# Stientific ameriam. 

tion (figure 1) and the trumpet (figure 2) of an to a uniform size or density. improved drawing regulator for spinning cotton, patented by Newell Wyllys, Jan. 1851, and assigned to Charles Collins, of Hartford, Conn.

The object of this machine is to overcome the irregularities and defects in spinning cotton, occasioned by the want of uniformity in the extension or draw of the sliver, passing from the drawing frame.
The arrangement of mechanism in connection with the trumpet or condensing tube, is such that when the sliver is of the proper or required size, the lever on which the trumpet is mounted, occupies a neutral or mean position between the two extremes of its vibration, and the tendency to this neutral point increases in force in proportion to the distance it is moved therefrom. Any variation in the density or size of the sliver, varies the position of the lever to which the trumpet is attached, increasing or decreasing its effective length, and just in the same proportion increasing or decreasing the speed of the back or feeding rollers, thereby increasing or di-

## Great Railroad Speed.

A locomotive dispatched from Laporte, Ind , to Chicago, for physicians to attend Robert Doxtader, Esq, President of the road, who died at that place of appoplexy, ran the entire distance and back, in one hour and torty minutes. The distance is 58 miles each way, making a speed of 116 miles in 100 mi nutes. This is fully up, if not superior to the speed daily attained on the English Great Western Railroad between Paddington and London.

Description.-A is the roller beam of the drawing frame; $\mathbf{B}$ is the foot beam or girt $\mathbf{C}$ is the calender roll board; $\mathbf{G}$ are the top rollers H are the bottom or fluted rollers; I are the calender rollers; $P$ is the bevel gear on the end of front roller, $\mathrm{H} ; \mathrm{Q}$ is the bevel gear on the end of upright shaft, $i$, and is driven by gear, $\mathrm{P} ; i$ is an upright shaft connecting the front roller, H , with the lower cone; $k$ are the bevel gears on shatts, $i$ and $g$ driving the cones, $b ; j$ is an upright shaft connecting the upper cone with the back roller: $l$ are bevel gears on shafts, $j$, and upper cone shaft. $g$, driven by the cones, $b ; m$ is the pinion on the end of lower cone shaft, $g$, which drives the spur gear, $n ; y$ is the vibrating beam, turning on a shatt, and driven by the spur gear, $n$, to which it is connected near the circumference. On the upper end of the vibrating beam are catches operatiing the ratchet wheel, $s ; s$ is a ratchet wheel, on a shaft between the escapement, $t$, and the vibrating beam, $y ; t$ is an escapement, connected by rod $u$, to the end of lever, $v$, on the ho

Singular Lakes. The Crateur Lakes, in the town of Manlius, Onondagua Co., N. Y., are curiosities, and are supposed to be of volcanic origin. They are, by the inhabitants about there, called the Green Lakes. One of them is on the top of a hill, and is in the form of a tea-cup. The banks are two hundred feet high, and the water four hundred feet deep. The water appears of a deep green, but when taken up in a glass, it is perfectly clear and transparent. Trees and limbs which fall into the water
compression, the ef the trumpet shaft, T. The moving of the fective length of the lever, E, is shortened trumpet, $M$, either way, by turning the shaft, , gives a corresponding motion to the escapement, so that the catches on the vibrating beam take effect on the ratchet wheel. At the other end of the shaft to which the ratchet wheel is attached, is a spur gear, $p$, which drives the pinions, $o$ and $r$, turning the screw shaft, $e$. The revolution of the screw shatt moves the belt guides right and left, and through the bevel gears, $l$, regulates the speed of the back rollers; $M$ is the trumpet, which revolves on a perpendicular pin, 2, attached to the end of a lever, E , the other end of which is attached to an upright shaft, T , that turns in a tube or stand, N , as represented in gure 2. Whatever may be the situation of e lever, E , the mouth of the trumpet is always presented to the drawing. and turns out and in, either way from an angle of about forty-five degrees with the line of the calen-
der rollers, according to the size of the sliver or friction of the drawing compressed in the trumpet. Whenever the trumpet is moved to ward the calender iollers, I, by an increas.
oon become encrusted with a bright green substance, which, on being exposed to the air, becomes hard. The timber decays and leaves his incrustation in the shape of hollow tubes Wood saturated with this water and burned, emits a strong odor of sulphur. A farmer who resides near, once heard a great rush of water, and looking round saw the lake rising over the banks. He was alarmed and fled with his team, but the water soon receded to its usual level, and he returned to his furrow more puzzled than instructed.
correspondingly, and lengthened in the same proportion when the motion, owing to a decreased quantity of drawing, is towards the drawing rollers H and G .
This arrangement obviates the continual vibration of the trumpet each way from the central point, and prevents those defects and irregularities in the drawing, or sliver, which will occur where use is made of the direct action of the lever.
These machines can be seen in operation in the mills of Hon. Charles Jackson, Rhode Island, at Scituate and Fiskeville, also at Crompton Mills. We have seen a letter from Mr. Jackson, speaking in the highest terms of its merits. Mr. Collins has assignments from those who have patents for other drawing regulators, so as to prevent trouble about conflicting rights. One of these machines will be in operation in the Crystal Palace, in this city when it opens, where its action can be seen and judged of, and more information can be obtained by letter addressed to Mr. Collins, at Hartford, Conn.

The Baltic arrived at this port on last Sun day evening; her news is of considerable interest, inasmuch as it is now believed by our "press" (sensible men never believed otherwise) that there will be no war between Russia and Turkey at present.

Capt. Vanderbilt was quite a hero in England; the authorities of Southampton had given him a grand entertainment, and he, in return, had invited them to 3. short pleasure trip and a dinner on board of his steam yacht.

## MISCELCHNEOSS.

## A Huge Anatomical Demonstration

Dr. Cartwright, of New Orleans, amuses himself with the anatomical dissection of alligators, his object being, as he alleges, the demonstration of certain new physiological views that he entertains. On a recent occasion he cut up three of these monsters in the presence of a large number of scientitic gentlemen, with the following results, according to the New Orleans papers:-"He divided the spinal marrow in three places-at the base of the neck, in the middle, and at the base of the back; nay, he divided the nerves emerging from the spine-and still, on irritating the nerve between the section and the extremity, he demonstrated the animal possessed a diffused sensibility, a capacity to recognize pain, and even an intelligent power to act against or attempt to escape the cause of the pain.or attempt to escape the cause of the pain.-
Cuthead of the animal, jobbing Cutting off the head of the animal, jobbing
out the spinal marrow, dividing the nerves coming from them, and irritating them along their distal portions, they still retained this independent sensibility, and the mutilated limbs of the headless animal would make intelligent motions for getting rid of the local torture. These are curious and curious discoveries. Dr. Cartwright contends, against long odds, it is true, that in the lungs, not the heart, resides the motive power of the circulation; that literally, as Moses asserted, the blood is the life of the flesh, and the air the lite of the blood. He affirms that after death, when the pulse has stopped, the heart is still, and the body is insensible to pain; by producing artificial respiration, by inflating the lungs, the blood can be started anew, its life revived, and the body resuirected absolutely from the cold abstractions of death. Both of his alligators had their windpipes tied, and one of them had his chsst opened, with his heart, lungs, stomach, \&c., exposed. In the course of two hours both animals were dead, pulseless, and quiet over flames of fire. Then, a bellowsbeing inserted into the trachea, inflation was begun, and continued for some minutes. We saw the motionless heart throb, the blood beginning to flow from the lungs to that organ -the eyes of the alligator opened, and the hapless "victim" lived again! The aligator whose chest was exposed, had his carotid artery accidentally cut, thereby losing a considerable quantity of blood, and hence it was not made so briskly alive as the other, who retained all its vital fluid."
[The above reads very much like a " great fish story."

## Floods of the Ohio.

We have received a letter from Joseph $E$. Holmes, superintendent of machinery at the Crystal Palace, wherein Mr. Ellett's views respecting his proposed mode of improving the navigation of the Ohio River, and our own opinions respecting them, as expressed on page 309, Vol. 8, Scientific American, are dissented from. He believes, as he is acquainted with the grounds on the head waters of the Ohio the plan is impracticable but not impossible. 'It is not," he says, " what is possible should be done, but what is politic." Of the policy spoken or, the people in that section of the country are the most interested, and no doubt
the best judges. If any great work-no matter what its magnitude may be-can be demonstrated to produce beneficial and economical results, we like to advocate the measure, and the greater the work the more highly do we desire to see it executed. We like to hold up the accomplishment of great works to our people. If Mr. Ellett's data can be trusted, then the work can be done, and done to produce good results. We cannot contradict his data, and the only way to show the impracticability, is to point out the incorrectness of his calculations, statistics, \&c.

