)
- Parametric, acute peritricus from 592
- Paramyoclonus multiplex** 136, 137
- retracted head from 589
 - Paraphimosis 173
- PARAPLEGIA** 510
- ankle-clonus in 39
 - ataxic (see Ataxic Paraplegia)
 - from lateral cerebral softening 545
 - cases of sudden onset 544
 - from cauda equina tumour 545

1 day (tenkari conjunctivitis) (Plate XI) . . . 230
 Phacocleisis . . . 188
 Phacotomy, defective, in
 - bulbar paraflexis . . . 155
 Phosphates, acetic acid test
 - for . . . 524
 - aluminum simulated by 524
Phosphate, ammonio-mag-
nesium . . . 524
 - crystals of . . . 524
 - ammonium, solubility of
 - calcium deposit of . . . 524
 - in intestinal sand . . . 524
 - solubility of . . . 525
 - stellar crystals of . . . 524
 - urine cloud from . . . 1
 - iron, white precipitate of
 - magnesium, deposit of . . . 524
 - needles of . . . 524
 - solubility of . . . 523
 - urine cloud from . . . 4
 - potassium, solubility of
 - sodium . . . 523
 - dihydrate . . . 523
 - monohydrate . . . 523
Phosphate, triple . . . 524
 - crystals of (Fig. 221) . . . 524
 Phosphates, cleared up by
 acetic acid 4, 183, 574
 - discolored by blood
 pigment . . . 9
Phosphates, effects of heat
on 523
Phosphates, litmus and 523
 - normal amounts of, in
 - urine . . . 522
 - potash not dissolving . . . 740
 - pus simulated by 524, 571
Phosphates, solubilities 523
 - sources of . . . 522
 - urates simulating . . . 740
 - in urine, diminished in
 - nephritis . . . 10
 - urine turbid from . . . 183
Phosphatic deposits, physio-
logical chemistry of 523
Phosphatic diabetes 522, 523
PHOSPHATURIA . . . 522
 acetic acid in diagnosis 108
 - chlorides and . . . 523
 - chyluria simulating . . . 108
 - definition of . . . 522
 - gonorrhoea suggested by 524
 - nocturnal micturition
 - from . . . 218
 - and oxaluria alternating
 - with . . . 424, 524
 - spermatorrhoea suggested
 - by . . . 524
 - sulphates and . . . 525
 - urine milky on passing . . . 108
 Phosphorus, amra from 10, 11
 - bleeding gums from . . . 72
 - death from . . . 73
 - fatty degeneration from
 - heart from . . . 53, 212
 - liver from . . . 574
 gastritis simulated after 766
 haemorrhages from 295, 398
 - induced from 525, 526, 536
 - large liver from 326, 374
 - poisoning, acute yellow
 atrophy simulating 336
 - albuminuria in . . . 13
 - albumosuria with . . . 16
Phosphorus poisoning, gener-
al . . . 336
 - post-mortem appear-
 - ances in . . . 357
 - urine changes in . . . 336
 - uric acid from . . . 378
 - in uric acid-marking . . . 73
 - necrosis of jaw from 682
 - pyralis from . . . 542
 - stomatitis from . . . 75
 - vomitum from . . . 766
 Phosphotungstic acid
 - Fehsser's test . . . 73
PHOTOPHOBIA . . . 524
 - from lebonia . . . 526
 - conjunctivitis . . . 231
 - electric blindness . . . 702
 - erythroptosis with . . . 742
 - from glaucoma . . . 231, 255
 - hysterical . . . 526
 - from iritis . . . 231

Photostaphy, contd.
Photophobia, list of causes
of . . . 524, 525
 - from meningitis . . . 315
 - occupation and . . . 525
 - from sick headache . . . 526
 - in snowy blindness . . . 702
 - the doublestray . . . 417
 - from ulceration of cornea
 Phrenic nerve (see Nerve,
 Phrenic)
Phrenic neuralgia . . . 431
 Phthisias, pementation
 - in . . . 527
 Phthisis, abnormal apical
 - sizes in . . . 159
 - without abnormal physio-
 - logical signs . . . 286
 - albuminuria sputum in . . . 644
 - albuminuria in . . . 31
 - albumosuria with . . . 13
 - adhesions in . . . 532
 - anaemia due to 21, 32,
 - 35, 572
 - aneurysm simulating . . . 291
 - anorexia nervosa simulat-
 - ing . . . 771
 - apical mottling in . . . 104
 - sizes with . . . 476
 - bacillus prodigious sug-
 - gesting . . . 641
 - bronchial glands and . . . 385
 - bronchitis simulated by 644
 - bronchopneumonia from 159
 - cachexia from 13, 173, 313
 - calcareous particles in
 - sputum in (Fig. 273) 644
 - Cohnste's test in . . . 768
 - carcinoma of tonsil with
 - caecous mass in sputum
 - in . . . 644
 - catarrh of small intestine
 - from . . . 172
 - cutaneous laryngitis with
 - exudation in . . . 643
 - chest in . . . 166
 - chronic, clubbed fingers
 - from . . . 111
 - with emphysema . . . 266
 - congenital heart disease
 - and . . . 288
 - cough in 88, 150, 159,
 - 161
 - early . . . 288, 476
 - cyanosis from . . . 159
 - in diabetes . . . 264
 - diarrhoea from . . . 172
 - diarrhoea reaction in . . . 173
 - dyspnoea from . . . 322
Phthisis, elastic fibres in
sputum in 159, 269,
286, 642
 - emphysema biblis with . . . 532
 - empyema from . . . 101
 - family history in 104, 568
 - fatty haemoptysis in . . . 288
 - fatty heart from . . . 212
 - fever in . . . 572
 - fibroid lung from . . . 292
 - - distinguished from 216
 - fibroid, vocal cord par-
 - alysis from . . . 495
 - fatal bronchitis simulat-
 - ed by . . . 643
 - foul breath from . . . 86
 - - sputum with . . . 86, 643
 - taste in . . . 705
 - in Froehreich's ataxy . . . 513
 - gangrene of lung in . . . 259
 - simulated by 269, 299
Phthisis, general account of 286
 - emphysema with . . . 71
 - gumma of tonsil with . . . 645
 - haemoptysis from 149,
 - 159, 286, 288
 - headache from . . . 296
 - horns of lung in . . . 169
 - hydropneumothorax from 652
 - impotence from . . . 313
 - indurated from . . . 315
 - indigestion simulated by
 - inosoma from . . . 322
 - knee-jack exaggerated in
 - lardaceous disease from
 - 8, 375, 655
 - leucocytosis in . . . 360

Phthisis, contd.
 - lichen serofulosorum with
 - loss of appetite in . . . 288
 - - weight in . . . 288, 768
 - malaise from . . . 572
 - mediastinal tumour simu-
 - lating . . . 647
 - - micrococcus cutarrhalis in 641
Phthisis, miner's . . . 288
 - - haemoptysis in . . . 288
 - - skiagram of (Fig. 70) 159
 - - syphilis and . . . 288
 - - no tubercle bacilli in
 - - nausea in . . . 315
 - - neurasthenia simulated
 - by . . . 313
 - - night sweating in 288,
 - 476, 634
 - - offensive sputum from . . . 261
 - - opaque index in dia-
 - gnosing . . . 768
 - - orthopnea from . . . 323
 - - osteo-arthropathy from
 - (Figs. 164, 165) . . . 351
 - - pain in chest from 432, 435
 - - neck in . . . 432
 - - shoulder in 432, 471, 476
Phthisis, physical signs of 286
 - pigment in mouth from
 - 527, 528
 - pleural adhesions in . . . 432
 - - pleuritic effusion from . . . 104
 - - pneumococci in . . . 641
 - - pneumonia simulating . . . 289
 - - suppressed on . . . 289
 - - pneumothorax from 159,
 - 531, 532
 - - prognosis in, diazo-reac-
 - tion and . . . 173
 - - pulmonary aneurysm in
 - - pyogenic organisms in
 - cavities of . . . 641
 - - rarity in children . . . 285
 - - riding of nails in . . . 769
 - - secondary infection in
 - - 35, 86, 104, 641, 643
 - - skiagram of (Fig. 41) . . . 103
 - - shortness of breath early
 - simulated by hydral of
 - lung . . . 291
 - - infiltration of lung . . . 106
 - - iodium tropicale . . . 646
 - - simulating bronchoectasis
 - without signs . . . 288
Phthisis, sputum in 104,
 149, 288, 641
 - without sputum . . . 641
 - - staphylococci in . . . 641
 - - stercor in . . . 290
 - - streptococci in . . . 641
 - - succession in cavity in
 - 651, 652
 - - syphilis of larynx with
 - tenderness from 708, 709
 - - tracheitis from . . . 572
 - - tubercle bacilli in sputum
 - with 86, 159, 286, 288,
 - 293, 588, 476, 532, 612, 643
 - - not found in sputum . . . 641
 - - 641, 644
 - - tuberculin in diagnosis 768
 - - tuberculous laryngitis with 293
 - - tuberculous arthritis rare
 - with . . . 218
 - - caecum with . . . 458
 - - glands and . . . 379
 - - stomatitis from . . . 542
 - - tonsil with . . . 615
 - - ulcer of palate with . . . 388
 - - ulceration of bowel in
 - 76
 - - ulcer of tongue with . . . 749
 - - vomiting in . . . 315, 765
 - - von Brunn's test in . . . 268
 - - waxing in 159, (Fig. 165) 351
 - - above and below
 - - aricles in . . . 169
 - - of deltid in . . . 61
 - - infrascapular in . . . 61
 - - pectoralis major in . . . 61
 - - suprascapular in . . . 61
 - - weakness from . . . 572
 - - x-ray examination in
 - 104, 150, 287, 288,
 - 458, 476, 768
 - (and see Tuberculosis)

Physical signs of ascites 43, 44
 Physical signs of bronchi-
 ectasis . . . 292, 643
 Physical signs of cystic
 kidney . . . 354
 Physical signs of dilated
 stomach . . . 521, 522
 Physical signs of emphy-
 sema . . . 217
 Physical signs of enlarged
 heart . . . 206
 Physical signs of en-
 larged kidney 352, 353, 629
 Physical signs of enlarged
 spleen . . . 353, 628, 629
 Physical signs of fibroid
 lung . . . 292, 643
 Physical signs of gall-
 bladder enlargement . . . 353
 Physical signs, hepatic . . . 366
 - of hepatoptosis . . . 368
 Physical signs of lobar pneu-
 monia . . . 642
 Physical signs of mitral
 stenosis . . . 2
 Physical signs of pancreas
 tumours . . . 661
 Physical signs of pericar-
 ditis . . . 213, 433
 Physical signs of phthisis . . . 288
 Physical signs of pleural
 effusion . . . 168, 299
 Physical signs of pneumo-
 thorax 168, 432, 530
 - - Sawyer's . . . 94
 - - illustrations from . . . 167
 - - of stenosed bronchus
 290
 Physical signs of sub-
 diaphragmatic abscess 658
 Physical signs of swellings
 of abdominal wall . . . 655
 Physiological albuminuria
 15, 537
 Physiological cup, appear-
 - ances of . . . 415
 Physostigmine, unequal
 pupils from . . . 552
 - Praxist's cramp . . . 151
 Piano-playing, deteriora-
 - tion in quality of, in
 - general paralysis . . . 120
Pica . . . 43, 99
 - alternative names for . . . 99
 - relation to intestinal
 - worms . . . 99
 - - malaria . . . 99
 - picking of lips . . . 365
 - - Phosphoric acid (see Acid,
 Phosphoric)
PIED-EN-GRIFFE . . . 109
 Pigeon chest (Fig. 78) 167, 187
 Pigeons, feeders of, asper-
 - gillus of lung in . . . 645
 Pigment, blood, carried
 - down by phosphates 9
 - granules in malaria
 - parasites . . . 31
 - - urine . . . 82
Pigment patches in retina 416
 - - in scotoma from . . . 700
 - - producing micro-orga-
 - nisms . . . 286
 Pigmentation of eyelids, in
 - Graves's disease 215, 236
PIGMENTATION IN THE
MOUTH . . . 526
 - - in Addison's disease
 - 33, (Plate XXI)
 - 526, 528, 765, 770
 - - amyloid disease . . . 527
 - - from arsenic . . . 537
 - - in cachexia . . . 527
 - - from carcinoma . . . 527
 - - malignant disease . . . 528
 - - Negro blood . . . 526, 528
 - - in pernicious anaemia
 - 35, (Plate XXII) 526, 528
 - - phthisis . . . 527, 528
 - - from syphilis . . . 527
 - - mucous membranes, in
 - Addison's disease 82, 528
PIGMENTATION OF THE
SKIN . . . 527
 - - from abdomen of tu-
 - bercle . . . 528
 - - Addison's disease 82,
 - 526, 528, 765, 770

Pigmentation of the skin, cont'd.
 — from arsenic 53, 54 (Plate 111) 61, 75, 528.
 (Fig. 225) 529
 — in bronzed diabetes . . . 528, 528
 — cadaveria . . . 528
 — chlorasia . . . 528
 — chromatosis, amniotic . . . 529
 — in emphyse . . . 35, 51
 — from endothelioma . . . 39
 — after erythema papulatum . . . 189
 — from fibroid of uterus . . . 215, 236 (Pls. 222)
 — 527, 732
 — from haemochromatosis . . . 528
 — after herpes . . . 710
 — in Heberlein's disease . . . 527
 — from intestinal stasis . . . 528
 — in infants . . . 527
 — in Kaposi's disease . . . 528, 731
 — leprosy . . . 250, 528
 — with leucoderma . . . 529
 — from leucoderma . . . 39
 — after licium plants . . . 187
 — in melanin disease . . . 527
 — in malignant disease . . . 527
 — in melanosis . . . 528, 734
 — in melanotic disease . . . 116, 261
 — pellagra (Plate IX, A) . . . 226, 228
 — pernicious anemia . . . 527
 — pharyngitis . . . 527
 — pregnancy . . . 527
 — from radium . . . 225
 — in rheumatoid arthritis . . . 53, 542, 527
 — round scars of syphilis . . . 569, 527
 — from silver . . . 529
 — solar phlebotomy . . . 527
 — in still-born child . . . 378
 — from syphilis 209, 219, 190, 528, 529, 569, 737
 — time venereal 250, 529
 — with tuberculous perforations . . . 657
 — in urticaria nigricans . . . 528
 — from uterine disorder . . . 527
 — round varicose veins . . . 531
 — from vesicles . . . 527
 — with vitellus . . . 529
 — in von Recklinghausen's disease 710, 732
 — xanthoma . . . 732
 — from x-rays . . . 225

Pigmentation of tongue in Addison's disease (Plate XXI)

— arethra, in Addison's disease . . . 528
 — vulva, in Addison's disease . . . 528

Pigmentated crescent of disc
 in retina . . . 115

Piles, swelling in
 — from . . . 171
 — backache in . . . 169
 — bearing down pain from . . . 126
 — blood per omm from . . . 78
 — from eruption of pectum cutaneous . . . 51
 — fullness, distended from . . . 128
 — development from . . . 193
 — levator contraction from . . . 193
 — general excretion in . . . 194
 — stricture of sphincter . . . 128
 — speculum in diagnosis of . . . 191
 — stricture from . . . 619
 — venousness from . . . 126
 — pain in penis from . . . 171, 173
 — rectum from . . . 78
 — periproctal abscess from . . . 719
 — proppin from . . . 568
 — rectal examination in . . . 581
 — relation of stricture after operation for . . . 12
 — sense of fullness in rectum . . . 78
 — weight in rectum from . . . 78

Piles, cont'd.
 — something coming down to tum . . . 78
 — tumours from . . . 718
 — Phlegmasia, erythema from . . . 222
 — pyrosis from . . . 512
 — Pilo, arria opened by . . . 267
 — in knee, hopping from . . . 362
 — asophagus perforated by . . . 267
 — in rectum . . . 581
 — in testing analæta . . . 606
 — in metha . . . 181
 — Pins and needles, sense of, in proxy-mal diaphragm . . . 703
 — — peripheral neuritis . . . 465
 — Pink-eye . . . 251
 — Pit workers, noises in the . . . 496
 — Pits, from snuff-dip . . . 561, 601
 — Pituitary body, anatomical . . . 492, 499, 537
 — and . . . 499, 499, 537
 — — dystrophical adiposogenitalis and . . . 499
Pituitary deficiency, symptoms of . . . 410
 — gland defects, delayed sexual development from . . . 490
 — — fatness from . . . 490, 499
 — — glycosuria from . . . 490
 — — headache with . . . 490
 — — in children and . . . 189, 190
 — — polyuria from . . . 190
 — — vomiting with . . . 490
 — lesions, high blood-pressure and . . . 388
 — secretion, menstruation and . . . 388
 — tumour, from ossification . . . 390, 390, 390
Pityriasis, ringworm diss.
 — tinguished from . . . 219
 — scalp affected by . . . 219
 — rosea, erythrasma simulating . . . 251
Pityriasis rosea, general account of . . . 604
 — herald patch of . . . 604
 — itching in . . . 510
 — macules in . . . 383
 — parts affected by . . . 604
 — psoriasis distinguished from . . . 604
 — scales in . . . 604
 — seborrhœa distinguished from . . . 604
 — syphilis distinguished from . . . 604
 — time, eruption distinguished from . . . 604
 — — vesicular simulating . . . 250
 — rubra, after dermatitis herpeticorum . . . 604
 — desquamation in . . . 604
 — after drug eruptions . . . 604
 — eczema . . . 604
 — erythema multiforme . . . 604

Pityriasis rubra, general account of (Plate XXI) . . . 604
 — — itching in . . . 510
 — — after licium plants . . . 604
 — — psoriasis . . . 604
 — — scales in . . . 604, 602
 — — pilars, crusts in . . . 601, 188
 — — eczema simulating . . . 604
 — — exfoliative dermatitis distinguished from . . . 189
 — — fingers affected by . . . 259

Pityriasis rubra pilaris, general account of . . . 488
 — — crust of health in . . . 489
 — — affected by . . . 189
 — — hair follicles and . . . 188
 — — itching in . . . 510
 — — slight in . . . 489
 — — licium plants distinguished from . . . 189
 — — on palms . . . 604
 — — papule of . . . 187, 188, 604
 — — parts affected by . . . 187
 — — plaques, how to . . . 188

Pityriasis rubra pilaris, psoriasis distinguished from . . . 489, 604

Pityriasis rubra pilaris, cont'd.
 — — scales in . . . 188, 601, 601
 — — on soles . . . 604
 — — vesicular (see Time) . . . 250
Placenta, delivery of . . . 201
Placenta, delay in delivery of
 — disease of, delivery from . . . 201
 — — ectropia from clots . . . 146
Placenta prævia, diagnosis of
 — — hemorrhage from . . . 393
 — — Plague, dengue from . . . 245
Plaque, glandular enlargement
 — — from . . . 376, 378
 — — purpura in . . . 533
 — — purpura from . . . 595
Plantar reflex, mode of testing
 — — plantar reflex from . . . 571
 — — plantar reflex from . . . 571
 — — plantar reflex from . . . 571
 — — plantar reflex from . . . 571
 — — plantar reflex from . . . 571
 — — plantar reflex from . . . 571
PLANTAR REFLEX, EXTENSOR . . . 68
 — — distal end reflex lost . . . 358
 — — in alcoholism . . . 69
 — — in myopathia . . . 362, 362
 — — under rheumatism . . . 508, 517
 — — under rheumatism . . . 39
 — — in toxic paraplegia . . . 69
 — — in infantile paraplegia . . . 502
 — — Brown-Sequard paralysis . . . 197
 — — from cerebellar disease . . . 517
 — — spasm . . . 517
 — — tumour . . . 68, 517
 — — cerebral disease . . . 68
 — — embolism . . . 68
 — — hemorrhage . . . 68
 — — thrombosis . . . 68
 — — in clonus . . . 69
 — — coma . . . 69
 — — from continued degeneration of cord . . . 114
 — — in coarctation . . . 69
 — — disseminated sclerosis . . . 118, 207, 207, 206, 502, 517, 728
 — — epilepsy . . . 69
 — — evidence of organic disease . . . 758
 — — in Friedreich's ataxia . . . 39, 68, 517
 — — hemiplegia . . . 39, 68, 517
 — — in chorea . . . 129, 202
 — — with increased knees . . . 59
 — — in infantile . . . 69, 510
 — — new growth in spine . . . 711
 — — paraplegia . . . 39
 — — pernicious anemia . . . 69
 — — primary lateral sclerosis . . . 68
 — — with pyramidal tract . . . 59, 68, 110, 517
 — — in scurvy . . . 68
 — — phlogothly . . . 69
 — — during sleep . . . 69
 — — in spastic paraplegia . . . 511, 512
 — — symmetrically . . . 68, 508
 — — of hips, and . . . 112
 — — in transverse myelitis . . . 62, 68
 — — in uremia . . . 69
 — — flexor, in hysteria . . . 69, 97
 — — in infantile paralysis . . . 68
 — — in Landry's paralysis . . . 66
 — — in neuritis . . . 68
 — — paraplegia . . . 68
 — — primary, muscular . . . 68
 — — dystrophy . . . 68
 — — in sciatica . . . 138
 — — of toes dorsally . . . 68
 — — in "tooth's" paraplegia . . . atrophy . . . 68

Pleurides . . . 758
Plethora . . . 221
Pleura, pneumothorax after
 — — lung . . . 458
 — — aneurysm ruptured into . . . 431
 — — fibrous thickening of . . . 167
 — — from pleurorrhoea . . . 167
 — — gas in (see Pneumothorax)
 — — malignant disease of, blood-stained effusion from . . . 102
Pleura, new growth of . . . 104
 — — pain in back from . . . 716
Pleural adhesion (see Adhesions, Pleural)
PLEURAL EFFUSION . . . 101
 — — from abscess of liver . . . 101
 — — albuminuria and . . . 101
 — — in Bright's disease . . . 101
 — — bronchitis after . . . 292
 — — diaphragm depressed by . . . 658
Pleural effusion, expansile pulsation of . . . 694
 — — about lung after . . . 292
 — — heart displaced by . . . 694, 691
 — — from heart failure . . . 101, 105
 — — in . . . 88
 — — liver depressed by . . . 267
 — — from mediastinal sarcoma . . . 312
 — — nephritis . . . 101
 — — œdema and . . . 101
 — — orthopneic and . . . 101
 — — population of . . . 181
 — — particles of growth in . . . 107
Pleural effusion, physical signs of . . . 299
 — — from pnea . . . 99
 — — with pneumothorax . . . 432
Pleural effusion, pneumothorax from tapping of . . . 532
 — — pleuritic . . . 531, 531
 — — after . . . 88
 — — first sign of . . . 88
 — — skatule resonance with . . . 611
 — — in splenomegaly . . . 633
 — — œthema . . . 633
 — — tinged in jaundice . . . 224
Pleurisy, abdominal pain
 — from . . . 115
 — acute, blood-stained effusion from . . . 102
 — — in acute pleuritis in . . . 611
 — — adhesion pericardium after . . . 54
 — — from aneurysm . . . 434
 — — appendix . . . 169
 — — in bronchopneumonia . . . 105
 — — diaphragm, appendix . . . 432
 — — acute, simulated by . . . 432
 — — chronic, simulated by . . . 432
 — — liver depressed with . . . 267
 — — pain in shoulder from . . . 799
 — — perforations . . . 432
 — — phlegm near diaphragm . . . 431
 — — labing . . . 431
 — — no ribs with . . . 132

Pleurisy, diaphragmatic, sites of pain with
 — — empyem after . . . 597
 — — in emphysema . . . 31
 — — traction sounds in . . . 432, 435
 — — herpes zoster simulating . . . 254
 — — indigestion simulated by . . . 716
 — — from infection of liver . . . 196
 — — infection from below diaphragm . . . 196
 — — intercostal neuralgia simulated by . . . 707
 — — from pleural vein thrombosis . . . 105
 — — lateral sinus thrombosis . . . 105
 — — liver abscess . . . 370
 — — in lobes pneumonia . . . 105
 — — mediastitis and . . . 308, 751
 — — after operation . . . 105
 — — from old abscess . . . 108
 — — pain in back from . . . 432
 — — no breathing from . . . 432
 — — in the chest from . . . 152

Plantar reflex, mode of testing
 — — Plantaris, nerve supply of . . . 198
 — — longus, rupture of . . . 571
 — — plantis, fallus from . . . 96
Plants, dermatitis from . . . 755
Plates, coloured, list of

from coughing from . . . 432
 - at chest of shoulder . . . 432
 - in the epigastrum from 436
 - hypocondrium from
 - iliac fossa from 450, 451
 - like a knife from 452
 - in limbs with . . . 465
 - shoulder from 474, 476
 simulating pericarditis
 - from phthisis . . . 433, 595
 - pleurodynia simulating 431
 - pleuropericardial adhesions from . . . 54
 - pneumoococcal . . . 105, 432
 - in pyæmia . . . 595
 - pyæxia in . . . 34, 192
 - septæ, cough from . . . 150
 - referred pain in . . . 432
 - rigor after . . . 557
 - shortness of breath from
 - stabbing pain from . . . 432
 - from subpleural abscess
 - subphrenic abscess simulating . . . 658
 - systolic bruit from . . . 90
 - thrill with . . . 720
 - tearing pain from . . . 432
 - tenderness of chest from
 - 432, 706, 708, 709
 - in typhoid fever . . . 595
 Pleuritic effusion in acute
 - rheumatism . . . 165
 - - acrophony with . . . 448
 - - anemia with . . . 196
 - - from appendicitis . . . 106
 - - with arterio-sclerosis . . . 11
 - - from ascending nephritis . . . 196
 - - bacillus coli in . . . 196
 - - from blood diseases . . . 106
 - - blood-stained . . . 290
 - - breath sounds diminished with . . . 168
 - - in Bright's disease . . . 105
 - - bronchitis after . . . 292
 - - cancer cells in . . . 290
 - - cardiac impulse displaced by . . . 296
 - - chest bulged on one side by . . . 168
 - - shrunk on after . . . 168
 - - from cholera . . . 106
 Pleuritic effusion, chyloous 106
 - - from injury to thoracic duct . . . 106
 - - - leukemia . . . 106
 - - - nephritis . . . 106
 - - - new growth . . . 106
 - - clubbed fingers from 111
 - - distinguishing features 104
 - - dullness over . . . 168, 296
 - - from diaphragmatic ulcer . . . 196
 - - fibroid lung after . . . 292
 - - from gall-bladder infection . . . 106
 - - gastric ulcer . . . 106
 - - with granular kidney 11
 - - from growth of lung . . . 159
 - - gumo-pig inoculation from . . . 104, 165
 - - from gumma in liver 106
 - - heart displaced by 168
 - - from hepatic abscess 196
 - - in Hodgkin's disease 196
 - - from hydatid cyst of liver . . . 106
 - - hydatid of liver simulating . . . 375
 Pleuritic effusion, from infection from below diaphragm . . . 106
 - - in leukemia . . . 196
 - - liver pushed down by 168
 - - in lymphadenoma 196
 - - lymph-gland enlargement with . . . 106
 - - from mediastinal new growth . . . 104
 - - micrococcal contamination of . . . 104, 290
 - - movement of chest deficient with . . . 168

Pleuritic effusion, contd.
 - - - from new growth . . . 290
 - - - in liver . . . 106
 - - - palpitation from . . . 484
 - - - from pelvic peritonitis 196
 - - - perinephritis . . . 196
 - - - peritonitis . . . 196
 - - - in pernicious anemia 196
 - - - phthisis . . . 104
Pleuritic effusion, physical signs of . . . 168
Pleuritic effusion, pneumothorax from tapping of . . . 532
 - - in polyserositis . . . 196
 - - pseudo-leukæmia infantum . . . 106
 - - - pyeloplebites . . . 196
 - - - pyosalpinx . . . 196
 - - from renal calculus . . . 196
 - - retraction of chest after
Pleuritic effusion, rheumatic, diagnosis from tuberculous . . . 105
Pleuritic effusion, simple . . . 105
 - - skodæ resonance with . . . 168, 611
 - - in splenic anemia . . . 196
 - - splenic enlargement with . . . 106
 - - - from subpleural abscess . . . 659
 - - - tinged in jaundice . . . 324
 - - from tuberculous kidney . . . 106
 - - - tuberculous, simulated by mediastinal new growth . . . 194
 - - - tubular locating with . . . 168
 - - - unilateral . . . 194
 - - - vesicular murmur deficient over . . . 296
 - - - vocal fremitus diminished with . . . 168
 - - - voice sounds diminished with . . . 168
 Pleurodynia, a form of myalgia . . . 467
 - - pain in the chest from . . . 430
 - - pleurisy simulating . . . 431
 - - pneumonia simulating . . . 431, 432
 - - tenderness with 151, 706, 707
 Pleuropericardial adhesions, common . . . 54
 Pleuropericarditis, pneumothorax simulated by . . . 433
 Plexus, cervico-brachial, diaphragm of . . . 507
 Plexus, lumbar, diaphragm of . . . 500
Plexus, lumbar, distribution of . . . 498, 499
 - - mesenteric, meteorism from lesion of . . . 389
 - - - pampiniform, thrombosis of, pressure from . . . 528
Plexus, sacral, diaphragm of . . . 500
Plexus, sacral, distribution of . . . 498, 499
 - - - growth invading . . . 113
 - - - Plexus, solar, meteorism from lesion of . . . 389
 - - - pimentation from irritation of . . . 527
 - - Plucked-toad-skin, in pityriasis-rosea parulis . . . 188
 - - Plumbeum, see Lead Poisoning
 - - - Pleurisy, acute from . . . 117
PNEUMATIA . . . 529, 530
 - - from carcinoma petri . . . 582
 - - pneumothorax, in cerebrospinal fluid . . . 305
 - - - sore throat due to . . . 613
 - - in sputum . . . 613
 Pneumonia, acute, as types
 - - from . . . 47

Pneumococci, contd.
 - - in ascetic fluid . . . 48
 - - - bacteriuria from . . . 69
 - - - bronchopneumonia from 568
 - - - in cerebrospinal fluid . . . 305
 - - - empyema from 103, 104, 105
 - - - gastritis from . . . 267
 - - - in infective endocarditis . . . 209, 567
 - - - laryngitis from 158, 199, 418, 419, 616, 650
 - - - meningitis from 305, 367, 590
 - - - nasal discharge due to 178
 - - - nephritis from . . . 9, 69
 - - - in otitis media . . . 422
 - - - in phthisis . . . 641
 - - - pleurisy from . . . 105
 - - - pneumonia from . . . 105
 - - - recovery on blood culture . . . 597
 - - - rheumatoid arthritis from 35
 - - - septicæmia from 425, 590
 - - - sore throat due to . . . 613
 - - - in sputum . . . 613
 - - - sulfoacetate laryngitis from
 - - - pythitis from . . . 158, 616
 - - - pyelonephritis due to . . . 69
 - - - necrus serpens from . . . 731
 - - - urethritis due to . . . 69
 - - - urethritis due to . . . 70
 - - in urine . . . 69
 Pneumogastric nerve (see Nerve, Vagus)
 Pneumonia, acute abdominal pain from 115, 425
 - - dilatation of stomach . . . 173
 - - acute, in influenza . . . 165
 - - acute nephritis from . . . 10
 - - albuminuria in . . . 13, 14
 - - albuminuria in . . . 16
 - - - appendix simulated by 460
 - - - arthritis due to . . . 359
Pneumonia, aspiration, general account of . . . 259
 - - after immersion . . . 260
 - - bacillus influenza in 290, 643
 - - bacteriemia in . . . 597
 - - - bleeding gums in . . . 72
 - - - distending from . . . 14
 - - - thinness of lips in . . . 593
 - - - bronchodilation after 654
 - - - bronchio- after anæsthetics . . . 289
 - - - age incidence of . . . 289
 - - - albuminuria in . . . 13
 - - - bacillus influenza in . . . 290
 - - - bronchiectasis from . . . 292
 - - - caseous, cyanosis from 159
 - - - in children . . . 160, 289
 - - - convulsive movements of chest in . . . 160
 - - - cough from . . . 149
 - - - cyanosis from 159, 160, 420
 - - - dyspnoea from . . . 590
 - - - empyema from 103, 160
 - - - engorgement of lung in
 - - - general tuberculosis . . . 259, 652
 - - - simulating . . . 510
 - - - hæmoptysis from 286, 289
 - - - hyperpyrexia in . . . 509
 - - - from influenza . . . 289
 - - - knee-jerk absent in . . . 510
 - - - diminished in . . . 510
 - - - laryngitis simulating 160
 - - - leucocytosis with 35, 361
 - - - orthopnea from 418, 422
 - - - from otitis media . . . 289
 - - - pleurisy rare in . . . 105
 - - - pneumoococcal 105, 568
 - - - prolonged pyrexia from . . . 563, 568
 - - - retracted head from . . . 389, 590
 - - - shortness of breath . . . 88
 - - - from sinus thrombosis . . . 290
 - - - sticky rales in . . . 289
 - - - streptococcal causing . . . 568
 - - - sucking in of intercostal spaces from . . . 160, 420
 - - - caseous bronchio, cyanosis from . . . 159
 - - - leucocytosis in . . . 360

