## TABLES OF <br> CALCULATED HOUR-ANGLES <br> and <br> ALTITUDE AZIMUTH TABLE <br> $30^{\circ} \mathrm{N}$. то $30^{\circ} \mathrm{S}$.

# COMBINED HORARY AND AZIMUTH TABLES 

By H. S. BLACKBURNE.

From JOHN COLES, Esq., formerly in the R.N.<br>Instructor in Practical Astronomy and Surveying to the Royal Geographical Society 6Th June 1897.

"As you and I have talked over the utility of your tables, you already know the high opinion I have of them; in proof thereof I endorse a cheque, and I trust they will receive the support they deserve. They are most excellent tables, and will be of great service to Navigators ; their arrangement is good, and simple, and that, I think, is about the best thing that can be said of any tables for the use of seafaring men."

From Lieut. VINCENT J. ENGLISH, R.N., Teacher of Navigation. Author of "Navigation for Yachtsmen." 7TH June 1897.<br>"Many thanks for the sheets of your new book. I am of opinion that they will be most useful to the overworked Ship Master, and they excel other short methods by their exceeding accuracy."

From A. C. JOHNSON, Esq., R.N.<br>Formerly Naval Instructor for H.M. Training Ship "Britannia." Author of several concise Azimuth Tables, and other Nautical Works. 7 TH JUNE 1897.

"I have no doubt that Captain Blackburne's Tables for finding the time would be very useful within the limits which they comprise, and that they are sufficiently accurate and safe. The facility they afford for obtaining the Azimuth simultaneously is certainly remarkable."

From Lieut. GEORGE WHITE, R.N., late Navigating Lieut., R.N. ilth June 1897.
"I have carefully examined the specimen copy of your Horary and Azimuth Tables, and have, as a test of their accuracy, worked several examples. I have therefore much pleasure in stating that I think them (especially the Azimuth Table) admirably adapted for their intended purpose. Having been for many years Navigating Officer in the Telegraph Service, I should have been very glad of such tables, especially when arriving on the intended grappling ground in the early morning, or late in the evening, as they would have so readily given the ship's position by double Altitudes of suitable stars."

## From Captain T. S. ANGUS, P. \& O. S.S. "Ballaarat." Now Nautical Inspector, P. \& O. S. N. Company, London. <br> $$

THIS BOOK IS DEDICATED TO

## Mr CHARLES WESTLAND

of glen muick, Canterbury, new zealand
AS A TOKEN OF GRATITUDE AND ADMIRATION FOR HIS VERY ABLE, GRATUITOUS, UNSELFISH, PAINSTAKING, AND LABORIOUS WORK IN HELPING THE WRITER WITH THE COMPILATION OF HIS PREVIOUSLY PUBLISHED EX-MERIDIAN TABLES, AND OF SEVERAL OF THE STAR REDUCTION TABLES IN THIS WORK

## EXPLANATIONS RE THE PUBLICATION OF THE CALCULATED HOUR-ANGLE TABLES

In view of the fact that other works have been published partly for the same purpose for which these Tables of Calculated Hour-Angles are intended, and especially considering the work which was published only a few years ago by Mr Percy Davis on very similar lines to these (except for Davis's omission to utilise the latitude variations for the azimuth), I feel that it is necessary for me to explain something about the reasons which have led me to publish these tables (which I began many years before Mr Davis thought of publishing his work), lest it should be thought that I was simply following Mr Davis, with some improvements and additions. I am glad to say that Mr Davis has generously mentioned in the Preface to his work that he knew of my MS. and previous efforts in this direction. I began the calculation of these tables about thirty-eight years ago, and worked at them every spare minute of my time for a few years, until (after tabulating about 80,000 calculations, including the variations) I was told about Lynn's famous "Horary" Tables, which were published in 1827 , but were even then out of print. This somewhat damped my ardour. I had discovered in the meantime that the latitude variations which had been calculated to three places of decimals gave the azimuth accurately to $\frac{1^{\prime}}{2}$ of arc. This discovery was due to Mr A. C. Johnson's little book, Latitude and Longitude in Cloudy Weather. In this work the latitude and sun's azimuth are used to find the correction of longitude due to $I^{\prime}$ of error in the latitude. I therefore rightly concluded that, inversely, the azimuth could be obtained if the latitude and longitude correction due to $I^{\prime}$ of error in the latitude were known ; finding how accurately this came out with my Hour-Angle Table, I tried a small skeleton table published by Adams of Southampton without any author's name, which was in general use in some of the mail-steamer lines under the title of $A$ and $B$ Tables for Correcting the Longitude for Error in Latitude.

I found, however, that this table was too inaccurately computed to give a true azimuth, so I determined to compute a table for every four minutes of time, which, with the aid of only half a dozen figures, would give the azimuth as accurately and quickly as by Burdwood's and Davis's tables, and which would include many azimuths that had been omitted in the large tables of inspection, and which I felt were much needed in double altitude work, especially in low latitudes, where no azimuths were given sometimes for two hours on each side of noon, and no azimuths at that time were given when the declination was over $23^{\circ}$. I accordingly then devoted all my spare time to this smaller work, $A$ and $B$ Tables for Time Azimuths., etc., which were published early in 1883, for latitudes from $60^{\circ} \mathrm{N}$. to $60^{\circ} \mathrm{S}$., and for any hourangle from the meridian. In the Preface to these tables I mentioned that I had begun the calculation of my Horary Tables seven years before. Three or four years after this I handed over the manuscript of my Horary Table work to Captain Martin, R.N., then Naval Instructor of Greenwich College, with full permission to give them to anyone who was willing to continue the
work and publish them on the same plan as I had begun them. He had them in his possession for a few years, but after giving up the sea I asked for them again, as no one seemed inclined to take them up, and Captain Martin returned them to me about eighteen years ago.

A year or two after this Mr Percy Davis, of the Nautical Almanac Office, and author of the famous Time Azimuth Tables, wrote to me of his intention to publish these tables, asking my advice, etc., about them, and I assisted him for a very short time in choosing suitable altitudes, and planning about the variations, etc., which I persuaded him to give for latitude, altitude, and declination. I was unable, however, to persuade him to follow my plan altogether in utilising the tables for azimuths as well. My disappointment that the tables were to be published with their utility so much curtailed led me-after having given Mr Davis full notice of my intention-to endeavour to publish them myself, at any rate for the latitudes of which I had already calculated so much, and which fortunately were of a different zone of latitude from that which Mr Davis was then contemplating publishing for trial. About two years after this I accepted an appointment, which I still hold, under the New Zealand Government, and found that I was not allowed then to publish on my own account, and the Government were not prepared to publish the work themselves. However, about four years ago I received permission from the Minister of Marine to publish the work on my own account, and have also been granted permission to publish with them some Ex-Meridian Tables and Calculated Star Reduction Tables, which, combined with the Hour-Angle Tables, make the work specially valuable for quickly fixing ship's position from two sun or star observations.

Mr Davis, however, was far in advance of me, and published his book several years ago, and his work now includes latitudes from $0^{\circ}$ to $50^{\circ}$.

I hope and confidently expect that the publication of these tables will not only not injure the sale of Mr Davis's work, but will actually increase it, as I prominently bring to the notice of navigators by several examples the value of the tables in connection with fixing the ship's position by combined altitudes of either sun or star observations, and the Altitude Azimuth Table may be used with the latitude variations from Davis's table, with amply sufficient accuracy for position-line purposes, though his variations would not give sufficient accuracy for azimuth purposes on account of their having been calculated for the mid-interval of latitude.

HAROLD S. BLACKBURNE.

[^1]
## PREFACE

The main purpose of these tables is to make as easy as possible the problem of finding the ship's position from combined altitudes of sun, moon, or stars, and especially to encourage the at present much neglected and apparently little valued practice of determining the ship's position from two or three stars at twilight, a few minutes before sunrise, and a few minutes after sunset. The writer, having made a regular practice of such observations for several years of his sea life, is fully alive to the great value of the problem, and considers it to be the most valuable problem in navigation, and has consequently for the last thirty and odd years deplored the neglect of the authorities to give it in the Board of Trade examination for masters and mates.

It ought to be the rule, instead of the rare exception, in all seagoing steamers to take such observations daily. In spite of the discouragement I have received from those whom I might most naturally have expected to help and encourage me, and the continued opposition of the authorities to the use of my tables and methods in the examination room, it will be seen that I have not yet given up my efforts to stir up and encourage shipmasters and officers to get out of the rut of relying wholly on their morning longitude and noon latitude position, and am still working to make easier and more popular the above-mentioned problems, and I have been much encouraged of late to find that my methods and tables are now being very generally used by the younger generation of officers, at any rate in the ships which trade regularly to New Zealand, and even by some of our coasting shipmasters.

My greatest incentive, however, to continued effort in this direction has been the knowledge that such observations tend greatly to the saving of lives and ships from destruction. In the course of my duties in the investigation of witnesses' evidence in wreck inquiry cases in New Zealand, I was struck by the fact that within three years no less than three ships were wrecked, and many lives lost, which would in all probability have been saved had the officers been in the habit of determining the ship's position by simultaneous observations of two stars at twilight ; but no Court of Inquiry could justly censure the master for neglect to take such observations when the determination of this problem is not provided for in the Board of Trade examination for either the mate or master. At about the same time I also received letters from two shipmasters gratefully acknowledging the value that my books had been to them, and telling me that the determination of their ship's position by stellar observations (after experiencing exceptionally strong currents) had been the means of saving their ships from great risk of stranding, one in the China Sea, and the other in the Bay of Bengal.

By the aid of the Calculated Star Reduction and Azimuth Tables in this work, a latitude and position-line can be obtained at any time when the stars are visible, almost as easily as by a meridian altitude of a star. Nothing, so far as the writer knows, has ever been published to so quickly, simply, and accurately solve the problem of finding the ship's position from two or three stellar observations out of the meridian, or for determining the latitude
and position-line from a single observation, which may often be used in conjunction with a sounding, or the bearing of some mountain peak or light, in determining the actual position of ships, as shown in example on page lii.

The below-Pole reductions and azimuths are of most value when only the azimuth or latitude and position-line are required, as the body is then changing very slowly, both in bearing and altitude; but owing to the small change of bearing, even up to two hours from the meridian, it is seldom that the position-lines resulting from bearings east and west of the meridian from two stars is sufficiently large to give a reliable " cut " for determining the position from two ex-meridian observations; but a good "cut" can always be made by combining a longitude by chronometer with one of these ex-meridian observations. The below-Pole reduction tables are also confined to extra tropical latitudes. The calculated reductions and bearings of stars from upper meridian, however, cover a much wider limit of latitude, and, owing to the much more rapid change of bearing when near the upper meridian, two stars can often be chosen from the Calculated Reduction and Azimuth Tables, where the position-lines cut one another at an angle of from $40^{\circ}$ to $50^{\circ}$, which is amply sufficient for a good determination of the ship's position. The reductions and azimuths of twenty-seven of the brightest stars have been tabulated for about one hour from upper meridian, and the reductions of a few of the high declination stars to two and three hours from the meridian. Another great advantage of these tables is that the approximate bearing of the bright stars, and their altitude for setting on the sextant, is determined very simply, so that there can be no mistake in the star, and no need of any star maps, which are, however, of little value when observing stars in twilight. It is my hope, therefore, that the publication of these tables will stimulate and encourage greatly the practice of determining the position of the ship from twilight observations of two or three stars; also of the more frequent determination of the ship's position from combined altitudes of the sun, after considerable change of bearing, or of the sun and moon, and not only in high latitudes but even in the tropics. If this work fulfils its aim in this direction, I shall be gratified by a knowledge that I have helped in some measure to save ships, and lives, from disaster.

Probably owing to the fact that all the "Sumner " problems in our Board of Trade examinations for masters and mates have for many years been set between the parallels of $46^{\circ}$ to $52^{\circ} \mathrm{N}$. and S. latitudes, an impression exists among many officers in the merchant service that a "Sumner" position is of no value in low latitudes. The lengthy and not very accurate way, especially in low latitudes, by which the candidate is obliged to work the problem in our examinations also tends to the neglect of officers practising the "Sumner" problem at sea. Also another great drawback is the difficulty about the chart : the coast charts are on too large a scale, and the ocean charts too small, and there are comparatively few yet who realise the fact that a plane chart (which does for any latitude) may be used with equal accuracy as a Mercator chart, as shown by examples in these pages. As my method of utilising the plane chart is not allowed in the examination room, none of the navigational guide-books mention it.