Singular Nutriment of the "Digger Indians.
The "Columbia (California) Gazette" says that there are two considerable Indian villages in that vicinity at the present time, and the Indians, who looked as lean and gaunt as half-famished wolves during the past winter, now appear to be enjoying all the luxuries that an abundant supply of clover and an occasional supply of beef and bread can afford.

The hills in the vicinity are verdant with nice, tender clover, which is devoured by these poor savages with as much gusto as an epicure would devour the most dainty dish. They gather the clover in baskets and prepare it for use by heating large stones and placing a layer ot clover well moistened between each layer of stones. It soon becomes ready for use, and each one of them will eat a supply of clover thus prepared, that would almost satisty a horse.

A terrible riot occurred Wednesday night, the 22 nd inst., at the residence of Dr. George A. Wheeler, in Seventeenth street, this city, caused by the finding of some human bones on the premises. A mob of 3,000 collected, armed with clubs, axes, and stones. Dr. Wheeler's store and dwelling were attacked, the inmates driven out, and the premises completely gutted. Nobody killed, though some police officers were injured.

As may be inferred by any intelligent man, the mob was composed of a low and brutally ignorant class. Our daily papers say they were mostly foreigners and Irish. Of this we know nothing, but that they were all savage ignoramuses we have not the least doubt. Not one of the mob who had his arm or leg broken, but would run or get carried to a doctor to get it set, and how could he do this unless he was acquainted with the anatomy of the human body?

## IMPROVED MIACHINE FOR DRESSING HEMP.

Figure 1.
Eigure 2.

Figure 1 is a perspective view of the cylinder, which contains the heckler teeth or combs and beaters-detached from the frame in which it.revolves, and figure 2 is an end elevation of the whole machine
The object of the improvement is to furnish a machine, which shall admit of employing several workmen at the same time, an perform the work in a manner quite su perior to the method heretofore used. In the accompanying engravings a strong frame is represented, to which the platiorm, $F$, is attached, upon which the workmen stand when attending to the machine; within suitable bearings in this frame, the cylinder revolves, being propelled by any power desired, at a moderate speed or motion, suitable for the pertormance of good work. This cylinder is constructed in the form and manner shown in perspective in figure 2 , with horizontal beaters, A , and heckle teeth, D , set in its circum-

## New Blasting Invention.

A correspondent who is well qualified to judge of such matters, sends us an account of a new invention for blasting rorks. He writes after an examination of the process :"The apparatus is the invention of Mr. A. Stickney, of Norwich, Vt. It is a platinum tube about ten inches in length, with holes in its side. Connected with this is an iron tube of any required length. This is the apparatus, and now for the operation. A hole is drilled in the rock to any length; this tube $1 s$ filled with charcoal and ignited in the platinum, and inserted in the drill hole. A blacksmith's bellows is applied to the upper end of the tube, and the most intense heat is forced through the small holes upon the sides of the rock, scaling it off in fine powder at a rapid rate. When the heat is sufficient, the tube is withdrawn, and water poured in, which enlarges the hole at the bottom. The effect of powder upon a rock when confined in such a way must be tremendous. The experiment has been tried with the most perfect success.' - Boston Transcript.
[To us it appears as if the above invention was both slow and expensive, and not so good for the purpose as the one described by us about two years ago, whereby the bore was enlarged at the bottom by the use of chloric acid. Practice, however, is the proof of the system.
New Mode of Constructing Flat-botomed Boate
An improvement in the mode of constructing canal boats, barges, and other flat-bottomed vessels, has been made by John McCausland, of Rondout, N. Y. Curved, timbers, or knees have heretofore been in use, and these timbers are attached to the timbers which
ference. The teeth are much shorter at the |called hands, to the left end of the guide bars end of the cylinder to the right of the operator, and gradually increase in length as they approach the opposite end ; B C are horizontal bars or guides for the hemp, set near the periphery of the cylinder and firmly attached to the frame of the machine; the opening between these bars is enlarged as they extend to the left of the end of the cylinder; the object of this is to form a convenient place for introduction of the hemp to the beaters and heckle teeth; $\mathbf{E}$ is an apron curved to fit the cylinder, and extending its whole length, and as far to the left of the cylinders as the bars, B and C, extend; it is stationary in the rame work of the machine, and serves to keep the several "hands" of hemp in contact with the teeth or combs and beaters. The hemp being previously prepared by rotting, breaking, \&c., is subjected to the action of this machine by being introduced in what is
form the keel; from thence they are curved upward and form the sides of the vessel. Mr. McC. dispenses with the knees altogether, and also with the use of any heavy timbers in the keel of the boat, but in the place of these he uses cross-tied plank, and gives strength to them at the sides, by means of stays which are constructed at less expense, and, at the same time, give lightness and the requisite strength, to the vessel. The inventor has taken measures to secure a patent.

## Sun Stroke.

Exposure to the mid-day sun, during the ast few days, has caused a large number of deaths. In this city, from Tuesday morning till Wednesday evening, last week, sixteen persons, principally laboring men, died from this cause alone. The following directions or treating these cases, is said to possess much efficacy, and until the attendance of a physicican is procured, it may be usetul to try it; it is to be applied early to be of any use :
"Place the patient in a cool and airy situation, with his head and shoulders elevated, and while one is removing his cravat, unbuttoning his shirt collar, and removing or loosening whatever else that may be tight about his person, dash suddenly cold water on the head. This may be done with a pitcher, or any suitable vessel, held at some little distance above the head, pouring out upon it a large and steady stream.

Mustard plasters may also be used over the upper part of the feet, and on the wrists.But continue the water, and the patient must be saved. It is hardly possible to speak too highly of the beneficial influences of cold verelys., killing five of the crew, and sewater in the treatment of coup de soleil. Ma- her first trip.

B C, and carried by the attendants (from one to six of which may work to advantage) to the right end of the cylinder. It is stated that this simple and ingenious mode of dressing, hemp, furnishes an article of much longer fibre than is obtained by any machine heretofore used. The hemp may be heckled by it to almost any degree of fineness required, or it may be very slightly dressed, as desired for the use to which it is to be applied. The expense of working and attending these machines is said to be comparatively small, and the amount ot work performed by them most satisfactory-it is a very good invention.James P. Arnold, of Louisville obtained a patent for this invention, Jan. 4, 1853. The claim may be found on page 142 , Vol. 8, Scientific American. More information concerning rights, \&c., may be obtained by letter ad dressed to the inventor.
ny violent cases of this, and also of apoplexy have been most successfully cured by it.

Special Manure for Grapes
The wine Committee, at the exhibition of the Cincinnati Horticultural Society, reported that of two specimens of wine, one from grapes to which a special manuring of potash had been given, the wine from the manure grapes was "bright, clear, and mellow, like an old wine." The other was declared to be less matured in all its qualities, nor was it clear. The glapes themselves, from the two portions of ground, were also presented to the committee. "Both were delicious and well ripened, but it was considered that those from the manured land were sweeter, and that the pulp was softer.'

## To keep Tires tight on Wheels.

A correspondent of the "Southern Planter" gives the following method tor keeping tires tight on wheels:-Beture putting on the tires, fill the felloes with linseed oll, which is done by heating the oil in a trough to a boiling heat, and keeping the wheel, with a stick through the hub, in the oil for an hour. The wheel is turned round antil every felloe is kept in the oil one hour.