Pneumonia, contd.
 - - - Cheyne-Stokes breathing in . . . 108
 - - - chlorides in urine in . . . 335
 - - - coated tongue in . . . 705
 - - - convulsions from . . . 144
 - - - cough from . . . 119, 335
 - - - crisis in . . . 571
 - - - delirium in . . . 169
 - - - in diabetes . . . 264
 - - - diazo-reaction in . . . 173
 - - - empyema with 35, 195, 194, (Fig. 71) 160, 194, 291, 574, 597, 643
 - - - ending by lysis (Fig. 71) 160
 - - - endocarditis in . . . 292, 283
 - - - cosmophla after . . . 218
 - - - fibracula representing . . . 464
 - - - foul taste in . . . 705
 - - - in Friedreich's ataxy . . . 313
 - - - gangrene of lung in . . . 259
 - - - gastric HCl deficient in . . . 270
 - - - heart block from . . . 546
 - - - herpes facialis in . . . 335
 - - - hot dry skin in . . . 335
 - - - hypothermia after . . . 511
 - - - infective parotitis in . . . 694
 - - - influenza complicated by 363
 - - - intercostal neuralgia simulated by . . . 322, 707
 - - - jaundice in . . . 325
 - - - laparotomy in error in . . . 593
 - - - leucocytosis in . . . 395
 - - - from liver abscess . . . 370
 - - - lobar (and see Pneumonia)
 - - - without abnormal signs . . . 289
 - - - bronchial casts in . . . 644
 - - - chlorides absent from urine in . . . 169, 289
 - - - crepitations in . . . 642
 - - - crisis in (Fig. 272) 642
 - - - cyanosis from . . . 160
 - - - diplococci in sputum in . . . 289
 - - - duration of . . . 160
 - - - ending by crisis . . . 160
 - - - - lysis . . . 160
 - - - fibroid lung from . . . 292
 - - - gangrene of lung from . . . 644, 652
Pneumonia, lobar, general account of . . . 642
 - - - hæmoptysis from 286, 289
 - - - herpes facialis in . . . 642
 - - - high respiration ratio in 289
 - - - hyperpyrexia in . . . 309
 - - - knee-jerks lost in . . . 359
 - - - leucocytosis with 35, 361
 - - - pain in iliac fossa from 454
 - - - perspiration after . . . 642
 - - - physical signs with 160, 642
 - - - without physical signs 642
 - - - pneumoococci in . . . 643
 - - - purulent skin in . . . 642
 - - - pyogenic metrorax from 652
 - - - ridges on nails after (Fig. 306) 569
 - - - rigor in . . . 594, 595
 - - - simulating phthisis . . . 289
 - - - skægnum (Fig. 136) 289
 - - - sputum in 119, 289, 355, 641, 642
 - - - stridor in . . . 495
 - - - sudden onset of 160, 642
 - - - superposed on phthisis 289
 - - - temperature charts of . . . 160, 642
 - - - urate deposit due to 741
 - - - vocal cord paralysis from . . . 495
 - - - lobular (see Pneumonia, Broncho-)
 - - - nerves active in . . . 595
 - - - nephritis from . . . 9, 42
 - - - pain in the chest from . . . 430, 432
 - - - iliac fossa from . . . 460
 - - - shoulder from 474, 476
 - - - side in . . . 335
 - - - peritonitis simulated by . . . 425, 593
 - - - pleurodynia simulated by 432
 - - - - simulating . . . 431
 - - - pleurisy with . . . 432
 - - - pleuritic rub in . . . 335
 - - - polymorphonuclear cells 55

Pneumonia, contd.
 - pneumonia after . . . 536
 - pulse-respiration ratio in . . . 555, 636
 - pylophibitis simulating . . . 567
 - pyrexia from . . . 574
 - rapid respiration rate in . . . 575
 - rise in . . . 555
 - after . . . 597
 - septic abscess from . . . 286
 - haemoptysis from . . . 286
 - shortness of breath from . . . 88
 - without signs . . . 132
 - sternal resonance with . . . 611
 - sordes in . . . 72
 - speech loss in . . . 624
 - spleen enlarged in . . . 632, 657
 - from subphrenic abscess . . . 570
 - in typhoid fever . . . 595
 - typhoid fever simulating . . . 637

Pneumoconiosis (Fog 70),
 159, 288
 - fibroid lung from . . . 292
 - haemoptysis from . . . 286, 288

Pneumoperitoneum, list of causes of . . . 652
 - liver indigestion test with . . . 656
 - ascussion in . . . 652
 - in typhoid fever . . . 655

PNEUMOTHORAX . . . 530
 - acute cyanosis from . . . 159
 - dyspnoea from . . . 159
 - fruit of aneurysm . . . 168
 - chest bulged on one side . . . 168
 - movement delinquent . . . 168
 - with . . . 168
 - from cuts of stabs . . . 532
 - cyanosis from . . . 132
 - diaphragm immobile with . . . 132
 - dyspnoea from . . . 132
 - from gangrene of lung . . . 532

Pneumothorax, general account of . . . 432
 - heart displaced by . . . 168, 650
 - failure from . . . 206, 652, 418

Pneumothorax, list of causes of . . . 531
 - liver dullness diminished . . . 566
 - depressed by . . . 567
 - metallic tinkling with . . . 168
 - onset during coughing . . . 132
 - orthopnoea from . . . 418
 - pain in chest from . . . 168, 430, 432
 - partial . . . 474, 531
 - from plethysis . . . 551, 552

Pneumothorax, physical signs of . . . 168, 432, 530
 - pleural effusion with . . . 432
 - protrusion from . . . 452
 - rapid feeble heart from . . . 432
 - rate from fractured rib . . . 552
 - sense of tearing at onset of . . . 452

Pneumothorax, subphrenic abscess simulating . . . 652, 658, 659
 - depression with . . . 168, 550
 - sudden onset of . . . 452

Pneumothorax, symptoms at onset of . . . 531
 - without symptoms . . . 552
 - from tapping an effusion . . . 532
 - tubercle bacilli in sputum with . . . 551
 - vesicular murmur diminished with . . . 168
 - vocal fremitus diminished with . . . 168
 - voice sounds diminished with . . . 168
 - x-rays in diagnosing . . . 452, (Fog 229) 551

Polykloctes (Platts II, III)
 22, 24
 Foikloctosis . . . 22
 - in pernicious anaemia . . . 569
 - severe anaemia . . . 572

Poisoning, anemia from . . . 10, 41

Poisoning by arsenic, general account of . . . 717, 718
 - (and see Arsenic)

Poisoning, delayed chloroform . . . 4

Poisoning, contd.
 - gastric contents on diagnosis . . . 119
 - by lead (see Lead)
 - mercurial (see Mercury)
 - by morphia (see Morphia)
 - by nystagmus after . . . 108
 - phosphorus (see Phosphorus)
 - ptomaine (see Ptomaine Poisoning)
 - Pot-onus, bradypnoea from . . . 81, 85
 - Cheyne Stokes breathing from . . . 108
 - diagnosis of . . . 108
 - hot taste from . . . 705
 - haemoglobinuria from . . . 284
 - hypothermia from . . . 311
 - in . . . 306

Poisons, jaundice due to . . . 336, 337
 - purpura from . . . 555
 - vomiting from . . . 765
 - Polarimeter, in estimating sugar . . . 263

Poli-encephalitis (see Encephalitis)
 Poliomyelitis acuta, in . . .
 - adult . . . 61, 515
 - atrophy of leg from . . . 500
 - in . . . muscles from 61, 509, 512
 - claw-hand from . . . 109
 - conditions arising from . . . 155
 - contractures after . . . 458, 459
 - convulsions in . . . 110, 509
 - electrical reactions in . . . 509
 - fever in . . . 110, 512
 - gastric upset simulated by . . . 512

Poliomyelitis acuta, general account of . . . 512
 - headache in . . . 110
 - infantile paralysis from . . . 112, 110, 510, 512
 - - Leondy's type from . . . 518
 - lymphatics in cerebro-spinal fluid in . . . 305
 - malaise in . . . 110
 - pares in . . . 110, 512
 - all over in . . . 509
 - paralysis from . . . 509
 - of one leg from . . . 509
 - paraplegia from . . . 510, 512, 514, 515
 - peripheral neuritis simulated . . . 512
 - latent . . . 110, 509
 - - paralytic in . . . 110, 509
 - - B. in . . . 61, 512
 - - polyves in . . . 509
 - - rigour in . . . 509
 - no sensory changes in . . . 509
 - shoulder wasting from . . . (Fog, 19) . . . 50

Poliomyelitis acuta, some effects of . . . 509
 - talipes from . . . 512
 - unequal knee-jerks in . . . 509
 - vasomotor changes in . . . 509
 - vomiting in . . . 110, 509
 - anterior choroid . . . 155
 - anterior corneal cells . . . 152
 - affected by . . . 152
 - chronic, case incidence of . . . 149
 - - constrictures from . . . 138, 149
 - - fibrillar contraction in . . . 149
 - - claw-foot from . . . 109
 - - poli-encephalitis related to . . . 132
 - Pottet's acometer (Fog, 75) . . . 164

Polychromatophilia (Platts II, III) . . . 22, 24

Polycystic kidney, general account of . . . 357
 - (and see Kidney, Cystic)

POLYCYTHAEMIA . . . 532
 - from altitude . . . 552, 554
 - - arsenic . . . 555
 - - asthma . . . 552, 554
 - - bronchocentasis and . . . 553
 - - bronchitis and . . . 553
 - - from cholera . . . 552
 - - chronic bronchitis . . . 552
 - - colour index in . . . 555
 - - with congenital heart disease . . . 215, 552, 553, 720
 - - delirium from . . . 169

Polygammoma, contd.
 - from drugs . . . 553
 - emphysema . . . 552, 553
 - fibroid lung . . . 552, 553
 - heart disease . . . 553
 - in haemoglobinuria and . . . 552
 - - mitral regurgitation and . . . 553
 - - from mitral stenosis . . . 552, 553
 - - with patent interventricular septum . . . 215
 - - from pregnancy toxemia . . . 553
 - - ptomaine poisoning . . . 555
 - - pulmonary stenosis . . . 217, 552, 553
 - - renal disease . . . 552, 554
 - - restricted fluid intake . . . 553
 - - severe diarrhoea . . . 553
 - - thirst . . . 554
 - - vomiting . . . 554
 - - shortness of breath from . . . 87
 - - spleen enlarged with . . . 641

Polyglycemia, splenomegaly, main features of . . . 634
 - - (Plate AXXA)
 - - (see Splenomegaly)
 Polyglythemia . . .
 - from summer diarrhoea . . . 553
 - Polygonium aviculare, erythema from . . . 292

Polygraph tracing, in diagnosing cause of total irregularity of heart . . . 550
 - - fibrillation from . . . 548
 - - heart block . . . 548
 - (Fog, 253) 546, 549

Polygraph, in heart cases . . . 544
 - - in paroxysmal tachycardia . . . 548
 - - pulsus bisinus . . . 550
 - - - bisinus (Fog, 255) 550
 - - ventricular extrasystole (Fog, 243) . . . 547

Polymorphonuclear cells, in ascitic fluid . . . 48
 - cerebrospinal fluid . . . 305, 511
 - characters of . . . 22
 - diminished in pernicious anaemia . . . 21
 - in Hodgkin's disease . . . 37
 - increased in emphysema . . . 364
 - - with liver abscess . . . 562
 - - suppuration . . . 375, 360
 - - in leucocytes simulating . . . 25
 - - (Plate IV, Fog, K) . . . 22
 - in pleuritic effusion . . . 102
 - pneumococci . . . 102
 - relative numbers of . . . 22

Polymissus acuta . . . 464
 - erythema in . . . 464
 - pain in the limbs from . . . 464
 - trichiasis simulated by . . . 164
 - Polyopa, from catarrh . . . 475

Polyorrhometis, general account of . . . 106, 107
 - hydroa from . . . 181
 - Polyraemia, definition of . . . 20

Polypus, cardiac . . . 550
 - of cervix, protruding . . .
 - from vagina . . . 550
 - of ear, from ear . . . 462
 - - dentures from . . . 155
 - - from otitis . . . 421, 423
 - - trinitis from . . . 723
 - malignant, in heart . . . 750
 - nasal, anaemia from . . . 612
 - - epistaxis from . . . 220
 - - headache from . . . 294
 - - with hypertrophic rhinitis . . . 179
 - - snoring due to . . . 613
 - - from splenoidal sinus . . . 251
 - - taste impairment from . . . 706
 - - loss from . . . 705
 - - rectal, blood per anum from . . . 516
 - - and menes stools from . . . 585
 - - carcinoma simulated by . . . 585
 - - in children . . . 78
 - - felt by finger . . . 78
 - - frequent desire to defecate from . . . 78

Polypus of rectum, general account of . . . 585

Polypus of rectum, contd.
 - intussusception simulating . . . 717
 - - latens . . . 717
 - - multiple . . . 78, 585
 - - periproctal abscess . . . 719
 - - from . . . 719
 - - protrusion of . . . 78
 - - sense of fullness in . . . 78
 - - - simulating prolapse . . . 78
 - - - speculum in diagnosing . . . 585
 - - - tenesmus from . . . 718
 - - - methan discharge due to . . . 183
 - - - seen with endoscopy . . . 183
 - - - uterus, blood-stained discharge from . . . 186
 - - - carcinoma simulating . . . 591
 - - - metrorrhagia from . . . 391, 591
 - - - metrorrhagia from . . . 592

Polypus of uterus, general features of . . . 391
 - - hysteroscope in diagnosing . . . 186, 391
 - - sarcoma simulating . . . 391
 - - sterility from . . . 646

POLYURIA . . . 534
 - - osmometry . . . 534
 - - albuminuria and . . . 537
 - - in arteriosclerosis . . . 12, 30, 537
 - - azotic diabetes . . . 537
 - - chronic nephritis . . . 14, 537
 - - - (Fog, 12, 191, 274, 298)
 - - - polyabsorbent . . . 536
 - - cystic disease . . . 12, 537
 - - diabetes . . . 260, 571, 719

Polyuria in diabetes insipidus . . . 537, 537
 - - mellitus . . . 533
 - - leters . . . 536
 - frequency of micturition and . . . 534
 - from granular kidney . . . 537, 537, 536, 537
 - - hydromeliosis . . . 536, 665
 - - in hysteria . . . 719
 - - interstitial nephritis . . . 30
 - - - lardaceous disease . . . 557, 656

Polyuria, list of causes of . . . 534, 7
 - in diabetes . . . 646
 - from movable kidney . . . 559
 - in myxoedema . . . 557
 - nephritis . . . 42
 - after oedema . . . 536
 - from pale granular kidney . . . 537
 - - periodic . . . 536
 - in phosphate diabetes . . . 536

primary interstitial . . . 190
 - after pneumonia . . . 556
 - in pregnancy . . . 264
 - from pyelonephritis . . . 536
 - renal inflammation . . . 577
 - - thirst and . . . 719
 - from tuberculous kidney . . . 577
 - after typhoid . . . 536
 - haemorrhage into . . .
 - - Haemorrhage, Pontine

Pons varoli, lesions, ataxia from . . . 58
 - crossed hemiplegia . . . 592
 - - from . . . 592
 - - double hemiplegia . . . 592
 - - from . . . 592
 - - paraplegia from . . . 598
 - - pyrexia from . . . 541
 - - tumour of, Cheyne-Stokes breathing . . . 108
 - - - deadness from . . . 166
 - - hyperpyrexia from . . . 509

Pontine haemorrhage (see Haemorrhage, Pontine)
 Popliteal abscess (see Abscess, Popliteal)

Popliteal artery, aneurysm of (see Aneurysm of Popliteal Artery)
 - - glands (see Lymphatic Glands, Popliteal)

nerve external Sensory Nerve, External Popliteal . . .
 - internal (see Nerve, Internal Popliteal)

Popliteal space, tumour in . . . 691
 - - acute aneurysm of . . . 411, 692
 - - - varicose . . . 692

Popliteo-nerve supply of
 Craniocarpals . . . 132
 contra-lateral from . . . 139
 convulsions from . . . 146
 diplegia from . . . 129
 dwarfism from . . . 188
 infantile diplegia from . . . 511
 mental defect with . . . 144
 muscular atrophy with . . . 144
 paralysis from . . . 144
 paraplegia from . . . 510
 spasm with . . . 144
 Pork, colic from . . . 117
 - from lime poisoning from 717
 - trichinosis from . . . 64, 729
 - urticaria after . . . 673
 Portal glands (see Lymphatic glands, Portal)
 pyramis, rucis in . . . 595
 - (and see Pylpelebitis)
Portal vein obstruction, 50, 51
 - by abscess of liver 330
 - from adhesive pylephlebitis . . . 272
 - albuminuria from . . . 272
 - in appendicitis . . . 51
 - ascites from 15, 51, 272
 - by carcinoma 51, 335
 - causes . . . 45
 - from cirrhosis . . . 272
 - by colon tumours . . . 46
 - congestion of stomach from . . . 765
 - dilated abdominal veins from . . . 272
 - by duodenal tumours . . . 46
 - enlarged gall-bladder 652
 - enlarged glands . . . 652
 - gamma of liver . . . 330
Portal vein obstruction, haematemesis from 265, 272
 - haemorrhagic erosions . . . 272
 - by hepatic aneurysm 46, 51
 - hydatid cyst of liver 330
 - kidney tumours . . . 46
 - leukæmia glands 45, 51
 - liver tumours . . . 46, 652
 - lymphadenomatous glands . . . 45, 51
 - malignant glands 45, 51
 - nausea from . . . 272
 - oedema of legs from . . . 272
 - by pancreatic tumours . . . 46, 652
 - pressure on portal vein . . . 272
 - by sarcoma . . . 330
 - by sarcomatous portal glands . . . 51
 - spleen enlarged from 652
 - spleen enlargement 272
 - stomach tumours 46, 652
 - suprarenal tumour . . . 46
 - thrombosis . . . 45, 51
 - tuberculous gland 45, 51
 - varicose gastric veins from . . . 272
 - varicose veins . . . 272
 - vomiting from 272, 765
Portal vein, thrombosis of 51
 - (and see Thrombosis of Portal Vein)
 Porter, arthritis of shoulder in . . . 476
 - bursa over spine in 155, 156
 - (Figs. 65) 156
 - kyphosis in . . . 155
 Portugal, Mediterranean fever in . . . 586
 Port-wine, priapism from 538
 Position, sense of, cord paths for . . . 607
 Post-hemiplegic atrophosis (see Atrophosis)
 - chorea . . . 131
 - Prerhitis, priapism from . . . 538
 Post-mortem examination
 - in diagnosis of aneurysm 261
 - carcinoma of duodenum . . . 692
 - congenital absence of bicuspid . . . 525
 - syphilis . . . 229

Post-mortem examination, contd.
 - in diagnosis of dia-phragmatic hernia 652
 - diverticulitis . . . 455
 - esophageitis . . . 120
 - heat-stroke . . . 120
 - leucostokes . . . 120
 - primary neoplasm of spine . . . 516
 - sinus thrombosis . . . 120
 - splenic vein thrombosis . . . 272
Post-mortem wart, 240
 - warts, cutaneous gland enlarged from . . . 281
 Post-partum hemorrhage (see Hemorrhage, Post-partum)
 Post-pharyngeal abscess (see Abscess, Post-pharyngeal)
 Post-puerperal sepsis, foul lochia from . . . 86
 - sores in . . . 86
 Posterior inferior cerebellar artery (see Thrombosis)
Posterior scapular nerve 504
Postural albuminuria 15
 Posture, cervical rib symptoms and . . . 444
 - clonus and . . . 136
 - effect on hoarse breath . . . 91
 - erythromelalgia and . . . 441
 - in testing knee-jerk . . . 357
 Potash, caustic, in examination for tubercle bacilli . . . 161
 - examining for psoroptosis . . . 730
 - ioduric test . . . 746
 - methylene blue and . . . 747
 - phosphates insoluble in . . . 740
 - test, for pus . . . 575
 - Trommer's test . . . 261
 - urates dissolved by . . . 740
 (and see Lignol Pot-assa)
 Potassium bromide (see Bromides)
 - carbonate, in Bang's process . . . 263
 - chloride, erythema from . . . 284
 - hydrochlorium from . . . 284
 - methemoglobinuria . . . 161
 - pyralism from . . . 542
 - purpura from . . . 553
 - sulphhemoglobinæmia from . . . 161
 - ferrocyanide in Perle's test . . . 24
 - iodoval sulphate . . . 314
 - iodide, for actinomycosis . . . 458
 - iodism from . . . 612
 - in diagnosing gamma . . . 229, 615, 619
 - nature of ulcer of tongue . . . 379
 - -syphilis 65, 199, 189, 288, 622, 735, 738, 739
 - gamma of liver and . . . 253
 - laryngeal obstruction from . . . 418
 - nerves in the head from oedema from . . . 413, 415
 - of face from . . . 413
 - of larynx from 418, 650
 - nasal catarrh from . . . 612
 - orthopnea from . . . 418
 - psylliaris of sweat after . . . 655
 - photophobia from . . . 525
 - purpura from . . . 553
 - stridor from . . . 650
 - syphilitic bone joints relieved by . . . 689
 - - pyrexia checked by (and see Iodide)
 - phosphate, solubility of . . . 525
 - -sulf, pyralism from . . . 535
 - sulphocyanate, in Bang's process . . . 263
 Pot-belly, in rickets . . . 655, 660
 Potemkin, phibism in . . . 117
 Potato particles in stools . . . 107
 Pott's curvature, psoas abscess with . . . 564

Pott's curvature, contd.
 - shortness of breath from . . . 89
 - from spinal curies 561, 516
 - disease (see spinal curies)
 - fracture . . . 114
Pouches, esophageal 496
 - age incidence of . . . 196
 - dysphagia due to . . . 563
 - vomiting due to . . . 765
 - X-rays in diagnosing (Figs. 36) 196
 Pouchitis, erythema from 222
 Poupard's elevation, fullness below, from psoas abscess . . . 564
 - line of . . . 674
 Pouting of lips in myopathy 235
 Poverty, pemphigus neonatorum and . . . 97
 - typhus fever and . . . 335
 Powdered-wig phenomenon in urine . . . 423
 Pozzi, coeloclele uteris of 645
 - dysmenorrhœa with 192
Pozzi's syndrome, of endometritis 387
 Preacher's hand in progressive muscular atrophy . . . 110
 - splanchnic . . . 110
 Pre-auricular lymph glands (see Lymphatic Gland, Pre-auricular)
 Precipitin reaction, in hydatid disease 226, 658
 Precoxy, sexual, with suprarenal tumour . . . 664
 Precoxium, bulged, with atheroma, pericardium . . . 215
 - in children . . . 89
 - by large heart . . . 296
 - from mitral recurgitation . . . 89, 210
 pain in (see Pain, Precoxium)
 - tenderness of . . . 708
 - veins distended in . . . 215
 Pregnycosum state, obesity and . . . 498
 Pregnancy, acetonuria in . . . 1
 - acute yellow atrophy and 273
 - albuminuria from 7, 9, 15
 - albuminuria in . . . 16
 - amnionitis in . . . 759
 - amenorrhœa during 48,
 - 295, 688, 689
 - appendicitis in . . . 691
 - appetite increased in . . . 264
 - perverted in . . . 45
 - ascending nephritis from 13
 - ascites simulated by . . . 44
 - haeterum in . . . 69
 - bladder distention simulated . . . 665, 688
 - Braun's sign of . . . 393
 - breast changes with . . . 689
 - breast nipples in . . . 420
 - chorea in . . . 133
 - chorion epithelioma after chloron nephritis from . . . 7
 - colic bacilluria in 12, 152
 - coma in . . . 144
 - constipation after . . . 127
 - convulsions in 137, 114, 146
 - decidual casts in . . . 195
 - desmorrhœa cured by 192
 - edema in . . . 116
 - ectopys . . . (see Ectopic Gestation)
 - epilepsy simulated in . . . 116
 - extra-uterine (see Ectopic Gestation)
 - fear of, amenorrhœa from 18
 - fibroid simulating . . . 688
 - softening during 294, 620
 - flushing in . . . 241
 - foetal heart in . . . 241
 - movements with . . . 689
 - glycosuria in . . . 264
 - haemostoma of vulva in . . . 791
 - hemocholuria in . . . 284
Pregnancy, hæmorrhage from uterus during 392
 - heart-impulse displaced by . . . 299
 - Hezar's sign of . . . 393

Pregnancy, contd.
Pregnancy, herpetic dermatitis in 96, 98
 - hydrops amnii with . . . 45
 - hypogastric swelling from 666
 - hysteria simulating 142, 390
 - impetigo herpeticiformis in 98
 - indigestion simulated by 315
 - leucocytes in blood in . . . 360
 - linea albicans from . . . 365
 - mastitis in . . . 683
 - meto-lymia in . . . 451
 - menstruation in . . . 688
 - milk flow from nipple 181
 - molluscæ ossium and . . . 242
 - Montgomery's glands in 459
 - morning sickness with . . . 393
 - need for examination 299
 - nephritis with . . . 6
Pregnancy nephritis, general account of 8, 9
 - neurosis in . . . 543
 - noises in ears and . . . 723
 - non-occurrence during lactation . . . 55
 - ovarian cyst simulating . . . 688
 - pain in the breast in . . . 129
 - palpitation from . . . 185
 - paræsthesia in . . . 705
 - pelvic bone tumour with . . . 691
 - swelling due to . . . 688
 - neuritis from . . . 61, 61
 - phantom tumour simulating . . . 659, 691
 - phlegmasia alba dolens in 737
 - pigmentation from . . . 527
 - polyuria in . . . 264
 - pyelitis in . . . 545
 - pyelitis in . . . 12, 151
 - relation to Bright's disease . . . 9
 - pyelonephritis in 12, 576
 - renal tube casts due to . . . 7
Pregnancy in retroverted uterus 689
 - secondary areola in . . . 430
 - severe vomiting in . . . 532
Pregnancy, signs of 19, 15, 393
 - supernivulation of uterus after . . . 19
 - swelling of breasts in . . . 685
 - in iliac fossa from . . . 678
Pregnancy, technique of examining during 200
 - tetany with . . . 3, 151
 - thirst in . . . 264
 - thyroid gland enlarged during . . . 721
 - toxæmia, polycythæmia from . . . 533
Pregnancy, with tumours 689
 - types of nephritis in . . . 9
 - uræmia in . . . 146, 759
 - urethral stenosis by . . . 3
Pregnancy, uterine hæmorrhages during 393
 - vomiting from 315, 764, 765
 - persistent in . . . 4
 - valvular varicose in . . . 791
 - Pre-hemiplegic chorea . . . 134
 Pre-renal, epithelioma of (see Carcinoma of Penis)
 - herpes of 181, 473, 553, 754
 Presentations, abdominal fetal . . . 290
 Pressure, prolonged, gangrenous from . . . 557
 - ulceration from . . . 230
 Presystolic bruit (see Bruit, Presystolic)
 - thrill (see Thrill, Presystolic)
 Presbyopia, eye-strain from 446
 - increased by glaucoma 233
 - pain in the eye from . . . 416
 Prevention of conception, menorrhagia from 386, 388
PRIAPISM 182, 537
 Priapism, list of causes of 538
 - from gonorrhœa . . . 182
 - prickling sensation, from malaria . . . 755
 - prickly heat, incline in . . . 540
Primary lateral sclerosis, general account of 517
 - (and see Lateral sclerosis)

Primary muscular dystrophy, (see Myopathy)

Prunella, *obconica*, bullae from 96

— dermatitis from 755

— erythema from 222

— pruritus from 530

Proctitis, abscess from 238

— bladder opened by 258

— tenesmus from 518

Proctoscope, in diagnosis

— adenoma recti 719

— carcinoma recti 129

— rectal ulcerations 129

— tenesmus 718

— Professional images 151

Progeria (*Fig. 35*) **191**

Prognosis, in acute encephalitis 120

— gonorrheal proctitis 125

— carcinoma of liver 374

— congenital heart disease 157

— obliteration of bile ducts 329

— Chyem's strokes (breathing and) 408

— in chlorosis 36

— chorea **133**

— epiphora with ascites 52

— delirium and 169

— in diabetes 264

— with gonorrheal delirium 645

— in hemorrhage **120**

— hemiplegia 355

— Hirschsprung's disease 127

— Hutchinson's chorea **134**

— leukæmia 24

— lymphatic leukæmia 25

Prognosis of meningitis **590**

— phthisis, diazocarcinoma and 173

— pseudoleukæmia 57

— purpura 554

— in strychnine poisoning 750

— tetanus 750

Progressive muscular atrophy, abductor pollicis affected by 110

— age incidence of 61

— anterior corneal cells

— affected in **62**

— quæ's hand in 110

— with bilateral paralysis 62, 589

— claw-hand from 109

— contractures in 158

— distinguished from

— brachial plexus palsy 62

— ulnar paralysis 61

— fibrillar contractures 155

Progressive muscular atrophy, general account of **61**

— associated arthritis 310

— mistaken for 310

— hand-wasting in 109

— hypochondriac muscles affected in 110

— laryngeal sclerosis with main-tenance in 61

— muscle wasting in 61

— paralysis of one leg from 500

— paraplegia from 500

— plantar reflex in 68

— protractor's hand in 110

— simulated by syncope 62, 110, 257

— transverse myelitis 62

— thoracic muscles affected in 110

— types of 135

— Protraction, eyelid process of 175

— Prolapse of bladder 619

— ure, from floor of vagina 553

Prolapse of pelvic floor **538**

— rectum, blood from 79

— retro-sigmoid, simulating 717

— polyypus simulating 78

— tenesmus from 718

— ulceration from 185

— of uterine, muscle simulating 794

Prolapse of urethra, notes on **700**

— vulva of swelling from 700

PROLAPSE OF THE UTERUS **538**

— albumen from 15

— ascending nephritis from 13

— backache from 468

— cystocele simulating 539

— extracervical of bladder 539

— simulating 539

— hypertrophied cervix simulating **539**

— inversion of uterine simulating 539

— from levator ani injury 538

— perineal injury 538

— recto-celo simulating 539

— retention of urine from 649

— stranguary from 649

— vaginal tumour simulating 509

— vulval swelling from 700

Protractor, epiphora, nerve supply of 504

— radial nerve, nerve supply of 504

Protractors, non-innervation of 509

PROPTOSIS **229**

— epiphora from 229

— from sphenoidal sinus disease 251

— tumour of optic nerve (and see Exophthalmos)

— Proptosis, in paralysis 725

— Prostate, abscess of (see Abscess, Prostatic)

— calculus in (see Calculus, Prostatic)

— carcinoma of (see Carcinoma of Prostate)

— enlarged, abscess of testis from 622

— edema in perineum from 171

— by adenomata 470, 487

— age incidence of 281, 391, 396, 712

— albumenuria from 13

— amuria from 12, 396

— bladder distended from 15, 277, 665

— growth simulating 396

— by calculus 170

— calculus behind 580

— by carcinoma 470, 587

— chronic nephritis from 7, 8

— coarcted catheter and 396

— cystitis from 576, 578

Prostate, enlarged, cystoscopic appearance of **284**

— difficult micturition from 281, 395

— frequent micturition from 395, 396, 554, 712

Prostate, enlarged, general account of **396**

— hæmaturia from 276, 281

— nocturnal micturition with 390

— no pain during micturition with 170

— priapism from 558

— in puberty 218

— polynephritis from 576

— pyelonephrosis from 576

— pyuria from 8, 276, 578

— rectal examination for 277, 281, 391, 396, 587

— nod tubercles with 7

Prostate, enlarged, retention of urine from **395, 396, 649**

— by stricture 587

— slow, torpid, urine

— stranguary from 294

— stranguary from 649

— tenesmus from 718

— tumenuria from 146

— urine dribbling due to 294

— lesions of, pain in anal region from 397

— perineum from 397

— rectal examination in diagnosing 397

— from urethritis 397

Prostate, cond.