I feel certain, too, that the Altitude Azimuth Table in this work will be much appreciated by navigators, both for compass correction and for laying off position-lines in connection with observations for fixing the ship's position. Excellent as the many Time Azimuth Tables are, especially Burdwood's and Davis's-and nothing can be handier for compass adjusters when the time is correctly known,-yet I have so often seen mistakes made in obtaining the azimuth at sea through using an erroneous time, that I feel sure that a good Altitude Azimuth Table would be much more valued by the ordinary seagoing
officer than the Time Azimuth Tables, and it would certainly ensure greater accuracy. On the other hand, this Hour-Angle Table will make the Time Azimuth Tables of much more value, as the correct apparent time can be found by it at once by simple inspection. It was for this purpose that I first contemplated bringing out these Horary Tables, as many captains under whom I sailed, especially in earlier years, would not allow their officers to use the Time Azimuth Tables. Now, I believe they are almost universally used, and many men become careless about the time being correct, being content to take the time by the ship's clock, which is often several minutes in error, through the ship's change of longitude, or through the change of the clock to mean time before arrival at some by-port.

The following mentioned ladies and gentleman have assisted me in the compilation of these tables:-Miss Elsie Chapman, Miss Marie Moys, Miss Ida Richardson, and Mr C. B. Maltby, and I consider myself most fortunate in having secured the services of such faithful, conscientious, and accurate assistants.

Although I have had so much assistance in the compilation of the tables, I have personally overlooked every single observation, and can truthfully state that the utmost care has been taken to ensure the most minute accuracy. The hour-angles have been calculated to the nearest decimal of a second by six-figure logarithms, and each one checked by differences. The variations to every degree of latitude, etc., are the variations at the degree, not the midinterval as it is given in Davis's work; they have all been worked out to three places of decimals, and checked by differences, and with such accuracy that I have always found the latitude variation (with three places of decimals) give the azimuth to the nearest $\frac{1_{2}^{\prime}}{}{ }^{\prime}$ of azimuth. The Reduction Tables have been calculated with the same minute carefulness, and I am confident that not one per cent. of the tabulated reductions will be as much as $O^{\prime} \cdot \mathrm{I}$ in error. In addition to the Hour-Angle and Altitude Azimuth Tables and Star Reduction Tables, there is also a very comprehensive general Ex-Meridian Table, which, though occupying very few pages, yet comprises more extensive limits of use than most other Ex-Meridian Tables. This will be found very useful for facilitating the work of fixing the ship's position by combined altitudes of two sun ex-meridians, or with a chronometer and ex-meridian observation. A few other useful tables are also given. The Azimuth Table corresponding to the latitude variation is given from the equator to latitude $60^{\circ}$, so that it may be used also with Davis's Hour-Angle Table for aiding in quickly taking out the position-line for use with either a plane or Mercator chart, when outside the latitude limits of the Hour-Angle Table of this work, which are at present confined to latitudes from $30^{\circ} \mathrm{N}$. to $30^{\circ} \mathrm{S}$. This table is also used in conjunction with Table VIII., Ex-Meridian Table.

To minimise the need of interpolation as much as possible, the reductions to the meridian and azimuths of all the bright stars have been calculated for the actual declination of the stars for a few years ahead; but as the declination of most of the stars changes so slowly, there will be no appreciable change in the tabulated reductions and azimuths for the next forty or fifty years, and, the results being exhibited in this tabular form, the value of an error in either the latitude or time is seen at a glance.

In the Hour-Angle and Altitude Azimuth Table a glance at the table will show the best time for observing, viz.-when the lat. var. is o, the body being then on the prime vertical. Also, when the declination is greater than the latitude the lat. var. shows at a glance when the body is nearest to the prime vertical.

In closing, I have much pleasure in acknowledging the kind, gratuitous help voluntarily tendered to me by Mr Charles Westland, and in thanking
him for his disinterested labours in the calculation of several star reductions. I would also like to thank the Hon. Ministers of Marine for their permission to publish a few of the smaller tables previously published by. the New Zealand Marine Department in their Azimuth and Reduction Tables, also some of their previously published Star Reduction Tables now further extended by myself, and my assistants.

In the words of Raper, the nautical author whose work I have used and valued more than any book on navigation, I would solicit the indulgence of the reader to errors and to deficiencies. As he truly says, absolute correctness, especially in tables, is scarcely attainable, and in a work which contains much that has not appeared before, I cannot reasonably flatter myself that, notwithstanding every care and attention, some small inaccuracies may not be found, especially as in my case, owing to the long distance from my printer, and my desire to keep faith with those who bought copies of the work before publication, I have had to trust to a single correction of the proofs.

Should, however, any errors be discovered in the work, I shall be most grateful to anyone who will bring such to my notice.

HAROLD S. BLACKBURNE.

Wellington, New Zealand, June 1914.

## PREFACE TO SECOND EDITION

In this Second Edition of these tables over 35,000 new calculations have been made and added to the tabulations of the previous Edition, and some new examples are published with surprising results from ex-meridians with very high altitudes. The Ex-Meridian Table has been considerably enlarged, and the limits of its use increased both in latitude and bearing from the meridian. This is especially the case with high altitudes, when nearly all other Ex-Meridian Tables fail. I am indebted for the idea of the new table to a little book published about two years ago by Captain Cook of Bowden, Jamaica, in which he gives a small table of two half pages giving the reduction to I min., corresponding to a given latitude and azimuth.

I found that although only roughly computed by the traverse table, it often gave very good results, and would be independent of the latitude variation, and I saw that if it were expanded, and accurately computed by a true formula, accompanied by a table giving the limits within which it might be used with safety, it was likely to prove a very useful table; and the results with very high altitudes have far exceeded my expectations, and I have no doubt will surprise a good many.

A well-known and up-to-date author, in a recent publication, when advocating the claims of the "New Navigation," tells us that an ex-meridian at $22^{\circ}$ from the meridian is an impossible thing; but an example is given on p. xxxviii of this book, with a very high altitude, where the latitude and longitude are accurately determined from two ex-meridians, one of them being over $70^{\circ}$ from the meridian.

It is probable that a wrong impression will have been gathered with regard to the immense amount of labour which has been put into this work, on account of the remarks made by the reviewer of one of the principal Nautical Magazines about most of the tables having seen the light in earlier publications, and mention being made of Lynn's and Davis's Hour-Angle Tables having been previously published on the same lines. I may say that although Lynn's tables were very complete in the tabulation of hourangles from sunrise to the meridian, no variations were given for any of the elements, and consequently interpolation was very tedious. With regard to Davis's tables, the variations are only given to one place of decimal, and for the mid-interval, instead of being the variation at the degree of latitude, altitude, and declination; consequently, they could not be expected to give hardly one-tenth of the accuracy obtained by these tables. I, at first, computed several thousand of my own variations for the mid-interval, as it was so much easier to do this, but finding that results did not give the accuracy which I was aiming at, I recomputed them as now published. Neither Lynn's nor Davis's tables give the azimuth, whereas I understand from some of those who have used these tables that the Altitude Azimuth Table in this book is preferred even to the world-famous Red Book Time Azimuth Tables.

I can truthfully state that every tabulated hour-angle and variation in the book has been rigorously calculated, either by myself, or by computers paid by me. No one could contest this, as no other work tabulates the results to the same degree of fineness, viz., to $\frac{1}{10}$ of a second. I alone am responsible for every tabulated result in the book, all the calculations having been
made either by myself, or under my direct supervision and scrutiny, so that I can confidently guarantee the extreme accuracy of all the tabulations.

The Ex-Meridian Table is entirely new, though on the same principle (with an extension of limits) as the Ex-Meridian Table in my book of A B C Azimuth and Reduction Tables ; also, about 50,000 new calculations have been made, and tabulated in the Tables of Calculated Reductions and Azimuths of Bright Stars.

These are the main tables in the book; the other small supplementary tables which were previously published in one or two of my earlier works only comprise a few pages.

I have been disappointed to find that there is small probability of the immense labour and great expense entailed in the production of this work being rewarded by the satisfaction of knowing that the tables and methods advocated in the work will be at all generally used in my own lifetime, as the present authorities prohibit their use in the Board of Trade examinations for masters and mates, and the great majority of ship officers in the merchant service appear to be still ignorant of the value of a position-line in connection with an ex-meridian for position finding, or even in connection with a calculated altitude as taught in the so-called " New Navigation" (now forty years old), owing to the regrettable conservatism of the authorities in only allowing the "Sumner" to be worked from the calculation of four hour-angles, and plotted on the chart from two parallels of latitude, notwithstanding that this method has been frequently shown to give errors of a few miles in the resulting position, besides taking twice as long in the calculation.

Quite naturally the numerous guide-books which are used in preparation for our examinations only present the methods which candidates are expected to use in the examination room, and other improved methods are only taken up by the comparatively few who take a special interest in Navigation.

Such men are usually conversant with all the best and shortest methods; but to ensure the greater safety of navigation generally, it is essential to encourage in every way possible the man who is not fond of lengthy calculations, or who has little time at his disposal to frequently take azimuths, and determine the ship's position by the simplest accurate methods; but when a candidate is given a problem such as our double altitude problem, either by the sun, planet, or a star, and he is required to get a latitude only by the use of numerous logarithms, all rigorously corrected for seconds of arc, it is apt to leave an impression on his mind that the determination of even the latitude at some distance from the meridian is a very difficult, tedious, and uncertain business. As we in New Zealand are bound by the Board of Trade regulations in our examinations for foreign-going certificates, we are unfortunately debarred from making use of our tables for quick position finding by two stars at twilight, or by any of the simple methods of obtaining the azimuth, or position of ship by sun or stars, presented in this book.

Notwithstanding this discouragement, I am still continuing my labours for the sake of the few in my day who will profit by them, and in the assurance that at least some ships and lives will be saved by these efforts, and in the belief that in some future generation these methods, with the tables still further extended in their limits, will be generally adopted.

HAROLD S. BLACKBURNE.

## EXPLANATION AND USE OF TABLES

## table l.--FOR FINDING HOUR-ANGLE AND AZIMUTH FROM ALTTTUDE

(pp. 2-245)
The arrangement of the arguments will be easily followed by attention to the following explanations, viz.:-

The latitude heads each page; the table begins at the equator, and comprises four pages to each latitude up to $30^{\circ}$ of latitude and declination of same name, then continues with latitude and declination of contrary names from $I^{\circ}$ to $30^{\circ}$, with another four pages to each latitude.

The declination immediately below the latitude runs horizontally through the four pages of latitude from $0^{\circ}$ to $23^{\circ}$.

The altitudes are arranged vertically on the left side of each page.
The hour-angle is given to the nearest decimal of a second for the full degrees of latitude, declination, and altitude.

The variation to $I^{\prime}$ of declination is given under the declination column on the righthand side of the hour-angle, and the variations to $I^{\prime}$ of latitude and altitude are given on the lower half of the page, L standing for latitude, and A for altitude. The variations to $\mathrm{I}^{\prime}$ of latitude, etc., are the variations at the degree in the same way as they are given in the Nautical Almanac. For instance, the variation at $8^{\circ}$ is found by dividing the difference between the hour-angles at $7^{\circ}$ and $9^{\circ}$ by $\mathbf{1 2 0}$, and the latitude and altitude variations are computed in the same way. It is important to bear this in mind, as the variations in Davis's Chronometer Tables have been calculated for the mid interval, and the apparent discrepancy between the variations as given in the two works might lead to some want of confidence in either work.

The latitude variation referred to Azimuth Table on pages $258-267$ gives the true azimuth, or bearing of the sun or other heavenly body, and on page 270 the position-line for a plane chart; or if the variation, considered as a difference of longitude, is converted into departure, it will give the true position-line for use on a Mercator chart.