An injunction was granted against the Second Avenue Railroad in this city, but it has been quashed, and the construction of it will now procecd,
The steam propeller "Challenge" running on Lake Michigan, exploded her boiler on the 22nd inst., killing five of the crew, and se-
verely wounding a number of others. It was

## [Tor the Scientific American.] <br> The Chemistry of Bread Making

The various modes of making bread have mainly for their object the production of sponginess or lightness, by which a larse quantity of air is retained in it, which gives to a loa that lightness and uniformity of structure for which it is so highly prized. There are va rious means by which this object is accom$\mathbf{p}$ ished, as by the re-action of acids upon the alkaline carbonates, which is the course generally followed in the extemporaneous preparation of breed. A process sometimes followed, though objectionable on some accounts, is that of thoroughly mixing bicarbonate of soda with flour, and then neutralizing it with an equivalent quantity of hydrochloric acid. The re-action that occurs in this case is best understood when expressed in symbols, thus Na. O. 2 C. ${ }^{2}{ }^{2}+$ H. Cl. $=$ Na. Cl. + H. O. +2 C $\mathrm{O} .{ }^{\mathrm{s}}$; that is, one equivalent of bicarbonate of soda and one equivalent of hydrochloric acid are resolved, when brought together, into one equivalent of the chloride of sodium or common salt, one equivalent of water. and two equivalents of carbonic acid gas. The advantages of this method are, that if proper care is taken, the products formed during the re-ac tion, are not in the least injurious to the system. The common salt is a necessary consti tuent of the blood, and the water and carbo nic acid are dissipated by the heat of baking the latter being retained by the pores or vesicles of the bread until it is baked, by which its lightness is preserved. The objections to this process are, that the acid may contain poisonons impurities, or may not be of uniform strength, and is itself a deadly poison and a dangerous substance to keep about a
house where there are children or careless servants. Should this substance be swallowed by accident or design, the antidote is carbonate of soda, or chalk-the former to be preferred in all cases. When this acid is spilled upon articles of clothing, carbonate of sod dissolved in water will remove it.
Another more common process for making bread is, by the use of cream of tartar or bis tartrate of potash, an acid salt, and bicarbsnate of soda. This process is based upon the fact that the tartaric acid in cream of tartar is not completely neutralized, and has the power to combine with the soda of the bicarbonate ot soda, and displace the carbonic acid of that substance. This re-action is easier compre hended when illustrated by symbols, thus K. O. H. O. Tre. +Na . O. $2 \mathrm{C} . \mathrm{O}^{2}=\mathrm{K} . \mathrm{O}$. Na. O Tre. $+2 \mathrm{C} . \mathrm{O}^{2} .+$ H. O. ; that is, tartrate of soda and potassa or Rochelle salt, which is a bibasic salt, is formed, and carbonic acid and water are displaced, performing the same office as in the other method. This mode of bread making is not liable to the objections urged against that where the muriatic acid is used, and according to some investigations made on this subject by my brother, Protessor C. W Wright, of this city ; bread made in this way agrees better with persons laboring under certain forms of indigestion, than that made by either yeast or the muriatic acid process. Th Rochelle salt, and in fact all salts containing an organic acid, are converted into carbonates of the bases with which they are combined when they are taker into the blood of animals; and in the present instance we hav tormed the carbonates of potassa and soda.

In former times pearl-ashes, or saleratus and sour milk, were more extensively used in bread making than at present. Occasionally carbonate of soda was substituted for saleratus. In this process it is the lactic acid which displaces the carbonic acid gas from the saleratus, or the carbonate of potash of chemists. The following is the re-action, expressed in symbols: K. O. C. $0^{2} .+$ Lc. $=$ K. O. Lc. + C. $\mathrm{O}^{2}$.; that is, the lactate of potash is formed and carbonic acid evolved. If an excess of saleratus be used, the bread is of a yellow color and disagreeable alkaline taste; if deficient, it is watery, heavy, and very indigestible. Saleratus, by itself, is a poison when taken in a large dose; several persons having lost their lives by swallowing it. The antidote is vinegar, or any oily or fatty substance, as sweet oil or butter.
Carbonate of ammonia is occasionally used in the preparation of bread, and being a very
self through the dough during the operation of baking, by which the same object is accomplished as in other processes.
The soapy taste which is perceived in the various kinds of pound-eakes, \&c., in which butter or lard is a constituent, is due to the ormation of a soap, and where the carbonate of ammonia or sal volatile is used, volatile liniment is generated, which is a species of soap. The carbonates of the alkalies should however, never be employed in the preparation of these substances, as they are very apt to produce derangement of the system of perons in delicate health.
The so-called "quick yeast," and all similar preparations, consist of the carbonate of soda and cream of tartar or tartaric acid, which, when dissolved in water, causes the volution of carbonic-acid, and which, by rising through the dough, is the cause of its lightness.
The foregoing substances are more frequently used in the preparation of biscuit, rolls, ac,, than other torms of bread.
The very ancient process of rising bread by means of leaven or yeast, depends also upon the developement of carbonic acid; but in this case the carbonic acid is formed from the sugar that exists in the dough, and which undergoes the vinous fermentation, whereby alcohol and carbonic acid are generated. The alcohol is expelled by the operation of baking, but by proper care can be collected and examined. The sugar is formed by the transformation of starch into that substance.
Bread, when first baked, is always lighter than it is after it has cooled, from the expanded state of the gases in its pores by the high temperature to which it has been subjected; but the contraction which it suffers after it but the contraction which it suffers after it
has become cold is due to the loss of water by has become
In the operation of baking, the starch is in part rendered soluble in water, being converted into a species of gum, at the same time sugar is tormed, and the breau rendered much more nutritive and digestible than flour that has not been subjected to this operation
Good bread generally contains about sof ent. of water. Common salt prevents the rapid drying of bread, and the same effect is produced by the admixture of potato meal. Various substances are used to improve the quality of inferior or damaged flour. Thus alum is used to whiten bread made of bad flour and make it rise better, and a small quantity is not injurious but decidedly advanta geous. Sulphate of copper or blue vitriol which is sometimes used, is a very poisonou adulteration, and should never be employed. The latter substance is used with the view of whitening the flour, which, when damaged, is generally of a yellow color, and by the admixture of a blue substance it is changed to white, on the same principle that indigo is used to whiten linen articles in washing.
There are establishments in this city wher the flour is worked up with soap-suds, made rom common yellow soap, instead of water. On several occasions I have seen distinct particles of soap in bread purchased from these bakeries, and it is frequently perceptible to the taste. What their object is in employing this nauseating substance, I cannot conjecture unless it is to neutralize the acid formed during the fermentation of the dough, and by which acetic acid or vinegar is formed, from a partial oxydation of the alcohol, which is al ways generated in these cases.

Mre. Julit A. Cook.
Cincinnati, June, 1853.

## A Rich Shovel.

The silver shovel recently used in the ceemony of breaking ground for the Mountain Lake Water Company, at San Francisco, was
banded with gold, and cost a thousand dol lars. With it a small quantity of the earth was shoveled up and placed upon a silver sal ver, upon which also were some of the wild flower plants so abundant. The same shovewas also employed at the dinner table in sho velling into the plates of the ladies present generous quantities of large ripe strawberries from a half bushel measure which was filled with this rich fruit, gathered in the vicinity

The old Merrimack Mill, at
burned down on the 16th inst.