— massage of, in detecting proctitis 183

— rectum opening through (Fig. 219) 586

— felt per rectum 587

— residual gonorrhœa in 67

— sarcoma of 587

— secretion of, retracted 183

— globules in 183

— separation of, ulceration of perineum from 619

— swollen, from prostatic abscess 182

— proctitis 182

— tender 182

— tuberculous (see Tuberculosis of Prostate)

Prostatotomy, epididymitis from 697

— testis after 620

Proctitis, acute, gonorrhœal 182

— infection of 182

Prostatic threads **399**

Prostatitis, edema in perineum from 171

— due to lith 70, 182

— chronic, in size of prostate in detecting 183

— difficulty in micturition with 395

— frequent micturition from 395, 470

— due to gonorrhœa 173

— hæmorrhagic infection 170

— non-gonorrhœal urethritis 182

— pain in legs from 112

— no micturition with 182

— in penis from 69, 170, 171, 173

— rectum from 578

— perineal pain from 581

— prostate swollen in 182

— pyuria with 182, 170

— pyuria from 575, 581

— rectal examination in diagnosing 182, 170, 581

— retention of urine from 182, 396, 581

— from septic metritis 173

— due to staphylococcus 70

— streptococcus 70

— suprapubic pain from 581

— tenderness with 182

— from urethritis 470, 578, 581

— vasculitis with 173

Prostatoid, benevolence from 260

Protein, defect of, rickets from 145

— non-infective, in Limpet from distributed 146

Protopathic sensibility **606**

Prurigo, crusts in 489

— barrier on 489, 490

— eczema distinguished from 190

— enlarged glands in 190

— hairy, of Hebra 189

— nutmeg-grater skin in 190

— itching in 189, 540

— lichen planus distinct 190

— gutted from 190

— herpetic from in 190

Prurigo mitis, general account of **489**

— micturition 489

— papule of 187, 189

— parts affected by 189

— peduncles distinguished from 190

— psoriasis distinguished from 190

— pustules in 190

— scabies distinguished from 190

— scales in 190

— simplex, acute simulating erythema multiforme 189

— sites in 190

PRURITUS (and see Itchiness) **540**

— itching-drawers, not affected by 101

— in urticaria 324

— tenderness of scalp from 710

Pruritic, anal reaction, in urine 746

— anal see Peri's test

Prostate, acid in vomit 705

Pseudo-anquina pectoris **434**

Pseudo-bulbar paralysis **178, 197, 493, 513, 588, 589, 627**

Pseudo-chylous ascites **50**

Pseudo-cyst 112, 659

Pseudo-epitheliosis **111**

— vulval swelling from 629

Pseudo-hemiplegia 646

Pseudohypertrophic muscular paralysis **513** (and see Myopathy)

Pseudo-leukæmia infantum **37**

Pseudo-leukæmia infantum, account of **634**

— anaemia in 37, 55

— scabies in 37, 160, 55

— blood changes in 635

— congenital syphilis and 57

— *Pro* 57

— leukoerythraemia in 57

— liver enlarged in 57

— oedema of legs in 443, 445

— pleuritic effusion in 106

— prognosis in 37

— purpura in 557

— pyrexia in 57

— rickets and 37, 635

— spleen enlarged in 37, 55, 631

— syphilis and 57

Pseudo-leukæmia infantum, various conditions in **634**

— Wassermann test in 634

Pseudo-neuritis 119

Pseudo-nystagmus **407**

Pseudoparalysis, mercury in 348

— syphilitic 348

Pseudo-plaque of Brocq **71**

— tenderness of scalp from 710

Pseudo-ruminations 29

Pseudo-syphilis, distinction from 56

Pseudo-trichinosis **464**

Psoriasis, disease (see Abscess, Psori)

Psoriasis, bursa (see Bursa)

— muscle, nerve supply of 190

— separation of, from spinal curv 156

Psoriasis, anhidrot with 654

— baldness from 71

— bathing-drawers 101

— affected by 101

— tubercles 696

Psoriasis, eczema distinguished from **603**

— allows affected by 191

— anisotropy rare in 219

— extension surfaces affected by 191

— far from and 604

— lichen simulating 247

— fingers affected by 249

Psoriasis, general account of **603**

— health and 540, 607

— itching in 191

Psoriasis, lichen glandis distinguished from **188, 603**

— lichen affected by 365

Psoriasis, lichen erythematous distinguished from **603**

— nodules affected by 259

— papules in 603

— parts affected by 602, 603

Psoriasis, pityriasis rosea distinguished from **604**

— tuba sites 604

Psoriasis, pityriasis rubra nilaris distinguished from **489, 604**

— paronychia distinguished from 190

— ringworm distinguished from 219

— from 601, 602

— scales in 189, 191, 601, 602, 603

— scalp affected by 219

Psoriasis, *psorale*,
 rash of skin from . . . 600
 xanthine smulating . . . 491, 603, 604
 tinea circinata distum-
 bled from . . . 249
Psorosperms in Page's
 disease . . . 750
 Psychalgia, head pain from
 pain in the arm from . . . 445
 Psychasthenia, neuropathy
 with . . . 240
 Psychic reflex of pupil 551, 552
 Pterygium . . . 399
Ptomane poisoning, bac-
 teriology of . . . 717
 -- diarrhoea from . . . 717
 -- epulemic . . . 554, 717
 -- erythema in . . . 229, 234
 -- from Gaertner's bacilli 554
*Ptomane poisoning, general
 account of* . . . 229
 -- general wasting from . . . 54
*Ptomane poisoning, notes
 on* . . . 717
 -- oedema from . . . 415
 -- ocella smulating . . . 235
 -- polydysphagia in . . . 552
 -- from pork . . . 717
 -- purpura from . . . 552, 554
 -- severe diarrhoea in . . . 533
 -- from shellfish . . . 415
 -- summer diarrhoea allied
 to . . . 717
 -- vertigo from . . . 752
 -- vomiting from 171, 717
 . . . 224, 717
PTOSIS . . . 540
 -- congenital . . . 542
 -- from conjunctivitis . . . 541
 -- hysterical . . . 441
 -- myasthenia gravis . . . 541
 -- myopathic . . . 535
 -- oedema . . . 541
 -- paralytic of cervical
 sympathetic 541, 552, 722
 -- of seventh nerve
 (Figs. 227, 229, 230) . . . 540
 -- third nerve . . . 540
 -- simulation of . . . 540
 -- from syphilis (Fig. 229) . . . 541
 -- in tubercularis . . . 256
 -- from thyroid gland en-
 largement . . . 722
 -- tracheal . . . 542
PTYALISM . . . 542
 definition of . . . 542
 from drugs . . . 542
*Ptyalism, from gastric re-
 flex* . . . 543
Ptyalism, list of causes of . . . 542
*Ptyalism, from paralytic
 dysphagia* . . . 543
 -- stomatis . . . 542
*Ptyalorrhoea, general ac-
 count of* (and see Salivation) . . . 543
 Puberty, age at . . . 489, 559
 Puberty, albinuria of . . . 15
 breast changes at . . . 686
 delayed, in atresia . . . 191
 earliest disappearing at . . . 218
 earliest at . . . 221
 excessive ovarian activity
 at . . . 287
 menorrhoea at . . . 387, 392
 metrorrhoea at . . . 181
 milk flow from nipple at . . . 452
 pain in otopne testis at . . . 488
 epiphysis from . . . 328
 osteo-tissue enlarging at . . . 287
 the testes, necrosis of . . . 697
 -- ovar, precocious, with
 hypoparathyroidism (Fig.
 174) 408, 409, 630
 -- testis, absence of hair on . . . 558
 -- uterine fever, endocervi-
 calitis in . . . 596
 -- pain in joints in . . . 296
 -- rheumatism simulated . . . 296
 -- rigor in . . . 595, 596
 -- vaginal discharge with . . . 596
 -- infection, infective para-
 titis with . . . 691

Pulmonary abscess (see
 Abscess of Lung)
 -- abscess of brain . . . 91
 -- definition of . . . 91
 -- artery (see Artery, Pul-
 monary)
 -- embolism (see Embolism,
 Pulmonary)
Pulmonary incompetence
 -- infant (see Infant of
 Lung)
**Pulmonary osteo-arthropathy,
 general account of** (Figs.
 264, 265) . . . 352
 -- fingers enlarged of . . . 111
 -- swelling of bones in . . . 670
 -- second sound, accentuated 1
 -- with mitral re-
 gurgitation . . . 210
**Pulmonary second sound,
 reduplicated** . . . 2
 -- with mitral re-
 gurgitation . . . 210
 -- stenosis, acquired . . . 91, 92
 -- ascites from . . . 46
 -- back pressure from . . . 46
 -- heart of . . . 111, 156, 157
 -- in children . . . 91
 -- clubbed fingers and
 toes in 91 (Fig. 46)
 . . . 111, 217
 -- toes from . . . 217
 -- congenital . . . 217
 -- cyanosis from 111, 156, 217
 -- dyspnoea from . . . 217
 -- (Fig. 67) . . . 157
 -- heart failure from . . . 46
 -- incompetence with . . . 217
 -- palpitation from . . . 184
 -- patent interventricular
 septum with . . . 111, 215
 -- polythaemia from . . . 217
 -- right ventricle enlarged
 from . . . 215, 217
**Pulmonary stenosis, systolic
 bruit of** . . . 91, 217, 533
 -- thrill with . . . 91, 111,
 . . . 157, 217, 720
 -- systolic bruit (see Bruit)
 -- thrombosis . . . 289
 -- vein, aneurism ruptured
 into . . . 324
 -- method of slowing . . . 348
 Pulsatile liver (see Liver,
 Pulsatile)
 -- tumour (see Swelling,
 Pulsatile)
 Pulsating noises in head . . . 496
**Pulsation, abdominal aortic,
 moine** . . . 684
 -- over aneurysm . . . 208
 -- capillary, in anaemia . . . 93
 -- in aortic disease . . . 211
 -- regurgitation . . . 95, 207
 -- method of slowing . . . 93
 -- in Turkish bath . . . 92
 -- cessation of, in arteries . . . 54
 -- ear in detecting . . . 208, 692
 -- epigastric, from fibroid
 lung . . . 216
 -- from large heart . . . 206
 -- mitral regurgitation . . . 210
 -- stenosis . . . 216
 -- over-train of heart . . . 214
 -- patent interventricular
 septum . . . 215
 -- when right ventricle
 enlarged . . . 215
 -- expansive, from aneurysm . . . 664, 667, 674, 676,
 . . . 678, 681, 692, 695, 714
 -- hernia cerebri . . . 694
 -- pulmonary . . . 694
 -- meningococcal . . . 694
 -- of pleural effusion . . . 694
 -- in sarcoma . . . 693
 -- precordial, from fibroid
 lung . . . 216
 -- mitral stenosis . . . 216
 -- transmitted, by care of
 oina of pancreas . . . 51, 330
**PULSATION, UNEQUAL AB-
 DOMINAL AORTIC** 543
 blue brain and . . . 163
 -- noises in head with . . . 496

Pulsation, conti.
 -- of veins in neck . . . 92, 369
 -- violent arterial, in aortic
 regurgitation . . . 691
 -- -- exophthalmic goitre 694
Pulse, alternating . . . 545
 -- anacrotic, in aortic sten-
 osis . . . 208
 -- collapsing, with aortic
 regurgitation . . . 217, 485
 -- delay of one, from aneur-
 ysm . . . 550
 -- diminished radial, by
 cervical rib . . . 110, 414
 -- dropped beat in . . . 547
 -- -- pulsus alternans . . . 546
 -- high tension, in chronic
 nephritis (and see
 Blood-pressure, High) 274
 -- imperceptible, from snake-
 bite . . . 337
**Pulse, intermission of the,
 general account of** . . . 549
 -- in Kirckland's disease 616
PULSE, IRREGULAR . . . 544
 -- with aortic regurgita-
 tion . . . 207
 -- from arsenic . . . 78
 -- athlete's heart . . . 214
 -- arricular fibrillation 548
 -- cerebral disease . . . 295
 -- in children . . . 549
 -- from dropped beats . . . 549
**Pulse, irregular, from extra-
 systoles** . . . 547, 549
 -- fatty heart . . . 212
 -- fibroid heart . . . 213
 -- heart-block . . . 545, 549
**Pulse, irregular, main types
 of** . . . 545
 -- from neurosis . . . 117
 -- mitral regurgitation . . . 210
 -- stenosis 14, 53, 55,
 . . . 81, 216
 -- myocardial changes 14,
 . . . 212, 300
 -- in nervous subjects . . . 549
 -- from over-train of heart 214
 -- pulsus alternans . . . 549
 -- with toxic diarrhoea . . . 171
 -- (and see Irregular)
 -- olditeration of, from
 embolism . . . 551
 -- in pneumonia . . . 626
 -- pyrexia and . . . 553
**Pulse, paired, from partial
 heart-block** . . . 550
 -- rapid, in acute rheuma-
 toid arthritis . . . 342
 -- in appendicitis . . . 677
 -- with arricular fibrilla-
 tion . . . 548
 -- from corrosives . . . 268
 -- in diphtheria . . . 466
 -- diverticulitis . . . 453
 -- excitement . . . 549
 -- feedie, in phosphorus
 poisoning . . . 536
 -- pneumothorax . . . 452
 -- in fevers . . . 702
 -- Graves's disease . . . 549
 -- from hamatemesis . . . 268
 -- in infections . . . 549
 -- with lateral sinus
 thrombosis . . . 84
 -- mastoid abscess . . . 84
 -- mitral stenosis . . . 55, 216
 -- myocardial affections . . . 14
 -- from nervousness . . . 88
 -- in neurasthenia . . . 88
 -- over-train of heart . . . 214
 -- paroxysmal tachy-
 cardia . . . 549
 -- in rheumatoid arthritis 341
 -- from smoking . . . 186
 -- with suppurative men-
 gitis . . . 84
 -- in tuberculosis . . . 549
 -- (and see Tachycardia
 rate, after abdominal
 surgery . . . 565
 -- in acute peritonitis . . . 392
 -- eversive and . . . 88, 485, 486
 -- in general tuberculosis 636
 -- over 200 . . . 703, 704
 -- in typhoid fever . . . 355

Pula, conti.
 -- relatively slow, in ty-
 phoid fever . . . 564, 636
 -- rising rapidly of, in
 acute peritonitis 425, 593
 -- slow, from alternating
 extrasystoles . . . 548
 -- from bile salts . . . 524
 -- cerebellar abscess . . . 592
 -- cerebral abscess . . . 592
 -- tumour . . . 711
 -- in convalescence . . . 531
 -- cretinism . . . 248
 -- from heart-block 546,
 . . . 548, 549
 -- increased intracranial
 pressure . . . 548
 -- jaundice . . . 224, 548
 -- myxoedema . . . 255
 -- in relation to tempera-
 ture, in yellow fever 273
 -- Stokes-Adams's disease
 . . . 146, 546
 -- typhoid fever . . . 571
 -- (and see Bradycardia)
**Pulse, slow, various causes
 of** . . . 548, 549
**Pulse, summary of peculi-
 arities of** . . . 548, 549, 550
 -- small, in mitral stenosis 216
 -- splashing, in aortic dis-
 ease . . . 211
Pulse, totally irregular . . . 550
 -- variations with respira-
 tion . . . 549
 -- swallowing . . . 549
 -- waterhammer, in aortic
 regurgitation 95, 94,
 . . . 207, 208, 720
 -- in yellow fever . . . 556
PULSES, UNEQUAL . . . 532
 -- from anatomical causes 530
**Pulses, unequal, from aneu-
 rism** . . . 551, 692
 -- axillary . . . 667
 -- atheroma . . . 550, 551
 -- cervical rib . . . 550, 551
 -- embolism . . . 550
 -- mediastinal growth . . . 550
 -- new growth . . . 551
Pulsus alternans . . . 546, 550
Pulsus bisferiens . . . 549, (Fig. 265) 550
Pulsus bigeminus . . . 547, 550
 -- paralytic, with all heart
 paralytic . . . 90
 Puneta . . . 552
 Punctate basophilica (see
 Basophilica, Punctate)
 Puncture, lymph gland . . . 28
 -- splenic . . . 29, 633
**PUPIL ABNORMALITIES
 OF THE** . . . 551
**Pupil, Arnyll Robertson,
 definition of** . . . 551
 -- in tubes 146, 429,
 . . . 144, 166, 514, 551,
 . . . 650, 749, 768
 -- simulated in neuritis . . . 511
 -- changes, from optic nerve
 lesion . . . 552
 -- paralysis of cervical
 sympathetic . . . 552
 -- from cerebral tumour . . . 552
 -- contracted, in accom-
 modulation . . . 551
 -- from cerebral tumour 552
 -- cervical sympathetic
 lesion . . . 722
 -- cord lesion . . . 501
 -- encephalitis . . . 552
 -- hypermetropia . . . 551
 -- in infants . . . 551
 -- from intracranial ab-
 scess . . . 552
 -- by light . . . 232
 -- in old age . . . 551
 -- paralysis of arm with
 -- from paralysis of cer-
 vical sympathetic . . . 541
 -- spinal lesion . . . 547
 -- sympathetic paralysis 247
 -- in tubercularis 236, 551
 -- thyroid gland en-
 largement . . . 722
 -- uremia . . . 40, 170

Pupil, round.
 - dilatation to light, in
 - cases . . . 552
 - dilated, from alcohol . . 170
 - - aneurysm . . . 552
 - - by atropine . . . 232
 - - belladonna . . . 170, 205
 - - from cataplexy . . . 552
 - - epilepsy . . . 552
 - - by fright . . . 551
 - - in glaucoma 292, 293, 761, 762
 - - Graves's disease . . . 256
 - - infant . . . 552
 - by sudden sensory
 - stimuli . . . 551
 - double, from accident . . 175
 - - congenital . . . 175
 - - diplopia from . . . 175
 - - from operation . . . 175
 - eccentric, from mid brain
 - tumour . . . 727
 - in epilepsy . . . 137, 552
 - fixed, from alcohol . . . 170
 - belladonna . . . 170
 - in glaucoma . . . 232
 - peripheral neuritis . . . 214
 - uremia . . . 170
 - in hysteria . . . 137
 - immobile, in general paral-
 - ysis . . . 116
 - to light, in Babes . . . 215
 - inactive, with iris . . . 232
 - after clogged ulceration . . 551
 - dislocation of lens . . . 551
 - injury . . . 551
 - monodiplopia . . . 551
 - iritis . . . 551
 - in persistent pupil-
 - lar membrane . . . 551
 - after rupture of
 - sphincter . . . 551
Pupil, irregular shaped . . . 551
 - large, from brain lesions . . 552
 - in myopia . . . 551
 - loss of convergence reflex
 - in, in alcoholism . . . 551
 - - diplopia . . . 551
 - - tubes . . . 551
 - psychic reflex in . . . 552
 - non-reaction to accom-
 - modulation in dissemi-
 - nated sclerosis . . . 760
 - - paralysis of, complete . . 551
 - pup-point, from opium
 - poisoning . . . 119, 310
 - - pointlike hemorrhage . . 210
 - - 119, 210

Pupil reactions, altered
 - after diphtheria . . . 61

**Pupil reactions, in hemia-
 nopsia . . . 302**

**Pupil reflexes, general ac-
 count of . . . 551**

**Pupil, reacting to light but
 not to accommodation 551**
 - not reactive to light, in
 uremia . . . 761

Pupil reflex, hemianopic . . 552

**Pupils, unequal, from cen-
 tral disease . . . 295**
 - - diplopia . . . 729
 - - gross intra-ocular lesion 118

**Pupils, unequal, general
 account of . . . 552**
 - in general paresis . . . 552
 - - 116, 170, 552
 - - glaucoma . . . 552
 - - iritis . . . 552
 - - paralysis of cerebral
 - sympathetic . . . 552
 - - third nerve . . . 552
 - - polyosteoromy . . . 552
 - - without significance . . 552
 - in tubes dors. 236, 552
 - - trazeumal neuritis . . . 552
 - - variations with age . . . 551

**Pupillary membrane, com-
 pletely persistent of**
 - Punctures, in acute con-
 - stipation . . . 129
 - - code from . . . 124
 - - constipation from . . . 769
 - - lessening effect of . . . 122
 - - loss of weight from . . . 769
 - - tetanus from . . . 718

Purin bodies, list of . . . 742

PURPURA . . . 552
 - in acute leucis . . . 554
 - - yellow atrophy . . . 273
 - - albuminuria with . . . 16
 - - from alcoholism . . . 555
 - - anemia from . . . 32
 - - from antiphthritic
 - serum . . . 554
 - - bacteriology in diagnosis
 - - cause of . . . 557
 - - bleeding gums in . . . 72
 - - from blood diseases . . . 556
 - - in Bright's disease . . . 555
 - - cerebrospinal fever . . . 554
 - - meningitis . . . 291
 - - cirrhosis . . . 635
 - - diphtheria . . . 554
 - - from drugs . . . 554
 - - in epilepsy . . . 554
 - - epistaxis from . . . 221
 - - in Landaul alcoholism
 - - jaundice . . . 332
 - - fulminans . . . 553, 556
 - - in fungating endothelitis
 - - (*Fig.* 256) . . . 555
 - - general tuberculous . . . 553
 - - gangrenis and . . . 557
 - - hematemesis in . . . 296
 - - hemorrhagia in . . . 275, 283
 - - hamorrhage into tongue . . 654
 - - - herpes proceratilis . . . 618
 - - hamorrhagic erosions in 269
 - - hamorrhagic . . . 553, 556
 - - - blood per annum in . . . 76
 - - - counts in diagnosis . . 275
 - - - culture in diagnosis . . 275
 - - - ing . . . 275
 - - - hamatemesis in . . . 275
 - - hamoptysis with . . . 287
 - - in Henoch's erythema . . 372
 - - Henoch's (see Henoch's
 - Purpura) . . . 554
 - - in hysteria . . . 554
 - - idiopathic . . . 557
 - - in jaundice . . . 555
 - - leukæmia . . . 25, 556
Purpura, list of causes of . . 553
 - - malnutrition of . . . 554
 - - in meshes . . . 554
 - - meningitis . . . 225
 - - metrorrhagia from . . . 386, 387
 - - from missile rupture . . . 554
 - - ptomaines . . . 554
 - - pyæmia . . . 555
 - - pyuria (see alveolaris) 74, . . 555, 557

**Purpura rheumatica, general
 account of . . . 556**
 - - unknown before fifteen . . 545
 - - rotund varicose veins . . . 554
 - - in sarciniosis . . . 555
 - - scarlet fever . . . 275, 554
 - - scurvy . . . 38, 72, 275, 556
 - - septicæmia . . . 555
 - - simplex . . . 553, 556
 - - parts affected by . . . 562

Purpura in small-pox . . . 554
 - - small-pox stimulating . . 562
 - - in splenomegaly poly-
 - erythæmia . . . 635
 - - tongue swollen with . . . 698
 - - tonsils and . . . 557
 - - from toxæmia . . . 76
 - - in typhus fever 355, 554, 638
 - - yellow fever . . . 275, 336

Pus, little albumin in . . . 12
 - - methyloxytic coloured 360

PUS IN THE CHEST . . . 103
 - (and see Empyema)
 - chocolate-and-milk from . . 252
 - - hepatic abscess . . . 252
 - - empysemata, in tube casts . . 6
 - - from ear (see Otorrhœa)
 - - from nipple . . . 181
 - - from nose . . . 178
 - - phosphates mistaken for 324
 - - peritonium, from abscess . . 385
 - - sterile . . . 349
 - - to stool . . . 170

PUS IN THE STOOLS . . . 557
 - - from abscess ruptured
 - - into bowel . . . 557
 - - - cholera . . . 557
 - - - colitis . . . 557
 - - - dengue . . . 557
 - - - dysentery . . . 557

Pus in the stools, void.
 - semioscope in dia-
 - gnosing cause of . . . 557
 - from ulceration of
 - bowel . . . 557
 - tube casts of . . . 578
 - urates stimulating . . . 719
 - in urine, characters of . . 571
 - - phosphates . . . distri-
 - - buted from . . . 574
 - - urates diminished . . .
 - from . . . 574
 - (and see Pyuria)
 - - Vesicle, moderate . . . 559
 - - cystitis from . . . 222
PUSTULES . . . 557
 - Pustules in acne 489, 557, 569
 - bacillus pyocyaneus
 - - causing . . . 97
 - - from bromides 98, 559, 567
 - - contents of . . . 574
 - - crusts from . . . 558
 - - in dermatitis herpeti-
 - - ica . . . 755
 - - from dissection wounds . . 216
 - - eczema . . . 557
 - - eczema . . . 557, 569, 755
 - - furunculosis . . . 557
 - - granulosis rubra nasi . . . 654
 - - herpes proceratilis . . . 618
 - - impetigo . . . 557, 558, 569
 - - from iodides 98, 559, 567
 - - in ichthy scrophulorum . . 488
 - - newborn . . . 557
 - - purpura . . . 490
 - - rhinophyma . . . 755
 - - scalp . . . 558, 609, 755
 - - scrofuloderma . . . 559

 - - - kidney from . . . 576
 - - - when in loin from . . . 576
 - - - in acute fevers . . . 576
 - - - albuminuria from . . . 578
 - - - amount of pus small in . . 12
 - - - anuria from . . . 49, 12
 - - - from bacillus coli . . 12, 69
 - - - bacillus pyocyaneus with . . 69

Pyelonephritis, acute
 - from accumulation of bladder contents .. 576
 - chronic .. 576
 - cystitis .. 576
 - cystitis complicated by .. 578
 - from enlarged prostate .. 578
 - from ureteric obstruction .. 578
 - from ureteric calculus with .. 578

Pyelonephritis, general account of .. 576
 - from haematogenous infection .. 576
 - kidney enlarged in .. 555, 576
 - leucocytosis slight with .. 560
 - pus from .. 576
 - perinephric lymphatics and .. 576
 - pneumococcal with .. 69
 - in pregnancy .. 576
 - pyrexia from .. 576
 - pyuria from .. 555, 575
 - scars in .. 575
 - renal pain from .. 575
 - tenderness from .. 576
 - urinary and harsh with .. 576
 - uraphylococci with .. 69
 - from stone in kidney .. 577
 - trophococci with .. 69
 - from stricture .. 576
 - tongue glazed in .. 576
 - tubercle bacilli with .. 578
 - tubercle bacilli with .. 578
 - uremia from .. 575
 - urine changes with .. 576

Pyephlebitis, sub-acute, haematogenous from .. 572
 - mediastinal from .. 572
 - portal obstruction with .. 572
 - spleen enlarged with .. 572
 - sudden ascites with .. 572
 - thrombosis of portal vein in .. 572
 - haematemesis from .. 565
 - obstructive pyrexia due to prolonged pyrexia from .. 573
 - septicaemia from .. 573
 - suppurative abscesses of liver from .. 332, 596
 - albuminuria with .. 16
 - from appendicitis 326, 332, 567, 596
 - appendicitis simulated .. 567
 - diarrhoea with .. 596
 - chyluria from .. 100
 - hepatic fever with .. 596
 - icterus from 526, 535, 596
 - leucocytosis with .. 560
 - liver enlarged from .. 333, 596
 - often overlooked .. 333
 - pain over liver from .. 596
 - peritonitis simulated by pleurisy from .. 106
 - pneumonia simulated 567
 - prolonged pyrexia from 345
 - pyrexia from .. 345
 - pyuria from 326, 335, 567, 596
 - septicæmia from .. 567
 - tender liver with .. 596
 - typhoid fever simulated by .. 567

Pyelo-cystitis, adhesions, round, from diaphragm above .. 174
 - gall-stones .. 174
 - cystic ulcer .. 174
 - peritonitis .. 174
 - pyeloma of vesicoureteric junction of stomach .. 174

Pyelorus, congenital stenosis of .. 384
 - **Pyelorus, hypertrophic stenosis of .. 766**
 - in distal jejunum .. 678
 - normal, palpable in children .. 660
 - spasmodic, dyspepsia from .. 660
 - in infants .. 660
 - stenosis of, from adhesions .. 174
 - benign and cystic in diagnosis 174, 211, 245, 652
 - from dilated cyst .. 174
 - from duodenum 174, 270, 297, 518, 652, 660

Pyelorus, stenosis of, causes **765**
 - tube smallened by .. 113
 - constipation from .. 123
 - copious vomiting due to .. 318
 - by cyst .. 653
 - dilatation of stomach .. 174, 217, 653, 660
 - flatulence with .. 211
 - from gall-stones .. 174
 - gas in stomach from .. 245
 - gastric juice changes with .. 318
 - from gastric ulcer 289, 653
 - gastro-enterostomy for 174
 - from healed ulcer 297, 660
 - heartburn from .. 297
 - from dilated cyst .. 174
 - indigestion from .. 123
 - in infants .. 660
 - keratin-coated capsules in diagnosis .. 653
 - methylene blue in diagnosis .. 653
 - need for operation with 174

Pyelorus, stenosis of, notes on .. 766
 - from old ulcer .. 174
 - renal tumour .. 174
 - sarcoma with 211, 320, 653
 - by spasms .. 653
 - stomach tube in diagnosis .. 124, 245
 - after ulcer .. 317
 - visible peristalsis .. 245, 317, 521, 653, 660
 - vomiting with 115, 174, 245, 653, 765

Pyelorus, stenosis of, without vomiting .. 653
 - weakness from .. 123
 - without many symptoms .. 123
 - cystitis with .. 211, 320

Pyoderma, leucocytosis slight with .. 560
 - *Pyometra, age incidence of 186*
 - from carcinoma 186, 392
 - endometritis .. 186
 - mal discharge due to 186, 392
 - metastasis from .. 392
 - sound in detecting .. 186

Pyonephrosis, from carcinoma of bladder .. 577
 - ureters .. 577
 - simulates .. 576
 - diarrhoea with .. 577
 - from enlarged prostate .. 576

Pyonephrosis, general account of .. 356, 576
 - kidney enlarged from .. 552, 555, 536, 575
 - leucocytosis slight with .. 560
 - normal urine with .. 577
 - pallor with .. 577
 - pelvic swelling due to .. 688
 - polyuria from .. 557
 - pyrexia with .. 557
 - pyuria from 557, 556, 577
 - from 575, 576, 577
 - without pyuria 557, 575
 - from renal calculus 279, 357, 576, 577
 - renal tumour from .. 577
 - sweating with .. 557
 - from tuberculous kidney .. 576
 - ureteric calculus .. 578
 - variations in size of .. 557

Pyopneumopericardium, from tubercle coli .. 652
 - chloroform smelt with .. 652
 - from epithelium of vesiculae .. 652
 - phagocytosis .. 652
 - from body .. 652
 - subphrenic abscess 652
 - suppuration in chest from 651

Pyopneumothorax, general account of .. 652
 - routine in diagnosis .. 650, 651, 652
 - diagnosis of .. 651

Pyopneumothorax, subphrenic .. 658
 - suppuration with .. 651
 - from alveolar ducts, acute cystitis from .. 247

Pyorrhæa alveolaris, acute
 - anæmia from .. 32, 74
 - arthritis from .. 71, 648
 - bleeding gums from 72, 73, 74
 - blood-spitting due to .. 245
 - death from .. 74
 - dyspepsia from .. 74
 - foul breath from .. 74

Pyorrhæa alveolaris, general account of .. 73, 74
 - gum recession from .. 73
 - hæmorrhages due to .. 555
 - hidden .. 74
 - joint lesions from .. 552
 - loss of weight from .. 769
 - non-tuberculous from .. 74
 - pain by the neck from 648
 - purpura from 74, 555, 557
 - pyæmia from .. 74
 - retraction of gums from 589
 - septicæmia from .. 657
 - still-neck from .. 648
 - stomatitis from .. 542
 - teeth loose from .. 73

Pyosalpinx,aching in lumbosacral region from .. 582
 - acute ascites from .. 17
 - peritonitis from .. 592
 - albuminous with .. 174
 - anæmia from .. 35
 - appendix abscess simulated by .. 678
 - bacillus coli in .. 530
 - cystitis from .. 582
 - diverticulitis simulating .. 153
 - empyema from .. 106
 - frequent micturition from 394
 - leucocytosis with 360, 361
 - leucorrhœa from .. 582
 - opening into bladder .. 575
 - pain in lumbosacral region from .. 582
 - after parturition .. 678
 - pelvic pain from .. 468
 - - swelling due to .. 688
 - periods profuse with .. 582
 - pleurisy from .. 106
 - pus in stools from .. 557
 - pyuria from .. 575
 - felt per rectum .. 587
 - rupture of .. 468
 - into bladder .. 581, 582
 - simulating dysmenorrhœa .. 193
 - septicæmia from .. 657
 - simulates by diverticulitis .. 153
 - typhoid fever 331
 - suppurative peritonitis from .. 17
 - swelling in Douglas's pouch from .. 587
 - vaginal discharge with .. 678
 - examination in detecting .. 582, 587, 678

Pyramidal tract, focal fibrosis of .. 192
 - lesions, ankle-clonus with .. 29
 - Babinski's sign in .. 68

Pyramidal tract lesions, effects of .. 496
 - extensor plantar reflex with .. 39, 68
 - motor-slow knee-jerk with .. 39, 258
 - results of .. 591, 592
 - (and see Hemiplegia and Paraplegia)

Pyrexia, from acute congestion of liver .. 534
 - paratyphoid .. 661
 - peritonitis .. 131
 - pleurisy .. 192
 - rheumatism .. 228
 - rheumatoid arthritis 341
 - yellow atrophy .. 333
 - from alveolar abscess .. 683
 - in alveolar calcaneous disease .. 376
 - anæmotic syndrome .. 226, 414, 699
 - appendicitis 115, 285
 - 154, 469, 582, 665, 677
 - from botryomycosis .. 70
 - bad night .. 573

Pyrexia, contd.
 - in blood disease .. 596
 - in billous dermatoses .. 59
 - from carcinoma .. 574
 - of bowel .. 577
 - of liver 17 (*Fig. 115*) .. 326, 375, 374, 574
 - of caseous glands 308, 704
 - with catarrhal jaundice .. 329
 - with cellulitis .. 110
 - cerebellar abscess .. 517
 - cerebral abscess .. 84, 306
 - hæmorrhage .. 81, 306

Pyrexia, in children .. 573
Pyrexia, in children, without apparent cause .. 573
 - from child morbus .. 369
 - cholecystitis .. 450

Pyrexia in cirrhosis of the liver (*Fig. 12*) 35, 326, (*Fig. 167*) 571, 570, 574
 - colibacilluria 455, (*Fig. 193*) 456
 - colic .. 593
 - colitis .. 663
 - congestion of liver .. 369
 - from convulsions 114, 571
 - corresponding pulse-rate of .. 573
 - - respiratory rate of .. 573
 - in coryzal cold .. 178
 - crises of, in cerebro-spinal meningitis 566, 590
 - from cystitis 282, 470, 578
 - diarrhoea with .. 171
 - delirium with .. 169
 - in dengue .. 166
 - dermatitis herpetiformis .. 75
 - diphtheria .. 574

QUADRATUS LUMBORUM, nerve supply of ... 499
 Quadriceps extensor femoris, myoclonus of ... 137

Reaction of degeneration, conditions causing

- diabetes .. 51
- wall, focal paralysis .. 193
- in gumma of nerve .. 61
- in infantile paralysis .. 60
- in strabismus .. 506
- in injury .. 61, 63
- in arthritis .. 513
- in arthritis .. 517
- in growth .. 53
- partial .. 587
- from pelvic tumours .. 61
- in shepherd's neuritis .. 56
- 59, 60, 61, 140, 165, 512, 514, 515
- in atrophy .. 513
- in polyneuritis .. 509, 512
- in progressive muscular atrophy .. 61
- in ataxia .. 61, 63
- in myosymphysis .. 61
- in thipes .. 112
- in tooth's paronychia .. 61, 63, 115
- in tuberculous neuritis .. 61, 62
- in tumour of optic chiasm .. 61

REACTION, OIAZO .. 173

Reaction of stools .. 170

Reaction, Wassermann's (see Wassermann)

Reaction, Widal's (see Widal)

Reactions, electrical

- in tetany .. 5

Reading, book seeming to

- eye-strain from .. 763
- eye-squint from .. 146
- headache from .. 449
- pain in the eyes from .. 146

Recess, umbilic, oblique, obstructed, chyloous ascites

- from .. 50
- in chyluria from .. 50
- in rupture of .. 109
- in scission of gums .. 589

Recess, from labes

- in carcinoma .. 173, 519, 520, 521
- in obstruction, in acute .. 129
- in fistula and .. 78
- in oesophagus felt on .. 587
- in appendicitis .. 116, 283, 454, 557, 677
- in appendix felt on .. 587
- in ascites .. 49
- for carcinoma of colon .. 130, 172, 530
- recti .. 78, 129, 130, 153, 587, 718
- in case of hernia-down pain .. 127
- in fascia pain .. 116
- in oedema .. 8
- of one leg .. 111
- in pus in stools .. 557
- in cauda equina tumour .. 63
- in chyluria .. 109
- in oedema .. 587
- in pyelonephritis .. 17
- in infection of bladder .. 171, 372, 579, 580
- in enlarged .. pelvic glands .. 172
- in polypus .. 585
- in retroversion of uterus .. 587
- in subcutaneous abscess .. 587
- in uterine enlargement .. 587
- in diagnosis and fissure .. 194
- in fissure .. 587
- in carcinoma of prostate .. 470
- in cause of swelling in the fossa .. 665
- in gonorrhoea .. 453
- in proctitis .. 121, 128
- in enlarged prostate .. 277, 281, 587, 394, 396
- in impaction of ureter .. 172, 718
- in hernia of rectum .. 159

Rectal cancer, contd.