In using the table, enter it with the latitude, declination, and altitude, each to the nearest degree, and take out the recorded hour-angle ; correct for the odd minutes of latitude, etc., by the previously mentioned variations. This may be effected either by simple multiplication or by reference to the Proportional Sexagesimal Table on pages $246-25$. The resulting hour-angle will seldom be more than $\frac{1}{2}$ second in error, and more often than not it will be within O.I s. of the truth.

Strict attention, however, must be paid to the signs which are given with each of the variations.

Formula used in the calculation of the table:-
Haversine H.A. $=\sec l . \operatorname{cosec} p \cdot \cos \mathrm{~S} \cdot \sin \mathrm{~S}-a$,

$$
\text { where } a=\text { alt., } l=\text { lat., } p=\mathrm{P} \text {. Dist., and } \mathrm{S}=\frac{a+l+p}{2}
$$

Examples of Finding the Time and Azimuth from Tables
Example i.-In latitude $30^{\circ} 12^{\prime}$ S., p.m. at ship, decl. $16^{\circ} 18^{\prime} \mathrm{S}$., and altitude $32^{\circ} 40^{\prime}$. Required the hour-angle and sun's bearing.

The nearest degrees are L. $30^{\circ}$, D. $16^{\circ}$, and A. $33^{\circ}$.

Variations. $\begin{gathered}\text { Minutes } \\ \text { (in excess }+, \\ \text { in defect }- \text { ). }\end{gathered}$

| S. | S. |
| ---: | :--- |
| D. $+2.0 \times+18=$ | $+36^{\circ} \circ$ |
| L. $+0.07 \times+12=$ | +0.8 |
| A. $-4^{\circ} 62 \times-20$ | $+\underline{92^{\circ} 4}$ M. S. S. |
| Cor. | $+129^{\circ} 2=29^{\circ} 2$ |

For the Azimuth.
s.
L. Var. $+{ }^{\circ} \circ 7$ gives (p. $25^{8}$ ) Azimuth S. $89^{\circ} \cdot{ }^{\circ} \mathrm{W}$.

Example 2.-In latitude $30^{\circ} 8^{\prime}$ N., P.m. at ship, decl. $14^{\circ} 48^{\prime}$ S., and altitude $20^{\circ} 12^{\circ}$. Required hour-angle and sun's bearing.

s.
L. Var. -2.84 gives (p. 258) Azimuth S. $58^{\circ} .4 \mathrm{~W}$.

These examples were taken at random with the highest latitude of the tables, and with latitude and decl. of same, and contrary names.

The resulting hour-angle from the tables will seldom be more than $\frac{1}{2}$ second in error, and if the tabulated variations are interpolated, results will seldom be more than 0.1 s . or 0.2 s . in error. Azimuths, if correctly interpolated, should never be more than $0^{\circ} \cdot 1$ in error, and the azimuth will generally be correctly given by the latitude variation to the nearest minute of arc, if Table V. is used in conjunction with the traverse table.

## TABLE II.-SEXAGESIMAL PROPORTIONAL TABLE (pp. 246-251)

This table may be used by those who prefer to look out results from a table instead of making the simple multiplication of the variations. It shows at a glance the error due to $0 \cdot 1 \mathrm{~s}$. for any number of minutes.

> Example.—Alt. vår. $4^{\cdot 1} 5 \mathrm{~s} . \times 24^{\prime}($ page 248$) 4 \cdot 10 \mathrm{~s}=98 \cdot 4 \mathrm{~s}$. $4 \cdot 20 \mathrm{~s} .=100 \cdot 8 \mathrm{~s} . \quad \therefore \quad 4 \cdot 15 \mathrm{~s} .=99.6 \mathrm{~s}$.
> -I S. $\quad 2.4 \mathrm{~s}$.

## TABLE II.-TABLE SHOWING THE ERROR IN TIME OR LONGITUDE PRODUCED BY AN ERROR OF $1^{\circ}$ IN THE ALTITUDE (pp. 252-257)

The arguments are latitude and azimuth, and with these elements the table shows at a glance the value of any single observation for determination of time when outside the limits of the hour-angle table. The table may also be usefully employed as an azimuth table, with altitude and time, following the rule for which the author is indebted to Mr H. B. Goodwin, R.N.

Formula used in the calculation of the table :-
Error in time $=$ sec. of lat. $\times \operatorname{cosec}$ of azim. $\times 4$.

## Rule for Finding the Azimuth

With H.A. as azim. and decl. as lat., go to Table III.
Take out co-efficient, call it M.
With alt. as lat. and M, take out azim. at top of page.
Example.-In lat. $44^{\circ} 15^{\prime}$ S., alt. of Canopus $14^{\circ} \cdot 6 .$, H.A. 2 h .57 m . Find the azimuth.

Lat. (dec.) $52^{\circ} \cdot 6 \mathrm{~S}$. , azim. (H.A.) $2 \mathrm{~h} .57 \mathrm{~m} .=44 \frac{1}{4}^{\circ}, \mathrm{M}=9.44$.
Lat. (alt.) 14.6 and M 9.44 gives azim. $26^{\circ}$.
Table III. will be found very useful in working out separately a set of observations, both with artificial horizon and at sea; or for working out another person's observations, taken within a few minutes of the same time. It also shows at sight the degree of dependence of any observation. And if at any time it is found that an erroneous altitude has been worked with, the longitude will readily be corrected by this table, a greater altitude giving a smaller hour-angle, or with A.m. sights a greater altitude making the longitude more to the eastward and a lesser altitude making the longitude more to the westward-vice versa with P.M. sights.

It will also be found useful when taking time azimuths by the sun or stars (when altitude is low) for readily obtaining the correct hour-angle, as in the following example :Lat. $20^{\circ} \mathrm{N} .$, * Arcturus bearing N. $71^{\circ} \mathrm{E}$. (true), altitude $5^{\circ}$. Table III. at lat. $20^{\circ}$ and azimuth $7 \mathrm{I}^{\circ}$ gives 4.5 m . of time to $\mathrm{I}^{\circ}$ change of alt. Table 26 (Raper), lat. $20^{\circ} \mathrm{N}$., decl. $20^{\circ} \mathrm{N}$., gives *'s hour-angle at rising or setting 6 h .30 m .

$$
\begin{aligned}
& 4.5 \mathrm{~m} . \times 5^{\circ}=-22 \frac{1}{2} \\
& * \text { 's H.A. at } 5^{\circ}=6 \quad 7
\end{aligned}
$$

The results of the table can be easily found by inspection from the traverse table. At the equator, when the sun or any other heavenly body is on the prime vertical, it moves at the rate of $I^{\circ}$ in 4 m ., or $I^{\prime}$ in 4 s . of time; and in any other latitude, when the sun is on the prime vertical, the ratio of its movement will be dep.: diff. long. Having, then, the rate of movement in any latitude on the prime vertical, the rate of movement on any other bearing may be found by the traverse table.

Example.-In latitude $30^{\circ}$, and $\odot$ 's bearing N. $63^{\circ}$ E., required the rate at which it moves. In latitude $30^{\circ}$, against 4 in D. lat. column, is 4.62 in dist. column; with $\odot$ 's bearing $63^{\circ}$, and 4.62 in dep. column, we have 5.18 in distance column $=5.18 \mathrm{~s}$. to $\mathrm{I}^{\prime}$ of altitude.

Further examples in the use of the table are given on page xlii.

## TABLE IV.-AZIMUTH TABLE (pp. 258-267)

Enter table with lat. var. to $\mathrm{I}^{\prime}$ at side, and latitudes on top of page running horizontally. Corresponding azimuth is given to nearest decimal of a degree, and the rule for naming the azimuth is clearly given at head of page.

Formula of calculation :-Cot azim. $=$ lat. var. $\times \cos$ lat. $\times 4$.
Example in Use of Table.-Lat. $20^{\circ}$ N., decl. $0^{\circ}$, alt. $50^{\circ}$, lat. var. -2.05 s. gives azim. (page 258) S. $64^{\circ} \cdot 25$.

## TABLE V.-AZIMUTH CORRESPONDING TO LATITUDE VARIATION IN DEPARTURE (pp. 268-269)

This table is given for cases where the azimuth is required to the nearest minute of arc.
Rule.-Consider the lat. var. as a d. long. and convert it into dep. by the traverse table. The azimuth corresponding to this factor may then be taken out to the nearest minute of arc.

Formula of calculation :-Cotan azim. $=$ lat. var. $\times 4$.
Example in Use of Table.-Lat. $20^{\circ}$ N., decl. $0^{\circ}$, lat. var. $-2.05 \mathrm{~s} .=$ dep. 1.926 s . gives azim. (page 268) S. $64^{\circ} 17 \frac{1_{2}^{\prime}}{}$.

## TABLE VI.-POSITION-LINES CORRESPONDING TO LATITUDE VARIATION FOR USE WITH THE PLANE SCALE CHART IN THE " SUMNER" PROBLEM (p. 270)

This table is given for the purpose of plotting a "Sumner" position on a plane chart. The position-lines corresponding to the lat. var. give the same result as to latitude and longitude on a plane chart as the true lines of position would give on a Mercator's chart. One chart, therefore, does for any latitude, or, with the aid of a small 6 -inch rule with a protractor and diagonal scale of inches marked on it, the chart may be dispensed with and the position plotted in the work book. To do this, set off the points of two longitudes on the parallel of the D.R. latitude at a distance from one another of, say, I in. to ro' of longitude. From these points lay down the "Sumner " lines, and from the point where they intersect draw a perpendicular to the parallel of D.R. lat. The longitude at the point struck by the perpendicular is the longitude required, and can be measured from either of the points of longitude. The same scale is used for the latitude as for the longitude.

It must be borne in mind that this table does not give the true geographical lines of position. If this is required for a Mercator chart, consider the lat. var. as a diff. long. and convert it into dep. by the traverse table. The position-line corresponding to this dep. will be the true geographical line of position.

Formula of calculation :-Tan position-line $=$ lat. var. $\times 4$.
Example.-a.m. at ship in lat. $30^{\circ} \mathrm{N}$., lat. var. was $+\cdot 75 \mathrm{~s} .=$ dep. $\cdot 650 \mathrm{~s}$., which gives true position-line $\mathrm{S} .9^{\circ} \cdot 2 \mathrm{E}$. and N. $9^{\circ} \cdot 2 \mathrm{~W}$.

## TABLE VII. AND VII.--LIMITS OF EX-MERIDIAN TABLE (pp. 272 and 292)

These tables show at a glance the hour-angles at which it is safe to use the Ex-Meridian Table so that with the correct time the reduction will not be in error more than $\frac{\frac{1}{2}^{\prime}}{}$. It must, however, be borne in mind that the resulting latitude is the latitude corresponding to the meridian of longitude used in the deduction of the time. The latitude variation will readily show the line of position which must be laid down, on the meridian of the D.R. longitude used in determining the time; or if the azimuth has been determined, Table IX. will show at a glance the error due to $1^{\prime}$ of longitude.

## TABLE VII.-AZIMUTH EX-MERIDIAN TABLE (pp. 278-291)

The factors under the heading of Azimuth abreast lat. are the reduction at 1 m . from the meridian to apply to an altitude to reduce it to the meridian altitude.

## Instructions concerning the Use of Table, and Rule for Application

Multiply the factor corresponding to the latitude and azimuth in Tables VIII. and VIII $a$., and abreast lat. var. in Table VIIIb., by the number of minutes and decimals in the hour-angle from the meridian, which gives the correction to apply to the observed altitude to reduce it to the meridian altitude. Add this correction to the observation taken near the upper meridian passage, and subtract the correction when observation is taken near the meridian below the Pole. This reduction will not be more than $\frac{1^{\prime}}{}{ }^{\prime}$ in error when the hour-angle is less than that shown in the preceding Tables VII. and VIIa.; the " "g", against the factor in the table signifies that the true reduction will be greater, and " 1 " less, than the tabular reduction.

The table gives the correct reduction at I min. from the meridian for any azimuth up to $60^{\circ}$ from the meridian, and has been rigorously calculated by seven-figure logarithms from the following formulæ :-

> Cot. $\mathrm{ZD}=$ Sin Azim. . Cot H.A. I min.
> Tan. Decl. $=$ Sin H.A. I min. . Cot Azim.