The United States Patent Office. We often speak of reforming this and that evil, not because there is a universal shouting everywhere for reform at the present day, but because the reform or reforms we advocate in our opinion, would be more than a mere change of system-they would result in permanent benefits. We never declaim against an evil until we have a remedy to propose and have made ourselves acquainted with both the evil and proposed remedy. We are conservative in that which is, until we know of a superior substitute. It is, however somewhat fashionable at the present day, for would-be patriots and philanthropists to talk loudly of great reforms, which, when calmly examined by the light of knowledge and rea son, are nothing but destructive and injurious changes. Of this character is a reform proposed for the United States Patent Office by a Washington correspondent of the "New York Tribune," in a letter in that paper of the 15 th inst. Of some things he speaks sensibly and well, but when he speaks of the way alleged new inventions should be examined, and the practice of the Patent Office in examining them, he exhibits a want o correct knowledge of his subject. He says:
" With all our worship of the Baconian philosophy, it seems never thoroughly to have penetrated the Patent Office. A machire or process is submitted to the Examiners, and they rummage their hooks, brains, and perhaps the modeI shelves, to see whether the same combination or method has been devised for that or any other purpose before If not, it is new, and, being of course useful, a patent is issued. The last thing the Examı ner or Honorable Commissioner thinks of is to inquire whether this new invention is practically superior to others for the same purpose that have preceded it. The law enjoins no such inquiry, unless it be in regard to a claim expressly for an improvement. But has not every man a right to the exclusive use and property ot his own invention, whether it is superior, practically, to all others or not? It may be so. Let him have a patent if he insists on tt . But by all means let the office thoroughly and scientifically test the practical superiority of the invention over practical superiority of the invention over
older ones for the same purpose, and if that is found nil, let that fact be certified, or the reverse it otherwise. In other words, let the Patent Office be organized with suitable officers, to try this important question and report in every case, not so much opinions, as honest facts, from which the public may form their own.
The
The present state of the Patent Law and practice is so much the reverse of this, so completely $u n$-Baconian, that the author of a worthless invention stands a better chance of getting a patent than does the author of a valuable one. A really good invention is almost uniformly more simple and direct in its combination of means ; and just in proportion as it is simple, does it become difficult for the Examiner to find in it novelty-that almost sole legal element of patentability. He is puzzled to get hold of what he calls a " new principle" in it. It may work infinitely better than anything ever employed for the same purpose-indeed, it may accomplish its purpose while every previous machine has proved a failure-and yet, because the Examiner cannot see, from models, drawings, or specifications, a new or distinct 'principle,' ( 0 , the mystery there is in that word!) he will refuse a patent! A Baconian commission, working mald practically test the results with of the new machine with recorded results of the older ones, would probably bring in a very different verdict. So it happens that from the Patent Office, as at present organized and regulated, real, practical inventors find it very difficult to get protection, while the country at large gets unboundedly cheated." We have quoted the article fairly in order to point out its defects. The law gives the Commissioner of Patents power to decide both upon the usefulness and the novelty of an
invention, and it the invention has nothing novel (new) about it, then it must be old and consequently a patent cannot be granted ; to do so would be granting a patent for another man's invention. It a new machine operates
some reason for its doing so; it must have some new part, or arrangement to enable it to operate better, consequently that new past or arrangement can be claimed and a patent will be granted if the case is carried up by appeal. There can be no doubt of this, and the writer of the article quoted, shows himself to be ignorant of law in this respect. A certain machine exactly like another may operate better, because more work has been expended upon it, but that is not an invention, and for mere excellence in workmanship, no patent can be granted. The manner proposed of carrying out the said correspondent's Baconian philosophy in the Patent Office savors strongly of gammon. To carry it out, would require every inventor to construct and furnish a large working machine, and there would have to be commissioners appointed to test and examine the same, whose expenses, no doubt, the inventor would be called upon o pay, and after all their judgment might be inefficient, and they might condemn a good machine, and recommend a worthless one It is quite easy to deceive some of the smart est men appointed to power and place; witness the letter of the late Secretary of the Navy, J. H. Kennedy, on the "Ericsson," which subsequent events have proven to be a piece of nonsence. The government has aiready paid handsomely for useless inventio: 8 recommended by appointed commissioners and we don't want government commission ers to be judges of the merits of inventions; inventors are the best judges of the value of their own inventions, and they take patents on their own responsibility. The public are not so easily deceived with inventions as some imagine; there would be far more deception practised if government commissioners were appointed to place their seal of ap proval or disapproval on inventions. The present system of examining and granting patents has no defects in law, if there are some in practice, and these we hope to see reformed before many months pass over our heads.

A colu wo Bollers.
no Bollery.
e is sponem ot in The steam is produced a new invention.The steam is produced without boilers by simply injecting cold water into generators. The amount of steam required to torce out or return the piston rod is made by the introduction to the influence of the fire at each mo ment of precisely the quantity of water needed, thus doing away with the necessity of boilers. It is claimed that there is no possibility of an explosion, that greater power is obtained and less room occupied for the necessary machinery. The water falls into the engine, being first raised by a force pump into reservoir situated above the engine, and thence inducted down as wanted.-[Ex.
【The above project is nothing new. The same thing was proposed more than twenty years ago. It is founded upon a wrong principle and cannot succeed.

## Water through [Lead Pipes

We are frequently told of the deleterious ffect upon the system, of water which passes through a lead pipe, but only occasionally are we made sensible of the extent of the danger. Several days ago a gentleman living a few miles out of the city, caught a couple of trout and placed them in a trough, the water of which was supplied through a lead pipe, intending to keep them there. In less than three hours they were both dead. Suspicious ot the reason of this sudden death, he determined to make another trial, and placed in the trough another trout. The same result followed in less time, and he made a third ex periment. The result was still the same, and he considers it a settled fact that a trout, a native of the pure, sparkling stream, cannot live in a lead-impregnated water. If such water is poisonous enough to kill fishes, it cannot be without its destructive effects upon the human system.- [Manchester (N. H.) Democrat.

The boiler of locomotive No. 58, New York and Erie Railroad, exploded on the 16th inst. which eleven persons were instantly killed and several others wounded. The cause was over pressure.

## WEW IWVEMTOS.

## New Car Wheel and Truck

An improvement in the construction of car wheels and trucks, for turning curves upon railroads, has been invented by John T. Denniston, of Lyons, N. Y. It is well known to our'readers that a multiplicity of devices have been brought before the public for obviating the difficulties encountered in turning curves; many of these inventions have been very good ones, although but few of them have ever been thoroughly tested in practical use. A device was described in the Scientific American a few weeks since, in which, by a very ingenious contrivance the axles of the cars were made to assume the form of radii to the curve. Many other contrivances have been used, some of which were very good and others of no practical utility. The one invented by Mr. Deniston has certainly one thing to recom mend it, and this is simplicity ; in his improvement the object is accomplished by making the rim of the wheel somewhat thicker then is used, and forming the flange in the centre of this rim, thus forming two treads, one upon each side of the flange. The circumference ot the tread upon the inside of the flange being larger than that upon the outside. When the curve is turned, this inner tread takes a new rail, placed near the outer rail of the curve, and thus causes the cars naturally to run in a circular direction. It will be observed that the outer wheel, in turning curves thus instantly, becomes larger than the inner wheel, which gives the curvilinear motion. The inventor has taken measures to secure a patent.

## New Stump Machine.

J. B. Creighton, of Tiffin, Ohio, has made an improvement in the mode of constructing stump machines. The plan adopted by the inventor, Mr. C., is to place a large screw vertically in the frame, and so constructing a nut to work upon this screw, above the frame, that a sweep may be attached to it permanent. ly and with convenience. The power being applied to this sweep, raises the stump perpendicularly from its firm bed. The nut turns with the sweep, but the screw is prevented from turning by its attachment to the stump Another teature of the invention consists in constructing adjustable rollers, by which the machine may be transported from one place to another with great ease. Measures have been taken to secure a patent.

Now Model for Steamboats.
G. M. Ramsey, of this city, has shown us a new model for a boat, designed for an ocear steamer. The design of the model approaches more nearly the conical shape than those in use,-the greatest bread th of beam, or line from which it is tapered being, about three-quarters the distance from the bow to the stern. It is constructed with particular reference to its power to rise upon the surface of the water, as it is thrown ahead by the action of the paddle wheels, and for the accomplishment of this purpose the inclination of the keel from the point of the greatest breadth of beam to the bow, is more acute than the models of our best sailing vessels. This is a a very good principle, and has been applied to great advantage in our best ocean steamers but not to the extent to which it is applied in the plan proposed by Mr. R. A test experiment will demonstrate what are the sailing qualities of the proposed improvement-nothing buta trial can demonstrate it fully. The inventor sets the shaft of the paddle wheels a short distance ahead of the greatest breadth of beam, at an inclination to the line of motion, and the buckets at right angles to the line of motion, and at a slight inclination to the shaft of the wheels.

## Clover Separator.

Jemes Allen, of Frease's Store, Ohio, has taken measures to secure a patent for an improvement in clover separators, the nature of which consists in a peculiar arrangement of what is called the "tail-boards" at the outer end of the shoe and sieves, and a chamber or passage containing a screen at the bottom of the shoe, by which arrangement the seed is prevented from passing off the upper screen with the chaff, and is thus more perfectly separated than heretofore.

## Smut Machine.

David S. Mackey, and Jarvis R. Smith, of Batavia, N. Y., have made cerbain improvements in machines tor extracting the smut and other impurities from grain, for which measures have been taken to secure a patent. The improvement may be briefly described as follows:-Two circular plates or discs are placed within a cylinder both nearly horizontal with each other, one of which revolves

STEAMI ENGINE EQUALIZER.