- in diagnosing .. 159
- in obstruction .. 159
- in obturator hernia .. 681
- in ovarian tumour .. 331
- in piles .. 194, 584
- in prostatic abscess .. 182, 470, 581, 587, 620
- in abscesses .. 397

bolism, Retinal)
— — changes, with nephritis 42
— — anæmia ... 146
— — examination, with growth
in liver ... 52
 hæmorrhage (see Hæ-
morrhages, Retinal)
— vein, thrombosed (see
Thromboses, Retinal)

**Retinitis, albuminuric, ap-
pearances of 416, (Plate XX)
418**
 — with arteriosclerosis ... 1
 — black spots before eyes 72
 — — cerebral hæmorrhage
 and ... 119
 — in chronic nephritis
 11, 212, 271, 408
 — granular kidney 1, 106
 — heart failure with ... 1
 — high blood-pressure ... 1
 — — mitral regurgitation 212
 — — optic neuritis simu-
 lating ... 416
 — in uræmia ... 215
 — — macular with ... 759
 — — arteriosclerosis ... 90
 — cerebral hæmorrhage and
 in diabetes ... 264
 — with high blood-pressure
 interstitial nephritis ... 80
 — nephritis ... 47
 — — optic in interstitial oph-
 thalmitis ... 7
 — photophobia from ... 7
 — pigmentous, lamellæ of 264
 — night-blindness from
 764, 763
 — ophthalmoscopic ap-
 pearances of 761, 763
 — visual field constricted
 in ... 769, 764
 — — uræmia and ... 759
 — — of yellow spot, myasthenia
 in ... 759

Retraction of the Abdomen
(see Abdomen, Re-
traction)

**RETRACTION OF THE
EYEBALL 217**
 — — eyeballs, in Graves's dis-
 ease 722
**RETRACTION OF THE
GUMS 589**
**RETRACTION OF THE
HEAD 589**
 — from bronchopneumonia
500
 — capillary bronchitis ... 599
 — cerebral lesions ... 592
 — dyspnoea ... 599
 — increased intracranial
 pressure ... 599
**Retraction of the head, list
of causes of 589**
 — from meningitis 225,
228, 566, 590, 649, 649
 — tuberculous meningitis 649
 — supple, from carcinoma
of Pott's disease ... 730
**Retraction of ribs, systolic,
with adherent peri-
cardium 90, 213**
 — in normal persons 90

Retrolabial neuritis (see
Neuritis, Retrolabial)

Retroluxion of uterus (see
Uterus, Retroluxion)

Retropneumone (see, dilata-
tion of stomach from
171, 653)

**Retropneumone cyst, notes
on 661**
 — — (see Lamphart's
Glands, Retropneumone)
 — — lenticular ... 452
 — — tissue, aneurysm-like
 into ... 129

Retropharyngeal abscess,
(see Abscess, Post-
pharyngeal)

Retropulsion, in paralysis
actions ... 725

**Retroversion of uterus (see
Uterus, Retroversion)**
Retroverted gravid uterus
(see Uterus, Retro-
verted Gravid)

Rhabdomyoma of kidney 556
Rheumatic fever (see Rheu-
matism, Acute)

Rheumatism, acute, acute
endocarditis in ... 214
— — — myocardium mistaken for 358
— — — adherent pericardium
— — after ... 53, 54
— — — see incidence of ... 194
— — albuminuria in ... 43
— — albuminuria in ... 46
— — anæmia from ... 34
— — aortic disease from 16, 209
— — regurgitation from 35
 arthritis ... 337

**Rheumatism, acute, associ-
ated conditions of 14**
 — bronchitis in ... 654
 — cerebral embolism and 119
 — — in children ... 164
 — — chorea in 165, 133, 1
 — — — 337, 464, 644
 — — chronic mesh-stasis
 from ... 751
 — — com in ... 117
 — — diaphragm in ... 169
 — — does not affect one
 joint only ... 341, 364
 — — drenching sour sweats
 in ... 328
 — — endocarditis in 90, 96, 165,
 292, 283, 164, 574, 614
 — — eosinophilia from ... 218
 — — erythema in ... 225, 337
 — — — multiforme from ... 165
 — — nodosum from 105,
 128, 644
 — — simplex in ... 228
 — — family history and
 132, 337, 164, 614
 — — times inflamed in ... 645
 — — — fibrinoid representing 164
 — — traction very rare after 339
 — — "slitting" of joint joints
 in ... 378

**Rheumatism, acute, general
account of 337**
 — — incidence of arthritis
 mistaken for 338, 349
 — — growing pains and
 heart-block from 166
 — — disease and 55, 166
 — — 89, 93, 105, 299,
 337, 464, 485, 504
 — — — hypertrophy in 169,
 309, 310, 574
 — — — infantile from 189
 — — — lamellæ in ... 325
 — — — joint pains with 195,
 228, 644

Kakland's disease simu-
lating
 — — lenticular ... 543
 — — history of heart ... 14
 — — disease ... 181
 — — hyperpyrexia in 169,
 309, 310, 574
 — — — infantile from 189
 — — — lamellæ in ... 325
 — — — joint pains with 195,
 228, 644

Kakland's disease simu-
lating
 — — lenticular ... 543
 — — history of heart ... 14
 — — disease ... 181
 — — hyperpyrexia in 169,
 309, 310, 574
 — — — infantile from 189
 — — — lamellæ in ... 325
 — — — joint pains with 195,
 228, 644

Rheumatism, acute, peliosis

and . . . 556, 160
 pericarditis in . . . 44
 . . . 105, 337, 464, 614
 permanent stiffness
 rate after . . . 338
 pleurisy in 51, 611, 461
 with effusion from 105
 polyarthritides from 105
 precordial pain in . . . 241
 puerperal fever simulating . . . 396
 pulmonary stenosis
 after . . . 396
 purpura of, age in . . . 942
 disease of . . . 343
 pyrexia in . . . 228
 rheumatoid arthritis
 distinguished from 343
 rigor in . . . 595
 sialicycles and 34, 228, 464, 614
 reducing temperature
 time in 89 (Fig. 149) 338, 574
 scleriforma simulated by . . . 228, 614
 septic arthritis mistaken for . . . 339
 septicaemia simulating sore throat in 228, 464, 613
 spleen enlarged in . . . 632

Rheumatism, acute, subcutaneous nodules in

105, 228, 405
 noduloma in . . . 338
 never suppurates 338, 339
 suppurative arthritis mistaken for 338, 341
 tachycardia from . . . 794
 thyroid gland enlarged in . . . 702
 tonsillitis in 105, 241, 337, 611
 traumatic arthritis mistaken for . . . 338
 trichinosis simulating 464
 tuberculous arthritis mistaken for . . . 338
 unknown in infants . . . 341
 urate deposit due to . . . 741
 uric acid in 741
 bacterial noduloma and . . . 442
 chronic, exercise relieving 464
 interscapular pain from
 massage relieving . . . 454
 pain in the hand from
 joints from . . . 466
 limbs in . . . 465, 464
 muscles from . . . 466
 sarcoma simulating . . . 467
 weather and . . . 466
 writers' cramp simulated by . . . 351
 contractures from . . . 442
 epiphyseo-osteitis from 478
 gonorrhoeal (see Arthritis, Gonorrhoeal)

Rheumatism, muscular 431, 467

locaheal neuritis simulating . . . 443
 simulating tetanus . . . 338
 stiff-neck from . . . 338
 tenderness of nuchae
 insertions in . . . 443
 nails affected by . . . 250
 cranial . . . 340

Rheumatism, tabetic pain, mistaken for 436, 440

tenderness of scalp in . . . 712
 spine from . . . 713
 nodulitis from . . . 381

Rheumatoid arthritis, acute (see Arthritis, Rheumatoid)

Rhone Valley, molhies, osseum in . . . 242
 Rheutis, atrophic, anisometria
 from . . . 612
 crusts in nose from . . . 179
 nasal discharge from . . . 179
 oedema from . . . 179
 taste loss from . . . 705
 cases, not tuberculous
 chronic, from syphilis . . . 179
 epitheloma of skin with 558

Rheutis, catth.

total leucocythemia . . . 87
 hypertrophic, adenoids
 from . . . 179
 anisometria from . . . 612
 inability to breathe
 through nose from 179
 nasal discharge from 179
 oedema from . . . 179
 polyva from . . . 179
 sneezing due to . . . 613
 taste loss from . . . 705
 tonsils large from . . . 179
 mentobasis, not always
 aliphatic . . . 179
 purulent (see Discharge, Nasal)
 rhinoliths from . . . 179
 taste impairment from 706
 tuberculous . . . 179
 ulcer of cornea from . . . 733
 Rhinoliths . . . 179
 Rhinophlynia (see Epitheloma)
 Rhinorrhoea (see Epitheloma)
 Rhinoscleroma, epitheloma simulated by . . . 733

Rhinocleroma, general account of 733

skin tumour from . . . 732
 Rhomboid, nerve supply
 of . . . 591
 root innervation of . . . 599
 Rhoncha, with bronchitis . . . 167, 217
 typhoid fever . . . 636
 Rhubarb, chrysophanic acid
 in . . . 744, 745
 erythema from . . . 222
 heartburn relieved by 237
 oxalate from . . . 124
 oxaluria after . . . 284
 pink urine after . . . 745
 yellow urine from . . . 744
 Rhus, sarsaparilla from . . . 239
 toxicodendron, blisters
 from . . . 37
 bullae from . . . 26
 dermatitis from . . . 755
 erythema from 222, 224
 pruritus from . . . 549
 Rib, carcinoma of . . . 707
 caries of, pain in the chest from . . . 431
 cervical (see Cervical ribs)
 fractured (see Fracture of Rib)
 hydatid of . . . 707
 periostitis of, after typhoid fever . . . 686
 resection in empyema . . . 105
 retraction, systolic, with adherent pericardium . . . 54, 20, 215
 sarcoma of . . . 707
 tuberculosis . . . 698, 686

Ribs, beaded, in rickets

in . . . 155, 167, 635
 eroded by aneurysm . . . 434
 everted, from emphysema 566
 in rickets . . . 635
 Ribs, lesions of, tenderness due to . . . 707
 local bulging of, from
 liver abscess . . . 570
 over-expanding of, from
 fibroid lung . . . 168
 peritonitis of . . . 707
 pushed out, by ascites . . . 45
 splenitic nodules on . . . 639
 Ribs, disarticulated, hernia and . . . 65, 226, 114
 in cholera . . . 717
 Ribs, warty stool . . . 268, 275
 Riem, haemoglobinuria from 281
 Rickets, age in disease of . . . 151, 242, 364
 ankle-foot disease simulated by . . . 364
 ankles . . . large from (Fig. 85) 186
 anterior fontanelle in . . . 115
 baldness in . . . 711
 Barlow's disease simulated by . . . 556
 beaked pelvis in . . . 187
 bending of bones from . . . 242
 bones noduly curved in 635

Rickets, contd.

bow-legs from . . . 184
 bronchitis in . . . 145
 coxemia with . . . 29
 corneal contractions
 and . . . 152, 429
 cutting cold in . . . 145
 Rickets, chest in (Fig. 76) 167
 coma in . . . 111
 constipation in 123, 145
 convulsions from 114, 145, 429
 coryza in . . . 145
 cribratules from 152, 295
 defective hygiene causing . . . 145
 diarrhoea in . . . 145
 diet and . . . 145

Rickets, distinguished from achondroplasia 188

Rickets, distinguished from osteogenesis imperfecta 188

dwarfism from (Fig. 85) 186
 eosinophilia in . . . 249
 epiphyseal large in . . . 655
 fat heavy child in . . . 385
 flabbiness of muscles in 714
 flat feet from (Fig. 85) 186
 fontanelles delayed in . . . 635
 forebrain bulging in . . . 187
 large in . . . 204
 gastro-intestinal upsets in . . . 145

Rickets, general account of 145

greenstick fracture from 242
 Harrison's sulcus in 145, 167, 187, 635
 head large in 145, 295, 511
 head-rolling in . . . 145, 711
 inter-joint disease simulated by . . . 364
 hot-cross-bun head in . . . 187, 295
 hour-glass pelvis in . . . 187
 hydrocephalus simulating 204
 infantile scurvy and . . . 99
 isonomia from . . . 321
 irritability in . . . 145
 knee-joint disease simulated by . . . 364
 knock-knee from (Fig. 85) 186
 kyphosis from . . . 155, 188
 larynx-mus-tri-lobus and . . . 145, 429
 limping from . . . 362, 363
 liver depressed by . . . 367
 long bones curved in . . . 145
 lordosis from . . . 188
 marasmus from . . . 385
 mucous stools in . . . 145
 muscular debility in . . . 145
 night sweats in . . . 634
 points in the bones in . . . 364
 poroparula from . . . 549
 pigeon breast in . . . 187
 potbellied in . . . 655, 699
 pseudo-brochisma and 37, 635
 quadrate head in . . . 635
 radius thickened in 154, 155
 restlessness in . . . 711
 ribs beaded in . . . 145
 ribs in . . . 145
 rostrate pelvis in . . . 187
 sabre tilar from . . . 186
 sacro-iliac joint disease simulated by . . . 364
 scoliosis from . . . 155, 154
 screaming in . . . 145
 scurvy (see Scurvy, rickets)
 short legs from (Fig. 85) 186
 Rickets, signs of . . . 145, 635
 spasmophilia and . . . 429
 spinal caries simulated by 714
 curvature from 187, 714
 spleen enlarged in 632, 635
 sweating of head in . . . 145
 teeth delayed in . . . 155
 tooth bones in . . . 145, 714
 sculp from . . . 710, 711
 spine in . . . 714
 tetrag with . . . 7, 145, 151
 transverse colon visible in . . . 699
 tuberculous spine simulated by . . . 364

Rickets, contd.

Wegener-Hoffmann paralysis . . . 135
 wrists large from (Fig. 85) 186
 Ricketts on small-pox . . . 561, 562, 757
 Ricketty grille . . . 187
 Riedel's disease, cyanosis
 from . . . 158
 dyspnoea from . . . 158
 lobe . . . 692
 age incidence of . . . 366
 floating kidney simulated by . . . 367
 gall-bladder simulated . . . 663, 678
 gall-stones and . . . 366
 Riedel's lobe general account of . . . 366
 kidney simulated by 353
 laparotomy in diagnosing . . . 252
 movable kidney simulated by . . . 663
 sex incidence of . . . 366
 simulating enlarged . . . 252
 movable kidney . . . 252
 night-haematuria . . . 366
 Riggs's disease (see Pyorrhoia Alveolaris)

RIGIDITY OF THE ABDOMEN 592

from acute peritonitis 121, 388, 425, 592, 767
 appendicitis . . . 677
 appendicular abscess 592
 colic . . . 425, 593
 diverticulitis . . . 453
 in infant . . . 321
 after injury . . . 593
 from nervousness . . . 592
 pleurisy . . . 593
 pneumonia . . . 593
 pyelitis . . . 451
 ruptured tubal gestation . . . 593
 suppurative nephritis 594
 of the back from aneurysm . . . 461
 arthritis of spine . . . 461
 fibrositis . . . 461
 infective arthritis . . . 461
 myeloma . . . 467
 typhoid . . . 161
 spinal caries 361, 429, 461, 681
 new growth . . . 461
 spondylitis deformans . . . 461, 714

in combined degenerations of cord . . . 139

degenerate . . . 139
 in Friedreich's ataxy . . . 139
 Rigidity, hemiplegia and 139, 303
 iliac, in appendicitis . . . 454
 from uterine colic . . . 454
 in lateral sclerosis . . . 139
 muscular, from bilateral cortical softening . . . 725
 in disseminated sclerosis . . . 728
 epilepsy . . . 729
 meningitis . . . 729
 paralysis agitans . . . 725
 polymyositis . . . 464
 from neck, from caries . . . 648
 fracture . . . 648
 in paralysis agitans . . . 236
 of spine, from caries . . . 713
 in spondylitis deformans . . . 712
 tenderness with . . . 448
 in transverse cord lesions 139

Rigor, description of typical 594

RIGORS 594

in anæmia Ludovici . . . 699
 in anæurotic œdema . . . 697
 absence of liver . . . 592
 after appendicitis 329, 682
 from bacteræmia . . . 70
 blood cultures in diagnosing cause of . . . 595
 in blood diseases . . . 596
 bronchæstasis . . . 598
 after childbirth . . . 596

Rings, cord.

- in treating albuminuria .. 714
- Rosary, in rickets .. 145, 167

Rose Bradford kidneys, general account

- after insulin-test .. 11
- start time .. 228
- Roselli, in tongue .. 166
- in albugo .. 560
- splanchnic 73, 324 (Fog, 170) 384, 615
- Rose spots in typhoid fever .. 76, 345, 561, 676
- Rosette crystals .. 711
- Rosstrae pelvis .. 187
- Rotheln (see Glycerin)
- (Moles)
- Rother's test for acetone 81**
- Round, ligament, ulgno .. 681
- in malarial deposits in .. 636, 657
- Round-worms .. 520
- Round worm case Asiatic (Lambdoides) .. 520
- Rowing, enlarged heart from .. 241
- Rowing men, albuminuria of 15**
- cramps in .. 150
- occupation muscles in 176
- pain in shoulder in .. 176
- tenderness of spine in 715
- Rowlands, R. P., illustration of .. 141
- Rub, in perspiration .. 213
- pentonite 34, 373, 788, 592
- over liver .. 388, 592
- over spleen .. 388, 592
- over spleen infarct .. 629, 640
- in pneumonia .. 335
- over pulmonary infarct .. 160
- over subpharyngeal disease .. 658
- (and see Eric's sound)
- Rubber workers, acute atrophy in .. 334
- chloride of sulphur used by .. 334
- Rubella, various .. 222
- Rubella (see Measles)
- Rubro-pinal infarction, of .. 729
- Rummation case Myrvisio .. 467
- Rimming, as an act of eye .. 47
- enlarged heart from .. 214
- at eyes (see eryth)
- at nose (see Discharge, Nasal) .. 178
- Rupia, in syphilis 600, 601**
- Rupret (see Herpes)
- Rupture of aortic valve, general account of 208, 210**
- bladder .. 278
- heart .. 217
- spleen .. 611
- Ruptured tubal gestation (see Ectopic gestation)
- Rust, epidemic zymozoon in .. 259
- Rusty nail, tetanus from .. 599, 730
- spurium 119, 289, 611, 642
- Rye, enzootic from .. 259
- SABOURAUD, classification of endothelitis 218**
- on mucous membrane .. 250
- 250
- Saeh in ureter .. 552
- Saevulation of colon .. 657
- from obstruction .. 657
- Sacral plexus, diagram of 503**
- Sacral plexus, distribution of 498**
- growth involving .. 115
- Sacral plexus, muscle connections of 499**
- region, parazo oblique 489
- Sacral segments of cord, muscle connections of 499**
- Sacraglia, from pelvic lesions 468**
- Sacrotuberous abscess (see Abscess, Sacrotuberous)
- joint abscess, abscess in .. 680
- from .. 680
- backache from .. 469

- Sacrotuberous joint dis .. 680
- dilated to diste .. 318
- lipid-case simulated .. 364
- by .. 364
- lameness from .. 247, 343
- muscle-wasting with .. 63
- pain in the fossa .. 451
- from .. 451
- on joining hip .. 364
- simulating cauda .. 63
- spina tumora .. 63
- swelling in the fossa .. 665, 678
- from .. 665, 678
- Sacrum, abscess of, felt .. 587
- broken over .. 257
- examination of, per .. 581, 587
- from .. 581, 587
- Sacrum, fracture of 608**
- new growth of, felt per .. 587
- pain over .. 78, 680
- Sickness, appearance of, in .. 256
- tables dorsalis .. 736
- Sacrum, alkaloph, in .. 736
- in staining fat deposits .. 188
- Saffran test for sugar 262**
- Saffran capsules, in testing .. 191
- St. Gothard Tunnel, anky-
- lism in .. 521
- St. Vitus's dance (see Chorea)
- Sabalates in acute rheu-
- matism 34, 228, 339,
- 661, 614
- mamma from .. 745, 747
- black urine from .. 384
- brachyuria from .. 166
- albumin from .. 169
- effect on pyruvic acid in .. 149
- thionin in .. 29, 412
- 149, 338, 574
- erythema from .. 222
- ferric chloride reaction after .. 170
- growing pains relieved by .. 363
- head ache from .. 295
- in neuralgia of parvax in .. 338
- gonorrhoeal arthritis .. 311
- in gonorrhoeal arthritis .. 556
- rheumatoid arthritis (Fog, 452) 341
- - various forms of .. 339
- - nodes in the head from .. 723
- - tubitis from .. 170
- - urine after .. 744
- - urtica from .. 573
- - Salivary acid .. 554
- Saliva, blood-stained, in .. 143
- - causes effect of mercury on .. 542
- - deficient, from paralysis .. 491
- - dribbling of (see Dribbling of saliva, and Ptyalism)
- - not tinged by gamboge .. 324
- - Salivary calculus (see Calculus, Salivary)
- - glands, enlarged (Fog, 3) 25
- - from calculus .. 604
- - in albumen .. 556
- - amount .. 605
- - in infective parotitis .. 694
- - leukemic .. 685
- - lymphadenoma .. 685
- - lymphatic leukemia .. 685
- - Mendel's syndrome .. 685
- - mumps .. 617, 694
- - syphilis .. 685
- - tuberculosis .. 685
- - Salivation, from cholera .. 706
- - from parotitis .. 542
- - from mercury 73, 73, 726
- - in parotitis .. 101
- - pellagra .. 225
- - stomatitis .. 447
- - the donkey .. 447
- - (and see Ptyalism)

- sallowness, from disease of
 liver 352
 in oedema 99
 in uræmia 371
 Salol, black urine from . . . 745
 - carbolic from 746
 - ferric chloride reaction
 after 170
 glyceric acid from 261
 reduction by urine after
 urine after 370
 Salpingitis, appendicitis,
 simulated by 456
 - frequent micturition from . 294
 - generally bilateral 457
 - hamaturia from 274, 283
 - pain in hypochochium . . . 454
 - thiac fossa from
 452, 454, 456
 - pelvis from 468
 Salpingo-ophoritis, amenorrhœa from 19
 - dysmenorrhœa from 192
 - dyspareunia from 193, 194
 - ectopic gestation simulat-
 ing 690
 - endometriitis with 387
 Salpingo-ophoritis, general
 account of 690
 levator ani spasm from 493
 menorrhagia from 386, 387
 - pelvic adhesions from . . . 193
 - pelvic bone tumours simulat-
 ing 691
 - pain from 193
 - swelling due to 688
 - sterility from 646
 - swellings behind uterus
 from 193
 - vasomotor from 193
 Salpingopharyngeus, tick-
 ling in ear due to 723
 Salt, taste of 706
 - thirst from 720
 Salvarian, condylomata
 cured by 700
 - distress from 166
 - in diagnosing gonorrhœa . . . 250, 415
 - - syphilis 190, 550, 588, 739
 - - 418, 604, 622, 728, 739
 - erythema from 221
 - gonorrhœa of liver and 253
 - in pernicious anemia 226
 SAND, INTESTINAL 599
 - - (Plate XXIII) 598
 - under skin, sense as of,
 from cocaine 611
 Sandalwood oil, erythema
 from 222
 Santonin, alkali test for . . . 744
 - convulsions from 141
 - pink urine after 745
 - arteria from 744
 - yellow urine from 744
 - xanthopsia from 762
 Saphena varix, general ac-
 count of 675
 - - herma simulated 675, 680
 - - impulse on coughing in
 674, 675, 680
 - - venous thrombosis 8, 749
 Sarcina, haemoglobinuria
 from 284
 Sarcina, loss of weight
 from 769
 - - mior in 595
 - - with carcinoma of
 stomach 630, 767
 Sarcina ventriculi 115
 (Fig. 121) 211, 318,
 320, 655, 766
 Sarcoid, multiple benign . . . 405
 Sarcosina, alveolar, hyper-
 nephrosia and 356
 - of uterum 685
 - bacilliferous, blood-spur-
 ting due to 285
 - blood cysts in 673
 - of bone, abscess simulat-
 ed by 672
 - - calculus simulating 672
 - - central necrosis simulat-
 ing 668
 - enchondroma simulat-
 ing (Fig. 282) 671, 672
 - eosinophilia from 219
 Sarcosina, oval
 Sarcosina of bone, general
 account of 671
 - - metastasizing in lung from . 671
 - - microscope in dia-
 gnosing 672
 - - from osteitis deformans . . . 670
 - - osteitis simulating 693
 - - osteomyelitis simulated
 by 672
 - - pain in 671, 672
 - - rheumatism simulated
 by 672
 - - secondary in spine 714
 - - spontaneous fracture
 from 212, 243
 - - syphilis simulating
 669, 672
 - - x-rays in diagnosing
 668, 672, 693
 - brain, hemiparesis from 301
 - breast, age incidence of 687
 - - blood discharge from 181
 - - fibro-sarcoma simulat-
 ing 687
 - - exchæta from 413, 415
 - - of osseum, swelling in
 right iliac fossa from 665
 - cauda equina 662
 - cervical glands 380
 - cord, diagnosis by lumbar
 puncture 395
 - crista pectus, caries of pubis
 simulating 698
 Sarcosina, endosteal 672
 - - of eye, secondary in liver 365
 - - tumour, lumping from 365
 - - popliteal aneurysm
 simulated by 692
 - - skiagraph in diagnosing 692
 - - fibula, lumping from 362
 - - general wasting from 39
 - - of groin glands 680
 - - heart, heart-block from 83
 - - limb, pain in iliac fossa
 from 151, 160
 - - from injury 480
 - - of innominate bone 488
 - - scrotum simulated by 678
 Sarcosina of jaw 683, 684
 - - odontoma simulating 684
 - - spread to nose 179
 - - kidney, acting in loin
 from 278
 - - Cheyne-Stokes breath-
 ing from 108
 - - colic from 278
 - - hamaturia from 275, 278
 - - rarity of 355
 - - renal enlargement from 278
 - - secondary deposits in
 195
 - - simulating enlarged
 gall-bladder 252
 - - uremia from 198
 - - legs, hemiparesis from 287
 - - lay, ulceration of 738
 - - leucocytosis with 360
 - - of liver, ascites with
 16, 47, 52, 330
 - - lamella with 32, 330
 - - liver enlarged with
 32, 252, 330
 - - primary 374
 - - secondary to eye 374
 - - loss of weight from 262
 - - of lung, hemiparesis from
 287, 290
 - - secondary to bone 671
 - - to kidney 195
 - - to various primary
 growths 290
 - - skiagraph of (Fig. 12) 105
 - - mediastinum, bronchus
 elevated by 287
 - - hamaturia from 287
 - - hypothermia with
 (Fig. 113) 312
 - - inter-septular pain from 401
 - - pleural effusion from 312
 - - pyrexia from (Fig. 218) 570
 - - vena caval obstruc-
 tion by 751
 - - melanotic, in eye 253, 374, 379
 - - - black spots before
 eyes from 72
 Sarcosina, melanotic, oval
 - - in inguinal glands 381
 - - in liver 253, 374, 746
 - - secondary to eye 371
 - - melanoma from 374, 716
 - - from mole 379, 381
 - - of pre-auricular gland 379
 - - secondary in spine 711
 - - of skin 680
 - - of toe 381
 - - microscope in diagnosing
 74, 391, 588, 615, 672, 731
 - - mycosis fungoides simulat-
 ing 731
 Sarcosina, myeloid 672
 - - of bone 243
 - - jaw, bleeding gum from 72
 - - pytalism from 542
 - - (Figs. 286, 287) 673
 - - spine 618
 - - of neck, pyrexia from
 (Fig. 218) 579
 - - nose, discharge from 159
 - - osseum of legs from 113, 115
 - - of palate, microscope in
 diagnosing 588
 - - parotid gland 695
 - - pelvic 678
 - - aneurysm simulating 681
 - - sneral plexus invaded
 by 113
 - - salpingo-ophoritis simulat-
 ing by 691
 - - simulating cauda equina
 tumour 213
 - - periosteal, of frontal bone 494
 - - prolonged pyrexia from 563
 - - of prostate, petal ex-
 amination for 587
 - - pulsation in 693
 - - of radius, skiagraph of 672
 - - rib tenderness from 797
 - - Scarpa's triangle 676
 Sarcosina of skin 680, 731
 - - papules from 487
 - - spine, kyphosis from 154
 - - x-rays in diagnosing 154
 - - spleen, excessive rarity of 632
 - - sternum, tenderness of 707
 - - stomach, spleen simulat-
 ing 650
 - - tumour in epigastrium
 from 660
 - - suprarenal, secondary in
 cranial bones 711
 - - simulating enlarged
 gall-bladder 252
 Sarcosina of testis 480, 696
 - - thymus, vena caval ob-
 struction by 751
 - - tibia, lumping from 362
 - - skiagraph of 671
 - - tongue 698, 699
 - - tonsil 285, 615
 - - ulna, skiagraph of 672
 - - uterus, from fibroid 391, 690
 - - in girls 387
 - - menorrhagia from 387
 - - metrorrhagia from
 390, 391
 - - microscopic diagnosis 391
 - - stricture by 688
 - - rapid enlargement of
 uterus with 391
 - - of vertebra, inter-septular
 pain from 461
 - - vulval swelling from 700
 - - x-rays in diagnosing
 154, 668, 671, 672, 692, 693
 Sarcosinosis, chloroma
 - - allied to 556
 - - purpura in 553, 555
 Sartorius, nerve supply of
 498, 499
 Sartin-wood, bulla from 96
 - - dermatitis from 755
 - - erythema from 222
 - - pruritus from 540
 Saturday night palsy 65
 Saturnine encephalopathy
 - - Babinski's sign 119, 116, 117
 - - coma in 118, 114
 - - convulsions with 114
 Saunders, Dr. P. W., illus-
 tration supplied by 508
 Saviour 706
 Sawlust, dermatitis from 755
 - - pruritus from 540
 Sawyer's Physical Signs 94
 - - illustrations from 167
 Sawyers, serratus magnus
 paralysis in 506
 Scabies, bulle in 600
 - - eczema simulated by 755
 - - eosinophilia rare in 219
 - - face not affected in 755
 - - fingers affected by 239
 - - itching in 490, 540
 Scabies, notes on 755
 Scabies, parts affected in
 401, 563, 755
 - - prurigo distinguished
 from 490
 - - pustules in 558, 600
 - - scabs in 600, 753
 - - sand burrows in 562
 SCABS 599
 - - in anthrax 674
 - - dermatitis herpetiformis 755
 - - eczema 600
 - - over epithelioma 621
 - - in erythema iris 756
 - - multifloro 600
 - - herpes 431, 460
 - - impetigo 558, 600
 - - scabies 600
 - - from scratching 600
 - - in seborrhœa 600
 - - small-pox 561, 601
 - - syphilis 600
 - - yaws 601
 Scalding or micturition,
 from bacteriuria 70
 - - gonorrhœa 182, 700
 Scalds, albuminuria from 13
 - - bullæ from 96
 - - hyperpyrexia after 309
 Scales from belladonna 602
 - - carbolic acid 602
 - - drugs 602
 - - in eczema 488, 601, 602, 603
 - - mercurium 250
 - - erythema scarlatiniforme 602
 - - simplex 602
 - - from fevers 602
 Scales, general account of 601
 - - from ichthyosis 602
 - - iodine 602
 - - keratosis pilaris 601, 602
 - - lichen scrofulosorum 488
 - - lupus erythematosus 212,
 602, 603
 - - vulgaris 602, 603
 - - pemphigus foliaceus 601
 - - nice-like, in pityriasis
 rubra pilaris 458
 - - in mycosis fungoides 731
 - - pityriasis rosea 604
 - - rubra 601, 602
 - - - pilaris 488, 601, 604
 - - prurigo 490
 - - psoriasis 249, 488, 491, 601-3
 - - from quinine 602
 - - in ringworm 601
 - - scrofularia 601
 - - seborrhœa 600, 601, 602
 - - seborrhœic dermatitis 401
 - - eczema 242
 - - syphilis 190, 491, 601, 602
 - - tinea circinata 249
 - - umbreata 250
 - - tonsurus 602
 - - versicolor 250, 329, 601-2
 - - urticaria 602
 - - xeroderma 602
 - - (and see Desquamation)
 Scalp, fibroid aneurysm
 of (Plate XXXV) 694
 - - eczema, seborrhœic of 491
 - - epithelioma of 378
 - - favus affecting 246
 - - hyperæsthesia of, in
 neurasthenia 611
 - - inflammation, hyperæsthesia
 from 508
 - - multiple benign saroid 405
 - - nerve supply of (Fig. 290) 710
 - - pityriasis of 249
 - - psoriasis of 249, 603