In Lat. $0^{\circ}$, Decl. $=M Z D$, and $Z D-M Z D=$ Reduction at Lat. $0^{\circ}$.
Then Cos Lat. $\times$ Redn $=$ Redn. for succeeding Latitudes.

## TABLES VIIa. AND VIIb.-EX-MERIDIAN TABLES (pp. 293-299)

Table VIII $a$. gives the reduction at I min . to three place of decimals corresponding to azimuths from $26^{\circ} 36^{\prime}$ to $74^{\circ}$, in lat. $o^{\circ}$.

The reduction for other latitudes may be quickly found by the Traverse Table. By taking the reduction at r min. in dist. column, the corresponding reduction for any latitude is found in D. lat. column : or cos. lat. $\times$ Redn. at i min. $=$ reduction for latitude required.

Table VIII $b$. is a continuation of Table VIII $a$., but must be used in conjunction with Table IV. (Azimuth Table), as shown in the following example.

Example.-Lat. $20^{\circ}$ azimuth $9^{\circ} \cdot 3$ gives lat. var. 26.00 sec., which gives Redn. at $1 \min =I^{\prime} \cdot 147$.

Pages 296 and 297 of Table VIIIb. have been recalculated with the formula above stated, but as there was no appreciable difference in the results when the azimuth was small between this formula and that employed in the first edition of the book, pages 298 and 299 have been retained. These two pages were calculated by the following formula :-Reduction for $\mathrm{r} \min .=\frac{30 \mathrm{~V}}{4+\mathrm{V}^{2}}$ where $\mathrm{V}=$ lat. var. in time, i.e. the error in time due to $I^{\prime}$ of error in lat. Table VIII. will be found the most convenient to use, but a reference to Tables VII. and VIIa. will indicate under different circumstances which table should be used to get the best results.

## table IX.-ERROR IN LATITUDE BY EX-MERIDIAN DUE TO 4 SECS. IN TIME, OR 1' OF LONGITUDE (pp. 300-301)

This table (pages $300-301$ ) shows at a glance the error which would result in the latitude from any single observation out of the meridian for every 4 secs. of time, or $\mathrm{I}^{\prime}$ of longitude. When two observations are taken the factors given in this table facilitate the problem of finding the ship's position from two ex-meridian observations, or one chronometer observation and an ex-meridian. See pages xxxiv, xlii, xlviii and xlix.

Formula used in the calculation of table :-Lat. error $=$ long. error $\times \tan$ azim. $\times \cos$ lat.

## table X.-The mean places of 108 of the brightest stars, in order OF RIGHT ASCENSION, FOR 1ST JANOARY 1914

On pages 302-303 the mean places of no8 of the brightest stars are given, in the order of their right ascension, for the Ist January 1914. In the column headed "Mag." the adopted unit of brightness is designated $\mathrm{I}^{\circ} \mathrm{o}$. The magnitudes of stars are determined to tenths of a magnitude with reference to this adopted unit. The magnitudes of the ten stars brighter than the unit are indicated by figures less than $1 \cdot 0$ : thus, the value 0.3 for Arcturus indicates that that star is seven-tenths of a magnitude brighter than the unit; the value -1.4 for Sirius that it is 2.4 magnitudes brighter than the unit. As the right ascensions and declinations of the stars do not change uniformly throughout the year, the correction for intermediate months cannot be made accurately by multiplying the annual change by a fraction of the year ; but the change is so small that for navigational purposes at sea the right ascensions and declinations here given may be used without appreciable
error for azimuths and latitudes, and even for longitude the error due to using these elements would seldom exceed a mile. When greater accuracy is required the navigator should use the Admiralty Nautical Almanac for the year, where the right ascensions and declinations of these and many other stars are given very minutely for every ten days throughout the year.

## TABLE XI.-APPROXIMATE APPARENT TIMES OF THE MERIDIAN PASSAGES OF THE PRINCIPAL FIXED STARS (pp. 304-306)

The times are given in this table for the ist of each month and the meridian of Greenwich. To find the time for any other day, subtract the portion of time corresponding to the day of the month in the day-correction table. Add 1 min . for every $90^{\circ}$ of east longitude, and subtract I min. for every $90^{\circ}$ of west longitude.

The time of the meridian passage of each star has been carefully calculated to the nearest second of time for the year 1910, and is given in the table to the nearest minute.

For the circumpolar stars which never set in higher latitudes than $50^{\circ} \mathrm{N}$. or S . the times of the meridian passages of the inferior as well as the superior transit have been given.

## Example and Caution in using this Table

Required the meridian passage of $* \beta$ Centauri on 3 1st October, in longitude $10^{\circ} \mathrm{W}$. н. M.

Mer. pass. of $* \beta$ Centauri on Ist Oct. is Cor. for 3ist day

Approx. time
2nd cor. required
Approx. mer. pass. $* \beta$ Centauri
$130 \mathrm{P} . \mathrm{m}$.
I 52

```
31 23 38=11 38 a.m. on Ist Nov.
        -4
    D.-
    31 23 34 or II 34 a.m. on Ist Nov.
```

The interval in this case is within 2 hours of 31 days instead of 30 days, therefore nearly 4 minutes more correction is required to be subtracted. The correction for longitude would be less than io seconds.

The table is calculated for the year rigro, but will be within 2 min . for many years, with the single exception of the $*$ Polaris, which has an annual and increasing change in R.A. of over 27 s ., and will therefore be about 5 min . later in passing the meridian in io years' time.

## TABLE XII.-ALPHABETICAL LIST OF 30 OF THE BRIGHTEST STARS WHOSE REDUCTION TO THE MERIDIAN AND AZIMUTH HAS BEEN CALCULATED AND TABULATED IN the following pages. also the order of these stars in r.a., giving the SIDEREAL time of star's meridian passage above and below the pole FOR THE CIRCUMPOLAR STARS (p. 307)

This table will be useful for reference in quickly determining which are the most suitable bright stars for latitude, longitude, azimuth, or position-finding from combined observations of two or three stars.

## TABLE XII.-REDUCTION TO THE MERIDIAN FOR * POLARIS, 1915

This table (page 308) has been calculated for star's declination in 1915, and shows at a glance the reduction to the meridian required for every 10 m . of hour-angle and every 10 m . of latitude from $10^{\circ} \mathrm{N}$. to $60^{\circ} \mathrm{N}$. latitude.

Examples in the use of the table are given at foot of page under the table.

## TABLE XIV.-STAR POLARIS AZIMUTH TABLE (p. 309)

The true bearing to the nearest decimal of a degree is given in this table for every 20 m . of hour-angle from $0^{\circ}$ to $60^{\circ} \mathrm{N}$. latitude. The declination of the star for the year 1915 was used in the calculation of the azimuth. The table is especially useful between $10^{\circ} \mathrm{N}$. and $30^{\circ} \mathrm{N}$., as for instance in the Red Sea. In a high latitude the altitude will be too high for compass correction work. It is therefore not given beyond $65^{\circ}$ of latitude.

## TABLE XV.-REDUCTION TO THE MERIDIAN AND AZIMUTH TABLES FROM 1 HOUR TO 3 HOURS FROM THE MERIDIAN ABOVE AND BELOW THE POLE OF 26 OF THE BRIGHTEST STARS (pp. 310-411)

These tables give at sight the reductions and azimuths of 29 of the brightest stars from about I hour to 3 hours from the meridian above and below the Pole. The reduction must be added to the altitude to reduce it to the meridian above the Pole, and subtracted from the altitude to reduce it to the meridian altitude at the inferior transit.

The azimuth will always be of the same name as the latitude at the inferior transit, and North or South at the superior transit according to whether the star's declination is North or South of the observer's latitude.

It is hoped that these tables will induce navigators to establish a habit of regular and systematic observation of stars for position-finding at twilight.

The reduction taken out at sight to the nearest couple of minutes, and applied to the calculated meridian altitude, would give the approximate altitude for setting on the sextant, and the bearing which is given on the same page will give the direction in which to look. There will be no need of star maps or celestial globes, as the altitude and bearing of the star will positively determine its identity.

The reductions which have been tabulated to the nearest tenth of a minute have been calculated to the nearest hundredth part of a minute. Most of them were calculated with Shortrede's seven-figure logarithm table, using the star's declination corrected to the nearest second of arc for the year 1920. The below-Pole reductions up to 1 h .15 m . from the meridian which were calculated at an earlier date, and first published in 1908, have been calculated for the year rgro. The difference would seldom amount to as much as $o^{\prime} \cdot 1$. The results have been carefully checked by differences of both time and latitudes, and can therefore be relied on for close accuracy.

The formula used in the calculations for the reduction tables is that deduced from dropping a perpendicular on the hour-circle from $Z$ at $N$ inside or outside the usual spherical triangle PZD, using the supplement of P. (H.A.) for below-Pole hour-angles.

Then PN $(\operatorname{arc} x)=\cos P \cdot \tan Z P$.
$\mathrm{ND}(\operatorname{arc} 2)=\mathrm{NP} \pm \mathrm{PD}$.
$\cos Z D=\cos P Z . \cos N D . \sec N P$.
Reduction $=Z \mathrm{D} \sim \mathrm{MZD}$.

## TABLE XVI.-ALTITUDE CORRECTIONS OF SUN AND STARS, AND ACCELERATION TABLE (pp. 412-413)

This table (the upper half for the sun, and the lower half for the stars) gives the lump correction to apply to their observed altitudes, involving for the sun dip, refraction, semidiameter, and parallax, and for the stars dip and refraction.

As the correction for very small altitudes changes rapidly, a supplementary table is given on page 413 for the correction of both sun and stars, at a height of 40 feet above sea-level, for altitudes between $3^{\circ}$ and $I x^{\circ}$, for every few minutes of altitude, and for other heights greater or less than 40 feet a second correction is given in same table.

Heights are given from 6 feet to 80 feet, so as to meet the need of navigators in every class of vessel, from the smallest to the largest. As standard authorities still slightly differ in their dip and refraction tables, a mean of the dip and refraction given in the three standard works (Raper, Inman, and Norie) has been used in the calculation of the table here given, and great care has been taken to ensure accuracy.

## TABLE XVIa.-ACCELERATION TABLE (p. 412)

This table is used for converting intervals of mean solar time into equivalent intervals of sidereal time. The seconds column which is given in most navigational tabular works has here been omitted for the sake of space, and because it is considered quite unnecessary in ordinary practical navigation. In practical navigation it becomes necessary in nearly all the problems where stars are used to convert mean solar time into sidereal time, as, for instance, in the time azimuth, longitude by chronometer, and the ex-meridian problems. In these problems the time is generally taken by a chronometer keeping mean solar time, and to compare this with the sidereal time found by the stellar observation it must be reduced to sidereal time.

Examples will be found among some of the worked-out problems following these explanations.

# GENERAL REMARKS, RULES, AND EXAMPLES 

## GENERAL REMARKS ON THE DOUBLE-ALTITUDE AND " SUMNER" PROBLEM

Many navigators undervalue Sumner's method in low latitudes: first, because of the small change of bearing between the usual times of taking the observations; and secondly, because with a high altitude the circle of altitude or line of position is not to the same extent a straight line on the chart. Those who do not think for themselves are further confirmed in the very common impression which one has so often heard expressed about the uselessness of attempting to get a "Sumner" position in low latitudes, owing to the practice of those who are responsible for setting the papers for the Board of Trade examinations for masters and mates in confining all their examples within the parallels of $46^{\circ}$ to $52^{\circ}$ of N . or S . latitudes, and compelling candidates to work the "Sumner" problem by the calculation of four hour-angles, plotting the position between two parallels of latitude instead of by the briefer, more accurate, and up-to-date method of working by positionlines taken from azimuth tables, and making the starting-point either from the meridian or parallel of latitude, according to whether the sun is nearest the meridian, or prime vertical. Naturally, all the navigational guide-books for candidates follow suit, and in consequence comparatively few officers in the merchant service know anything about utilising a position-line from an ex-meridian observation, or from the "intercept" of the altitude, as used in the Marcq St Hilaire method.