The amnexed engraving is a vertical section/connected therewith; $b$ is an arm having a a machine tor equalizing the action of fixed centre of vibration at $c$, and jointed at $d$. steam, when used expansively, and for which a patent was granted to the inventor, W Henry Morrison, of Indianopolis, Indiana, on the 21 st of last December.
The object of this improvement is to equalze the action of steam when used expansively in a reciprocating engine; so that during the tirst part of the stroke of the piston, when the tull power of the steam is admitted to the cylinder, a power shall be accumulated, to be returned to the engine when the power of the steam is lessened by expansion. In the annexed engraving, $a$ is a portion of the piston
rod of the steam cylinder, or of a rod suitably
rapidly and the other remains stationary.These plates or discs are each provided with two or more concentric inclined flanges hav. ing radial flutes or grooves cut in them for the purpose of thoroughly scouring and separating the smut and other impurities trom the grain These discs, made slightly concave, are sur rounded by a curb, which collects and con. centrates the grain. The whole is very con veniently arranged.
e point 4, the piston, $m$, ascends, the piston, $n$, still descending; thence to the end of the stroke, 6 , both pistons are ascending. The cylinders being full of air or of any other elastic fluid, compressed or otherwise, at the commencement of the stroke, the air in them is diminished in volume by the descent of the pistons until a point is reached seen in the dotted line, C , at 3 , that is until the arms of the toggle, $b e$, are in line; psssing this, at the point 4, dotted line, $D$, the piston, $n$, has attained its lowest depression; each piston, after passing its respective point of lowest depression, by the elasticity of the air or other elastic fluid, contained in its cylinder, contributes power during the remainder of the stroke. The central lines of the air tight cylinders are shown placed immediately under the points of one-third and two-thirds stroke of the piston, respectively. Should it be wished that the pistons should reach their greatest depression at one-third and two-thirds stroke respectively, the distance between their cylinders, o $p$, must be increased, until the points of attachment of the arms, $c f$, on the blocks, $g h$, are on a line respectively with 2 and 5 , and the centre, $c$ when the arm, $b$, is brought into the same straight line respectively with the arms $c$ and $f$. Any other required variations are made by altering the position of the cylinders or their number.
More information may be obtained by letters addressed to the inventor.

## A new Coffee Huller.

Robert Walker, of this city, has invented a new machine for extracting the hulls and impurities from coffee, for which he has taken measures to secure a patent. The important features of the invention consist in an arrangement by which one cylinder is made to revolve within another-the external surface of the smaller and the internal surface of the larger being covered with wire gauze or cloth, by which the hulls are scoured from the kernels by the revolution of the cylinder; a series of beaters are also placed upon the periphery of the revolving cylinder, which. serve to break the hulls from the coffee, and also to drive it from the end of the cylinder where it is introduced, to the opposite end, The external cylinder is stationary and nearly air-tight, so that a current of air may be drawn through between the cylinders, and the impurities of the coffee extracted and conveyed to a remote place of deposit, instead of being thrown into the room to injure the lungs of the occupant.

## Improvement in Valves

John E Arderson, of this city, has invented a balance throttle or regulator valve for which he has taken measures to secure a patent. In his constructien two cylindrica valves are used, which are made to balance each other perfectly, and are made to operate vertically, the steam being admitted through one valve in its downward motion, and the other in its upward motion-to the same end of the cylinder of the engine-and vice versa to the opposite end, in this manner the steam may be admitted with any amount of rapidity required, and the regulator and consequently the valve will be affected by very slight changes in the speed of the engine.

Vev Mode of Constructing Rocking Chairs. John Middleton, of Newark, N. J., has invented a new mode of constructing rocking chairs, which makes them more portable than heretofore, and at the same time equally easy and convenient for use. They may be folded up so as to occupy but a very small compass when it is required to carry them from one locality to another, or when they are not desired tor use. The improvement is in the man ner of connecting the severel parts of the trame together, so as to be easily, folded. The rockers are connected by joints and pivots, 80 that one end of the rockers may be detached from the legs when not in use. Measures have been taken to secure a patent.

The natural salt ponds on the Florida Keys, which, in 1848, yielded about 75,000 bushels of salt, have been, during the last winter greatly improved and extended, so that the evaporating surface is now 600 acres, and will soon be increased to 800 . During the winter the ponds have contained pickle sufficient to make 500 bushels of salt.

## Brientificamerican

## NEW－YORK，JULY 2， 1853.

## The Dignity of Lalor

Professed philanthropy is a very cheap and common commodity．There is an exceeding ly plentiful amount of wordy sympathy at the present day for working people，hence great swelling articles about the＂dignity of labor are paraded with extraordinary frequenc and in prolific abundance．Being the pro fessed advocates of industry，we at once say that there is neither dignity nor disgrace con－ nected with labor－mental or physical－in itself apart from the object of labor．If phy sical labor is of a dignifying nature，then the horse，ox，and steam engine possess a greate amount of it than man．If mere mental labo is of a dignifying nature in itselt，then forgers and plotting gamesters must stand on very elevated positions on the ladder of dignity The majority of articles which we have read on the dignity of labor are calculated to de－ ceive our working people ；it is for them they are intended，and their tendency is injurious． Idleness is an evil，and industry as its coun terpart is a righteous duty，but at the same time，intense labor in any cause，or at any business，whereby evil is done，cannot digni－ fy the actor，however assiduously he may toil to arcomplish his infamous ends．Mechanical and mental toil are honorable and dignified only because of the aims and objects of the laborers；the noble man（not titled）confers dignity upon the labor in which he is engaged－the labor cannot confer dignity upon him．We know it is no uncom－ mon feeling among all classes of rich and poor，to make wide distinctions，one looking down or up to another because of its particu－ lar profession or trade．Great excellence in mechanism，skill of hand，and mental abili－ ty will always command admiration，but the feeling we would desire to see generally cul－ tivated，is respect for all wise and honest men irrespective of their kind of labor．At the same time let us say that this feeling is more prevalent than some frothy philanthropists would have us believe．The great difficulty with many men is to make them respect themselves－they have not the correct idea of true dignity．A man cannot always choose his trade or profession，but he certain－ ly can choose his character．It is as easy for a mechanic to be a gentleman，and work amid oil，steam，and iron every day，as it is for a man who is worth his tens of thousands． It is also as incumbent upon every American mechanic to be a gentleman，as if he were a minister or professor ；there is no excuse for any of our mechanics being less than gentle． men，and certainly some of them are much finer gentlemen than many who ride in their carriages．＂＇Tis worth that makes the man，＂ and nothing else．Every man should live in such an atmosphere as to feel independent of his kind ot labor，his dignity lies in his cha－ racter－the man．To every working man we would say，look upon yourselt with respect，be intelligent，honest，industrious，with grace in your speech and conduct，and never give yourself a thought about the dignity of labor．If you are poor，none but fools will look down upon you as wanting in dignity because of your kind of labor．If a man is poor，not by his own fault，it is his misfortune， he cannot help that．A man may also be very illiterate from the lack of opportunities to improve his mind，that is also not his fault； if he strives to do well，he labors with a dig－ nified aim，and for this he should be respected．
In civilized communities，intelligent and moral worth exert the greatest influence；it is a law of the mind，that the civil qualities command respect，and for this reason，we of． ten，as part of our duty，have to direct the at－ tention of many of our readers to those quali－ ties which dignify the man，in order that they may not be led astray from the true path of duty．At the present day there is no excuse for ignorance on the part of any young man in America，whatever his occupation may be， －whether a mechanic or merchant；if he is not intelligent he is wanting in an essential ement of true dignity．

Preserved Milk，Coffec，Tea，and other Extracta． Gail Borden，Jr．，formerly of Texas，but now of this city，to whom was granted a
Council Medal at the World＇s Fair of 1851 ， for his celebrated meat biscuit，has taken measures to secure a patent for some exceed ingly valuable improvements in preparing and concentrating sweet milk in such a man ner that incipient deecomposition is complete ly prevented，and a concentrated extract pro－
duced either in cakes，or in a more fluid state，which will keep sweet in any climate for months and perhaps for years．We hav kept a quantity of this milk for three months and although it has stood in a tolerably warm place，it is as sweet to day as when we re－ eived it．
Mr．Borden，by the same improvements extracts and concentrates coffee，tea，and other useful dietary matters，and produces those extracts in such a form that the strength of a pound ot coffee can be carried in a vessel no larger than a small tea cup，and it will seep fresh in any climate，and for a number of years．We have given samples of the col fee，prepared by Mr．Borden repeated trials during the past four months，and cannot but speak in the most favorable terms respecting
its good qualities，and the real benefits which its good qualities，and the real benefits whic we anticipate from its introduction into public