Scalp, scalp
 - rheumatic nodules on 405, 732
Scalp, ringworm of 217, 248, 692
 - sebaceous cyst of 732
 - seborrhoeic eczema affecting 401, 693
 - segmental areas of (*Figs.* 292, 293) 712
 - some skin affections of 710
 - spherulids affecting 560
 - tender (see Tenderness in the Scalp)
 - varicella affecting the 756
 - warts from 599
SCALY ERUPTIONS 601
 - staining spots (see Spots in Scouting)
Scapula, pain under (see Pain in the Shoulder)
 - position of, in scrofula magna paraflexa 595, 596
 - systolic bruit below left 83
 - winged 506
Scar, epithelioma developing in 620
 - on head, in Jacksonian epilepsy 117
Scars, contracture from 143
 - are trophic from 229
 - from leucus 247
 - follicular decays in 71
 - headed granula (*Figs.* 227) 511, 737
 - after herpes zoster 131, 707
 - in leprosy 401
 - lupus 492
 - lupus erythematosus 71, 412, 217, 692, 693
 - multiple, benign, scarred 105
 - pigmented, from syphilis 560, 569
 - round mouth, in congenital syphilis 235
 - from small-pox 561
 - spherulids 560, 701
 - stripes from 114
Scarlet fever, acute endocarditis from 30, 209, 211
Scarlet fever, acute nephritis in 10, 14
 - rheumatic erythema 228
 - simulating 228
 - adenoid tonsil 10, 227
 - after 379, 617
Scarlet fever, albuminuria with 13, 14, 224, 227, 617
 - albuminuria in 16
 - angina and magna type of acute disease after 209
 - arthritis after 349
 - atypical rash in 227
 - bad tongue in 617
 - coma in 117
 - convulsions from 114
 - deafness from 166
 - delirium in 169
 - desquamation after 227
 - diagnosis from muscles 14
 - German measles 14, 228, 377
 - diarrhoea in 173
 - diffuse erythema resembling rash of 226
 - dilatation of heart in 214
 - empyema after 397
 - eosinophilia after 218
 - erythymatous 178
 - epistaxis from 229, 221
 - erythema in 227, 614
Scarlet fever, erythema exfoliativum simulating 227
 - simplex simulating 227
 - tuberculae representing 161
 - tooth disease simulating 229
 - gurgling 255
 - haemoglobinuria from 284
 - haemoptoea in 209
 - intertrichia from 189
 - infective arthritis after 648
 - Kikuchi's disease simulating 616
 - leucocytosis in 369
 - lysis in 227
 - malignant, delirium in 273

Scarlet fever, contd.
 - malignant, epistaxis in 273
 - haemolysis in 273
 - haematemesis from 265, 273
 - haematuria in 273
 - purpura in 273
 - pyrexia in 273
 - macules simulating 228
 - menorrhagia from 614, 765
 - nephritis from 3, 17, 14, 12, 614, 617
 - the sole evidence of 10
 - otitis media after 10, 617
 - orchitis from 227
 - pain in the limbs in 165
 - pale granular kidneys after 14
 - paraplegia from 516
 - peach-blossom faces in 228
 - peeling after 10, 614
 - purpura in 273, 553, 554
 - pyrexia in 227
 - rash of 228
 - without rash 10, 517
 - red throat in 227
 - rheumatic fever simulating 614
 - rizzoli in 595, 597
 - Rose Bradford kidney after 228
 - scales in 601, 692
 - simulated by choreo-pompholyx 97
 - after emmenia 224
 - small-pox simulating 560
 - softening of cord from 514, 517
 - sore throat in 224, 617, 617
 - spinal thrombosis from 516
 - spleen enlarged in 622, 637
 - strawberry tongue in 562
 - submaxillary gland enlarged from 379
 - testicular abscess in 622
 - tongue in 227, 562, 617
 - tonsillitis in 614
 - toxemia in 214
 - typhoid fever simulating by 637
 - urticaria simulating 774
 - valvular heart disease from 209, 185
 - vomiting in 224, 227, 614, 765
 - weak first sound in 214
Scarpa's triangle, hollow, with congenital dislocation of hip 156
 - swelling in (see Swelling, Femoral) 674
Scars, erythema from 222
Schönlein's disease, general account of 553
 - Schott's Naudem treatment, heart affection benefited by 185
Sciatic nerve (see Nerve, Sciatic)
Sciatica, acute brachitis, affixed to 177
 - ankle-berk lost in 438
 - from orchitis with 439
 - cauda equina tumour simulating 439
Sciatica, general account of 438
 - growth of unilateral 439
 - hip disease simulating 438
 - knee-jerk unaffected in 438
 - leg movements with 63
 - limbago with 438
 - lumbar puncture in 439
 - muscle wasting from 61, 63, 438
 - numbness in 438
 - osteo-arthritis causing 547
 - simulating 546
 - pain in the hip from 546
 - leg from 63, 438
 - pelvic disease simulating 438, 439
 - plantar reflex flexor in 438
 - R.D. from 61, 63
 - rectal examination in 438, 439

Scrotum, contd.
 - retroverted uterus simulating 449
 - fatness of 449
 - sarcoma of mimicking bone simulating 438
 - simulated by 62
 - epima tumour 439
 - skiagraphy in 439
 - sphincters in 439
 - spinal disease simulating 536
 - monogonitis simulating 515
 - spiculated 439
 - syphilis causing 147
 - tender spots of 438
 - tenderness in the leg from 63
 - on pressure in 436
 - urine examination in 439
 - vaginal examination in 438, 439
 - warts and 438
Scrofula 132, 139, 729
Scleroderma, anodosis with 654
 - distinction from leucoderma 529
 - eruption from 529
 - of lip 529
 - finger affected by 240
 - tricus arteriosus simulating by 599
 - tenderness of scalp from 710
Sclerosis, amyotrophic lateral (see Amyotrophic Lateral Sclerosis)
 - combined (see Combined Sclerosis of Cord)
 - disseminated (see Disseminated Sclerosis)
Sclerosis, primary lateral, general account of 517
 - (see Lateral Sclerosis)
Sclerotics, thickened in
 - achronosis 528
 - blue, with brittle bones 242
 - bluish, in chlorosis 274
 - Sclerosis, cause of 188
 - from fibrous lung 168, 216
 - in Friedreich's disease 149, 312
 - from short sight 515
 - in varicose veins 110, 350, 508
 - with warty 617
 - (see also Spine, Lateral Curvature of)
Scrofula (see Scapula)
Scrofula, black spot before eye from 760
 - central, from alcohol 760
 - from toxal 759
 - in disseminated sclerosis 517, 760
Scrofula, central, general account of 760
 - in hereditary optic atrophy 760
 - in lupus with 552
 - from lead 759
 - in malarial 759, 760
 - retrobulbar neuritis 760, 762
 - tobacco 759, 760
 - bacterial 760
 - penimeter in locating 760
 - from pigment in retina 760
 - retinal hemorrhage 760
 - ring, in macular 759
Scott, Dr., & Gilbert, skin 143
Scrofula, erysipelas from 568
 - Scrofulum, in hysteria 327
 - infants 131
 - from edema 117
 - from pyo-sequation 78
 - at night, from tuberculosis 547
 - in rickets 145
Scrofula 755
 - burnt de chloride in 725
Scrofuloderma, caecum, thick with 405
 - distinction from lupus 405
Scrofuloderma, general account of 459
 - lupus simulated by 492
 - syphilis distinguished from 405
 - Wassermann's test with 559

Scrofula, affections of skin
 - of 695
 - chancre of 621
 - epithelioma of 621, 623, 695
 - excitation of urine into 470
 - fistula in (see Fistula, Scrofula)
 - fungous tubercles on 621
 - mycetozoa of 732
 - myxoma of 621, 623
 - papilloma of 621, 623
 - pruritus of 549
 - scabies affecting 401
 - sebaceous cyst of 623
 - sinus of 622, 696
Scrotum, sores of 621
Scrotum, ulcers of 179, 621, 696
 - sweep's ulcer of 731
 - swelling in (see Swelling, Scrotum)
Scrotum, syphilis of 621, 696
Scruva, thymosarcoma with 46
 - jaundice from 58, 72, 273
 - leucoid gums in 74, 296
 - bromidrosis in 654
 - bulle in 96, 97
Scurvy, in children 72, 99, 556
 - diet and 72, 27, 29
 - epistaxis from 221
 - from not fresh vegetables 556
 - haematemesis in 266, 273
 - haematuria in 275, 283
 - haemoptysis in 287
 - haemorrhage into tongue 698
 - haemorrhages in 556
 - haemorrhagic swellings in 556
 - calves in 29
 - infantile, anaemia in 99
 - bleeding gums in 99
 - bones painful in 99
 - cachexia in 99
 - night sweats in 654
 - antiperistaltic hemorrhages in 99
 - microhaemia from 286, 287
 - metrorrhagia from 290, 292
 - oedematous from 765
 - periorbital hemorrhages 28, 92, 99
 - purpura in 72, 273, 553, 556
 - rickets of 29, 72
 - on ships 29, 72
 - sponge gums in 38, 273, 556
 - stomatitis in 72, 212
 - subcutaneous indurations in 273
 - tender bones in 72
 - tongue swollen in 698
Scurvy-rickets 38, 670
 - age in absence of 670
 - anaemia in 670
 - loss of presence of 670
 - diet and in 39, 670
 - hamorrhages in 670
 - painful bones in 670
 - periarthritis simulated by 670
 - spotty gums in 670
 - spontaneous fracture of 670
 - swelling on bone in 670
 - tenderness of bones in 38
Scybal, appendicitis simulated by 665
 - bit in bowel 121, 657, 666
 - of hepatic flexure 659
 - from mucous colitis 415
 - in spastic constipation 424
Scrofula, prokts, erythema from 222, 221
 - festering sores from 221
 - haemolysis from 221
 - osdena from 221
 - vomiting from 221
Sea-bike dwarfism 188
Seamen, beriberi in 411
Sea-mosses, actinomycosis in 645
 - cramp in 151
 - sporotrichosis in 299
Seasickness 765
 - headache from 296
Sebaceous cyst (see Cyst, Sebaceous)
 - of face 673
 - of 623

Shallots, foul taste from . . . 705
 Shams, blushing from . . . 241
 Sheep, distoma hepaticum
 in . . . 328
**Shelf, rectal, in abdominal
 malignant disease** . . . 587
 Shells, artery . . . 137
 Shell-fish poisoning, oedema
 from . . . 115
 — in urticae and . . . 49
 Sherman, on anaesthesia
 (Fig. 257) . . . 606
 Sherrington, decerebrate
 rigidity of . . . 139
 Shiga's bacillus, in dysen-
 tery . . . 172, 176
 Shingles (see Herpes)
 Shine, erythema nodosum
 affecting . . . 668
 Ships, beriberi on . . . 64
 — scurvy on . . . 39, 72
 Shivering . . . 594
 — from bilious colic . . . 116
 — from gall-stone . . . 147
 — and see Tremor
 Shock, from acute pneu-
 monia . . . 436
 — anuria from . . . 12
 — atelectasis after . . . 142
 — coldness from . . . 71
 — from blow on epigastrum
 back from . . . 81, 85
 — constipation from . . . 124
 — delirium from . . . 169
 — diabetes insipidus from . . . 547
 — distal, with adherent
 peritonium . . . 213
 — dyspnoea from . . . 249
 — from traumatic appen-
 dicitis . . . 136
 — hypochondria after . . . 341
 — with intestinal obstruc-
 tion . . . 131
 — paroxysmal tachycardia
 from . . . 703
 — from perforated diaphragm
 ulcer . . . 436
 — gastric ulcer . . . 436
 — pyelorrhagia from . . . 443
 — from semicircular cartilage
 injury . . . 765
 — sudden nervous, coma
 from . . . 418
 — from testis injury . . . 765
 — vomiting from . . . 765
 Short, Dr. A. Bondle, illus-
 trations by . . . 241
SHORTNESS OF BREATH 87
 from aneurism . . . 87
 ankylostomiasis . . . 621
 anoplague conditions
 . . . 87, 89
 bad air . . . 89
 bronchitis . . . 85, 88
 bronchopneumonia . . . 88
 in cirrhosis . . . 89
 from chest deformities . . . 89
 chronic nephritis . . . 137
 — nephritis . . . 11
 in oedema . . . 88
 cough and . . . 150
 from deformity of chest . . . 87
 in diabetes . . . 87, 88
 — from emphysema . . . 85, 89
 fatty heart . . . 53
 in levers . . . 87
 first sign of pleural
 effusion . . . 88
 — from irritating endo-
 carditis . . . 87
 — Graves's disease . . . 87
 — from laryngitis . . . 87
**Shortness of breath, from
 heart conditions** . . . 78, 88
 in bulimia . . . 87
 lung pneumonia . . . 88
 lung conditions . . . 87
 — an aneurism . . . 89
 with myocardial affec-
 tion . . . 14, 85, 90
 — overness . . . 88
 in neurasthenia . . . 88
 from obesity . . . 77
 partial asphyxia . . . 89
 in tetralogy . . . 141
 — pericarditis . . . 87
 pleuritis . . . 88

Shortness of breath, contd.
 — pleurisy . . . 89
 — polycythemia . . . 87
 — from Pott's curvature . . . 89
 — renal affections . . . 88
 — splenomegaly . . . 633
 — syphilis . . . 633
 — subphrenic abscess . . . 658
 — in uraemia . . . 87
 Shoulder, atelectasis of . . . 133
 — atrophy of muscles of, in
 amyotrophic lateral
 sclerosis . . . 508
 — blade, pain under (see
 Pain in the Shoulder)
 chloroform effecting . . . 131
 definition of . . . 175
 depressed, from fibroid
 ring . . . 246
 fall on, Fild's paper from . . . 507
Shoulder, fibrosis of . . . 475
 lowered, from hypodermic
 mycetoma . . . 136
 myopathy of . . . 514
Shoulder, myositis of . . . 475
 — occupation metritis of . . . 476
 — pain in (see Pain in the
 Shoulder)
 — pneumococcal arthritis of . . . 339
 — shaming to . . . 136
 — sore on, inflamed axillary
 glands from . . . 180
 — Spengler's, scrofula from . . . 353
 — tuberculous disease of . . . 247
 — wasting of, from poly-
 myelitis (Fig. 10) . . . 59
Shoulder-joint, arthritis of
 . . . 475, 476
 — neuritis simulated by . . . 506
 — effect of bacillus on . . . 477
**Shoulder-joint, method of
 testing movement in** . . . 475
 osteo-arthritis of . . . 515
 rarity of joint of . . . 515
 synovitis of . . . 514
 Shoulders, asymmetry of
 high and, separate, in
 emphysema . . . 167
 — low affecting . . . 549
 linear abrasions on . . . 365
 local fatness of, in
 Bierman's disease . . . 410
 — multiple benign seroid
 affecting . . . 405
 pain between (see Pain,
 Intercostal)
 — epiphysitis of . . . 499
 Sir Philip's membrane, per-
 foration of . . . 123
 Slender, in stools . . . 172, 399, 478
 Slingshot, the . . . 136
 Smiling gait in paralysis
 agitans . . . 198
 Slowness, blushing from . . . 241
 Solly, Kalyasar in . . . 653
 Sock, beddicable, gastric ob-
 struction stopped by . . . 526
**Sick headache, general
 account of** . . . 526
 — epiphysitis . . . 255
 — hereditary . . . 526
 — hyperaemia from . . . 398, 399
 — migratory and . . . 526
 — photophobia in . . . 525, 526
 — rigor in . . . 595
 — vomiting from . . . 526
 Sickness (see Vomiting)
 Sickness, sleeping (see Sleep-
 ing Sickness)
 — siderosis . . . 288
 Siedler's epiphysitis, in Gall's
 test . . . 165
 Sight, impairment of, from
 phthisis . . . 34
 — loss of, from cerebral
 tumour . . . 98
 — retrobulbar neuritis . . . 145
 — short, kyphosis from . . . 155
 — and see Blindness; and
 Vision, Defects of
 Sight, repulsive, vomiting
 due to . . . 765
 Sigmond colon, carcinoma
 of (see Carcinoma of
 sigmoid)
 — dilated . . . 676
 — in rectum distending . . . 676

Sigmoid colon, contd.
 — palpable . . . 666, 676
 — sigmoid in . . . 666
 — thickened in colitis . . . 676
 — tuberculous . . . 667
 — sinus, thrombosis of . . . 537
 sigmoidoscopy in ascites . . . 49
 — diagnosing adenoma . . . 719
 — carcinoma of bowel
 . . . 77, 78, 126, 129,
 142, 585, 676
 — of sigmoid . . . 676
 — of arch of colon . . . 172
 — cause of obstruction
 . . . 211, 316
 — in pus in stools . . . 557
 — colitis . . . 76, 78, 172, 717
 — diverticula . . . 125
 — sigmoid . . . 125
 — intestinal obstruction . . . 459
 — in diarrhea . . . 170
 — cases of bearing-down
 pain . . . 127
 — tenesmus . . . 718
Sign, Braun's, of pregnancy 393
 — Stigm, Chevostek's . . . 393
 — in tetany . . . 152
 — Hüllerynple's . . . 722
 — Kild's in tetany . . . 152
Sign, Hegar's, of pregnancy 393
 — Kery's in metritis . . . 152
 — of Hegar . . . 611
Sign, Meubius's . . . 215, 229
Sign, Rosenber's . . . 57, 609
Sign, Stellweg's . . . 215, 229, 722
 — Trousseau's . . . 13, 151, 152
Sign, von Graefe's . . . 229, 722
 Signs, proper names
 — associated with (see end
 of Index)
 Silesia, in intestinal smel . . . 599
 Silexosis . . . 288
 Silken creptus . . . 152
 silver nitrate, alkaloid and . . . 746
 — uretra from . . . 729
 — in irritating bladder . . . 277
 — testing for chlorides . . . 376
 — as vesical styptic . . . 589
 — in spraying radium . . . 223
 Sin, the unardonable . . . 495
 Singing in the ears, in
 arteriosclerosis . . . 11
 — head in insanity . . . 495
 — (see Noses in the Head)
 Sinu-auricular node . . . 546
 — rhythm, slow . . . 515
 Sinus, atrial, (see Atrium
 of Heart)
Sinus arrhythmias . . . 545
 — cavernous, uterine com-
 munication with . . . 604
 — emissary vein from . . . 229
 — thrombosed (see Throm-
 bosis of Cavernous
 Sinus)
 — of breast, from tubercle
 . . . 686
 — from emphysema . . . 635
 — ethmoidal, blood-spitting
 from lesions of . . . 285
 — distended, orbit dis-
 tending from . . . 239
 — infected, foul taste
 from . . . 705
 — inflammation, central
 disease simulating . . . 463
 — foul taste from . . . 705
 — nasal discharge from
 . . . 179, 181
 — suppuration in, head-
 ache from . . . 294
 — meningitis from . . . 596
 — of breast, distal case Antrum
 of . . . 299
 — frontal, blood-spitting
 from lesions of . . . 285
 — disease of, cerebral
 abscess from . . . 147, 592
 — from nose, due to . . . 179
 — distended, orbit dis-
 tending from . . . 239
 — pain over eyebrow
 from . . . 209, 449
Sinus, frontal, empyema of 180
 — cerebral with . . . 204
 — infectious, . . . 671
 — infectious, central disease
 — simulating . . . 163
 — foul taste from . . . 705

Sinus, frontal, contd.
 — infected, headache
 from . . . 294
 — — subjective smells
 from . . . 612
 — infection, foul taste from
 lateral, eroded . . . 121
 — thrombosed (see Throm-
 bosis of Lateral
 Sinus)
 — in stork, suppuration in,
 headache from . . . 294
 — perimed, from prostatic
 abscess . . . 620
 — tuberculous, prostate . . . 620
 — from periostitis . . . 668
 — serous, from testicular
 abscess . . . 622
 — from tubercle . . . 622, 696
 — sigmoid, thrombosis of . . . 597
 — sphenoidal, blood-spitting
 from lesions of . . . 285
 — infected, foul taste
 from . . . 705
 — headache from . . . 294
 — intracranial swelling
 from . . . 251
 — meningitis from . . . 596
 — nasal discharge from
 . . . 179, 181
 — optic atrophy from . . . 251
 — neuritis from . . . 251
 — polyp from . . . 251
 — proptosis from . . . 251
 — from spinal curv . . . 665
 — superior longitudinal,
 emissary vein from . . . 229
 — thrombosis of (see
 Thrombosis)
 Sinuses, bone, aneurism with . . . 55
 — joint, osseum with . . . 55
 — nasal, distended, blind-
 ness from . . . 762
 — — epiphysitis from . . . 229, 230
 — orbital, tubercle simu-
 lating . . . 220
 — supporting, earache
 from . . . 292
 — thrombosis from . . . 229
 in neck, from actinomy-
 cosis . . . 683
 Sixth nerve paralysis (see
 Paralysis of Sixth
 Nerve)
Size, abnormal sensations of 763
Skeletal dwarfism 186
 Silesia's tubes, aneurism in . . . 187
 Skiagram of aneurism (Fig.
 100) . . . 209, 455
 — of bean in bronchus . . . 195
 — bismuth shadow pneumonia
 of asphyxias . . . 196
 — in normal colon . . . 126
 — bone carcinoma in rheu-
 matoid arthritis . . . 544
 — carcinoma of spleen
 diverting . . . 125
 — stomach . . . 209, 270
 — Charcot's hip . . . 350
 — change periostitis . . . 668
 — cervical rib (Figs. 186,
 187) . . . 445
 — dropped stomach . . . 318
 — endothoracic of hand . . . 671
 — exostosis of femur . . . 670
 — gall-stones . . . 327
 — hairy hands . . . 346
 — hands in acute rheu-
 matoid arthritis . . . 542
 — hour glass stomach (Fig.
 129) . . . 298
 — lateral cyst of lung . . . 291
 — idiopathic dilatation of
 aneurysms . . . 198
 — normal pneumonia . . . 289
 — normal stomach . . . 269
 — pads on fingers . . . 347
 — phthisis . . . (Fig. 11) 106
 — pyelography in hydro-
 nephrosis . . . 556
 — pyroantimonious . . . 279
 — renal calculus from . . . 184
 — carcinoma of lung . . . 672, 673
 — rib . . . 672, 673
 — ribs . . . 674
 — spine on . . . 675
 — 449

- Skin, appearance in jaundice* . . . 324
- Skin, benign tumours of** . . . 732
- brown paper, in prurigo . . . 490
 - blood crusts on, from jaundice . . . 324
 - capillary pulsation in . . . 297
 - coarse, in eczema . . . 254

- paralysis of bowel from .. 389
- prostatic defaecation from .. 315
- incontinence with .. 314
- rigidity from .. 439
- Spinal cord lesions, sensory disturbances with .. 607**
- stiff (peloid) fissure from .. 507
- pupal from .. 507
- in Galles .. 57
- trypsinites from .. 389
- urine stream changes from .. 391
- oedema of, alcohemia from .. 17
- oedema of, ataxia from .. 58
- Brown-Sequard phenomenon from 58, 426

Spinal cord, contd.

- neurop-in of, paralysis of one leg from .. 495
- pachymeningitis of .. 516
- reflex centrus in (Fog. 211) .. 518
- sarcoma of .. 305
- sensory localization in (Fog. 210) .. 518
- tracts in 55, (Fog. 258) 607
- softening of, alcohemia from .. 17
- from enteric .. 516
- from injury .. 319
- paraplegia from .. 516
- penile erection absent from .. 313
- from scarlet fever .. 516
- syphilis .. 516
- thrombosis .. 516
- not tinged by jaundice .. 324
- tumour of, atrophic: paralysis of arm from .. 509
- paralysis of one leg from .. 500
- spastic paraplegia .. 509
- spinal endarteritis .. 17
- gliosis, pain in arm from 413
- lesions, scrotica simulated by .. 438, 439
- x-rays in diagnosing .. 461
- meningitis, tumour of, hyperosthosis from 610
- segment, 5th cervical, effect of lesion of .. 507
- 6th cervical, effect of lesion of .. 507
- 7th cervical, effect of lesion of .. 507
- 8th cervical, effect of lesion at .. 501, 507
- 1st dorsal, effect of lesion at .. 501, 507
- Spinal segments, cervical, muscle distribution of 509**
- Spinal segments, cervical, muscles supplied by .. 504**
- lumbar, muscle combinations of .. 498
- lumbar plexus and .. 498
- sacral, muscle combinations of .. 498
- sacral plexus and .. 498
- thrombosis (see Thrombosis, Spinal)
- tumour, pain in arm from 413
- Spinati, paralysis of, in Erb's palsy .. 509
- root intervention of .. 507
- Spindled fingers, in rheumatoid arthritis (Fog. 153) 542, 578
- Spine, actinomycosis of .. 713, 714
- aneurysm eroding .. 516, 661, 670
- carcinoma of 154, 467, 648
- caries of (see Spinal Caries)
- congenital defect of .. 713
- SPINE, CURVATURE OF 153**
- angular, from aneurysm .. 714
- new growth .. 714
- tubercle .. 715
- asymmetrical chest from .. 168
- from caries .. 618
- dwarfism from .. 684, 721
- liver depressed by .. 567
- Pott's, shortness of: both from .. 89
- abscess with .. 675
- in rickets .. 187, 714
- syringomyelia 257, 508
- and see Kyphosis; Lordosis; and Scoliosis
- Spine, entasement of .. 499**
- coded by aneurysm 434, 713
- pain in testis from 483
- by metastatic new growth .. 474
- fracture of (see Fracture of Spine)

Spine, contd.

- growth of, kyphosis from 154
- pain in the back from 428
- prominence of back from .. 469
- hydratal of 154, 155, 632, 714
- kyphosis from .. 154
- tenderness of spine from .. 714
- hyperosthosis of, in neurasthemia .. 611
- Spine, hysterical .. 715**
- Spine, infective arthritis of 648**
- inter-spinal pain .. 161
- pain in iliac fossa from .. 152, 514
- Spine, injury of, effects of 715**
- (and see Injury)
- invaded by new growth .. 713
- irritable .. 715
- Spine, lateral curvature of (and see Scoliosis) .. 153**
- backache from .. 428
- in hunters' boys .. 154
- from caries .. 154
- caries simulated by .. 429
- from diptheria 153, 154
- emphysema .. 153
- fibroid lung .. 155
- in Friedrich's ataxy 154
- from hysteria .. 153
- infantile paralysis 153
- myopathy .. 153, 154
- in mus-sicals .. 154
- occupation and .. 154
- from paralysis of back muscles .. 153
- peripheral neuritis .. 153, 154
- rickets .. 153, 154
- sore throat .. 154
- Sprengel's shoulder .. 153
- unequal legs .. 153
- weak back .. 153
- weight carrying 153, 154
- wry-neck .. 153, 154
- lumbar, injury to, sciatic nerve paralysis from 113
- talipes from .. 113
- malignant disease of, pain in arm from .. 413
- testis from .. 483
- nervous, swelling in the fossa from .. 678
- new growth of, aneurysm simulating .. 714
- angular curvature .. 714
- backache from .. 469
- caries simulating .. 516
- girdle pain from .. 714
- intercostal neuralgia simulated by .. 707
- malnourishing simulated by .. 714
- pain in back from .. 714
- neck from .. 648
- shoulder from .. 475
- umbilicus from .. 484
- paralysis of one leg .. 499
- paraplegia from 514, 714
- post-mortem diagnosis of .. 516
- primary very rare .. 516
- from prostate .. 714
- rigidity of back from 461
- root-palsies from .. 509
- from sarcoma .. 714
- secondary to breast .. 516, 648, 714
- thyroid .. 618, 721
- simulating neuritis .. 477
- spastic paraplegia from .. 113
- spinal caries simulated by .. 618
- simulating .. 714
- stiff neck from .. 618
- from testis .. 714
- transverse myelitis from .. 516
- x-rays in diagnosing .. 461, 477, 481
- ois oculos .. 449, 671
- skiagram of .. 449
- osteo arthritis affecting .. 515, 516

Spleen, contd.