Some of the problems in this work have been purposely given in low latitudes and with very high altitudes, and it will be seen that a perfectly accurate result is obtained with an altitude as high as $89^{\circ}$ and $37^{\circ}$ from the meridian, when the same problem worked by the above-mentioned method would be as much as $9^{\prime}$ in error in the latitude. If observations are used intelligently, accurate "Sumner" positions may be obtained in any latitude, and no altitude need be considered too high-the only consideration is to make sure that the sun has changed sufficiently in bearing to make a good "cut" of not less than $40^{\circ}$, and, to ensure this, one of the observations should be made within half an hour of noon when in the tropics. In the winter months an hour from noon will sometimes give a sufficiently large angle to make a satisfactory "cut"; but when the observer is nearly under the sun, one of the observations should be taken within a few minutes of noon, and under such conditions a right-angle "cut" may sometimes be obtained within an interval of five to ten minutes, by A.m. and p.м. observations.

The writer has served a great deal of his sea time in low latitudes, and never found any difficulty in getting good reliable positions from double-altitude observations, although in those days, to the best of the writer's knowledge, there were no ex-meridian tables published which would give a reliable latitude when the sun was over $30^{\circ}$ from the meridian. He may, however, be wrong in this surmise, as, notwithstanding the fact that at least three or four such tables are now on the market, a very well-known and up-to-date author of nautical works, as lately as r9r3, considered that an altitude of a star which was only $22^{\circ}$ from the meridian was an impossible ex-meridian. On page xxxviii of this work an example is given where position of ship is accurately determined by these tables from two ex-meridians, one of them being over $70^{\circ}$ from the meridian, and the proof of the accuracy of the determination is verified by other methods.

In obtaining the latitude by the double-altitude or "Sumner" method, it is best if the observations are taken on the same side of the meridian for the same person to observe both; and generally the truest latitude will be found if both observations are taken on the same side of the meridian, as it is probable that if for any reason the altitude is observed too high, or too low, the same thing will occur in both observations. For the same reason the truest longitude will be found from observations taken on different sides of the meridian.

## REMARES ON THE POSITION-LINE AND "SUMNER" PROBLEM IN CONNECTION WITH EX-MERIDIANS

Although most navigators are now fully alive to the value of the position-line in connection with the longitude by chronometer, the value of the position-line in connection with the latitude by ex-meridian is seldom presented in works of navigation. It is generally supposed that an ex-meridian, if taken within a certain time from noon, will give a correct latitude, and that therefore the ship's line of position is anywhere on that parallel of latitude. This, however, is only the case when the ship time (which depends on the longitude) is nearly correct.

The further the object is in bearing away from the meridian, the greater will be the error due to an error in the time. (See Table IX., pp. 300-301.)

The time, however, might be uncertain to 4 or 5 minutes, and yet the ex-meridian observation may be of great value in connection with the position-line, either when near the land by combining this line of bearing with some sounding (see p. lii), or bearing of the land, or by combining it with another astronomical position-line, as in the "Sumner" problem. When the body which is used as an ex-meridian is within the limits of exmeridian tables, an accurate latitude for a particular meridian may be obtained with very few figures. For cases where the body is outside the usual ex-meridian limits the formula here given ( $\mathrm{pp} . \mathrm{xxv}$-xxvii) will give a correct latitude for any time from the meridian corresponding to the true hour-angle of the sun, or other heavenly body, and the latitude on an approximate D.R. longitude will give the starting point for the position-line, which these tables give, cutting this longitude meridian at that latitude.

It is very generally believed by navigators than an observation taken near the meridian is of no use in connection with the "Sumner" problem. To some extent this is true when the problem is worked by the usually taught methods and the D.R. latitude is much in error. I have endeavoured to show by the following examples how the ex-meridian problem may be combined with the chronometer observation in the "Sumner" problem; and, if this is done, it matters little how the sun or stars bear when the observations are taken, provided there is a suitable difference in bearing (say 3 points or more) between the two position-lines.

The ex-meridian and star reduction tables in this work enable the navigator to very readily obtain his position from two ex-meridians or by an ex-meridian and chronometer observation, which may be worked as a double altitude, or plotted on the chart, just as accurately and even more rapidly than it could be worked from two chronometer observations. Tables of still wider limits by Blackburne and Westland were published by the New Zealand Marine Department in 1908.

When observations are taken at the best possible time-shortly before sunrise and after sunset, when probably only three or four of the brightest stars are visible-we cannot expect always to get two stars sufficiently far from the meridian and prime vertical as is considered by some necessary (vide Wvinkles, gth ed., p. 514) for a satisfactory double altitude to be worked on the "Sumner" principle. However, if advantage is taken of the methods shown in the following examples it will be seen how little this matters. The only necessary condition of importance to ensure good results is that the stars should be sufficiently far apart in bearing to give a good cut; and if one observation be near the prime vertical, and the other one near the meridian, the writer would say so much the better, rather than that this should be looked upon as an objection.

By the following formula a true latitude may be calculated when the correct hourangle is known, and if an approximate longitude is used for finding the hour-angle, the latitude and position-line from this meridian is just as valuable as any position-line drawn from a given longitude on a D.R. parallel of latitude.

## FORMULE FOR CALCULATION OF LATTTUDE BY EX-MERIDIAN WHEN OUTSIDE THE LIMITS OF EX-MERIDIAN TABLES

Case No. I.-Object above the Pole. Angle at Z ( $=$ bearing of object) more than $90^{\circ}$ reckoned from observer's Pole.

In the spherical triangle ZPD , let $\mathrm{ZP}=c o$. lat., $\mathrm{ZD}=\mathrm{co}$. alt., and $\mathrm{PD}=\mathrm{P}$. Dist.
Given ZD, PD, and angle at P : to find $P Z=c o$. lat.
From D drop a perpendicular on the meridian at $M$, then in the right-angled spherical triangle PMD we have PD and angle at P to find $\mathrm{PM}=\operatorname{arc}(\mathrm{I})$.

Formula : $-\operatorname{Cos} \mathrm{P}=\tan \operatorname{arc}(\mathrm{I}) \cdot \cot \mathrm{PD} \quad \therefore \tan \operatorname{arc}(\mathrm{I})=\cos \mathrm{P} \cdot \tan \mathrm{PD}$.
Next find $Z M=\operatorname{arc}(2)$.

In the spherical triangle $\mathrm{PMD}, \cos \mathrm{PD}=\cos \operatorname{arc}(\mathrm{I}) . \quad \cos \mathrm{MD}$.

$$
\begin{gathered}
\therefore \quad \frac{\operatorname{Cos}(2)}{\operatorname{Cos}(1)}=\frac{\cos Z D}{\cos P D}+\therefore \cos (2)=\cos (1) \cdot \cos Z D \cdot \sec P D . \\
P Z \cos . \text { lat. }=\operatorname{arc}(1)-\operatorname{arc}(2) .
\end{gathered}
$$

Case No. 2.-Angle at $Z$ less than $90^{\circ}$. Same formula as in previous case, but $\mathrm{PZ}=\operatorname{arc}(\mathrm{I})+\operatorname{arc}(2)$.

CASE No. 3.-Object below the Pole. In the spherical triangle PMD, angle at $\mathbf{P}=$ supplement of hour-angle.

Then follow the same formula as in Case No. I.

$$
\mathrm{PZ} \text { (co. lat.) }=\operatorname{arc}(2)-\operatorname{arc}(1)
$$

By using the complements of PD and ZD and complement of PM for arc (I) when the object is above the Pole, or complement of ZM when object is below the Pole, the formula may be arranged as follows, and the rule as below applied :-

## Object above the Pole

Cot $\operatorname{arc}(\mathrm{I})=\cos$ H.A. . cot decl.
Cos arc (2) $=\operatorname{cosec}$ decl. . sin arc ( I ) . sin alt.
Name arc (1) same as decl.
Name arc (2) contrary to bearing of object-i.e. N. or S. of the prime vertical.
Add like and subtract unlike names. Sum or difference of arc (1) and arc (2) = latitude.

## Object below the Pole

Tan arc ( I ) $=$ cos. supplement of H.A. . cot decl.
Sin $\operatorname{arc}(2)=\operatorname{cosec}$. decl. . cos arc (1) . sin alt.
Name both arc (1) and arc (2) same as the decl.
Latitude = sum of arc (I), and arc (2) always named same as decl.
Note.-It is not advisable to use the formula here given when the declination of object is within $3^{\circ}$ or $4^{\circ} \mathrm{N}$. or S. decl. If it is then used, six-figure logarithms should be taken out and the corrections made for odd seconds of arc.

In the above-mentioned case it is recommended to calculate arc (2) after the azimuth has been calculated by the following formula as deduced from the spherical triangle MZD, viz.:-

Above-Pole Observation.-Tan arc (2) $=\cos$ Z. cot alt.
Below-Pole Observation.-Cot arc (2) $=\cos$ Z . cot alt.
As the azimuth is nearly always required to make use of an observation taken out of the meridian, this last-mentioned formula is preferred to the foregoing one, and is in the writer's opinion the best formula for an ex-meridian latitude that he knows of. For accuracy the azimuth should be calculated by the following formula :-
$\operatorname{Sin}$ azim. $=\sin$ H.A. . cos decl. . sec alt.

## CALCULATION OF EX-MERIDIAN LATITUDES. No. i Method

## Examples to Illustrate each Case

Case No. I.-H.A. 3 h. 00 m ., decl. $22^{\circ} 0^{\prime}$ S., alt. $22^{\circ} 2 I^{\prime} \cdot 8$ S.Elg. .

CASE No. 2.-H.A. 2 h .40 m. , decl. $50^{\circ} \mathrm{N}$. , alt. $54^{\circ} 2^{\prime} \cdot 6$ N.E ${ }^{\text {ty }}$.

CASE No. 3.-* Capella, H.A. 2 h. 6 m. from lower Pole, decl. $45^{\circ} 54^{\prime} \cdot 7$ N., alt. $7^{\circ} 2^{\prime}$ N.W. (Bee p.xlviii)

The accuracy of this method may easily be proved by reversing the process, and finding the hourangle from the latitude, declination, and altitude given.

Case No. 3 is especially useful, as with high declination stars the latitude will generally be fairly correct even when the time is in error a couple of minutes, and the body observed is an hour or more from the meridian below the Pole, as may be seen by a glance at the Reduction Tables of some of the high declination stars.

## FORMULE FOR CALCULATION OF EX-MERIDIAN LATITUDES WHEN AZIMUTH IS KNOWN. No. 2 Method

## Previous Examples Worked by this Alternate Method

Arc (I) is calculated as shown in the preceding examples, and from the foregoing figures it will be apparent that Arc (2) ZM may be found from the right-angled spherical triangle MZD by the following formula :-

$$
\begin{aligned}
& \text { Above-Pole Observations } \quad . \quad . \quad . \quad \begin{array}{l}
\operatorname{Tan} \operatorname{Arc}(2)=\operatorname{Cos} Z \\
\text { Below-Pole Observations }
\end{array} \quad . \quad . \quad \operatorname{Cot} \text { Alt. } \\
& \operatorname{Cot} \operatorname{Arc}(2)=\operatorname{Cos} Z
\end{aligned} \quad \operatorname{Cot} \text { Alt. }
$$

Note.-The Supt. of the hour-angle is used for the below-Pole observations, and for convenience of the rules and arrangement of the formula, Comp. of ZM is called $\operatorname{Arc}(2)$ in the deduced formula used.

CASE No. I.-H.A. $3 \mathrm{~h} .00 \mathrm{~m} .$, decl. $22^{\circ} 0^{\prime}$ S., alt. $22^{\circ} 2 \mathrm{I}^{\prime} \cdot 8$ S.Ely.

| H.A. | 3 h .00 m . | Cos | 9.84948 |  | Sin | 9.8495 | Azim. | $45^{\circ} 9^{\prime}$ | Cos | 9.84835 |

Case No. 3.-H.A. 2 h .6 m . from lower Pole, decl. $45^{\circ} 54^{\prime} \cdot 7$ N., alt: $7^{\circ} 2^{\prime}$ N.Wly.
H.A. Supt. 2 h. 6 m .