For persons going on sea voyages，or on ong overland journeys，a few small tin can－ nisters will be sufficient to equip them for
partaking，with a little warm water，of a good milk and coffee beverage，properly sweeten ed，in the midst of the ocean，or in the depths of the forrest．
For domestic use it will be the means of saving much in families，especially in warm weather，and at no time need there be any necessity for a person taking a cup of milk less coffee，even after a thunder storm，or week of hot weather，with the thermomete daily at $97{ }^{\circ}$ in the shade，as it has been in this city during the past week．
The means by which Mr．Borden prepares his extracts are new，ingenious，and philoso phical，but as measures are adopted for secu－ ring patents abroad，we cannot describe them at present，suffice it to say that although milk and other vegetable extracts have been mad heretofore，the new process is entirely diffe rent and very superior．The milk prepared by the improved process of Mr．Borden，even atter it is months old，will，when dissolved in warm water and left to cool，produce a beau tiful and sweet covering of cream．The cof fee and tea have all their aroma preserved and retain all their peculiar qualities．In large dairies at a distance trom cities，large quantities of sweet milk can be prepared by Mr．Borden＇s apparatus，and sent dow to be sold in every grocery，and it may ye become as common to ask for a cake of milk as it is now to ask for a quart．The mode o preparing these extracts is economical，safe and certain，and we believe it is one of th best and most useful improvements that has ever been discovered．

Railroads for Broadway
If Broadway，the great aristocratic street of New York City，was a living identity，and could appreciate the attention and devotion of its admirers，it certainly would be filled with a most intense conceit of itself．Broad－ way is a crowded street，and to relieve it from confusion，various schemes，from time to time，have been proposed，railroads being the suggested remedies．Railroads on the street a railroad over the street，one on each side of the street，and one under the street，have all been planned and proposed．Various sus－ pension railways have been invented，and some of them are not of a very recent date but we never expect to see an elevated rail road in it，although almost every inventor who has given the subject attention has con－ cluded on suspending his rails．The owner of property are the persons to consult about allowing such a railway，for there is nothing impracticable in it．The only railroad to re－ lieve Broadway that has received any favor has been one of two tracks to be laid in th street．The present Common Council－ sometimes in irony called Ali Babi＇s gang， granted to a certain company in this city，the privilege of constructing such a railroad，for a certain equivalent，and measures were tak
to prosecute the work；but some of the citi zens believing that our magistrates acted wrong in granting such a privilege，especially as higher offers were made for it，brought the subject before our courts，and obtained an in－ junction to restrain its construction．Our Common Council in their prosy wisdom， treated the decision of the court with great contempt，and for so doing were found guilty of misdemeanor．The case，however，is not finished yet ；it has formed a fine fat job for the lawyers，for it is still banging away in the Superior Court，and no one can tell when it will be finished up．In the mean time let us say to those inventors who have recently pro－ posed so many elevated railways for Broad－ way，exercise your patience，not a little，but great while longer，and wait the progress of vents in the case of the railroad now at law．If it gets out of such a place without being the greatest rascal that ever rode upon arail，we are greatiy mistaken．We believe that a good railway would be a benefit to Broadway，and we have so expressed our－ selves，but we have also said，and entertain the same opinion still，that no railroad should e constructed through any street against the will of a majority of the owners of property in it．

## Patent Pavements．

In another article we have presented the case of a railroad at law，caused by the inca－ pacity or rapacity of our Common Council； we have also a few words to say respecting a pavement at law．The Common Council of New York City made a contract with a firm named Russ \＆Reid，for paving one of the treets with what is named the＂Russ Pave－ ment．＂The contract granted to Russ \＆ Reid allowed them $\$ 6,50$ per square yard，while another responsible person offered to do it for $\$ 3,50$ per square yard．A perpetual injunc－ tion has therefore been moved for to restrain the execution of such a contract，and we hope it will be granted．What is called the＂Russ Pavement，＂is no doubt a very excellent one， but no Mr．Russ ever invented it．and it is no youth．It has been contended that as Mr． Russ has a patent，the contract could not be given to any other person．It is true that a patent was granted in March 1848，to Mr． Russ，but not for a pavement（although we be－ lieve he applied tor that）but for making the inder stratum of concrete below the pave－ ment，in pannels．The patent was not ob－ tained for the concrete understratum，for that was used before he was born，but for making it in pannels．
No one，therefore，can use his pannelled concrete，but all the rest of the pavement， viz．，concrete understratum and granite sur－ face blocks，are common property．It is our opinion that our streets can be paved for $\$ 3$ ，－ 50 per square yard，with as good blocks，and
in as substantial a manner as any that ever in as substantial a manner as any that ever was laid down．

## Events of the Week．

City Domestic Telegrph．－A number of gentlemen are making arrangements for the purpose of setting in operation a Metro－ politan Telegraph for communication with al parts of this city．The present idea is to es－ tablish in the upper part of the town ten offi－ ces，with House＇s printing instrument，and wires connecting with the office in Wall st They will transmit brief messages for a very small sum，and must necessarily do a large business．In fact，it is not improbable that the telegraph may be so extended as to do nearly all the real business correspondence between up town and down town．The post office is too slow，and we want such a tele－ graph．
Another American Yacht for Europe －The beautiful American yacht Silvie，of 105 ons burden has left this country under the command of Capt．Comstock，for the purpose of contending for the prize at the yacht race off Cowes，on Tuesday the 2nd of August next．The Silvie was built by Mr．George Steers，the successful builder of the America， and at the same time．It is confidently sta－ ted that the Silvie is the fleetest sailer of the wo，and on that account her success in com－ ing off the victor is sanguinely expected．
Ship Challenge．－Chambers \＆Heiser of
ship Sweepstakes a race of 2,000 miles out and back；against any other ship for $\$ 10,000$ ， the rules and regulations to be prescribed by the New York Yacht Club
Cotton Picker．－A．H．Burdine，of Pano－ la Co．，Miss．，has invented a machine for picking cotton from the stalk，by which，it is said，one hand can gather as much as two without it，and in much better condition．－ ［Charleston Mercury．
［We hope this is true，but to be successful it must do more than pick twice the quantity of one hand．
Dock Failure．－A correspondent of the Savannah Courier＂pronounces the Naval Dock recently constructed at Pensacola a fail－ ure．The frigate Columbia was taken up in it，but the dock swagged in the centre，and the ship was so pressed that the doors of her ward room could not be closed．It was also found impossible to take the dock，with the ship on it，into the basin prepared to receive it．
Tabli Moving Abroad．－By the recent accounts from Europe the table moving phe－ nomenon had become quite a rage among the for fans of Paris；and had furnished a theme The and fancy articles in the papors．－ The spirit rappings had also found believers
among some of the sages in England．Ro－ among some of the sages in England．Ro－
bert Owen，the famous communist，and now nearly 80 years of age，has become a believer in communicating with departed spirits by raps on a table．We do not know what the next movement will be，but we hope it will be a movement of Prof．Porter＇s celebrated xroport in the atmosphere on its journey to California，Japan，or some other place far away on the other side of Montezuma swamp．

## singular Phenomenon．

We have received a letter from Professor A．C．Carnes，of Burritt College，Tenn．，with the tollowing account of a singular phenome－ non，that was seen by a number of the stu－ dents，on June 1st．，at 4⿳亠口冋1 A．M．，just as the sun was rising ：－
＂Two luminous spots were seen，one about $2 \circ$ north of the sun，and the other about 30 minutes further in the same direction．When seen，the first had the appearance of a small new moon；the other that of a large star．－ The small one soon diminished，and became invisible；the other assumed a globular shape， and then elongated parallel with the horizon． The first then became visible again，and in－ creased rapidly in size，while the other di－ minished，and the two spots kept changing thus for about half an hour．There was con－ siderable wind at the time，and light fleecy clouds passed by，showing the lights to be onfined to one place．＂
The students have asked for an explana－ tion，but neither the President nor Protessors are satisfied as to the character of the lights， but think that electricity has something to do with it．The phenomenon was certainly not an electrical one，so far we can judge，and possibly was produced by distant clouds of moisture．