- osteo-arthritis of, pain in iliac fossa from .. 452, 454
- penetrating wound of, acute bed-sore from .. 258
- peritonitis of .. 715
- Spleen, railway .. 715**
- rarity of gout of .. 315
- pyramic abscess of .. 713
- rheumatoid arthritis of .. 343
- rigidity of, with caries .. 154
- from Pott's disease .. 116
- spontaneously deformans 648
- sarcoma of .. 151
- tender (see Tenderness in the Spleen)
- tuberculous disease of .. 347
- in anaemia from .. 312
- (and see Spinal Caries)
- Spleen, typhoid .. 340**
- Spuno-cerebellar ataxy, tremor in .. 727
- SPIRALS, CURSCHMANN'S 153**
- Spirilla, in Vincent's angina 611
- Spirillum, of relapsing fever (Plate XXVII) .. 611
- of Vincent's angina (Plate XXVIII) .. 611
- Spirochaetes, in chancre .. 618, 674
- syphilis .. 739
- Spirochaeta obermeieri, in blood films .. 637
- pallida (Plate XXVIII) .. 614
- Spirochaeta obermeieri, characters of .. 28**
- figure of (Plate XXVIII) 611
- Leishman's stain for .. 28
- in relapsing fever 287
- in .. 336, 596, 637
- pallida, in cerebrospinal fluid .. 305
- from chancre 619, 620, 701
- fixing method for .. 701
- rheumatoid arthritis from .. 53
- sore throat due to .. 613
- stains for .. 701
- in syphilis .. 73, 334, 697
- stain for .. 388
- Sprague of blood (see Hamoptysis)
- Splanchnic vessels, arterio-sclerosis of .. 1
- Splashing, gastric (see Succussion)
- Spleen, abscess of (see Abscess of Spleen)
- carcinoma rare in .. 632
- dipping over .. 44
- dislocation of 629, 630, 611
- embolism of (see Embolism of Spleen)
- Spleen, enlarged, heart disease and .. 632**
- in Hodgkin's disease .. 37, 55, 61, 376, 580, 669
- impacted in pelvis .. 628
- from injury .. 641
- in kala-azar .. 29
- Spleen, enlarged, kidney simulated by .. 353, 662**
- simulating .. 664
- laparotomy in diagnosis of .. 662
- in Marfan's disease .. 8, 35, 375, 635
- leukæmia, 24, 55, 61, 99, 273, 283, 570, 611
- Spleen, enlarged, list of causes of .. 631, 632**
- in lymphadenoma 51, 329, 679
- lymphatic leukæmia .. 25, 51, 556
- in malaria 273, 274, 508, 637
- Malta fever 466, 566, 637
- movement with respiration .. 629
- Spleen, enlarged, notes on 662, 664**
- omental tumour simulating .. 661
- ovarian tumour simulating .. 620

- Stain*, *Stain* 21
 — for malaria parasites 157
 Nussard's 644
 — alpha-theta bacilli and Romanowsky's, for malarial parasites 568
- Stain, Ziehl-Neelsen, technique of** 641
- Staining of skin, after eczema 602
 — brown (see Pigmentation of Skin)
- after herpes 640, 754
 — psoriasis 603
 — from syphilis 608
 stains, for fat droplets 128
- Stammering** 608
Stammering bladder 395
- Stapes, muscle, paralysis of 493, 494
 Stapes, foot fixed, sounds heard better in noise with 465
 — test for 465
 — pressure on, dullness from 553
- Staphylococci (*Staf*)
 — in ascitic fluid 48
 — lacturaria 65
 — long swelling from 267
 — in cerebrospinal fluid 405
 — empyema from 471
 — epididymo-orchitis due to 108
 — in impetigo 558
 — laryngitis from 650
 — membranous conjunctivitis from 231
 — meningitis from 305
 — nasal discharge due to 178
 — orchitis due to 67
 — pemphigus neonatorum due to 97
 — in phthisis 641
 — pyelitis from 576
 — recovered by blood culture 597
 — rheumatoid arthritis from septicemia from 335
 — sore throat due to 643
 — suffocative laryngitis from 616
 — in syphilis 358
 — urethritis from 681
 — urethritis from 70, 182, 581
 — in urine 689
- Staphylococcus pyogenes albus, in furuncles 422
 — in normal urethra 69
 — in otitis media 422
 — urethritis due to 70
 — in furuncles 422
 — infective embolism 209

 — mothy, currents in testing 320
 — normal capacity of 244
 — perpendicular position 244
 — site of 663
 — skiagrams of 245, 269
 — paralysis of 173
 — percussion, little value of 244
 — sarcoma of 630, 660
- Stomach succussion, general account of** 174, 241, 244, 322, 651, 652, 653
 — size of, moles of determining 241
 — tube, in diagnosing pyloric obstruction 124, 245
 — ulcer of (see Gastric Ulcer)
 — various branches to 148
 — rays and bismuth in outlining (see X-rays)
- Stomach-ache, spinal curv simulated by 151
- Stomatitis, acute gastritis from 267
 — of base of tongue in 498
- Stomatitis, anithous** 740
 — bacteriology in diagnosing nature of 542
 — bleeding from 72, 74
 — blood-spitting from 285
 — with dermatitis herpetiformis 74
 — dysphagia from 74, 198
 — with erythema bullosum 74
 — foul breath from 74, 87
 — taste from 705
- Stomatitis, general account of** 74
 — inflamed neck glands 379
 — lips swollen from 74
 — from mercury 33, 73, 74, 726
 — microscope in diagnosing nature of 542
 — from sodium alkalies 74
 — pain from 74
 — perleche with 366
 — with pemphigus 74
 — from phosphorus 73
 — ptyalism from 542
 — salivation from 74
 — in scurvy 72
 — sprue 172
 — from syphilis 73
 — taste loss from 705
 — tongue swollen from 74, 699
 — tuberculous 738
 — ulcer of tongue from 542
- Stomatitis, ulcerative** 740
- Stomatitis, varieties of** 542
 — Wassermann's test in diagnosing nature of 542
- Stone (see Calculus)
- Stomachoscopy, hinc, hæmorrhoids from 286
- Stools, abundant, in hypopituitarism 410
 — acid, from fermentation 170

Swelling in the fossa, cont.

- - - right, from lip-point disease 665, 678
 - - - hydrated . . . 678
 - - - due abscess . . . 665
 - - - impacted . . . 665
 - - - infarction . . . 678
 - - - kidney . . . 678
 - - - local peritonitis . . . 665
 - - - movable kidney . . . 665
 - - - osteomyelitis . . . 678
 - - - pharyngeal tumour . . . 659
 - - - psoas abscess . . . 665
 - - - Riedel's lobe . . . 678
 - - - retrochiloid point disease 665, 678
 - - - sarcoma . . . 678
 - - - of osseum . . . 665
 - - - spinal disease . . . 678
 - - - stomat . . . 678
 - - - tuberculous aetiology 677
 - - - glands . . . 677
 - - - wandering spleen . . . 678

SWELLING, INGUINAL 678

Swelling, inguinal 582, 664, 665, 666, 679, 680
 - testes causing . . . 681

SWELLING, INGUINO-SCROTAL 682

SWELLING OF THE JAW, LOWER 683

SWELLING OF THE JAW, UPPER 685

- in lumbar region, from enlarged spleen . . . 628

Swelling in lumbar region, left 664

- - - right . . . 662, 663

SWELLING, MAMMARY 685

- - in mastodynia . . . 431

- of muscles in rat-bite fever . . . 598

- neck, from thyroid-gland enlargement . . . 721

SWELLING, PELVIC 688

- - in erysipelas . . . 18

- - from extra-uterine gestation . . . 295

Swelling, pelvic, list of causes of 688

- - - rectal examination in diagnosis . . . 678

- - - rising into the fossa . . . 678

- - - from salpingo-oophoritis . . . 195

- - - vaginal examination in diagnosis . . . 678

- - - and see Pelvic Tumours

SWELLING, POPLITEAL 691

SWELLING, PULSATILE 693

- - aneurysm causing 76, 92, 93, 168, 208, 271, 331, 428, 429, 437, 469, 516, 693, 711, 729

- - egg-shell rickling with 150

- - meningococci causing 239

- - osteosarcoma causing 150, 152

SWELLING OF THE SALIVARY GLANDS 694

- - and see Salivary Glands

SWELLING, SCROTAL 695

- from hydrocele . . . 181

- - spermatocele . . . 181

- - and see Testis, Enlarged

SWELLING OF THE TONGUE 698

- unilateral, from carcinoma . . . 183

- - from cyst of epithelium . . . 183

- - mesenteric duct . . . 487

- - displacement of recti . . . 487

- - granuloma fissure . . . 487

- - hernia . . . 487

- - intertrigo . . . 487

- - new growth . . . 483

- - and see Tongue

Swelling in umbilical region 663

- from enlarged spleen . . . 628

- - due to pancreas . . . 661

- - from sarcoma of cyst tuberculous . . . 183

- - tuberculous . . . 183

- - tuberculous . . . 183

Swelling, contd.

SWELLING, VULVAL 699

- - Swimmer, cramps in 150

- - dead fingers in . . . 162

- - 600

- - Syccosis, ulcers in . . . 699

- - leprosy mimicking . . . 699

- - lips affected by . . . 699

- - pustules in . . . 557

- - fungiform distention of . . . 219

- - vulvitis, acute simulating . . . 559

- - crusts in . . . 559

Sycosis vulgaris, general account of 558

- - - not to be confused with 559

- - - parts affected by 558

- - - pustules in . . . 558

- - - sycophylosis in . . . 558

- - - sycophlebotomized 559

Symphathetic paralysis of cervical sympathetic 527

- - - pigmentation from irritation of . . . 527

Symptoms, proper names associated with (see end of Index)

Syncope in Addison's disease 33, 179

- - with fatty heart . . . 212, 213

- - from anaemia . . . 298

- - in heart block . . . 516, 519

- - myocardial changes . . . 200

- - in Stokes-Adams disease . . . 83, 516

- - thymic enlargement . . . 181

- - Symplicia from ribs . . . 72, 232

Synovial membrane, genua of 318

Synovitis of ankle, pain from 478

- - - crepitus from . . . 152

- - - gonorrhoeal (see Arthritis, Gonorrhoeal) . . . 298

- - - infective, anemia with 32

 - survey-riekers 38
 - secondary syphilis 669
 - cysteæ meningitis 467
 - syphilis 615
 - of breast, from mastitis 683, 686
 - in mastodynia 706
TENDERNESS IN THE CHEST 431
 - from diaphragm lesions 709
 - liver abscess 709
 - in pleurisy 423
 - from stomach lesions 709
 - over colon, in colitis 78, 663
 - along diaphragm insertion, from neuralgia 431
 - of ear, from furuncle 422
 - epiphysitis 697
 - epigastrum, diffuse, from gastritis 457
 - with diaphragm ulcers 37
 - with cystitis 299
 - gastritis 287
 - liver lesions 709
 - local, from gastro-ulcer from pancreatitis 664
 - in phosphorus poisoning 356
 - from stomach lesions 719
 - subdiaphragmatic abscesses 658
 - eye, from retrobulbar neuritis 566
 - eyelids, in glaucoma 562
 - over eyelids, from frontal sinus distention 250
 - of feet, in erythromelalgia 411

Tender *ss.*, *contd.*
 - from frontal sinus empyema 180
 - of gall-bladder, from gall-stones 291, 437
 - from cholecystitis 597
 - if inflated 522
 - general, in cerebrospinal meningitis 591
 - gluteal, in sciatica 438
 - of gum, with aurital abscess 462
 - head, from neuralgia 296
 - from herpes 754
 - in hypostœgium, right, from liver lesions 709
 - hypocondrium, from subdiaphragmatic abscess 658
 - in phosphorus poisoning 336
 - hysterical 351
 - diarr. in appendicitis 454, 677
Tenderness, intercostal 707
 - over kidneys, from hæmaturia 70
 - legs, from peripheral neuritis 463
 - sciatia 463
 - from cholangitis 335, 569, 597
 - gall-stones 272
 - nutrient change 368
 - suppurative, pylophlebitis 596
 - tropical congestion 369
 - in loin, from pyelitis 556
 - with suppurative nephritis 594
 - from tuberculous kidney 579
 - tumor, in sciatica 438
 - over McBurney's spot 454
 - mastoid 292, 597
 - of metastases, in Morton's disease 439
 mid-orbital, from astigmatism 149
 - of mouth, from stomatitis 71
 - in muscles in hysteria 141
 - multiple neuritis 566
 - myalgia 131
 - from over-stim 465
 - in peripheral neuritis 440, 465
 - polymyositis 464
 - rheumatism 443
 - tetanus 152
 - tetany 151
 - over musculospiral nerve, in brachial neuritis 142
 - of neck, in Kirkland's disease 616
 - posterior triangle, in brachial neuritis 442
Tenderness, pain with 427
 - of pelvis, in erythema, Keritoides 492
 - over pancreas, from pancreatitis 767
 - of peri-stom, in infantile scurvy 556
 - from peripheral neuritis 607
 - psoasohal, in angina pectoris 708
 - heart disease 708
 - of prostate 182
 - rectal, from abscess 385
 - in sigmoiditis 454
 - renal, from pyelonephritis 576
 - stone 451
 - tubercle 355, 473
 - over vertebral joint 680
TENDERNESS IN THE SCALP 710
 - from cerebral tumour 711
 - compression 711
 - in diabetes 712
 - from hair lesions 712
 - hy-trepa 712
Tender *in the scalp.*
 list of causes of 710
 - from lung lesions 712
 - in malaria 712

Tenderness in the scalp. *contd.*
 - from meningitis 711
 - middle-ear suppuration 712
 - neuralgia 711
 - in neurasthenia 712
 - rheumatism 712
 - rickets 711
 - from stomach lesions 710
 - in syphilis 615, 711
Tenderness of scalp, various visceral causes of 712
 - sciatic, in sciatica 346, 438
 - scrotal, from perirectal abscess 697
 - in shoulder, from diaphragmatic pleurisy 709
 - from liver lesions 709
 - from subacromial bur-sitis 476
 - skin, from peripheral neuritis 465
 - skull, from cerebral disease 295
 - soles, in erythema keratoides 405
TENDERNESS IN THE SPINE 712
 - from abscess formation 714
 - from caries 154, 444
 - from hysteria 715
Tenderness of spine, after injury 715
Tenderness of spine, list of causes of 713
 - from Fott's disease 116
 - in rickets 711
 - from spondylitis deformans 711, 715
 - after typhoid fever 125
 - from visceral disease 716
 - vertebral growth 444
 - sternum 708
 - behind sternum, from osteophagial lesions 709
 - over superior maxilla, from aurium disease 180
 - of testis, from epididymo-orchitis 478
 - in the thigh, from anterior cruritis 439
 - over tuberculous bone 669
 - over aliar nerve, in brachial neuritis 442
 - over ureters, from bac-teruria 70
 - of ureters, from metritis 194
 - of vertebral spines, with caries 516
 - in valva, from kraurosis 701
 Tendon, injury of, contrac-ture from 143
 - ossification of 671
 - reflexes absent early in hemiplegia 503
 - sheathis, gonococcal in-fecton of 340
 - gout of 345
 - rheumatic nodules over 495
TENOSMUS 716
 - in acute infective diar-rhœa 717
 - from arsenic 717
 - atheroma 457
 - bearing-down pain with from carcinoma of sig-moid 666
 - in cholera 717
 - from colitis 171, 717
 - drugs 718
 - dysentery 76, 172, 716, 717
 - infantile diarrhœa 717
 - intussusception 663, 717
Tenosmus, local pelvic causes of, list of 718
 - from pericarpitis 719
 - ptomaine poisoning 717
Tenosmus from lacer 719
 - tuberculous of bowel 406
 - uric fruit 717
 - vesical (see Strangury) 719
 - from vesical calculus 719
 Tennis, plantaris longus rupture during 574
 Tennis-players, subacromial bur-sitis in 476

Tenosynovitis, crepitus from
 — 150, 152
 — melan-seed bodies in .. 152
 — pain in the hand from .. 151
 — water's crump simulated 151

Tensor tascie tenons,
 nerve supply of 498, 499

Teratoma of parotid gland 695

Tetosis major, nerve supply
 of .. 505
 — root innervation of .. 509
 — motor, nerve supply of .. 509
 — root innervation of .. 509

Terrae, pupil dilated by .. 551

Tertian malaria (see Malaria)

Test, acetic acid and boiling,
 for albumin 4
 — for phosphates .. 524

Test for Acetone (Plate XXXIV) .. 748
 — alkali, for erythronium
 acid .. 744
 — santonin .. 744
 — strychnin .. 743
 — ammonium sulphide, for
 lead .. 65

**Test for Bence-Jones's
 protein** .. 16

Test, benzinin, for blood .. 171

Test, Bial's .. 261

**Test, for bile pigment (Plate
 XXXV)** .. 750
 — for bile in stools .. 170
 — laurel, for albumose .. 16

**Test, bleaching powder, for
 indican** .. 314

**Test, boiling, for albumin,
 precautions in** .. 424
 — for boue conduction 164, 165

Test, Botlger's, for sugar .. 262
 — bromine, for melanuria .. 576
 — Cabot's, for tuberculin .. 573
 — Congo red .. 320
 — corrosive sublimate for
 urubulin .. 170

**Test, for diacetic acid
 (Plate XXXVI)** .. 170

Test, diazo .. 173

Test, Fehling's .. 261

Test, fermentation, for glucose .. 743

Test, fermentation, for sugar .. 262
 — form, for bile .. 743
 — Gellé's .. 165
 — Gmelin's, for bile pig-
 ment .. 743
 — guaiacum, for blood .. 19
 — indine in urine and .. 98

**Test, Günsberg's (Plate
 XXXVII)** .. 750

Test, Heller's .. 15
 — for albumose .. 16
 — Holmgren's, for colour
 blindness .. 262

**Test, Hupper's, for bile
 pigment** .. 743, 744
 — for indican (Plate
 XXXVIII) .. 743

Test, iodine, for bile pigment
 — iodine, for bile pigment

Test, Jaffe's, for indican .. 314

Test, Legal's, for acetone .. 3
 — Marsh's, for arsenic .. 575
 — Test meal, in chrome diazo-
 theon .. 170, 172
 — hydrochlorhydria .. 319
 — simple .. 319
 — meals, importance of .. 320
 — methyl orange .. 292
 — Moore's, alkalapon and .. 262
 — indican and .. 262

Test, Moore's, for sugar
 — Monro's tuberculin (Plate
 XXXIX) .. 750

Test, nitric acid, for albumin
 — albumose .. 15, 16
 — bile pigment .. 743
 — indican .. 311

**Test, nitroprusside, for
 acetone** .. 3
 — melanuria .. 746

Test, Nylander's, for sugar .. 262

Test, oculi,
 — for occult blood .. 81, 171
 — ozone ether, for pus .. 373

Test, Pavy's .. 261
 — Petri's .. 24

**Test, phenylhydrazine, for
 sugar** .. 262, 743
 — ploughman .. 261
 — for phosphates .. 524
 — phosphotungstic, for
 albumose .. 16

Test, picric acid, for sugar .. 262
 — Prussian blue, for melano-
 uria .. 746
 — Reusch's, for arsenic .. 578
 — for rumen .. 320
 — Rinne's .. 164, 165

**Test, Rothera's (Plate
 XXXI)** .. 748

Test, Rothera's, for acetone .. 3

Test, safrafin, for sugar .. 262
 — silver nitrate, for alkali-
 tion .. 746
 — two-glass .. 183
 — in gonorrhoea .. 182
 — urethritis .. 584

Test, Trommer's .. 261

**Test, Uffelmann's, for lactic
 acid** .. 320
 — for urubilin .. 325
 — (Plate XXXIV) .. 748
 — von Fiquet's, in tuber-
 culosis .. 573
 — watch .. 164
 — Weber's .. 165
 — who-petted voice .. 164

Widal's (see Widal)

Woodcock's tuberculin
 (Plate XXXII)

768

**Testes, eversion of, obesity
 from** .. 408
 — in growth, in pseudo-
 hermaphroditism .. 646
 — incapacity of, physi-
 cal .. 66
 — in ascended, in diabetes .. 191

Tetanus, sensation, lost, in
 myeloma of testis 181

**Testis, abscess of (see
 Abscess of Testis)**
 — absence of deep tenderness in
 testes .. 545
 — after gonorrhoea .. 108, 479
 — after injury .. 343
 — obesity from .. 408
 — after orchitis .. 343
 — penile erection absent .. 343
 — carcinoma of (see Carcinoma of Testis)

— chronic torsion of (see
 Torsio Testis)

Testis, cysts of the .. 481
 — hydrocele simulating 481
 — ectopic, appendicitis
 simulated by .. 482, 481
 — in orchitis .. 481
 — in gonorrhoea .. 482
 — hernia with .. 483
 — simulated by .. 681
 — in menal canal .. 681
 — intra-talal cyst simu-
 lated by .. 681
 — liable to malignant
 disease .. 483
 — pain in .. 482
 — in peritonium .. 681
 — Scarp's triangle .. 676
 — strangulated, hernia
 simulated by .. 483
 — in thigh .. 681
 — torsion of .. 483

Testis, embryoma of .. 480, 696
 — enlarged, by abscess .. 622
 — from epididymo-orchitis .. 478
 — by gynaecia .. 622
 — from malignant disease .. 480
 — syphils .. 479
 — epithelioma of scrotum
 invading .. 621
 — involving .. 482
 — gonorrhoea of .. 482
 — connective infection of .. 623

Testis, gumma in .. 479,
 — hernia of .. 622
 — in menal canal .. 66

Testis, oculi,
 — inquiry by, neurosthenia .. 715
 — shock from .. 765
 — vomiting from .. 765

Testis, malignant growths of
 — misplaced, acting in peri-
 tonium from .. 474
 — atrophy of .. 456

**Testis, misplaced or retained,
 general account of** .. 482
 — neoplasm of, hæmatocele
 simulating .. 481
 — hydrocele simulating .. 481
 — after injury .. 481
 — tubercle simulating .. 480
 — pain in (see Pain in the
 Testicle)

— painless, syphilitic .. 622

**Testis, relationship to hydro-
 celes** .. 695
 — retained, appendicitis
 simulated by .. 457
 — impingement .. 363
 — pain in iliac fossa from ..
 452, 454, 457
 — swelling in three fossa .. 457

Testis, sarcoma of .. 480, 696

Testis, syphilitic .. 479, 696
 — scrotal fistula from .. 621
 — therapeutic test of .. 622

**Testis, syphilitic, tuberculous
 distinguished from** .. 622
 — torsion of, strangulated
 hernia simulating .. 682
 — tuberculous (see Tubercu-
 culosis of Testis)

Testis, various affections .. 477, 81

Tests for acetone .. 3

Tests for albumin .. 4

Tests, for albumose .. 5, 15, 16

Tests for alkalop .. 746
 — clinical, too great debility
 of some .. 4
 — for cystin .. 161

Tests for dextrose .. 261

Tests for hæmatoporphyrin .. 744

Tests, for hearing .. 745

Tests for indican .. 743
 — for methylene blue .. 747
 — for pentose .. 261
 — proper names associated
 with .. 912
 — tuning-fork .. 164

Tests for urales .. 740

Tetanic contractions .. 137
 — versus tonic .. 137

Tetanus, asphyxia in .. 730
 — bacilli of .. 138, 599, 730
 — hæmatocœl exantema .. 599
 — in hydrophobia .. 730
 — convulsions in .. 138, 729
 — drumstick bacilli in .. 417

Tetanus, general account of
 138, 730
 — habit spasm simulating .. 138
 — heart failure in .. 138
 — hydrophobia simulating .. 138
 — hyperæsthesia in .. 599
 — hyperpyrexia in .. 599
 — hysteria simulating .. 138,
 417, 729, 730
 — localized convulsions from 114
 — lockjaw in .. 138, 417, 599
 — mind clear in .. 417
 — in new-born .. 730
 — without obvious wound .. 599
 — opothotonis in 417, 599, 730
 — pain in .. 138
 — from penetrating wound .. 599, 730
 — retracted head in .. 589
 — rigor in .. 595
 — risus sardonicus in 138,
 417, 598, 599, 730
 — from rusty nail .. 730
 — simulated by pupated
 teeth .. 138, 730
 — meningitis .. 138
 — muscular thrombosis in 138
 — strychnine poisoning .. 138, 729

Tetanus, oculi,
 — from soil .. 730
 — spastics in .. 599
 — stiff neck in .. 138, 417, 730

**Tetanus, strychnine poison-
 ing distinguished from** .. 599
 — tetany distinguished from 132
 — simulating .. 138
 — trismus in .. 152, 649, 730
 — from a wound .. 138, 417

**Tetany, accoucheur's hand
 in** .. 151
 — age influence of .. 152
 — calcium salts and .. 151
 — cataplexal contractions
 in .. 730

Tetany, causes of
Tetany, characteristic hand
 in .. 2
 — from chlorotonia .. 151
 — Chvostek's sign in .. 152
 — cramps in .. 139, 151
 — from diarrhoea and vomit-
 ing .. 151
 — electrical reactions in .. 584
 — epilepsies of .. 151
 — Erb's sign in .. 152
 — from eruct .. 151
 — fevers .. 151
 — gastroparesis .. 151

Tetany, general account of .. 151
 — during lactation .. 151
 — from lead .. 151
 — localized convulsions from 114
 — muscle excitability in-
 creased in .. 151, 152
 — muscles tender in .. 151
 — paralytic and .. 152

— position of arms and
 legs in .. 151
 — during pregnancy .. 151
 — good prognosis in .. 3
 — respiration undisturbed
 in .. 151
 — in rickets .. 145, 151, 120

Tetany, signs of .. 2, 3
 — strychnine poisoning dis-
 tinguished from .. 152
 — tetanus simulated by .. 138, 152
 — after thyroidectomy .. 151
 — trismus in .. 730
 — Trousseau's sign in 151, 152
 — from typhoid fever .. 151

Tetralogy, cyanic acute
 — yellow atrophy from .. 334
 — hæmorrhagic hæmaturia .. 334
 — epigastric pain from .. 334
 — flatulent dyspepsia from .. 334
 — hæmaturia from .. 334, 337
 — loss of appetite from .. 334
 — vomiting from .. 334

Tetralol, bromidrosis from .. 84
 — coma from .. 118
 — Thapsia, saw fingers from .. 332

Theatre, insaniam, atrophy of
 (see under Atrophy of)

Theon muscles, atrophy of .. 509
 — poor innervation of .. 509

Theonin acetate, polyuria
 from .. 535

Therapeutic test, for actinomyces
 mycosis .. 458
 — acute rheumatism 164, 611
 — adherent pericardium 214
 — ascaria abdominalis .. 335
 — .. 115, 346, 436
 — asthma .. 336
 — chlorosis .. 511
 — erythema .. 511
 — diarrhoeic cause of .. 662
 — interscapular pain 622
 — type of constipation 122
 — distinguishing erythema
 from Monard .. 338
 — .. 535
 — .. 230, 615, 619
 — of liver .. 553, 633
 — hypothyroidism .. 489
 — lichen planus .. 627
 — malaria 536, 568, 596, 627
 — myocardial disease .. 485
 — myocœl disease .. 485

 - - - - - oedema of face and arms from 413
 - - - - - from whitlow . . . 413
 - - - - - venous, in cachexia . . . 111
 - - - - - gangrene from . . . 258
 - - - - - in leukaemia . . . 411
 - - - - - leucocytosis with . . . 360
 - - - - - limping from . . . 562

Tongue, white, contd.

- with belladonna .. 42
- in anaemia .. 765
- epithelioma of (see Carcinoma of Tongue)
- erythema bullousum affecting .. 74
- fibrillar contractions in .. 155
- fibrillation of, in bulbular palsy .. 627
- fissured, in acromegaly .. 237
- Mongolian (*Fig. 119*) .. 739
- from syphilis .. 739
- turned, from acute congestion of liver .. 334
- - alveolar .. 43
- - alveolar abscess .. 683
- - appendicitis .. 677
- - catarrhal jaundice .. 329
- - chronic alcoholism .. 74
- - in cirrhosis .. 51, 371
- - from defective teeth .. 43
- - in fevers .. 705
- - foul taste from .. 705
- - from gastritis .. 43, 267
- - peritonitis .. 388, 765
- - pneumonia .. 705
- - septicaemia .. 705
- - serum infectious .. 705
- - taste loss from .. 705
- - from tobacco .. 43
- - in typhoid fever .. 705
- glazed, with pycnoleucoplithis .. 576
- - gumma of .. 379, 698, 739
- - foul taste from .. 705
- - haemorrhage into .. 698, 699
- - herpes of .. 734
- - impaired sensation in .. 706
- - from fibrillar lesion .. 706
- - indented at edges, from acute congestion of liver .. 334
- - by teeth, from gastritis .. 267
- - large, in acromegaly .. 237
- - diabetic .. 264
- - Mongolian (*Figs. 118, 119*) .. 739
- leukoplakia of .. 737
- like a bag of worms .. 135
- new of .. 283
- normal protrusion distance of .. 758
- paralysis of (see Paralysis of Tongue)
- penicilligns affecting .. 74

Tongue, pigmentation of, in Addison's disease (*Plate XXV*) .. 526

- protruded, in ecsthum .. 526
- - monolingual .. 190, (*Figs. 118, 119*) 237, 258
- Raynaud's disease affecting .. 286, 699
- - sarcoma of .. 698, 699

Tongue, sensory areas of skin corresponding to .. 449

- sore, in pellagra .. 225
- - syphilis and .. 569
- - in syphilis .. 491
- - stomatitis affecting .. 74
- strawberry, in erythema scarlatiniforme .. 257
- - scarlet fever .. 227, 562
- swelling, in angina .. 198, 699
- - Ludwig's .. 699
- - angioneurotic oedema .. 699
- - from hoarseness .. 699
- - carcinoma .. 198
- - dysphagia from .. 198
- - from glottitis .. 198

Tongue, swelling of, list of causes of .. 698

- from mercury .. 73
- - stomatitis .. 74, 699
- - Raynaud's disease .. 699

Tongue, syphilis of .. 739

- tooth-marked, in diencephalic .. 267, 698
- tremulous, from alcohol .. 51, 726
- - cirrhosis .. 51, 371
- - general paralysis .. 116, 726
- - from lead .. 726
- - syphilitic of 379, 698, 739

Tongue, contd.

- ulcer of (see Ulceration of the Tongue)
- - wasting of, in bulbular paralysis .. 543
- Tongue versus tetanic .. 137
- Tongue, absence of (see Quinsy)
- Tongue-silencing, death from .. 382
- - emure-cured by .. 218
- - paralysis of palate after status lymphaticus and .. 382
- **Tonsillitis, acute, bacteria causing .. 613**
- - acute endocarditis with .. 21
- - - pleurisy .. 379
- - - pyaemia from .. 542
- **Tonsillitis, acute, types of .. 613**
- - in acute rheumatism .. 105, 211, 614
- - aortic disease after .. 209
- - bacteriological diagnosis .. 379
- - bacteriuria from .. 69
- - - chronic, adenoids with .. 615
- - - in children .. 615
- - and diphtheria, relative .. 371
- - pyaemia from .. 292
- - sarcoma from .. 610
- **Tonsillitis, follicular (*Plate XXVI*) .. 610**
- - albuminuria from .. 13
- - diphtheria and .. 614
- - leucocytosis in .. 369
- - - syphilis simulating .. 614
- - - Vincent's angina simulating .. 614
- - - foul breath from .. 87
- - in fungating endocarditis .. 34
- - history of heart disease .. 14
- - infective arthritis after .. 618
- - pain in the limbs in .. 662, 664
- - peliosis rheumatica and .. 356
- - pyaemia from .. 34
- - rheumatic .. 11, 379
- - - fever and .. 357
- - rigor from .. 365
- - in scarlet fever .. 614
- - spondylitis deformans from .. 714
- - stiff neck from .. 617
- - submaxillary glands in .. 379
- - - trismus simulated by .. 729
- - - and see Sore-Throat
- Tonsils, change of .. 615
- - enlarged, adenoids with .. 615
- - - in children .. 615, 615
- - - from hypertrophic rhinitis .. 179
- - - in insomnia from .. 324
- - - in lymphatitis .. 382
- - - nightmare and .. 402
- - - sore throat with .. 615
- - - septic from .. 617
- **Tonsils, epithelioma of .. 615**
- - gumma of .. 615, 615
- - mucous patches on, in .. 618
- - - syphilis .. 618
- - - pharyngeal, inflamed, smearing due to .. 613
- - - sarcoma of .. 285, 645
- - - syphilis affecting 382, 615, 739
- - - tubercle of .. 645
- - - ulcers on, in syphilis .. 383
- **Tonsils, various affections of .. 613**
- - Tonsil, definition of .. 137
- **Tongue now maintained .. 137**
- Tooth, bulge from .. 26
- Tooth, in bronchus, haemoptysis from .. 287
- - - carcinoma (see Carcinoma, Dental)
- - - extraction, excessive .. 406
- - - bleeding after, from .. 275
- - - impacted wisdom, simulating tetanus .. 138, 730
- - - - pyaemia simulated by 729
- - - included, empyema of .. 259, 269
- - - in bony .. 157
- - - septic, alveolar abscess from .. 683
- Tooth's personal atrophy, age-predence .. 40

Tooth's personal atrophy, contd.

- - anterior coronal cells .. 61
- - - affected in .. 513
- - - big toe in .. 60
- - - flexed in .. 60
- - - distinguished from infantile paralysis .. 113
- - - family history in 512, 513
- - - (*Figs. 29 and 21*) .. 60
- **Tooth's personal atrophy, general account of .. 513**
- - - hereditary in .. 513
- - - lesion of .. 513
- - - - limping mouth .. 323
- - - - muscle wasting in .. 61
- - - myopathy simulating .. 60, 113
- - - paralysis of hands in .. 60
- - - - legs in .. 60
- - - paraplegia from .. 510
- - - plantar reflex in .. 68
- - - R.D. in 60, 61, 113, 513
- - - reflexes in .. 513
- - - simulating infantile .. 60
- - - - paralysis of .. 113
- - - - symmetry of .. 113
- - - - talipes in 60, 113, 513
- - - - theaur atrophy in .. 113
- - - - after whooping-cough .. 60, 513
- - - - 462
- - - - alveolar abscess and .. 683
- - - - oedema of face with .. 410
- - - Tooth-brush, bleeding gums from .. 72, 73
- - - - retraction of gums from .. 589
- - - Tooth-plate, aorta opened by .. 267
- - - - fibrillar due to .. 73
- - - - ill-fitting, pyaemia from .. 542
- - - - oesophageal stenosis from .. 194, (*Fig. 94*) 195
- - - - oesophagus perforated by .. 267
- - - - in oesophagus, pyocnemopericardium from .. 652
- - - - stump molar, pyaemia from .. 542
- - - - tongue swollen from .. 698
- - - - ulcer of tongue from .. 498
- **Torsio testis .. 696**
- - - abscess from .. 180
- - - - operation in diagnosing .. 180
- - - - strangulated hernia simulating .. 682
- Torticolis, asymmetry of .. 112
- - - face with .. 112
- - - - clonus with .. 137
- - - - congenital .. 142
- - - - contracture in .. 139
- **Torticollis, general account of .. 142**
- - - from hysteria .. 141
- - - - lateral curvature with .. 647
- - - - lymphadenitis simulating .. 142
- - - - rheumatic myositis simulating .. 142
- - - - scoliosis from 152, 154, 647
- - - - spasmodic .. 648
- - - - retroverted head from .. 589
- - - - spinal carus simulating .. 142
- - - - sternomastoid muscle and .. 142
- - - - stiff-neck with .. 647
- - - - from sternomastoid rupture at birth .. 142
- - - - still-neck with .. 142
- - - - Torticollis in urtic .. 261
- - - - vomit .. 115
- - - - Tottaring gait in general paralysis .. 726
- - - - Toxæmia, in acute fevers .. 214
- - - - from alcoholism .. 406
- - - - - arsenic .. 406
- - - - - aspirin .. 406
- - - - - brachial neuralgia and .. 442
- - - - - from constipation .. 406
- - - - - convulsions from .. 146
- - - - - dilatation of heart from .. 406
- - - - - from drugs .. 406
- - - - - erythema from .. 226
- - - - - haemoglobinuria from .. 284
- - - - - headache from .. 296
- - - - - infantilis from .. 189
- - - - - intestinal .. 189, 406, 415
- - - - - from isle of potassium .. 406
- - - - - - noses in the head from 406

Toxæmia, contd.