Decl. $45^{\circ} 54^{\prime} \cdot 7 \mathrm{~N}$.
Arc (I) $39^{\circ} 33^{\prime} \cdot 3 \mathrm{~N}$.
Cos 9.93077 . . . . . Sin 9.718 I

Cot 9.986 I 8 . . . . . Cos 9.8425
Tan $\xlongequal{9.91695}$ Alt. $7^{\circ} 2^{\prime} \quad \operatorname{Sec} 0.0033$. . Cot 0.90877

Arc (2) $7^{\circ} 33^{\prime} \cdot 2 \mathrm{~N}$.

Lat.
$47^{\circ} \quad 6^{\prime} \cdot 5 \mathrm{~N}$.
The foregoing formulæ for finding the latitude and azimuth when the body is far from the meridian is, in the writer's opinion, the very best known to him, and would be hard to beat.

Half of the logs are taken out at the same openings, and four figures of logs for the azimuth is amply sufficient.

## AN INTERESTING EXPERIENCE OF EXCESSIVE REFRACTION

A few years ago an old pupil of the writer, Captain W. H. Sweny, then commanding the P. \& O. s.s. Mooltan, had a remarkable experience of exceptional refraction on the evening before making Rottnest Light. He took observations of four different stars at about 6 p.m. on April inth, 19IO, and afterwards sent to the writer his own observations, asking him to work them out, and let him know what he made the resulting position, but without divulging what he made the result by his own calculations. This was done, and the observations were systematically worked on the plan mentioned at bottom of following page; and when Captain Sweny afterwards sent the results of his work, both observations were in agreement, and evidently not more than about $r^{\prime}$ in error in either latitude or longitude. The Captain also sent the worked-out observations of the other two officers, and from all these observations the writer was able to deduce fairly accurate separate positions, and it was evident from these observations that refraction was excessive all round the horizon, but greatest to the northward, where it was about $I I^{\prime} \cdot O$, and in other parts of the horizon averaging about $6 \frac{3^{\prime}}{}{ }^{\prime}$, the altitudes being smaller 'by these amounts than they should have been by allowing the usual tabular corrections. The height of eye when these observations were taken was 50 feet. If the captain had been satisfied with the ex-meridian observations of Procyon and Pollux, and the longitude of $\beta$ Centauri, he would have been $1 I^{\prime}$ or $12^{\prime}$ out in the latitude and $33^{\prime}$ out in the longitude. By using the observations intelligently he was practically correct in his position, and made Rottnest Light nearly ahead at 2 a.m. His position at the time was about $30^{\circ} 4^{\prime} \mathrm{S}$. and $113^{\circ} 47^{\prime} \mathrm{E}$.

The above-related experiences, though undoubtedly very exceptional, should tend to warn navigators not to trust too implicitly even in daylight to observations taken on one side only of the meridian or prime vertical ; for though such excessive refraction is very vave, and may not be experienced in the lifetime of a frequent observer, it is probable that such amounts as $2^{\prime}$ difference from the tabulated value of refraction are not uncommon.

## REMARKS ON P.M. OBSERVATIONS

Anyone who is in the habit of regularly taking p.m. sights must have noticed the large differences which sometimes occur between a.m. and p.m. observations, which is generally attributed to current, and some men have even been led to believe from this that p.m. sights are not of any value, as though the sun-or, rather, the earth-did not move as uniformly in the afternoon as in the forenoon. The principal difference between the results of the two observations is probably generally due to erroneous altitude, especially in rough weather, and sometimes, of course, to erroneous latitude, and the mean of the results from the two observations will generally be nearest the true position. It has often been noticed when there is a heavy sea on that p.m. sights place the longitude a long way to the eastward of the a.m. ones, owing probably to the sun being observed on the top of a wave, and consequently the altitude being too small, an error which in the morning would place the ship to the westward of the true position, but in the afternoon just as much to the eastward of it ; so that, supposing the ship to be in latitude $48^{\circ}$ and the sun to be $30^{\circ}$
from meridian at each observation, an error in the latitude of $2^{\prime}$ too little on both occasions would make a difference of $12^{\prime}$ of longitude, as may be seen from Table III., on page 256 . Suppose, then, that on the same occasion both observations have been worked with an error of $2^{\prime}$ south of the true latitude: this would make another difference of about $10 \frac{1^{\prime}}{}{ }^{\prime}$ of longitude, making the p.m. sights $22 \frac{1_{2}^{\prime}}{}{ }^{\prime}$ of longitude to eastward of the a.m. observation, and a slight easterly current in the interval between the two observations might easily make over $30^{\prime}$ difference. Generally, no doubt, one of these errors will in a measure counteract another, but exceptional occasions are almost sure to arise when they will all combine in the same direction.

## EFFECT OF ALTITUDE ERRORS

With a.m. sights too great an altitude will place a ship to eastward of true position, and vice versa with p.m. sights and too small an altitude. The amount of error in longitude or time due to $x^{\prime}$ error of altitude is shown in Table III., pages 252-257.

## THE UNRELIABILITY OF NOON POSITION FROM SUN OBSERVATIONS

The usually recorded noon position should never be relied on too implicitly, as it is generally liable to be a few minutes in error, and this may happen when three or four persons have taken observations and are all in agreement. The very agreement of so many observers would only give a false confidence, which is the more dangerous as there is no opportunity with the sun observation (except when near land) of checking it and thereby determining the error. Many well-known authorities, however, have recorded ${ }^{-}$ their experience of errors in the latitude from sun observations, due to excessive refraction, as amounting to from $7^{\prime}$ to 18 ' (see page 132 of Tables for Azimuths, etc., by Blackburne, and experience mentioned on previous page). Such refraction, however, is undoubtedly very exceptional : the greatest error in the noon latitude that the writer ever experienced was 7'-this was in the Malacca Straits; three observers on this occasion making the altitude practically the same, and at I p.m. the ship was abreast One Fathom Bank Lighthouse. It must be remembered also that the so-called noon longitude generally depends on an observation taken at about 8 a.m. or 9 a.m., and the calculation of the time from this observation is often made with an erroneous latitude, thereby giving a wrong result; and currents, or bad steering, etc., may again combine to still further throw the position out. In the winter months $x^{\prime}$ of error in the latitude used for the calculation of the time will often throw the longitude out as much as $2^{\prime}$. As the results of errors of both altitude and latitude are reversed with p.m. sights, it would be a good plan to adopt in recording the noon longitude to wait until p.m. sights had been taken for longitude, and then to take the mean of the a.m. and p.m. results, worked up to noon, as the true noon longitude.

As shown, however, in the lower part of this page, with the position obtained by simultaneous observations of three stars, errors resulting from uncertainty of refraction, etc., may be eliminated. The horizon shortly after sunset is generally very clearly defined, without any glare; and the latitude and longitude are obtained at the same instant of time. If shipowners made it compulsory for their officers to obtain the ship's position, whenever possible by stellar observations at twilight, it would, I believe, be the means of saving many ships from disaster, and the saving of not a few lives.

## THE SUPERIORITY OF STELLAR OVER SOLAR OBSERVATIONS

The two great advantages of stellar over solar observations are: ( 1 ) that by the stars the latitude and longitude can be obtained simultaneously, instead of having an interval of three or four hours between the observations, as is often the case when the sun is used; and (2) that uncertain errors in altitude resulting from personal equation, arc errors of sextant, or exceptional refraction may be practically eliminated by a proper choice of stars. If meridian altitudes can be obtained about the same time to the north and south of observer, it will be apparent to anyone that the errors would be eliminated by taking the mean result of the two observations for the true latitude; and in the same way the true longitude would be found by the mean result of observations taken nearly east and west of meridian. But it may happen that stars are not to be found north, south, east, and west of observer during the short time that the horizon is good for observation. The following is the plan that the writer used for several years with great success:-Take three stars, and of these choose two on the same side of the meridian northward and southward of the observer for a good latitude. If they both happen to be the same distance from the meridian, as in the example on page 114 of Blackburne's 1916 edition of Tables for Azimuth, etc., 10 ' of error in the altitude will make practically no difference in the resulting latitude as found by the "Sumner" or double-altitude problem. Then choose another star on the other side of the meridian, as near as possible the same distance from the meridian; cal-
culate the longitude with the latitude found from the previous observations, and the true longitude will be obtained by taking the mean between the eastern and western stars worked with the correct latitude.

On pages II4 and II5 of the work previously mentioned three stars were taken, and the altitude of each star was ro' in error (too great) ; but following the plan above mentioned, the calculation of ship's position was made, and did not differ more than $o^{\prime} \cdot \mathrm{I}$ in either the latitude or longitude from the correct position as determined from the correct altitudes of the same three stars.

## RULE FOR FINDING THE POSITION OF SHIP FROM TWO OBSERVATIONS BY AID OF these tables either with or without the use of chart

## From Two Chronometer Observations of the Sun

(1) Let two chronometer observations be taken at an interval in time during which the sun has changed at second observation not less than three points, and let the first be worked out with the D.R. latitude at the time of observation, or generally the nearest whole degree of latitude may be used.
(2) Let the D.R. latitude and longitude thus obtained be corrected for the run of the ship in the interval between the observations, and let the second observation be worked with the corrected latitude. Name these longitudes (I) and (2).
(3) With the hour-angle, latitude, and declination at each observation take out the lat. var. from the lower half of the page, and name the position-lines corresponding to this variation according to the instruction under the heading of Table No. VI. This variation divided by 4 gives the error in longitude due to $\mathrm{I}^{\prime}$ of error in latitude.

## When both Position-Lines go through the Same or Opposite Quadrants

(4) The difference between the two lat. vars. will give the difference in the resulting longitudes due to $I^{\prime}$ of error in the latitude. (See fig. 2 below.)

## When the Position-Lines go through Adjacent Quadrants

(5) The sum of the two vars. will give the difference in the resulting longitudes due to $I^{\prime}$ of error in the latitude. (See example on page xxxi and fig. I below.)

The three elements used in the calculation of time, or longitude, are altitude, latitude, and polar distance. Presuming that the altitude and polar distance are correct, the resulting difference in longitude between the two observations must be due to error in the latitude. The sum or difference of the two lat. vars. $\div 4$ gives the difference of longitude in the two observations due to $I^{\prime}$ of error in the latitude used in the calculation, and the amount of error in the latitude will therefore be found by a simple proportion sum (see page xxxi), from which it will be seen that the error or correction to be applied to the D.R. latitude will be found by dividing the difference between longitudes (I) and (2) by the sum or difference of the variation corrections. It must be applied to the latitude used in the last observation, and to the N . or S . according to whether the position-lines cut one another N. or S. of the D.R. latitude used in the calculation. The true longitude is then found by multiplying either of the $\frac{\text { lat. vars. }}{4}$ by the latitude error, and applying the correction according to the trend of the position-line.

To prevent the possibility of making a mistake in the application of the correction to the latitude, a short horizontal line representing the parallel of D.R. latitude may be drawn with a free hand in the work-book; on this line put down longitudes (I) and (2), and roughly draw the position-lines through each longitude, following the rule for naming the positionlines given on page 270, under the heading of Table VI., also bearing in mind that if the line runs in a north-easterly direction it is equally true that the line must also run in the opposite direction or south-westerly. No scale for longitude need be used, or protractor for laying down the bearings, but simply put longitude (I) or (2) to the right or left of the other, as they are to the east or west of one another, then draw the general trend of the position-lines through these two longitudes, thus :-

## For Stellar Observations

When finding the position of ship from stellar observations, it is best to observe the altitude of two stars which have a considerable difference in bearing from one another, and to take both observations within a few minutes of the same time. If the ship has not appreciably changed her position during the interval between the observations, both observations may be worked with the same latitude, and no correction for run need be applied to the first-observation latitude or longitude. Otherwise the same rules apply as for the observations by the sun.

When the ship has appreciably changed her position during the interval between the observations, rules Nos. I and 2 must be observed as in the sun observations.

## From Ex-Meridian and Chronometer Observation Combined, to Plot on Plane Chart

Let two observations be taken with a suitable difference in bearing between them, and let the one nearest the prime vertical be used for a longitude (working it with the D.R. latitude), and the other one for a latitude, using the time deduced from the longitude found by observation in the calculation for latitude; bring both results up to the same instant of time by applying the run in interval between the observations.