## To the New Yorl Evening Post．

The＂Evening Post＂will confer a favor upon an anxious people by letting them know how its Ericsson engine works－how it makes the presses fly，how much fuel it saves， and any other item of interest connected with ．It is now two month since the engine prepared tor the Post，was to be sent to France，and another was to be constructed at once．The said engine could certainly be duplicated in one month，consequently，we infer the＂Post＇s＂engine must be in opera－ tion．

Models．
We have a number of models in our office which lack the name and residence of the in－ ventors．We cannot therefore communicate with them．By simply attaching a card baring the name and residence of the inven－ or，delay and arnoyance is thereby saved．

A lump of wet saleratus，applied to the sting of a wasp or bee，it is said，will stop the pain in one moment，and prevent it from swelling．Pin this fact up somewhere for this season＇s use，for those who are not fond of the sensation of a sting．

## Improvement in the Manufacture ot India

 Rubber Goods.By reference to page 254, Vol. 8, Scientific American, our readers will perceive that a patent was granted to Charles Goodyear and Robt. Hearing, assignors to Charles Goodyear
of New Haven, Ct., for an improvement in the mode of manufacturing goods from india rubber, gutta percha, \&c., and a patent was granted in England, for the same process in
1851. The following abstract of the speciu cation. The following abstract of the surread rs. will be interesting to many or ouread in the patent
The improvements made are in the moulds which give form to the vulcanized rubber. \&c. heretofore metal moulds have been used with out good results. The invention consizts in using or employing sand pulverized soapstone plaster, or some similar granular, or pulveri porous matter, or moulds made of porous sub. porous matter, or moulds nade or porous sub-
stances, to sustain and keep the form of moulded articles composed of caoutchouc or its compounds, and other gums susceptible of vulcanzation during the process of heating or vulcanization. We take articles composed of compounds of caoutchouc or other gums suseptible of vulcanization in the green state We cause them to be pressed or otherwis formed into the exact shapes which they are required to have, after being vulcanized; then cover the surface of the articles with pulverized soapstone, or plaster, or other simila non-adhesive powder. We then place the ar ticles in a box filled with sand, the finer the sand the letter, or pulverized soapstone, or other similar equivalent granular or pulveri zed matter, so that each article shall be completely surrounded and covered by the sand or pulverized soapstone or plaster, \&c., and im bedded in the same, and thereby sustained when it is desired to give a very smooth sury surroued though sand may be employed about the lay er ot soapstone. We sometimes use moist and or pulverized soapstone. When the articles are thus properly placed in the box,
we subject the sand or other material to pressure, so that the box shall be solidly filled; we then by means of a cover, or sometimes by pressure, confine the sand or other material so hat the articles shall be at all times in contact with and pressed upon by the sand or
other material during the process of heating We then place the articles surrounded with and sustained by sand or pulverized soapstone or other material in an oven or heater, and subject the same to a high degree of artificial heat, moist or dry heat, say from 260 to $300^{\circ} \mathrm{Fah}$, for a period ot from three to se ven hours, and upon taking the articles out of the sand or other material, the articles will be found to be vulcanized in the same form in
which they wera when put into the sand; we are thus enabled to produce economically great variety of objects. Among them, emor masses ot red, or plaial sheets or plates or concave, such as pieces of furniture, book covers, buttons, toys of various kinds, \&c , or we make the moulds of plaster of Paris, 'best calcined), or other substance, which, when
dried will be porous and permit the escape of gases evolved from the matter under treatment, and all contained air, and thereby prevent the expansion of confined air and other gases trom injuring the surface of the moulded substance, or we mould the article in a mould which is to produce the figure, and pack in sand, or pulverized soapstone or other like granular pulverized substance to support the
other surface or surfaces of the article to be produced, and thus keep the face, which is to be figured, in contact with the partial mould of metal or plaster, or other material, and thus afford a tree discharge for air and gasses, whilst at the same time the moulds are greatly cheapned. The moulds or outer casing may be made of glass instead of iron or other metal,
but we prefer the first mode of procedure, as it avoids entirely the use of moulds during the
process of vulcanization. The sand or othe pulverized or grandular material, having the effect thoroughly to support and retain the
form previously given to the article by moulding or modelling. The prepared caoutchouc, gutta percha, \&c., if it is to be imbedded in moistened plaster should be previously varnished, and to keep the surface ot such articles to be thus vulcanized in sand, smooth india paper, should be interposed between such surface and the sand.
The claim for this invention may be found on page 254 , as a bove stated.

## SCIENTHIC NTOSEOM.

English Mine Explosions.
There is an excellent article in the last number (12) of "Littell's Living Age," taken from "Chamber's Journal," on the subject indicated by the above caption. It treats of the explosions in the coal mines of England, and it appears from a Parliamentary Report, that no less than 900 lives were lost by mine explosions in the short space of twenty-one weeks, in the year 1852. We entertained the opinion that our own country-Americawas distinguished above all others, for great accidents, and a reckless disregard of human lite, but we can entertain such an opinion no longer, hidden things will come to light, and England far surpasses the United States in the number of appalling accidents, yea, we are confident that there were not 900 lives sacrificed by accidents in all our country last year, and it was sadly distinguished for a number of fearful ones.
One thing appears to be singularly strange as the cause of many accidents in the English mines, it being nothing less than Davy's Safety Lamp. It has come to light that since this was introduced into the coal mines, the number of accidents by explosions, have greatly increased. This lamp is scientifically a safety lamp, but the ignorance of the coliers, and their carelessness, have made it a dangerous lamp. It was found in one pit that some of the miners had such a singular notion of its safety powers, that they looked upon its presence in the mine as a kind of charm to frighten away the fire damp, consequently, while one safety lamp was used, others were recklessly burning candles. The mi-
ners do not take the trouble nor care to keep ners do not take the trouble nor care to keep
their wire gauze clean, consequently it clogs up and becomes useless. There can be no doubt but Davy's lamp works beautiful in a lecture room, but in a coal mine the conditions are altoyether different from those of a chemists' laboratory, for it has been found that the wire gauze in. some lamps became er hat, consequently an explosion was inevitable. There are two reuedies proposed to prevent the frequency of such accidents, viz., the olucation of the miners scientifically in the use of the Davy lamp, and the expulsion of the gas from the mines by steam jets. If the latter plan be carried out, there will be $n$ ) use for the safety lamp.
Carburetted hydrogen is the gas which is the cause of mine explosions. It must, however, be mixed with a certain quantity of air betore it will ignite suddenly -explode; eight volumes of air to one of carburetted hydrogen forms the most explosive mixture. It has been found that 70 per cent. of deaths in coal mines are not caused first by the explosion, but by the carbonic acid gas as the product of an explosion; so speedy is the action of this gas that the miners suddenly sinks down asleep in death.Those who die from the effects of this gas sleep away placidly without a struggle. The coal mines in America are very tree from these gases, because they are so near the
surface, and are therefore far better ventilated than the deep coal mines of England, nevertheless, let us say to all those who use the safety lamp, " keep it clean or dread the worst consequences."

## Petrified Man.

The "Morris (III.) Yeoman" states that not long since, while some men were digging in a coal bank near the canal, they exhumed the body of a man in a perfect state of petrifaction. From the corduroy cloth in which the legs were encased; the cords and seams of which are perfectly defined, it is supposed to be the body of one of the Irish laborers engaged in the construction of the canal. The limbs are nearly perfect, and are completely transformed to stone

The valuation of personal property in the city of Cincinnati for the present year is about $\$ 14,000,000$, being an increase of nearly four millions over the valuation of last year.--
|Exchange. [Well, it is certainly greatly undervalued; for we are much mistaken if there is no more personal property in Cincinnati.