- - from parasites .. 223, 226
- - - parenchymous cartilag .. 214
- - - - changes from .. 214
- - - - from plumbism .. 406
- - - - of pregnancy, polyerthæmia from .. 533
- - - - from quinine .. 406
- - - - - salicylates .. 406
- - - - - tetany from .. 151
- **Toxic conditions, anaemia from .. 32**
- - - - - dementia from .. 19
- - - - - - notes in the head in .. 406
- - - - - Traclæta, aneurysm ruptured through .. 420, 287
- - - - - - compression of, no pain with .. 434
- - - - - - displaced, by thyroid gland enlargement .. 722
- - - - - - distoma in .. 287
- - - - - - epithelioma of .. 184, 650
- - - - - - invaded by carcinoma of thyroid .. 721
- - - - - - - epithelioma .. 651
- **Trachea, irruption of caseous gland into .. 420**
- **Trachea, obstruction of, by aneurysm .. 419**
- - - - - - - aneurysm gland 157, (*Figs. 68*) 158, 550
- - - - - - - cyanosis from .. 157
- **Trachea, obstruction of, list of causes of 418, 650, 651**
- - - - - by mediastinal new growth .. 419
- - - - - - - orthopnea from .. 418
- - - - - - - - stridor from .. 650
- - - - - - - - epithelial stenosis of .. 650
- - - - - - - - - liberation of .. 287, 721
- - - - - - - - - Tracheotomy, for acute laryngitis .. 158, 616
- - - - - - - - - in angioneurotic oedema .. 699
- - - - - - - - - for laryngeal obstruction .. 419
- - - - - - - - - - paralysis .. 495
- - - - - - - - - - stenosis after .. 650
- - - - - - - - - - - stridor after .. 650
- - - - - - - - - - - subcutaneous emphysema from .. 203
- - - - - - - - - - - tube, hæmoptysis from .. 287
- - - - - - - - - - - ulceration of trachea .. 287
- - - - - - - - - - - Tracheoma, entropion from .. 231
- - - - - - - - - - - (*Plate XII*) .. 232
- - - - - - - - - - - - papulus from .. 231, 734
- - - - - - - - - - - - trichiasis from .. 231
- - - - - - - - - - - - ptosis from .. 231, 544
- - - - - - - - - - - - ulcer with .. 731
- - - - - - - - - - - - Trades (see Occupations)
- - - - - - - - - - - - train goodness .. 792
- - - - - - - - - - - - - sickness, headache from .. 296
- - - - - - - - - - - - Training, lack of, tachycardia from .. 705, 704
- - - - - - - - - - - - Transverse, brachyplegia in .. 84, 85
- - - - - - - - - - - - - cerebral abscess simulating .. 420
- - - - - - - - - - - - - tumour simulating .. 129
- - - - - - - - - - - - - dangers of diagnosing .. 129
- **Trance, general account of .. 85**
- - - - - - heart sounds just audible .. 85
- - - - - - - by-terical .. 118, 120
- - - - - - - respiratory tests in .. 85
- - - - - - - simulating death .. 85
- - - - - - - thermometer in diagnosing .. 85
- - - - - - Transfusion, oedema from .. 112, 115
- - - - - - Transillumination of antrum .. 463
- - - - - - - in diagnosis of tumour .. 683
- **Transitional lymphocytes (*Plate II*) .. 221**
- **Translucency test, for cysts .. 82**
- - - - - - - - hydracole .. 181, 682
- **Transposition of .. 157**
- - - - - - - vessels .. 157
- - - - - - - - liver .. 266
- - - - - - - - - - - - - transverse .. 157, 452
- - - - - - - - - - - - - - dysphagia horrida and .. 196
- - - - - - - - - - - - - - Transverse myelitis (see Myelitis, Transverse)
- **Trapezius, paresis of .. 506**
- **Traube's space .. 611**
- **Trauma (see Injury)**
- **Treadler's cramp .. 151**
- **TREMOR .. 724**

- Tremor, contd.*
- Tremor, from alcohol** 146, 259, **726**
- Tremor, ataxia and** **727**
- from cerebral embolism 133
 - in chorea 727
 - chorea distinguished from 133
- Tremor, coarse, general account of** **727**
- Tremor, from drugs** **726**
- Tremor, fine, general account of** **724**
- after flushing 211
 - in general paralysis 146
 - Graves's disease 215, 299, 705, 722, 726, 770
 - after hemiplegia 134, 727
 - in hysteria 134, 727
 - infantile hemiplegia 58
 - intention, from cerebellar abscess 547
 - ataxia 727
 - tumour 517
 - cerebral diplegia 724, **729**
 - disseminated sclerosis 148, 307, 496, 517, 724
 - Parkinson's disease 149, 512, 728
- Tremor, intention, general account of** **728**
- in hysteria 724, 728
- Tremor, intention, from mid-brain lesions** **729**

 - in Bacteria simulating 282, 472
 - in debris simulating 579

Tuberculosis of bladder, cont.

- cystoscopy with ... 471, 579
- epithelioma simulating ... 282, 579
- frequent micturition from 471, 534, 579, 742

Tuberculosis of bladder, general account of

- haematuria from 275, 282, 397, 471, 579
- pain in penis from 397, 471, 579
- other parts affected in 397
- prostate affected with 282, 471, 579, 620
- pyuria from 282, 397, 471, 579, 579
- rectal examination in diagnosing ... 471
- renal tubercle simulating 282, 471, 579
- secondary to kidney ... 579
- seminal vesicles affected with 282, 471, 473, 579
- stranguery from ... 649
- testes simulating ... 650
- testes affected with 282, 471, 479, 579, 622
- tubercle bacilli in urine from 282, 471, 579
- ureteric calculus simulating ... 472, 578

Tuberculosis of bone, general account of 668, 669

- splanchnic simulating ... 669
- tuberculin in diagnosis 669
- von Pirquet's reaction in diagnosing ... 669
- x-rays in diagnosing ... 669
- (and see Caries)
- bony swelling from ... 667
- of bowel, bladder opened by ... 582
- diarrhoea from ... 458
- haematuria from ... 275
- hyperplastic colon from 661

Tuberculosis of bowel, incidence of ... 458

- peritoneoperitonaeum from ... 652
- pyemia from ... 575
- of liver, carcinoma simulated by ... 181
- mesenteric simulated by 686

Tuberculosis of breast, notes on ... 686

- pain with ... 429
- pus from nipple with 181
- simulating carcinoma 181
- caecexia from 4, 13, 33, 413, 415
- of caecum, appendicitis simulated by ... 677
- cure by excision ... 458
- (See 194)

Tuberculosis of caecum, general account of ... 458

- laparotomy in diagnosing ... 677
- pain in iliac fossa from 151, 458
- from phthisis ... 458
- simulated by tuberculous iliac glands 459
- simulating appendicitis 458
- carcinoma ... 458
- swelling in iliac fossa from 458, 677
- tubercle bacilli in faeces with ... 458
- Cohnheim's test in (*Plate XXXIII*) ... 770

Tuberculosis, cervical glands enlarged from ... 379

- of iodine (*Plate XX*) ... 418
- chronic mediastinitis from ... 751
- of colon, abscess from ... 663
- blood in stools from ... 666
- carcinoma from ... 666
- carcinoma simulated by ... 125, 666
- of cistern from ... 666
- of sinus from ... 666
- tumour in hypochondrium from ... 659

Tuberculosis, cont.

- of cornua ... 734
- from cow's milk 308, 378, 383, 631, 768
- deep-seated, obscure pyrexia from ... 573
- of ear ... 422
- epididymis ... 692

Tuberculosis of epididymis, general account of ... 479

- nodules in seminal vesicles with ... 473
- of testes from ... 479
- deep-seated, obscure pyrexia from ... 573
- of ear ... 422
- epididymis ... 692
- of general, in children ... 355
- choroidal tubercles in 440
- in guinea-pigs ... 110
- iodine in ... 440

- hypopyxia in ... 399
- kidney involved in ... 555
- no leucocytosis in ... 640
- liver enlarged in ... 375
- lumbar puncture in diagnosing ... 640
- of lungs, bronchitis simulated by ... 310
- bronchopneumonia simulated by 310, 568
- hyperpyrexia from ... 310
- after measles ... 285
- meningitis in ... 640
- optic neuritis in ... 640
- purpura in ... 555, 555
- relatively slow pulse in 636
- no renal symptoms with ... 577
- spleen enlarged in 632, 640
- typhoid simulated by ... 636, 640
- vomiting in ... 640
- general wasting from ... 39
- generalized lymph-gland enlargement in ... 376
- giant cells in ... 103
- of glands, lymphadenoma simulating ... 378
- guinea-pig inoculation in diagnosing ... 104, 577
- of glands, bleeding from 72
- haematoperilyngium from ... 744

Tuberculosis of hip-joint ... 363

- hyperthermia in morning with ... 312
- of ilio-psoal valve ... 158
- influenza simulating ... 564
- intestinal, acute ascites from ... 47
- albuminuria with ... 16
- perforation in ... 47
- suppurative-peritonitis from ... 47
- jaundice in ... 325
- of joints (see Arthritis, Tuberculous)
- of kidney, aching in loin from ... 279, 577
- see incidence of 277, 579
- albuminuria in 7, 279, 577
- anuria with ... 40, 42
- calculus stoned by 279
- Chyeme's streaks in bathing from ... 108
- colic from ... 117, 577
- cystoscopy in diagnosing 282, 355, 577, 579

Tuberculosis of kidney, cystoscopic appearance (*Plate XV*)

- cystoscopy from ... 195
- frequent micturition from 277, 279, 282, 355, 293, 577, 579
- of general, in children ... 355
- choroidal tubercles in 440
- in guinea-pigs ... 110
- iodine in ... 440
- local reaction in ... 440
- hypopyxia in ... 399
- kidney involved in ... 555
- no leucocytosis in ... 640
- liver enlarged in ... 375
- lumbar puncture in diagnosing ... 640
- of lungs, bronchitis simulated by ... 310
- bronchopneumonia simulated by 310, 568
- hyperpyrexia from ... 310
- after measles ... 285
- meningitis in ... 640
- optic neuritis in ... 640
- purpura in ... 555, 555
- relatively slow pulse in 636
- no renal symptoms with ... 577
- spleen enlarged in 632, 640
- typhoid simulated by ... 636, 640
- vomiting in ... 640
- general wasting from ... 39
- generalized lymph-gland enlargement in ... 376
- giant cells in ... 103
- of glands, lymphadenoma simulating ... 378
- guinea-pig inoculation in diagnosing ... 104, 577
- of glands, bleeding from 72
- haematoperilyngium from ... 744

Tuberculosis of kidney, general account of ... 279, 355, 577

Tuberculosis of kidney, cont.

- guinea-pig inoculation in diagnosing ... 577
- haematuria from 275, 277, 279, 280, 282, 355, 356, 577, 579
- kidney enlarged from 282, 352, 355, 579
- tender from ... 355
- pain in iliac fossa from 452, 454
- loin from ... 469
- penis from ... 579
- part of general tuberculous from ... 577
- perinephritis from ... 106
- pleurisy from ... 106
- polyuria from ... 577
- prostate affected in ... 280, 355
- pyonephrosis from ... 576
- pyrexia with ... 117
- pyuria from 117, 279, 282, 355, 460, 575, 577, 579
- rectal examination in ... 282, 282, 355, 577
- renal colic from ... 279
- tube casts due to ... 7
- seminal vesicles affected in ... 280, 355
- simulating calculus ... 117, 577
- tuberculous bladder ... 282, 471
- stranguery from ... 649
- tenderness in loin with ... 555
- testes affected in ... 479
- thickened ureter seen with cystoscope ... 576
- tubercle bacilli in urine with 117, 279, 355, 460, 577
- tuberculous elsewhere with ... 577
- tuberculous bladder from ... 579
- simulated by ... 579
- with tuberculous peritonitis ... 48
- typhoid simulated by 566
- uremia from 108, 116
- ureter felt per rectum with ... 579
- infected from ... 473
- ureteritis from ... 277
- vaginal examination in ... 280, 255
- wasting with ... 117
- x-rays in diagnosing 279, (*Pls. 13*) 280, 577
- of knee, Baker's cyst with ... 692
- lachrymal glands enlarged in ... 695

Tuberculosis of larynx, notes on 199, 293, 616, 617

- phthisis and ... 615
- sore throat due to ... 613
- tonsil affected with ... 615
- ulceration of ... 293
- voice change with ... 150
- latent, loss of weight from 768
- leucocytosis rare in ... 360
- helminthodermatitis with 188
- of liver ... 375

Tuberculosis of lymph glands (see Lymphatic Glands)

- metastatic from ... 385
- metastatic affected by ... 668
- Miescher's syndrome in 695
- tubercle bacilli enlarged in ... 117
- prolonged pyrexia from 596
- tumor in ... 595
- milk and ... 768
- morning pyrexia with ... 631
- Moro's test in (*Plate XXXIII*) ... 770
- of nails ... 490
- nose ... 179
- obscure cases of ... 385
- occipital glands enlarged 378
- oedema of legs from 413, 415

Tuberculosis, cont.

- opsonic index in diagnosing ... 479, 627
- orbital ... 229, 230
- orchitis from ... 465
- pain in limbs with ... 465
- of palate, lipus and ... 588
- perforation due to ... 588
- phthisis and ... 588
- sore throat from ... 613
- pancreatitis in ... 190
- of penis ... 617, 619
- peritonitis ... 707
- peripheral neuritis from 465
- of peritoneum (see Peritonitis, Tuberculous)
- without physical signs ... 566
- polyorbomenitis from ... 107
- of portal glands 45, 330
- portal glands enlarged in ... 51, 325
- prolonged pyrexia from 563
- of prostate ... 184, 697
- abscess from ... 581
- aching in perineum from ... 471
- difficulty in micturition with ... 395
- haematuria from 275, 581
- nodules in epididymis with ... 582
- seminal vesicles with ... 473, 582
- no pain during micturition with ... 470
- perineal sinus from ... 620
- rectal examination and ... 479, 620
- with renal tubercle 280, 355
- testis involved ... 622
- secondary to ... 479
- tuberculous bladder with 282, 397, 579, 620
- simulated by ... 471
- kidney with 280, 577
- pulmonary, acute, rigor in 594
- elastic fibres in sputum 598
- fibrinous representing 464
- miliary, no tubercle bacilli in sputum ... 643
- pain in the limbs in ... 463
- prolonged pyrexia from 566
- rigors from ... 595, 598

Tuberculosis, pulmonary, sputum in ... 641

- typhoid simulating ... 565
- rapid ... 519
- (and see Phthisis)
- of rectum, carcinoma simulated by ... 585
- abscess of ribs, submammary ... 686
- salivary glands enlarged in ... 695
- of seminal vesicles 184, 697
- aching in perineum from ... 471
- enlargement in ... 587
- nodules in epididymis with ... 473
- rectal examination and ... 479
- secondary to testis 587
- testis involved with 622
- tuberculous bladder with 282, 397, 579
- simulated by ... 471
- kidney with 355, 577
- prostate with ... 582
- simulated by paratyphoid 565
- of spine (see Spinal Caries)
- stomatitis from ... 742

Tuberculosis of testis, general account of 479, 622

- tuberculous testis, hernia testis from ... 622, 623
- other organs involved with ... 622
- primary ... 479
- prostate involved with 620
- with renal tubercle ... 355
- scrotal fistula from 621, 622
- secondary to bladder ... 479
- kidney ... 479
- prostate ... 479

Umbilicus, *contd.*
 - ovarian cyst and .. 41

 - dry tongue in .. 49
 - dyspnoea in .. 296
 - from enlarged prostate .. 146
 - gastritis in .. 315
Uremia, general account of 40
 - headache in 146, 291, 296
 - heart enlarged in .. 146
 - hiccough in .. 208
 - high blood-pressure in .. 85, 146, 515
 - hyperpnea in .. 509, 514
 - hypothermia in .. 211
 - indigestion, simulated by .. 40
Uremia, latent, general account of .. 40
 - from nephritis .. 42
 - new growth of kidney .. 108
 - opththalmia in .. 117
 - optic neuritis in .. 85
 - in pregnancy .. 146
 - pupal reaction in .. 761
 - pupils contracted and fixed in .. 170
 - small in .. 49
 - from pyelonephritis .. 576
 - renal disease .. 594
 - renal disease .. 594
 - retinal changes in .. 146
 - retinitis with .. 215
 - rigidity of bow in .. 729
 - rrors simulated in .. 594
 - shortness of breath from .. 87
 - simulated after severe haemorrhage .. 120
 - simulating cerebral abscess .. 85
 - - haemorrhage .. 85
 - - tumour .. 146
 - - epilepsy .. 146
 - from structure of urethra .. 146
Uremia, symptoms of 40, 42
 - tumidus from .. 723
 - tremor from .. 724

Uremia, contd.
 - tube cysts in .. 85, 117
 - from tuberculous kidney .. 108, 146
 - urea in blood in .. 85
 - cerebro-spinal fluid in .. 85, 504
 - uridrosis in .. 655
 - vesicostoma in .. 118
 - vomiting from 296, 315, 761
 Urate deposit, pink from .. 745
URATE DEPOSIT IN URINE .. 740
 - of sodium in bursa .. 344
 - of joint .. 344
 - on knuckles (*Fig.* 188) 545
 - skigram of .. 546
 - X-rays in detecting .. 545
 Urates, after biliary colic .. 471
 - cleared up by leucuria .. 574
 - crystals of .. 740
 - pink .. 574, 740
Urates, significance of .. 740
 - tests for .. 740
 - white .. 740
 - white ring from .. 5
Urea in acute yellow atrophy .. 273
 - in blood in uremia .. 85
 - cerebro-spinal fluid .. 504
 - in uremia .. 85
 - decomposed by fuming nitric acid .. 5
 - diminished in acute yellow atrophy .. 333
 - nephritis .. 10
 - nitrate, white ring from .. 5
 - in phosphorus poisoning 336
Ureometer in fermentation test .. 592
Ureter, appearance with tuberculous kidney (*Plate XV*) .. 282
Ureter, blood coming from (*Plate XV*) .. 282
 - calculus in (see Calculus, Ureteric)
 - kinking of, from movable kidney .. 7
 - lymphatics round, pyelo-nephritis and .. 576
 - obstructed by aneurysm .. 7
 - bladder growth .. 277, 284
 - carcinoma .. 41
 - fibrosis .. 41
 - hydronephrosis from .. 11, 356
 - pain over (see Pain)
 - patulous, with dilated renal pelvis .. 576
 - pointing of, in pyelitis .. 576
 - posas abscess opening into .. 582
 - papilloma of .. 278
Ureter, pus coming from (*Plate XV*) .. 282
 - from seen through cystoscope .. 576
 - thickened by tubercle .. 280, 576
 - tuberculous (see Tuberculosis of Ureter)
Urethritis, acute, general account of .. 455
 - pain in iliac fossa from .. 452, 474
 - appendicitis simulated by .. 455
 - B. coli with .. 69, 472
 - - pyocyanus with .. 69
 - calculus simulated by .. 455
 - from coli bacilluria .. 455
 - cystoscope in diagnosing .. 472
 - frequent infection from .. 472
 - Friedlander's bacillus with .. 69
 - from kidney tuberculosis 274
 - operation in diagnosing .. 455
 - pain in penis from 471, 472
 - pneumococcus with .. 69
 - streptococcus with 69, 472
 - streptococcus with .. 69
 - tubercle bacillus with .. 69
 - tuberculous .. 472
 - vesical lesions simulated .. 472
 - Urethra, abscess opening into .. 581

Urethra, contd.
 - B. Xerosis in normal .. 69
 - bacteria in normal .. 69
 - blood-thromb from, calculi extending .. 396
 - calculus in (see Calculus, Urethral)
 - carcinoma of (see Carcinoma of Urethra)
 - caruncle of (see Caruncle)
 - catheter in, discharge due to .. 181
 - cocaine in examining .. 183
 - congenital deficiency in 391
Urethra, discharge from (see Discharge, Urethral)
 - epithelium of (see Carcinoma of Urethra)
URETHRA, FÆCES PASSED BY .. 238
 - from carcinoma recti 582
 - fistula of (see Fistula, Urethral)
 - flatus passed through, from carcinoma recti 582
 - foreign bodies in 181, 184
Urethra, gas passed through 529, 530, 582
 - gonococci in female .. 185
 - herpes of .. 184
 - infectious into, discharge due to .. 181
 - - epithelium-orihtis from 478
 - injury of (see Injury of Urethra)
 - instrumentation of, epithelium-orihtis from .. 478
 - lacinated, from fractured pelvis .. 470
 - navis in .. 275, 283
 - obstructed, by bladder growth .. 396
 - by calculus .. 396
 - chronic nephritis from .. 7
 - papilloma of bladder .. 47
 - papilloma of .. 184
 - parts of, in relation to gonorrhoea .. 182
 - penetration of, in Addison's disease .. 528
 - polypos in, discharge due to .. 185
Urethra, prolapse of 700, 702
 - testum opening through .. 700
 - (*Fig.* 249) 586
 - rupture of .. 278
 - acting in penicium .. 474
 - - staphylococci in normal .. 69
 - - streptococci in normal .. 69
 - structure of (see Structure of Urethra)
Urethra, syphilitic lesions of 184
 - tuberculosis of .. 184
 - ulceration of .. 184, 478
 - Urethral crises in flies .. 515
 - ulcers, infection of .. 185
Urethritis, abscess of testis from .. 622
 - from bacillus coli .. 182
 - bacteriological diagnosis of .. 478, 581
 - cystitis from .. 581
 - simulated by .. 579
 - dyspareunia from .. 492
 - effect of alcohol on .. 184
 - instrumentation on .. 184
 - irritant injections on .. 184
Urethritis, endoscopic in detecting 183
 - epithelium-orihtis from .. 478, 696
 - fistula from .. 620
 - from gonococci .. 70, 182
Urethritis, gonorrhœal 182, 581, 742
 - priapism from .. 578
 - pyuria from .. 575
 - hamaturia from .. 275, 282
 - from injury .. 182
 - installations in treating .. 478
 - from instrument from .. 182
 - irritant injections .. 184
 - leucorrhœa in .. 500
 - from leucorrhœa .. 182
 - levator ani spasm from 195

Urethritis, contd.
 - due to micrococci carcinoma thalis .. 70
 - non-gonorrhœal .. 181, 182
 - cystitis from .. 182
 - epidihtis from .. 182
 - prostaticitis from .. 182
 - pain in penis from .. 469, 473
 - due to pneumococcus .. 70
 - posterior, diagnosis of .. 579
 - prostatic abscess from .. 182, 470, 581
 - affections from .. 397
 - prostatitis from 470, 578, 581
 - pyuria from .. 575, 581
 - retention of urine from .. 649
 - from thrombosis .. 181
 - septic, epithelium-orihtis from .. 478
 - from leucorrhœa .. 178
 - prostaticitis from .. 475
 - staphylococcal .. 70, 182, 581
 - stranguary from .. 649
 - due to streptococci .. 70
 - with structure .. 581
 - two-glass test in .. 581
 - uric acid and .. 742
 - uricæmia from .. 192
 - vesicular from .. 475
 - wall (see Hamaturia)
Urethroscopy .. 183
 - in diagnosing urethral injury .. 283
Urethrotonus, aura after 42
 - relief of (see Relief, Urethral)
URIC ACID DEPOSIT IN THE URINE .. 741
Uridrosis .. 655
URINE, ABNORMAL COLORATION OF .. 743
 - melæmie in (see Acetonuria)
Urine, acidity of, general account of 523
 - albumin in (see Albuminuria)
 - alkaline, disintegration of casts in .. 6
 - ammonia in normal .. 524
 - ammoniacal .. 524
 - amount of, diminished in acute nephritis .. 9
 - - heart failure .. 12
 - (and see Azoturia)
 - increased, in chronic nephritis .. 10, 42
 - from cystic disease .. 42
 - B. coli in .. 69, 70
 - paratyphosis in .. 69
 - pyocyanus in .. 69
 - typhosis in .. 69, 70
 - Xerosis in .. 69
URINE, BACTERIA IN .. 69
Urine, bacteriological examination of 69, 70
 - Bacter Jones's albumose in, tests for .. 5
 - bile pigment in, from carcinoma of the bladder .. 101
 - - pneumias .. 101
 - - from gall-stones .. 101
Urine, bile pigment in, general account of 743
 - from pneumias .. 101
 - - (and see Jaundice)
 - bilirubin ova in .. 282
 - bilirubin in .. 745, 745
 - glycolysis in .. 745, 745
Urine, black 745, 745, 746
 - in albuminuria .. 745, 746
 - carboidum .. 745, 746
 - drusus .. 745
 - hamatroporphyrinuria .. 745
 - hamaturia .. 745
 - hæmoglobinuria .. 281, 745
 - melæmie .. 745
 - omidæ .. 321, 745
 - melanuria .. 745
 - blood-red, from hæmoglobinuria .. 281
 - bilious, upon stained by undigested .. 324
Urine, blue .. 747
 - grounds in .. 98

Urine, brown 745
 - in acute nephritis 9
 - haemoglobinuria 284
 - in jaundice 521
 - - ring in, with nitric test 5, 214
 - album oxidate crystals in 218
 - death passed in 40

URINE, CAMBRIDGE'S RE-ACTION IN 100
 - carbolic acid in, ferric chloride reaction with 170

Urine changes in acute nephritis 9, 10, 14, 42
 - yellow atrophy 273
 - albuminuria 85

Urine changes in bacteriuria 70
 - with calculus 40

Urine changes in chronic nephritis 10
 - urticaria 371
 - cyclical vomiting 284
 - cystic disease 12

Urine changes in cystitis 578
 - diabetis mellitus 536

Urine changes with kidney new growth 7

Urine changes in lardaceous disease 8
 - with poly cystic kidneys 42, 357

Urine changes in pyelitis 578
 - hydrocephalus 376
 - stricture 8
 - chlorides absent in pneumonia 160, 355
 - diminished in nephritis 10
 - phosphorus poisoning 336
 - chlorides (see Chlorides)

Urine cloud on boiling, causes of 4
 - dots in 276
 - type with new growth 278
 - colourless 743
 - copious in, white ring from 5
 - cystic in 161
 - brown, from alkalion 261
 - brown, from haemoglobinuria 273
 - green 743

Urine, in diabetes 261
 - diastetic acid in 170
 - dribbling, from enlarged prostate 294
 - fractured spine 398
 - haemorrhage into spinal meninges 398
 - myelitis 398
 - paralysis of bladder 398
 - paraplegia 398
 - retention 395
 - retroverted gravid uterus 680
 - stricture 39, 394, 470
 - tubercles 398
 - effects of acetamide on - sulphonal on 157
 - - thionil on 157
 - - veronal on 157
 - effervescence with acetic acid 4
 - - nitric acid 5
 - epithelial cells in 9, 10
 - - in acute nephritis 575, 742
 - - in chronic 14
 - ether-d sulphates in 514
 - excretion and 534
 - extravasation of 278, 621
 - feculent 285
 - filaments in, from blood 183
 - fluorescent, from eosin 745
 - filaments of growth in 7, 276, 580
 - free haemoglobin in, in nephritis 10
 - Friedlander's bacillus in 69
 - 24-h (see The material)

Urine, green 747
 - green-brown, from jaundice 321

Urine, white
 - haematoporphyrin in (see Haematoporphyrinuria)
 - haemoglobinuria (see Haemoglobinuria)
 - high coloured from acute congestion of liver 331
 - - in haemorrhagic disease 8
 - - in peritonitis 321
 - - hydatid hooklets in 357
 - hyperactivity of, frequent micturition from 394
 - - incontinence of (see Incontinence of Urine)
 - melanin in (see Melanin, and Indicanuria)
 - - brown ring with nitric acid from 5, 8
 - - iodides in 73, 98
 - - uric acid coefficient of 100

Urine, jaundice and changes in 321
 - lead in 31, 73, 119, 147
 - leakage into vagina, from carcinoma 582
 - leucine in 765
 - - in acute yellow atrophy 273
 - leucocytes in, in acute nephritis 14
 - - (and see Pyuria)
 - line stained by jaundice 321
 - melanin in 374
 - methaemoglobin in (see Methaemoglobinuria)
 - micrococci in, in arthritis 70
 - - in melitensis in 69
 - - miliary, from chyluria 108

Urine, milky, from phosphates 108, 524

Urine, mucus in 399
 - from cystitis 194, 578
 - in myxoedema 38
 - nitrogen, diminished in phosphorus poisoning 336
 - normal amount of 333, 534
 - uric acid absent in, white ring from 5

Urine, nucleio-protein in 4, 5
 - in nephritis 10
 - with oxaluria 124
 - only, from cystitis 161

Urine, orange-coloured 743

Urine outflow, causes of obstruction to 7
 - obstructed, kidney 8
 - change from 172
 - over in, in bilharziasis 172
 - painful and frequent desire to pass (see Stranguria)
 - pale abundant, after angina pectoris 133
 - in diabetes 261
 - in lardaceous disease 8
 - passed through vagina 285
 - phosphates in, diminished in nephritis 10
 - (and see Phosphaturia)
 - perineal granules in, in urethra 21
 - - urea, pink 745, 744
 - - from drugs 745
 - - from eosin 745
 - - from quercetin in 69, 70
 - - after clamped, in acholic urine 335
 - - port-wine coloured 744
 - - powdered-lag appearance in 425
 - - prostatic threads in 183
 - - pus in (see Pyuria)
 - - reaction of, in acute - bacilluria 9
 - - - bacilluria 70

Urine, red 744
 - red corpuscles in, in acute nephritis 11
 - - in cystic kidneys 12
 - - in incontinence of ova-ovulation 6
 - - (and see Haematuria)
 - - reducing power of, with alkalion 746
 - - substituted in, after drugs 157
 - - reduction, life insurance and 743

Urine, renal tube casts in, general account of 6
 - (and see Tube Casts)
 - resin in, white ring with 5
 - retention of (see Retention of Urine)
 - - salivates in, ferric chloride reaction with 170
 - - salol in, ferric chloride reaction with 170
 - - sleep and 531
 - - smoky, in acute nephritis 9
 - - specific gravity of, in diabetes 261, 556
 - - - in diabetes insipidus 537
 - - low, in chronic nephritis 10, 274, 298
 - - - from cystic disease 12
 - - - in lardaceous disease 8
 - - - sugar in spite of 9
 - - - raised in acute nephritis 12
 - - spermatozoa in, with oxaluria 424
 - - spontaneous coagulation of 108
 - - - staphylococci in 69, 70

Urine stream, changes in 394

Urine stream, sudden stoppage in 394
 - streptococci in 70, 70
 - sugar in (see Glycosuria)

Urine, suppression of 39
 - sweet-earr odour of 161
 - tortile in 261
 - tube casts in (see Tube Casts)
 - tubercle bacilli in 69, 70, 279, 282
 - turbid, from phosphates 183
 - - tyrosin in 765
 - - in acute yellow atrophy 273
 - - urates in (see Urate)

Urea, in diminished in nephritis 10
 - - in urate in, white ring from 5
 - - uric acid in (see Acid, Uric)
 - - uriculin in (see Uriculin)
 - - urethane of normal 743
 - - weather and 534
 - - white precipitate in, from oxalates 123
 - - ring in, from albumos 15, 16

Urine, white rinns with nitric acid in, causes of 5

Urine, yellow 743
 - Urinometer, in measuring specific gravity of blood 554
 - Urobilin with cholangitis 101
 - - in fibres 743
 - - fluorescent test for (Plate XXXIV) 748
 - - with gall-stones 701
 - - jaundice 701
 - - red, with corrosive sublimite 170
 - - source of 743
 - - spectroscopic in detecting spectrum of (Fig. 36) 89

Urobilin, test for 325
 - urine colour from 743

Urobilinuria, in cirrhosis
 - fluorescence from 371, 743
 - - from intestinal putrefaction 743
 - - in typhoid 743
 - - 743

Urobilinuria, notes on 743
 - in pernicious anaemia 743
 - - spectroscopic in diagnosing 321, 325
 - - Prochnow's 743
 - - Froehner's 740, 743
 - - alkali test for 743