Take out the lat. var. for each observation, and with this enter Table VI., page 270, and take out the corresponding position-lines. We have then two latitudes and their corresponding position-lines starting from different points on the same meridian. Where these lines cut with one another on a plane chart will be the position of the ship.

For the ex-meridian observation, or if outside the limits of the Calculated Hour-Angle Table, the lat. var. must be found from Table IV. (Azimuth Table) from the approximate latitude and azimuth.

## From Two Ex-Meridian Observations on Different Sides of the Meridian

Let two observations be taken with a suitable difference in bearing between them, one east and the other west of the meridian, deducing the hour-angle by applying the equation of time and longitude by D.R. Bring both results up to the same instant of time by applying the run in interval between the observations. The latitude from either observation (if worked by a correct method) is the latitude where the circle of altitude of the body observed cuts the meridian used in deducing the time. If both latitudes agree when observations have a considerable difference in bearing between them, the longitude must be correct. If the latitudes do not agree, the true latitude and longitude may readily be found by plotting on the chart, or by the method explained below.

## Without the Aid of Chart

By aid of Table IX. giving the Error in Latitude by Ex-Meridian due to 4 sec . Error in Time, or I' of Longitude

By the aid of the above-named table the double-altitude problem may be worked from the meridian, on the same principle as two chronometer observations are worked from a parallel of latitude. If the azimuth is not over $85^{\circ}$ (the limit of the table), the problem may be worked from the meridian with either an ex-meridian and chronometer observation combined or from two ex-meridians.

When both observations are on same side of meridian, the difference between the two errors in latitude, due to $I^{\prime}$ of error in the longitude, taken from the table, will be the divisor for the two differences of latitude resulting from the two observations, and will give the correction for the longitude used.

When one observation is east and the other west of meridian, the error of longitude will be found by dividing the differences of latitude resulting from the two observations by the sum of the factors taken from the table. The error in latitude will then be found by multiplying the error in longitude by the correction taken from the table (in preference using the azimuth nearest to the meridian) and applying this to the ex-meridian latitude in the direction of the trend of the position-line, which is always at right angles to the bearing of object.

When the altitude is high and near the meridian the azimuth should be obtained by the time and altitude. This is most satisfactorily done by the rule of sines. (See examples on pages xxxii, xxxiv, xxxvi, etc.)

For examples from chronometer and ex-meridian observation see pages xxxii, xxxiv, xliv, xlvii.

For examples from two ex-meridian observations see pages xxxvi, xxxviii, xlii, xlviii, xlix, 1.

For examples from two longitude observations see pages xxxi, xlvi.
For examples by equal altitude and ex-meridian see pages xxxvii, li.

## EXAMPLES IN THE USE OF THE TABLES

POSITION FROM TWO A.M. LONGITUDE OBSERVATIONS OF THE SUN
1913.-On May 12th, a m. at ship, in approximate lat. $30^{\circ} \mathrm{N}$. and long. $20^{\circ} \mathrm{W}$., observed alt. of sun's L.L. was $9^{\circ} 25^{\prime}$ when a chronometer indicated M.T. Green. 19 h. 18 m .43 s .; and again a.m. at ship, observed alt. of sun's L.L. was $60^{\circ} 32^{\prime}$ when chronometer indicated 23 h .17 m .23 S . Course and distance run between observations, N. $36^{\circ}$, E. 40 m . ; height of eye, 30 ft . Required position of ship at and Observation, and Azimuth at time of ist Observation.
ist a.m. © Observation.

Course and distance run between observations N. $36^{\circ}$, E. $40 \mathrm{~m} .=32^{\prime} \cdot 4 \mathrm{~N} ., 23^{\prime} \cdot 5$ E. $=$ d. long. $27^{\circ} 2 \mathrm{E}$. gives lat. at and Observation $30^{\circ} 32^{\prime} \cdot 4 \mathrm{~N}$.

## For Stellar Observations

When finding the position of ship from stellar observations, it is best to observe the altitude of two stars which have a considerable difference in bearing from one another, and to take both observations within a few minutes of the same time. If the ship has not appreciably changed her position during the interval between the observations, both observations may be worked with the same latitude, and no correction for run need be applied to the first-observation latitude or longitude. Otherwise the same rules apply as for the observations by the sun.

When the ship has appreciably changed her position during the interval between the observations, rules Nos. r and 2 must be observed as in the sun observations.

## From Ex-Meridian and Chronometer Observation Combined, to Plot on Plane Chart

Let two observations be taken with a suitable difference in bearing between them, and let the one nearest the prime vertical be used for a longitude (working it with the D.R. latitude), and the other one for a latitude, using the time deduced from the longitude found by observation in the calculation for latitude; bring both results up to the same instant of time by applying the run in interval between the observations.

Take out the lat. var. for each observation, and with this enter Table VI., page 270, and take out the corresponding position-lines. We have then two latitudes and their corresponding position-lines starting from different points on the same meridian. Where these lines cut with one another on a plane chart will be the position of the ship.

For the ex-meridian observation, or if outside the limits of the Calculated Hour-Angle Table, the lat. var. must be found from Table IV. (Azimuth Table) from the approximate latitude and azimuth.

## From Two Ex-Meridian Observations on Different Sides of the Meridian

Let two observations be taken with a suitable difference in bearing between them, one east and the other west of the meridian, deducing the hour-angle by applying the equation of time and longitude by D.R. Bring both results up to the same instant of time by applying the run in interval between the observations. The latitude from either observation (if worked by a correct method) is the latitude where the circle of altitude of the body observed cuts the meridian used in deducing the time. If both latitudes agree when observations have a considerable difference in bearing between them, the longitude must be correct. If the latitudes do not agree, the true latitude and longitude may readily be found by plotting on the chart, or by the method explained below.

## Without the Aid of Chart

> By aid of Table IX. giving the Error in Latitude by Ex-Meridian due to 4 sec. Error in Time, or $\mathrm{I}^{\prime}$ of Longitude

By the aid of the above-named table the double-altitude problem may be worked from the meridian, on the same principle as two chronometer observations are worked from a parallel of latitude. If the azimuth is not over $85^{\circ}$ (the limit of the table), the problem may be worked from the meridian with either an ex-meridian and chronometer observation combined or from two ex-meridians.

When both observations are on same side of meridian, the difference between the two errors in latitude, due to $\mathrm{r}^{\prime}$ of error in the longitude, taken from the table, will be the divisor for the two differences of latitude resulting from the two observations, and will give the correction for the longitude used.

When one observation is east and the other west of meridian, the error of longitude will be found by dividing the differences of latitude resulting from the two observations by the sum of the factors taken from the table. The error in latitude will then be found by multiplying the error in longitude by the correction taken from the table (in preference using the azimuth nearest to the meridian) and applying this to the ex-meridian latitude in the direction of the trend of the position-line, which is always at right angles to the bearing of object.

When the altitude is high and near the meridian the azimuth should be obtained by the time and altitude. This is most satisfactorily done by the rule of sines. (See examples on pages xxxii, xxxiv, xxxvi, etc.)

For examples from chronometer and ex-meridian observation see pages xxxii, xxxiv, xliv, xlvii.

For examples from two ex-meridian observations see pages xxxvi, xxxviii, xlii, xlviii, xlix, 1 .

For examples from two longitude observations see pages xxxi, xlvi.
For examples by equal altitude and ex-meridian see pages xxxvii, li.

## EXAMPLES IN THE USE OF THE TABLES

## POSITION FROM TWO A.M. LONGITUDE OBSERVATIONS OF THE SUN

1913.-On May 12th, a m. at ship, in approximate lat. $30^{\circ} \mathrm{N}$. and long. $20^{\circ} \mathrm{W}$., observed alt. of sun's L. L. was $9^{\circ} 25^{\prime}$ when a chronometer indicated M.T. Green. 19 h .18 m .43 s. ; and again a.m. at ship, observed alt. of sun's L.L. was $60^{\circ} 32^{\prime}$ when chronometer indicated $23 \mathrm{~h} .17 \mathrm{~m}, 23 \mathrm{~s}$. Course and distance run between observations, N. $36^{\circ}$, E. 40 m. ; height of eye, 30 ft . Required position of ship at and Observation, and Azimuth at time of ist Observation.

IST A.M. © OBSERVATION.

Course and distance run between observations N. $36^{\circ}$, E. $40 \mathrm{~m} .=32^{\prime} \cdot 4 \mathrm{~N} ., 23^{\prime} \cdot 5$ E. $=$ d. long. $27^{\circ} 2 \mathrm{E}$. gives lat, at and Observation $30^{\circ} 32^{\prime} 4 \mathrm{~N}$.

## "SUMNER" PROBLEM AS GIVEN IN THE BOARD OF TRADE EXAMINATIONS FOR MASTERS and mates, WORKED BY the aid of davis's chronometer tables and BLACKBURNE'S EX-MERIDIAN TABLES

1898.-On June 20th, a.m., at ship, at sea, and uncertain of my ship's position: when a chronometer indicated M.T. Green. I9 d. 22 h .30 m . the true altitude of sun's centre was $52^{\circ} 9^{\prime}$; and again, a.m. on same day, when chronometer indicated 20 d .0 h .16 m . the true altitude of sun's centre was $65^{\circ} \mathrm{I} 8^{\prime}$, the ship having made 23 miles on a true N. $24^{\circ}$ E. course during the interval between the observations. Required the line of position and true bearing of the sun at time of rst Observation, and the position of the ship when 2nd Observation was taken, assuming latitudes $46^{\circ} \mathrm{N}$. and $47^{\circ} \mathrm{N}$.

With the desire to show the superiority of the method advocated in these pages for accuracy and brevity over the method still employed in the Board of Trade examinations of masters and mates, for the "Sumner" problem, the above example is given and plotted on the chart by both methods. For the sake of better illustrating the possible error due to the old method, a wider range of latitude has been taken than is usually given in the examination papers, though, considering the high speed of some of the presentday steamers, the range is not excessive, as the run in interval itself might often amount to over $r^{\circ}$ of latitude. In the tropics, with a much smaller range of latitudes, the error resulting from considering the line of position of the higher altitude as a straight line will sometimes cause an error of half a dozen minutes or more in the latitude, as may be seen from the example on two following pages.

## xxxiv <br> EXAMPLES IN THE USE OF THE TABLES <br> POSITION FROM CHRONOMETER AND EX-MERIDIAN OBSERVATION OF SUN, 2ND ALTITUDE OVER $88^{\circ}$

1913.-6th August, in latitude somewhere between $18^{\circ} \mathrm{N}$. and $18^{\circ} 40^{\prime} \mathrm{N}$., and approximate longitude when first observation was taken $69^{\circ} 30^{\prime}$ E., between heavy rain squalls in the S.W. monsoon, the sun appeared for a few minutes at about 7 h .48 m . a.m.; and only showed himself for a short space a little after noon. G.M.T. at rst Observation 15 h .13 m .19 S ., when true altitude of $\Theta$ was $30^{\circ} 12^{\prime}$; and again at p.m. M.T.G. was 19 h. 26 m .4 S., when true altitude of $\theta$ was $88^{\circ} 10 \frac{1^{\prime} S^{\mathrm{d}} .}{}$ Run in interval N. $77^{\circ}$ E. 56 m . gives $12^{\prime} \cdot 6 \mathrm{~N} .54^{\prime} \cdot 6 \mathrm{E} .=57^{\prime} \cdot 4 \mathrm{E}$. d. long. ## Table IX.

" (2) $1819.3 \mathrm{~N} . \quad$, S. 37 W . " $0 \cdot 74 \quad$, N. to W.
D. Lat. 6.7

Lat. Error 5.00

Lat. Error $5^{\prime} \cdot 0$ : D. Lat, $6^{\prime} \cdot 7^{:}:$Long. $I^{\prime} \cdot 0$ : Long. Cor. $I^{\prime} \cdot 3 \mathrm{~W}$. Long. Cor. $\mathrm{I}^{\prime} \cdot 3 \times 0^{\prime} \cdot 74$ gives Lat. Cor. $\mathrm{o}^{\prime} \cdot 97 \mathrm{~N}$.