## Termes Femina.

The Neuropters have two pairs of transpa rent wlngs, beautifully and minutely netted Mostare carnivorous ; they live in damp earth, in water, or on plants. Tue pupa is quiescent, or active, and terrestrial, as the white ant, or aquatic, as the dragon and day fly Dragon Flies have a large round head, large eyes, a slender body of varied colors, and can fly in all directions, forwards, backwards, and sideways. They have been seen 500 miles at sea. In two of the genera, the wings are al Flies) expanded. Ephemeral (Day or May Flies) in the larvæ state exist two or thre years burrowing in banks; but when perfect,
live but a few hours. In the latter condition, they take no food, their object being to propagate the race, after which they die. They are seen in great numbers along the margin of streams in the fine days of summer and autamn, distinguished by their spotted wings, and three long tails. They have a strong inclination for luminous objects, evident from their gyrations round a lighted flambeau; and yet thy never see the sun, as they appear appear after his sitting and die before his rising. Myrmidion flourish between the tropics of great size and brilliancy. Their larvæ, called ant-lions, are about halt an inch long, trianguar in shape, have twelve eyes, a mouth with orceps, and can walk no other way than backwards. They feed chiefly on, the formic
acid of the ant, to catch which they excavate conical pitfalls in fine sand, two inches deep and three in width at the top, and hide themselves at the bottom. Termites or White Ants, mostly found within the tropics, are carivorous, or omnivorous. They commit grea Arriving at their perfect state, they fly off in the night, but lose their wings before morn ing. Their societies consist of larva who ar the workers, most numerous, and one-quarter of an inch long-the pupæ or nymphs-neuters; who are the sentinels, ot large size, and blind-males and females, of which there is one of each in every society. The latter (represented above) is queen; in oviposition, her abdomen becomes more than three inches
long, equal to that of 25,000 workers, and by its peristaltic motion, extrudes 86,400 eggs day. These the larvæ carry to the nurseries The nests of these animals may be considered as a large city, numbering many houses, each having an infinity of cells. They are bnilt of clay and completed in three or four years, and are larger than a wigwam, being twelve feet in height, covered by a vast dome, and adorned by pinnacles, and turrets, so that a cluste resembles an Indian village. The upper part is used as a castle; the lower comprises the royal chamber for the king and queen-an arched vault of semi-oval shape, surrounded by a labyrinth of arched rooms; nurseries fo the young, made of wood, and half an inch wide; store-houses for food, as wood, gums, \&c., and numerous galleries and empty rooms.
We find also spiral thoroughfares, bridges of We find also spiral thoroughfares, bridges of
one elliptic arch, and Gothic arches receding as in perspective, not excavated but projected Subterranean roads, wider than the bore of a large cannon branch out on every side of the metropolis, to the distance of several hundred feet. These edifices are 500 times the height of the workmen, while the pyramids are only 120 times. Were the terms of human dimen sions, its buiding wou!d rise half a mile high and its tunnels expand to more than 300 feet
diameter.
VIII.-Heteroptera - ( Unequal-winged.)

Pentatoma Rufipes.
Like the Homoptera, these insects are suc torial; but have anterior wings coriaceous a the base and membranous at the tip. The
markings. Most of the Geocorisa or Land Bugs, when alarmed or touched, emit a powerful odor, in some species pleasing, in others disgusting. Some inject a poisonous fluid; in others the wings are undeveloped. The bed bug was not known in England at the beginning of the 16 th century. It was originally called chinche, punez, or wall-louse, and af terwards bug (Celtic for ghost or goblin) because they were "terrors by nighs," whence
bug-bear. It is mentioned in Hamlet, Act V, bug-bear. It is mentioned in Hamlet, Act V, tain the size of a cockchater. Some of another family have the body shaped like a ferryboat, and propel themselves over the surface of waters by the oar-like action of the two middle feet, using the hind legs, brought together as rudder. The Hydrocorisa or WaterBugs are of an obscure black color. One tribe, called boat-flies, trom swimming on their backs, have all their organs arranged for this position, and for rapid progression. The fore feet are claws for catching aquatic insects for ood; the hind pairs are bristled for paddling. In warm weather they are found stationary on the surface of their element; but descend on the approach of danger, which they quickly learn by their all-seeing eyes. They carry down air for respiration beneath the wings. The nepidæ are very predacious; and breathe by two tubes at the end body.

Shellac Varnish for Furniture, de.
This varnish has been employed by cabinet makers upon their ware, but not generaly as a finishing varnish. It has generally been employed when much diluted for the purnose of filling the pores of the wood to form a good body, previous to the application of copal or finishing polish. Shellac is prepared from a gummy substance deposited upon trees by an insect. Seed-lac is more costly and better than shellac, being the select parts rom the trees, free from many impurities, which exist in the latter, either kind forms a arnish when dissolved in alcohol, which al cohol should be a good article: say 0.80 to 0.85 , spe. gr. This is the kind of varnish most requently used by pattern makers, \&c., but is hardly suitable for furniture or other similat articles, on account of its containing a yellowish coloring matter, which injures the appearances of the surface to which it is applied Cabinet makers therefore employ a bleached solution of shellac particularly for white or light colored woods. The bleaching of shellac is generally effected on a large scale by chlorine or some of its compounds, or by sulphuric acid; the bleached article costs about 50 cents per lb., and the unbleached less than half this sum. The bleached shellac is requently dissolved in spirits of wine for use s a varnish by cabinet makers. This varnish is quite apt to stain any inlaid metallic ornament upon the furniture, or any metal attaining a smand consequence of the varnish repound in solution. Another process of bleaching may be adopted, which renders the varnish free from this objection, and very much reduces the cost of the bleached article of shellac or seed-lack. This process consists in the use of animal charcoal as a bleaching powder. It is prepared in the following manner. Any quantity of yellow shellac, previously broken in small pieces is conveyed into a flask, alcohol of 0.83 sp . gr. poured upon it and the whole heated on the hob, or, in the ummer in the sum, until the shellac is dissoled; upon this, so much coarsely powered animal charcoal is added to the solution that the whole forms a thin paste, the flask is closed, not quite air-tight, and left so for sometime, exposed to the sun; and in eight to fourteen days a small sample is filtered sufficient to ascertain whether it has acquired a light yellowish brown color, and whether it yields a clear, pure polish on light-colored woods. If this be the case it is filtered through coarse blotting paper, for which purpose it is best to employ a tin-funnel, with double sides similar to those employed in flitering spirituous solutions of soaps in the preparation of transparent soaps opedeldoc, \&c. The portion which first passes through the filter may be preserved separately, and be used as a ground or first polish. Then some more spirit is poured over the charcoal upon the filter, and
the solution used as a last coating. The solution of shellac purified by animal charcoal has a brown yellow color, but it is perfectly clear and transparent, when diluted with alcohol, the color is so slight that it may be used in this state for polishing perfectly, white wood, such as maple, pine, \&c., without the wood acquiring the least tint of yellow.
Shellac can be dissolved by an alkali, butit is rather a saponaceous compound, and it does not make a good varnish for resisting water. It is best to dissolve it in alcohol in order to get a good varnish, and one that will combine with coloring matters for various purposes. By adding some lampblack to alcholic lac varBy adding some lampblack to alcholic lac var-
nish, a beautiful varnish for black leather is produced.

Destroying Eflluvia.
The "North British Agriculturist" furnish es a statement of Lindsey Blyth, in relation to a very successful experiment for destroy ing a most offensive smell in a stable, arising from the decomposition of urine and dung. He tried the mixture of Epsom salts and plaster of Paris (gypsum) -" the most wonderful effects followed-the stable keeper was delighted." Previously, the stable was damp and unwholesome; and if closed for a few hours, the ammoniacal vapors were suffoca ting. After sprinkling the sulphates underneath the straw, and along the channel of the drain, the smell disappeared, and even the walls became drier. He recommends as an economical preparation for this purpose and for sewers, magnesia lime stone dissolved in sulphuric acid, (forming sulphate of magnesia or epsom salts,) with a portion of super phosphate of lime (made by dissolving bones in sulphuric aci!̣) -these, at the same time that they retain the escaping ammonia, also add greatly by their own presence to the value of the manure.

Inventors wishing applications made for foreign patents are referred to a notice in our ad vertising columns.

LITERARY NOTICES.
The Worrs of Shatspare-Reprinted from the
newly discovered copy of the folio of 1632 , in phs-

 parts, a very fine edition of Sakapear's Writings,