Uroerythrin in urine 743
 - Urographis (and see Hydronephrosis) 678

Urotopia, from gall-stones 358
 - haemoglobinuria from 281

Urotopia, count,
 - for pyuria 650

Urotopia, stranguy from 649, 650
 - anionerotic oedema simulated by 673
 - from aspirin 413
 - burning in 771
 - in dermatitis herpetiformis 38
 - - dermatitis herpetiformis simulated by 771
 - - diet and 771

Urticaria, drugs causing 771
 - erysipelas simulated by 771
 - erythema from 292
 - - multiforme simulated 489
 - - factitious, epidermolysis 98
 - - uric acid related to 284
 - - haemoglobinuria with 239
 - - fingers affected by 673
 - - from fish 698
 - - glutin, from serum 376
 - - from hydatid disease 189, 540, 771
 - - itching in 224
 - - lips affected by 365
 - - urticaria 328
 - - popular form 487, 771
 - - parts affected by 489
 - - pemphigus related to 771
 - - pigments, itching in 732
 - - - wheals in 732
 - - - xanthoma simulating 673
 - - from pork 489
 - - prurigo simulating 489
 - - in rat-bite fever 398
 - - scales in 602
 - - scarlet fever simulated by 771
 - - from serum 225, 554
 - - shell-fish poisoning and 702
 - - - tubercle bacilli in 225
 - - - wheals in 771

Uteris, absence of, sterility
 - from 645, 646
 - - affection of, pain in the back from 428
 - - anteversion of, from pendulous belly 290
 - - carcinoma of (see Carcinoma of Uterus)
 - - cervix of (see Cervix Uteri)

Uterus, casts of 193
 - chorion-epithelioma of 290, 391, 688
 - - coagulate, sterility from 645, 646
 - - congestion of, dysmenorrhoea from 192
 - - - menorrhagia from 286, 387

Uterus, congestion of, symptoms of 387
 - - discharges of, anaemia with 32
 - - displaced, bearing-down pain from 426
 - - - chronic nephritis from 7, 8
 - - - retained casts due to 7
 - - - simulating vulva equina tumour 63
 - - - sterility from 646
 - - distended with blood 18, 688
 - - double, with retention, anteversion with 18
 - - drawn up, by ovarian cyst 45
 - - - enlarged, by carcinoma 391
 - - - fibromyoma 386, 391
 - - - pregnancy 395
 - - - recent examination in 587
 - - - from sarcoma 391
 - - - felt per rectum 587
 - - - fibromyoma of (see Fibromyoma)

Uterus, gravid
 - - gravid (see Pregnancy)
 - - hour-glass contraction of 201
 - - - - dystocia from 290
 - - hyperinvolution of, sterility from 645
 - - impacted tumour of, backache from 468
 - - - pain in thigh from 168

Veins, varicose, contd.
 - subcutaneous nodules from ... 404
VEINS, VARICOSE THORACIC ... 750
 - from aneurysm (Pag, 39) 298
 - chronic mediastinal 435
 - mediastinal growth 104, 308, 419
 - new growth in chest 104, 290
 - new growth indicated by ... 751
 - vena cava obstruction of leg from ... 208, 413
 - ulcer of leg from ... 756
Vena cava inferior, contd.
venal, dystopia from 200
Vena cava inferior, invaded by low growth 7
 - obstructed, albuminuria from 13, 52
 - ascites from ... 52
 - by ascites ... 415
 - by carcinoma of kidney ... 750
Vena cava inferior, obstructed, causes of ... 749
 - by enlarged mediastinal glands 381
 - intrathoracic new growth ... 52
 - mediastinal growth 46
 - mediastinitis 46, 52
 - new growth ... 415
 - oedema of legs from 52, 41, 415
 - after phlebitis ... 414
 - reversal of blood flow in surface veins from ... 749
 - by thrombosis (see Thrombosis)
 renal growth invading ... 750
 superior, aneurysm opening into, acute dyspnoea from ... 92
 - limit of ... 92
 - cyanosis from ... 92
 - oedema of face and arms from 92
 - obstructed ... 750
 - by aneurysm 158, 159, 413, 415, 673
 - double-l facies from 158
Vena cava superior, obstructed, causes of ... 751
 - cyanosis from ... 157, 159
 - by enlarged mediastinal glands 381
 - by growth of lung 159
 - gamma ... 413
 - hemorrhage into intrathoracic sac ... 159
 - mediastinum ... 159
 - thymus ... 159
 - mediastinal fibrosis 159, 413, 673
 - gamma ... 415
 - new growth 415, 419
 - mediastinitis ... 413
 - new growth 102, 104, 290, 413, 673
 - oedema from ... 415
 - of face from ... 673
 - and arms from 159
 - neck and arms from ... 415
 - by thrombosis ... 413
 varicose thoracic veins from ... 413
 opened by aneurysm 159
 - excystosis from 159
 - dyspnoea from 159
 - swelling of face 159
 - stenosed by aneurysm (Pag, 39) 208
 - excystosis from ... 208
 neck veins distended (Pag, 39) 208
 varicose thoracic veins (Pag, 39) 208
 thrombosis (see Thrombosis)

General ulcer of rectum ... 79
 Venesection, leucocytosis after ... 360
 - for uræmia ... 118
 Ventilation, bad, appetite bad from ... 321
 - headache from 295, 321
 - insomnia from 321, 322
 - irritability from ... 321
 - sore throat and ... 615
 Ventricle, left, dilated, from aortic disease 211, 212
 - aortic regurgitation ... 94, 95

 - simulating ... 285
 - pain in kidney from 281
 - penis from ... 469
 - retention of urine from ... 281
 - stoppage of urine stream by ... 394
 - ureter obstructed ... 281
 Vincent's angina, bacteriology in diagnosing ... 614
 - diphtheria simulated by ... 614
 - follicular tonsillitis simulating ... 614
 - foul breath from 87, 611
 - fusiform bacilli in ... 614
Vincent's angina, general account of (Plate XVII) ... 612, 614
 - neck glands and ... 379
 - organisms of (Plate XVIII) ... 614
 - sore throat in ... 613
 - spirilla in ... 614
 - ulceration in ... 614
 Violin playing, deterioration in quality of, in general paralysis ... 120
 Violinists' cramp ... 151
Viper bite, general account of ... 337

Virginia creeper, rhus-toxi-
colendron instead of . . . 224
Vitis obovata (Fig. 56) . . . 426
- abdominal outline in . . . 426
- colon in (Fig. 183) . . . 426
- general abdominal pain
from . . . 426
- kidney displaced in . . . 426
- liver displaced in . . . 426
- nodes in the head in . . . 406
- r-rays in diagnosing
(Fig. 183) . . . 426
Visible peristalsis (see Peri-
stalsis, Viscid)

Vision, central . . . 758
Vision, colour . . . 758
- concentric limitation of,
in disseminated scler-
osis . . . 517
VISION, DEFECTS OF . . . 757
- from rhinophthalmia . . . 416
- dimness of from diabeto . . . 260
- double (see Diplopia)
- nerve paths of (Fig. 178) . . . 300
Vision, normal, general
account of . . . 757, 758
- peripheral . . . 758
Vision, red . . . 762
Vision, yellow . . . 762
Visitors, pyrexia from . . . 575
Visual acuity . . . 757
- aura . . . 68
- cortex, lesion, crossed
anidropsia from . . . 759
- hemianopia from . . . 759
- field, concentric limita-
tion of . . . 759
- constriction of, from
chloro-oculitis . . . 760, 761
- functional . . . 761
- glaucoma 760, 761, 762
- in hysteria . . . 612
- optic atrophy . . . 760
- retinitis pigmentosa . . . 761
- spiral constriction of . . . 759
- word centre (Fig. 266) . . . 625
- Visual, degeneration of . . . 625
Vitiligo, pigmentation with . . . 529
Vitreous, hemorrhage into . . . 72, 762
- lazy, in glaucoma . . . 761
- particles in . . . 71
Vocal cords, ataxy of . . . 59
- epithelioma (see Carci-
noma of Larynx)
- fibroma of . . . 535, 650
- paralysis of (see Para-
lysis, Laryngeal)
- tremulous (see Tarte-
Vocal Frenitum)
Voice, altered, with laryn-
geal paralysis 150, 191, 195
- laryngitis . . . 150
- mediastinal new growth . . . 124
- hesitant, from cerebellar
abscess . . . 517
- tumour . . . 517
- disseminated sclerosis . . . 517
- loss of, from laryngitis . . . 616
- and see Aphonia
- monotonous, in paralysis
agitans . . . 725
- nasal, after diptheria . . .
61, 151, 512, 589, 627
- in myasthenia gravis . . . 627
- from paresis of palate
sounds, absence of, over
empyema . . . 103
- with fibrinol lung . . . 643
- with pleural effusion . . . 298
- pneumothorax 432, 520
- dentant, with fibrinol
lung . . . 296, 292
- pleuritic effusion . . . 168
- pneumothorax . . . 168
- increased, from em-
physema . . . 217
Voices, hearing of . . . 123
- as an aura of epilepsy . . . 47
- in insanity . . . 405
- homicide urged by . . . 405
- suicide urged by . . . 405
Volatile oils, bulke from . . . 36
- cythema from . . . 222
Volkmann's paralysis
(Fig. 58) 141

Volkmann's paralysis, condt.
- of leg . . . 141
- nerve paralysis simu-
lated by . . . 506
- from splint . . . 61, 506
Volvulus, carcinoma caeci
simulated by . . . 459
- destruction of caecum from . . . 459
- intestinal obstruction
from . . . 139, 388, 539
- pain in right iliac fossa
from . . . 459
- sigmoid, abdominal dis-
tention from . . . 452
- general peritonitis
from . . . 452
- Hirschsprung's disease
and . . . 651
- immediate operation
for . . . 452
- pain in left iliac
fossa from . . . 452
- visible peristalsis from . . . 452
Vomit, bile in . . . 766
- black, in phosphorus
poisoning . . . 336
- in yellow fever . . . 273, 336
- colic-eroded, from . . . 298
- true carcinoma . . . 269
- in ulcer . . . 268
- thickens in . . . 328
- occult blood in . . . 630, 767
- pits in . . . 766
- reaction of . . . 766
- round-worm in . . . 767
- trouble in . . . 115
- (and see Gastric contents)

VOMITING . . . 763
- with undue abdominal
aortic pulsation . . . 543
- from acute conice-
tion of liver . . . 334
- pancreatitis . . . 661
- peritonitis . . . 767
- yellow atrophy . . . 273, 333
- in Addison's disease . . . 37, 766
- from alcohol . . . 726
- anaemia . . . 56, 768
- gastric ulcer simulated
by . . . 56

Vomiting, anæmic, general
account of . . . 36, 412
- after anaesthetics . . . 4
- in angina abdominalis . . . 115, 316
- angonastrotic odema . . . 226
- appendicitis . . . 431, 665, 767
- from arsenic 61, 73, 38, 767
- in . . . 171, 268, 717
- arteriosclerosis . . . 295
- bacteriuria . . . 70
- biliary colic . . . 116, 767
- bradypnea with . . . 81
- from carcinoma coli . . . 330
- of duodenum . . . 661, 662
- stomach, 270, 316,
436, 620, 678, 67
- cerebellar abscess . . . 517
- tumour . . . 517
Vomiting, cerebral 81, 295,
311
- from cerebral . . . 767
- 117, 296, 502, 597, 626,
768
- hemorrhage . . . 768
- tumour, 117, 294, 292,
296, 315, 429, 592,
525, 537, 626, 711, 768
- in chronic alcoholism . . . 51
- peritonitis . . . 47
- uræmia . . . 51
- with colic . . . 111, 115, 593
- from colitis . . . 633
- collapse from severe . . . 633
**Vomiting, conditions simu-
lating** . . . 763
- vomits dark, from acute
dilatation of stomach 173
- from corrosives . . . 267, 766
- cough and . . . 150
- from cryptomemorrhæa . . . 17
**Vomiting, cyclical, of chil-
dren** 1, 381, 761, 765
- in adipsia in . . . 581
- and diarrhea, general
wasting from . . . 59

Vomiting and diarrhea, condt.
- infantile, acetonuria in 4
- summer . . . 717
- tetany from . . . 151
- from dilatation of the
heart . . . 36
- stomach . . . 522
- in disseminated sclerosis . . . 295
- from distoma hepaticum . . . 328
- diverticulitis . . . 143
- duodenal ulcer . . . 75, 271
- eclampsia . . . 146
- encephalitis 120, 592,
511, 525
- after emema . . . 767
- from errors of diet . . . 384
- in exhaustion of labour . . . 291
- basal, from acute perito-
nitis . . . 767
- appendicitis . . . 767
- zinc-oxide formula . . . 765
- lactaria . . . 768
- intestinal obstruction . . .
131, 388, 766, 767
- from food . . . 39
- termination . . . 211
- after flushing . . . 211
- from gall-stones . . . 227
- gastric ulcer, 36, 75,
268, 269, 317, 437, 767
- gastritis . . . 267, 317, 766
- general peritonitis . . . 388
- glaucoma . . . 232, 761
- headache with . . . 768
- Heberde's purpura . . .
313, 556, 767
- from hour glass stomach . . . 766
- hypertrophic stenosis of
pylorus . . . 384, 766
- hyperæmia after severe . . . 311
- hysterical . . . 315, 167, 768
- due to increased intra-
cranial pressure . . . 590
- in influenza . . . 165
- from intestinal obstruc-
tion 115, 131, 315,
316, 436, 522, 593, 767
- mta-susception . . . 662, 678
- irritant poison . . . 766

Vomiting, list of causes of
764, 765
Vomiting, mechanism of
764
- Menck's disease . . . 226
- Menck's disease . . . 752, 768
- meningitis 120, 118, 225,
307, 315, 325, 511,
515, 525, 590, 768
- nuremia . . . 760, 762, 768
- morning, from alcohol 51, 267
- in . . . 271
- pregnancy . . . 293

Vomiting, nausea and 765, 766
Vomiting from œsophageal
lesions 763
- tooth . . . 196
- after operation . . . 4
- optic neuritis with . . . 768
- from otitis media . . . 292
- pachymeningitis . . . 525
- pancreatitis . . . 594, 767
- in pellagra . . . 229
- from peripneic abscess . . . 663
- peritonitis . . . 115, 425, 592
- in phosphorus poisoning . . . 336
- phthisis . . . 315
- pituitary infantilism . . . 190
- phlebotomy . . . 54
- polyneuritis . . . 116, 599
- with polyseric kidneys . . . 42
- from portal obstruction . . . 272
- pregnancy . . . 19, 515, 292,
3
- acetonia from . . . 4
- from ptomaine poisoning . . .
171, 224, 717
- in . . . 596
- pyloric obstruction 115,
174, 245, 318, 652
- in renal colic . . . 151, 267
- scarlet fever 224, 227,
611, 765
- from sea-salt pricks . . . 224
- serum mictions . . . 225
- severe, polyneuritis
from . . . 532
- in pregnancy . . . 332
- with sick headache . . . 326
- simple colitis . . . 78

Vomiting, condt
- sinus thrombosis . . . 129,
511, 597, 768
- in small-pox . . . 272
- from snake bite . . . 337
- strangulated hernia . . . 682
- suppurative hepatitis . . . 294
- of . . . 315, 768
- from tetrahydroferrum . . . 531
- thirst from . . . 720
- in tuberculous meningi-
tis . . . 574, 649
- typhus . . . 638
- meningitis . . . 49, 296, 315
- urate deposit due to . . . 740
- urgent, in tubes . . . 437
- wasting from . . . 381
- from weaver-fish pricks . . . 224
- whooping-cough . . . 150, 129
- worms . . . 767
- von Eschscholtz's disease (see
Graves's disease)

Von Graefe's sign . . . 229
- in Graves's disease . . . 215, 722

Von Jaksch's disease
(Fig. 10, 37, 63)

Von Piquet's reaction in
Addison's disease . . . 34

Von Pirquet's reaction.
General account of 768, 769
- in . . . AAA 117
- . . . 677
- in tuberculous . . .
459, 479, 506, 573,
621, 699, 696, 728, 740

**Von Recklinghausen's dis-
ease, fibroma, nodu-
cum simulatum** . . . 719
- nerves thickened in . . . 732
- neurofibromas in . . . 719
- pigmentation in 719, 732
- skin tumours in . . . 732
- tenderness of scalp 719

Vulva, condylomata of . . . 629
Vulva, cystic affections of 701
- epithelioma of (see Carci-
noma of Vulva)
- fibroma of . . . 700, 702
- hematoma of . . . 701
- hemorrhage from . . . 702
- irritation round, from
occurus Vermiformis . . . 520
Vulva, new growths of 702
- pigmentation of . . . 528
- Addison's disease . . . 528
- pruritus of . . . 510
- pseudo-epithelioma of . . . 704
- fistula opening through
(Fig. 251) . . . 586

Vulva, soft sores of 700
- swollen, inflamed, squan-
dled from . . . 381

Vulva, swellings affecting
the list of 699, 700
- phaloderm of . . . 420
- vulvæ of . . . 701
Vulvitis, dyspareunia from, 193
- erythema from . . . 218

**Vulvitis, leukoplakic, krau-
rosis distinguished from 701**
- testor an. specios from 195
- singularity of all in is of 700
- vulvargus from . . . 193
- vulval swelling from . . . 699

WADDLING gait . . . see
Gait, Waddling

Wart, pyrexia, rubra
- palmar afflicting . . . 489
Walking, affected . . . 510
- in interstitial ductile . . .
441
Walsham, Dr. Hugh, skin-
grains by . . . 668-73

Wandering liver . . . 368
- Warr, trench bed in . . . 224
- typhus fever and . . . 335

Warts, condylomata, distoma
- gumbed from . . . 190
- epithelioma from . . . 621, 714
- occupation and . . . 290
- post-mortem . . . 210
- sarcoma arising from 751
- on scrotum . . . 685

Wrist, gout of 345

Wrist-jerks, no raised .. 502

Wrist, hereditary neuroplegia .. 502

— hemiplegic .. 503

Wrist, attheros of .. 531

— limitation of action on .. 540

— gonosical affluents of .. 540

AN INDEX OF DIFFERENTIAL DIAGNOSIS OF MAIN SYMPTOMS.

Edited by HERBERT FRENCH, M.A., M.D. Oxon. F.R.C.P. Lond.,
Physician, Pathologist, and Lecturer, King's Hospital, etc.

WITH THE COLLABORATION OF 22 SPECIAL CONTRIBUTORS.

This work aims at being of practical utility whenever difficulty arises in deciding the precise cause of any particular symptom. It covers the whole ground of Medicine and Surgery, and deals with Diagnosis from a unique standpoint. It is an Index in that its articles are arranged in alphabetical order. Whilst the body of the book deals with *Symptoms*, the General Index, containing some 15,000 references, gathers these together under the various *Diseases* in which they occur.

"Having read most of the articles in the book, we have no hesitation in saying it would be in the hands of all practitioners and senior students. . . . The publisher is to be congratulated." *Brit. Med. Jour.*

"The first edition of this steadily volume has been exhausted within three years. . . . The editor has added new articles, revised old ones, and nearly doubled the number of illustrations. These are not only excellently reproduced, but deal with real difficulties in diagnosis." *Lancet.*

"Beyond question a *tour de force*, and reflects the highest credit upon all concerned in its production. The most remarkable feature in the book is its full index. . . . an essential part of the scheme." *Pinter.*

"A notable contribution to modern medicine. . . . an immense amount of valuable information. . . . The illustrations are remarkably good, especially the coloured ones, which in other books often are remarkably bad." *Thomp. Barst.*

7th Edition, 22nd Thousand, over 1,100 pp. Fully revised, and with additional Articles and Illustrations. 25 - net.

AN INDEX OF TREATMENT

Edited by ROBERT HUTCHISON, M.D., F.R.C.P., *Physician to the London Hospital* ;
and JAMES SHERREN, F.R.C.S., *Surgeon to the London Hospital.*

TOGETHER WITH 87 SPECIAL CONTRIBUTORS.

A COMPLETE GUIDE TO TREATMENT IN A FORM CONVENIENT FOR REFERENCE.

"We cannot do more than recommend it in terms of high laudation. It is a volume that should be in the hands of every practitioner of medicine." *Brit. Med. Jour.*

"Since we first reviewed this book on its appearance in 1908, six further editions have been issued. A striking evidence of success which establishes it beyond the reach of criticism. Its general plan and high standard of excellence are doubtless well known to our readers." *Lancet.*

Now Preparing. Second Edition, fully revised. Demy 8vo. Cloth. 25 - net.

AN INDEX OF PROGNOSIS AND END-RESULTS OF TREATMENT.

Edited by A. RENDLE SHORT, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng.,
Senior Assistant Surgeon, Bristol Royal Infirmary, Lecturer on Surgery, University of Bristol

IN CONJUNCTION WITH 23 SPECIAL CONTRIBUTORS.

The principal aims of this Volume are: (1) To set forth the Results, and particularly the End-results, of various methods of Treatment, in such a form as will enable the Practitioner to obtain a fair, unbiased, reasoned opinion as to the prospects of securing for his patient permanent relief, and the risks of such treatment; (2) To furnish data by means of which, apart from the question of Treatment, one may seek to arrive at an accurate forecast of what will probably happen to the individual patient.

"We have formed a high opinion of the value of the *Index of Prognosis*. . . . and desire to commend the work to our readers as one which they would do well to place upon their bookshelves." *Brit. Med. Jour.*

"The editor and his 24 contributors are to be warmly congratulated upon the result. The articles are short and compact, clearly written, and as comprehensive as it has been practicable to make them." *Lancet.*

"Truly an original and unique work which should prove of considerable value to the practitioner." *New York Med. Jour.*

"Its aims cannot fail to appeal to practitioners, for the art of prognosis is vitally important. . . . The usefulness of this work will be unchallenged; as a reference book it is unique." *Hospital.*

Published in July, October, January, and April. A Quarterly Journal devoted to Surgery,

It is the earnest endeavour of the Editorial Committee and the Publishers to present to English readers the world over all that is best in the Surgery of the Empire, in the brightest and most attractive form. The general dress and appearance is of the highest character, and the illustrations are a prominent feature.

"Such a Journal, in regard and controlled by a large body of clinical and teaching surgeons, must do much towards bringing about a co-operation of workers in surgery in the advancement of their art. . . . In the matters of printing, illustration, and general set-up, the new journal has been very well served. *The Lancet.*

"This Journal has been remarkable for the excellence of its illustrations, and those in the present volume form no exception." *Brit. Med. Jour.*

"An imposing quarterly symposium. . . . A word of special praise is due to the illustrations in colour: they are wholly admirable, and surpass the standard usually attained in medical periodicals." *Med. Press and Circular.*

WHEN TO ADVISE OPERATION IN GENERAL PRACTICE.

By A. RENDLE SHORT, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng.,

Senior Assistant Surgeon, Royal Naval Infirmary, Lecturer on Surgery, University of Bristol, Etc.

An attempt is made in this book to give the best guidance available at the present time towards the formation of a sound judgment in difficult cases.

"In all his opinions Mr. Short appears to us to adopt a very sound position, not unduly conservative, but never inclined to advocate operation except on very good grounds. . . . There is much to be learned from the author's personal experience." *Brit. Med. Jour.*

"So excellently conceived and full of common-sense and sound teaching that criticism is almost unnecessary. . . . there are few recent medical books so very well worth the price." *Hospital.*

"A praiseworthy effort to enable the man who has not for some years had the advantage of hospital practice to benefit by the experience of up-to-date surgery. . . . A subject of the utmost importance to practitioners in general. . . . We heartily commend the book." *Med. Press and Circ.*

LIGATIONS AND AMPUTATIONS.

By A. BROCA,

Professor of Operations et Affections de la Faculté de Médecine de Paris.

AUTHORIZED TRANSLATION BY ERNEST WARD, M.A., M.D., F.R.C.S.

"A great feature of this little book is the number and excellence of the illustrations—they show step by step each of the operations described. . . . We think this book, especially the amputation section, will be read with interest by the many surgeons who are now engaged in this class of work. . . . Anatomical descriptions are careful and complete. . . . A number of useful hints about possible mistakes are given. . . . The second part on amputations is admirably done." *Brit. Jour. Surg.*

"Operations are described in great detail, and illustrated by figures which show every step and follow one another in such close sequence that they may almost be compared to a cinematograph film. . . . extremely well done." *Brit. Med. Jour.*

"Meets a real want. . . . In it are described in careful and lucid detail the underlying principles of all these operative procedures as laid down by the master Frenchman. . . . The illustrations are models of simplicity and clearness. . . . The translator has done his work admirably." *Med. Press and Circ.*

JOHN WRIGHT & SONS LTD., PUBLISHERS, BRISTOL.

In Two Volumes. Third English Impression. With more than 1000 Illustrations and Plates, Super royal 8vo. Cloth Gilt bevelled boards. 50 net - or 25 net each Volume.

LEJARS' URGENT SURGERY.

TRANSLATED FROM THE SEVENTH AND LATEST FRENCH EDITION

By W. S. DICKIE, F.R.C.S. Eng.,

Surgeon, St. B. Riding Infirmary, Middleburgh; Consulting Surgeon, Ly-on Hospital,

And ERNEST WARD, M.A., M.D., F.R.C.S.

VOL. I.—SECTION I.—Introductory. II.—The Head. III.—The Neck. IV.—The Chest. V.—The Spine. VI.—The Abdomen. Index.

VOL. II.—SECTION VII.—The Genito-Urinary Organs. VIII.—The Rectum and Anus. IX.—Strangulated Hernia. X.—The Extremities. Index.

This unique work is not intended solely or even perhaps chiefly for the Surgeon; but will be found invaluable to the conscientious General Practitioner, who is at any time liable to be confronted by emergencies demanding surgical interference.

"It will prove of the greatest possible help to any medical man, not specially versed in surgery who is called upon to perform a major operation, and even specialist surgeons will derive much benefit from its perusal. . . . The author . . . has based himself strictly upon his own experience, so that the reader . . . finds the definite guidance which he seeks. . . . A safe guide, errorless if at all, on the side of conservatism." *Brit. Jour. of Surg.*

"The author . . . speaks precisely and definitely but not didactically, relying upon vast experience. . . . The chapters on abdominal surgery may be read with all the dispassion of the 'Archie's Notes' (Robert Semmellweis). It is due to the translation to say that his work has been extremely well done. The text reads as if composed in good English." *Lancet.*

"Although many readers will prefer the latest work of its kind." *Brit. Med. Jour.*

"Among the best surgical works produced in this country during the last forty years." *We say this deliberately.* *Hospital.*

"The translation is excellent and the illustrations beyond all praise." *Med. Press and Circ.*

Now Ready. 3rd Edition (Reprinted). Revised and largely rewritten. Crown 8vo. 5 net.

THE NEWER PHYSIOLOGY IN SURGICAL AND GENERAL PRACTICE.

By A. RENDLE SHORT, M.D., B.S., B.Sc. Lond., F.R.C.S.

"This most excellent book will do a great deal to secure the practitioner's interest in the physiological foundations of his everyday work. . . . It has done the profession a real service, especially in regard to the little volume. . . . It is written with delightful freedom from text-book rigidity, and we strongly recommend its perusal to even the latest with the suggestion that if he peruses it as a book of pleasure and not as a task." *Brit. Med. Jour.*

"Great as was the value of the book at its first issue, it is now indispensable to the practitioner who wishes to keep himself abreast of the rapidly augmenting area of physiological knowledge ready to be applied in medicine." *Lancet.*

"The author need have no apprehension concerning the success of this greatly revised edition. . . . It is evidence he doubted if there be any book of similar calibre which appeals so thoroughly to the general practitioner. . . . of the multitude of books he is importuned to buy, he may at least regard this volume as a safe investment." *Hospital.*

"There is something very fascinating about this book, and especially in connection with the present revised edition. . . . There is more that we can more conscientiously recommend to the student and practitioner." *Bulletin Med. Jour.*

"It is to be hoped that if there be anyone who has escaped reading this little book he will get it without delay; it is essential to be both interesting and instructive to him." *Bristol Med.-Chir. Jour.*

Eighth Edition. Large 8vo. 642 pages. 21 net. Postage 6d. With 262 Illustrations, including Four Plates.

TEXT-BOOK OF NERVOUS DISEASES.

FOR THE USE OF STUDENTS AND PRACTITIONERS OF MEDICINE.

By CHARLES L. DANA, A.M., M.D., LL.D.,

Professor of Nervous Diseases in Cornell University Medical College; Consulting Physician to Bellevue Hospital, and to the Massachusetts State Hospital, etc.

The matter has been completely remodelled and brought up to date. Many illustrations have been changed and many new ones added.

"The author is a neurologist and psychologist of great practical experience, and the book may be consulted with advantage by all." *Brit. Med. Jour.*

"We are much pleased with Dr. Dana's work." *Bulletin Med. Jour.*

"In its present attractive form Dr. Dana's text-book is assured still wider recognition and appreciation. To those in search of a not too bulky but not too superficial treatise. . . . written mainly from the clinical view-point, it can be confidently recommended." *Lancet.*

"We have no hesitation in recommending this book as one of the best text-books of nervous diseases which have appeared recently." *Review of Neurology.*

JOHN WRIGHT & SONS LTD., PUBLISHERS, BRISTOL.

DISEASES OF THE THROAT, NOSE, AND EAR.

By W. G. PORTER, M.B., B.Sc., F.R.C.S. Ed. (Major R.A.),

Late Surgeon to the Eye, Ear, and Throat Infirmary, Edinburgh, etc.

Fully revised for the Author while absent in the Service of his Country

By P. McBRIDE, M.D. Ed., F.R.C.P. Ed., F.R.S.E.,

Consulting Surgeon Ear and Throat Department, Royal Infirmary, Edinburgh, etc.

PUBLISHERS' NOTE.

The volume has been brought level with the latest teaching by the kindness of Dr. P. McBride, who generously undertook the revision for his friend during his absence. The publishers are confident that the great service thus rendered will be fully appreciated, and that Major Porter's untimely death in action in France, since the revision was made, will give an added interest to the volume.

"The book remains a source of sound teaching of moderate dimensions for the senior student and the general practitioner."—*Lancet*.

"A very successful attempt to compress a sufficiency of information on the throat, nose, and ear into the compass of just over 250 pages of text. . . . We know of no manual of its size better suited to the needs of the general practitioner."—*Brit. Med. Jour.*

"The second edition sustains well the high opinion which we expressed in 1913. Its author, absent abroad in the service of his country (and since killed in action), has been fortunate in securing the services of so eminent a physician as Dr. McBride to revise his second edition. . . . One of the most complete and accurate handbooks on the subject that we possess."—*Laryngology*.

"The late Major Porter was to be congratulated upon having the benefit of a master hand for the revision of his book. It is a manual which holds its particular position amongst those treating of the triple speciality, through giving just what the general practitioner requires in the attainment, roughly speaking, of two objects: first, the medical care of the slighter class of cases that come under his view, and, secondly, a capability of a full appreciation of what the expert can do when the time for his intervention arrives, and the diagnostic knowledge which is essential for such appreciation."—*Proc. Roy. Soc. Med.*

"Such a second edition is very welcome, and justifies the opinion we entertained of the book when it appeared."—*Practitioner*.

Demy 8vo. Copiously Illustrated in Black and White, and Colours. 17 6 net. Postage 6d.

THE

FÆCES OF CHILDREN & ADULTS: THEIR EXAMINATION AND DIAGNOSTIC SIGNIFICANCE, WITH INDICATIONS FOR TREATMENT.

By P. J. CAMMIDGE, M.D. Lond.

Diseases of the gastro-intestinal tract and disturbances of digestion are amongst the commonest ailments that medical men are called upon to diagnose and treat: but with rare exceptions advantage is not taken of the help which an examination of the faeces might give, and this to the great detriment of the patient.

"We commend the book to all who are interested in the scientific side of our profession, as a stimulating contribution to a comparatively little-known province of physiology and medicine."—*Lancet*.

"A volume on this subject was badly wanted in English, and English physicians may congratulate themselves that Dr. Cammidge has been persuaded to supply the gap. . . . The chapter in especial in which the author discusses the diagnostic value of examinations, is most stimulating and so also is that following, in which he discusses the indications for treatment."—*Practitioner*.

A COMPLETE TEXT-BOOK. Demy 8vo. Fully Illustrated. 12 6 net. Postage 6d.

MEDICAL DISEASES OF CHILDREN.

FOR GENERAL PRACTITIONERS AND SENIOR STUDENTS.

By REGINALD MILLER, M.D. Lond., F.R.C.P.,

Physician to Out-Patients, Paddington Green Children's Hospital, and St. Mary's Hospital.

"A book of teaching value, and indeed by this standard the work is an indoubted success. . . . The chapter on infective diseases is a gem. . . . Since Dr. W. B. Cheenille's original lectures on the rheumatic state in childhood, we do not know better account of the many and varying manifestations of rheumatism."—*Lancet*.

"Well worthy of ranking with the best. . . the root of the matter in a few sentences. . . . We think very highly of Dr. Miller's book."—*Med. Press and Circ.*