Note.-The resulting latitude by spherical calculation only differs by $o^{\prime} \cdot 1$, and the proof of correctness of position is established by recalculating the longitude, using the latitude found at 2nd Observation, and the same resulting longitude is obtained. Now, many navigators would have considered that an altitude of over $88^{\circ}$, more than four minutes after noon, and $37^{\circ}$ from the meridian, was of no use for anything; it is outside the limits of such well-known and excellent Ex-Meridian Tables as Brent, Raper, or Davis, and most of the formulæ given in the navigational guide-books for the calculation of latitude by ex-meridian methods would give very erroneous results; the Sumner as taught through our examinations would be hopelessly out, giving over 9 ' of error in the latitude, and even the "New Navigation" method if worked as advocated by some authors would be $7 \frac{1^{\prime}}{}{ }^{\prime}$ in error in the latitude. Possibly this is such a case as Lieutenant Simpson Baikie had in mind when he wrote (p. 8 of his book of Tables for working Combined Altitudes): "The azimuth of an object is such that an ex-meridian altitude is impossible, and a chronometer sight worse than useless." Personally the writer knows of no such cases. No observation, if used intelligently, is without value.

# EXAMPLE ON PREVIOUS PAGE WORKED BY THE "OLD SUMNER METHOD" AND ALSO BY THE MARCQ ST HILAIRE SYSTEM 

"OLD SUMNER METHOD"<br>ist Observation.<br>2nd Observation.<br>

Resultant Position plotted on the Chart at 2nd Observation : Lat. $18^{\circ} \mathrm{II} \mathrm{I}^{\prime}$ N., Long. $7 \mathrm{I}^{\circ} 6^{\prime} \mathrm{E}$.

## MARCQ St HILAIRE SYSTEM

ist Observation.

Azimuth N. $80 \frac{1}{2}^{\circ} \mathrm{E}$.
Resultant Position plotted on the Chart : Lat. $182^{\circ} 8 \quad$ N., Long. 7 I 2. $2^{\prime} 5 \mathrm{E}$. True Position . . . . . Lat. 1820.3 N., Long. 713.7 E .

Note.-The St Hilaire system would have given the same accuracy as by the Improved Sumner Method if the problem were worked by the method shown by Brent in his ex-meridian book (combining chronometer observation and the St Hilaire method), and no chart is needed; or an accurate result would also be obtained if the first observation had been plotted on the chart before the second observation was taken, and the approximate longitude from this position-line had been used in obtaining the hour-angle and azimuth for second observation.

The plotting on the chart, in a somewhat extreme case, has been here given to clearly illustrate the possible errors which may arise from following the plan as given above, and advocated by some recent authors. Although one of these authors, in a little work which has attracted some attention in the Merchant Service, gives examples where the D.R.lat. is over 40 and 50 miles in error, he was wise enough when advocating the above plan never to give much error in the D.R. long., although it is undoubtedly a much more uncertain element than the latitude.

With the methods advocated in this work it is quite immaterial what the D.R. latitude is, as no difference would result if it were $2^{\circ}$ or more in error.

# POSITION FROM TWO EX-MERIDIAN OBSERVATIONS OF SUN WITH ALTITUDES ONLY $1^{\circ}$ FROM ZENITH 

1914.-12th May, in approximate lat. $19^{\circ} \mathrm{N}$. and long. $72^{\circ}$ E., making Bombay. From the following observations find the position of ship. Work the problem first from the two ex-meridian latitudes and position-lines, and confirm resulting position by other methods.
 Run in interval East $\mathrm{r}^{\prime} \cdot 0$ of Long. Long. D.R. ist Öbsn. $71^{\prime \prime} 59^{\prime}$ E." Long. (2) $72^{\circ} \mathrm{E}$.

| Lat. (2) |  | 52 |

(2) 1853 N. $\odot$, S. $99 \frac{1}{2}$ W. Z.D. $=60$

Take $60^{\prime}$ in the dividers, "and with"one leg" on the $\odot$ and the other'leg on latitudes ( 1 ) and (2), sweep two arcs from these latitudes. The intersection of these arcs gives the position of ship.

Note.-This method may be used with very high altitudes when the D.R. longitude is uncertain, and if the D.R. longitude is in error more than $6^{\prime}$ or $7^{\prime}$ it will give a more accurate result than by the ordinary method of position-lines at right angles to the bearing of object, but in such cases the longitude will seldom be in error more than $3^{\prime}$ or $4^{\prime}$, as the sun would be nearly on the prime vertical throughout the whole day, except within a quarter of an hour from noon. If the true bearing of the sun could be accurately observed at the same instant as the altitude, the position of ship would be determined by one altitude and azimuth.

# POSITION OF SHIP BY SHORT EQUAL ALTITUDE OF SUN AND EX-MERIDIAN LATITUDE 

1914.-May 12th, in approximate lat. $19^{\circ}$ N. and long. $72^{\circ}$ E. From the following observations find the position of ship by equal altitude method:-
 Run in interval I'o of long. East (true).

## POSITION OF SHIP FROM ABOVE OBSERVATIONS DETERMINED INDEPENDENTLY, FROM THE CHART

We are indebted for this method to the writer's old friend, Captain T. S. Angus, Nautical Inspector for the P. \& O. S. N. Company, one of the keenest and most enthusiastic navigators he ever met. It is as follows :-When the sun's decl. or that of any other heavenly body is within $\mathrm{I}^{\circ}$ or $\mathrm{I}_{\frac{1}{2}}{ }^{\circ}$ of the latitude of ship, observations may be taken as soon before noon as the Z.D. is small enough to be conveniently measured on the chart with a pair of dividers, and again shortly after noon. Plot the geographical position of the sun (lat. $=$ decl. long. $=$ A.T.G.) (applying the run to position of first observation to bring both observations to same instant of time), and from this position as centre sweep an arc with Z.D. as radius in a direction opposite to the rough bearing of object. This is a position-line. The intersection of the two position-lines is the position of the ship. With an altitude of $89^{\circ}$ a right-angle cut can be obtained in just under 6 minutes, and with an altitude of $89 \frac{1}{2}^{\circ}$ a right-angle cut may be obtained in less than 3 minutes.

The following figures give all that is necessary for plotting on the chart :-

The chartlet on previous page shows the G.A.T. longitudes on the parallel of the $\odot$ 's decl. corresponding with the positions drawn from the azimuths from the calculated latitudes on the mer. of $72^{\circ} \mathrm{E}$.

## POSITION FROM TWO EX-MERIDIAN OBSERVATIONS OF SUN WITH ALTITUDES LESS THAN $1_{2}^{\circ}$ FROM ZENITH

1917.-March 19th, in approximate position in lat. $0^{\circ}$ and long. $45^{\circ} \mathrm{W}$.

With the following observations find the position of ship at time of second observation :-

(A.M. at ship) M.T. Green. I9 32 | I |

Lat.

On the meridian of $45^{\circ} \mathrm{W}$. lat. (1) is $0^{\circ} 12^{\prime} \cdot 2 \mathrm{~S}$. and $\odot^{\prime}$ 's bearing S. $72^{\circ} \mathrm{E}$. with Z.D. $79^{\prime}$.

$$
\text { " } \quad, \quad, \quad(2),, 032 \text { N. ", } \quad 3 . \quad \text { S. 18 W. } \quad, \quad 72 \cdot 6 .
$$

With one leg of the dividers on the $\odot$, in decl. $o^{\circ} 37^{\prime}$ S., and the Z.D. at time of each observation sweep two arcs from the latitudes found on the meridian of $45^{\circ} \mathrm{W}$. The intersection of the two arcs is the true position of ship.

Note.-This example, as an extreme case where both altitudes were near the zenith, and the D.R. position considerably in error, illustrates clearly the errors which would result from considering the positionlines as straight lines. A perfectly true position, however, is obtained by the method here shown. In such an extreme case, if it is inconvenient to adopt this method, a second calculation could very quickly be made by the use of the Ex-Meridian Table with a new hour-angle deduced from the approximate longitude obtained by the first calculation.

## DOUBLE PROOF OF CORRECTNESS OF POSITION AS DETERMINED BY THE METHOD AND CALCULATION OF PREVIOUS EXAMPLE

The following is a very good and simple -way of proving the accuracy of double altitude observations, viz. :-

With the resulting longitude deduce a new hour-angle, and recalculate the latitude by a true method from the observations. If both latitudes are the same as from previous determinations, it is a good guarantee of the correctness of position; or

With the resulting latitude recalculate the longitude from both observations. If they both agree with previous results we may rely with confidence on the correctness of the calculations, but of course this will not guarantee the correctness of position if a wrong altitude has been observed or a wrong declination used in the calculations.

Posn. on Chart, Lat. $\quad 18^{\circ} 33^{\prime} .8 \mathrm{~N}$. Long. $72 \quad 6 \cdot 2 \mathrm{E}$.

## POSITION FROM TWO CALCULATED LONGITUDES ON PARALLEL OF LAT. $18^{\circ} 30^{\prime}$ N.

POSITION REWORKED AND PROVED WHTH THE NEWLY FOUND LONGITUDE, $72^{\circ} 6 \frac{1}{2}$ E.

PREVIOUS CALCULATION PROVED BY DETERMINATION OF LONGITUDE WITH NEWLY FOUND LATTTUDE

NOTE.-The higher the altitude the greater will be the error in the resulting position due to considering the position-lines as straight lines when the D.R. position is much in error. The very small error in the resulting position of this example is due to the slight curvature in the short distance of $12{ }^{\prime}$.

## POSITION OF SHIP FROM TWO EX-MERIDIAN SUN OBSERVATIONS, USING THE EX-MERIDIAN TABLES

1913.-On December 22nd, in approximate lat. $13^{\circ} \mathrm{N}$. and long. $51^{\circ}$ E. Find ship's position from the following observations of the sun:-
(1) a.m. at ship M.T.G. by chron.
D. H. M. S.
(2) p.m.
$\begin{array}{llll}21 & 19 & 34 & 26 \\ 21 & 21 & 36 & 22\end{array}$
$\begin{array}{cccc}\text { Obsd. Alt. of Sun's L. L. } & 50 & 3 ́ & \text { S. } \\ \text { " } & \text { " } & 50 & 24 \\ \text { S. }\end{array}$

Run in interval between the observations N. $86^{\circ} \mathrm{W} .($ true $)$ distance $28 \mathrm{~m} .=2^{\prime} \circ \mathrm{N} .27^{\circ} 9 \mathrm{~W} .=\mathrm{d}$. long. $28^{\prime} \cdot 5 \mathrm{~W}$. gives long, at and Observation $50^{\circ} 3 x^{\prime} \cdot 5 \mathrm{E}$.; height of eye, 42 ft .

(p. 257) Lat. (decl.) $23 \frac{1}{2}^{\circ}$, Azim. (H.A.) $\mathrm{Ih} . \circ \mathrm{m},=\left(\mathrm{I} 5^{\circ}\right), \mathrm{M}=\mathrm{I} 6.85$.
(p. 256) Lat. (alt.) $50 \frac{35}{4}$ and M. 16.85 gives Azim. S. $22^{\circ}$ E.

Posn.-Line N. $68^{\circ}$ E.

| Lat. (I) Cor. | $\stackrel{1}{3}$ | $\begin{array}{r} 0.3 \mathrm{~N} . \\ 4.5 \mathrm{~N} . \end{array}$ | Long. (2) Cor. | 5 | $\begin{aligned} & \dot{3} \mathbf{I}^{\prime} 5 \mathrm{E} . \\ & \mathrm{II}^{\circ} \cdot 5 \mathrm{E} . \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Lat. in | 13 | $4^{\circ 8} \mathrm{~N}$. | Long. in | 50 | $43^{\circ} \mathrm{O}$ E |

Note.-True Position by rigorous calculation (by spherics) $13^{\circ} 4^{\prime \prime} 9$ N., long. $50^{\circ} 44^{\prime \prime} \mathrm{I}$ E.
Greater accuracy would have been obtained by calculating the Azimuth to the nearest minute of arc at both observations by the rule of sines formula; the use of Table III. is here given by way of example.

## EXAMPLE OF FINDING THE ERROR OF CHRONOMETER BY OBSERVATIONS IN ARTIFICIAL HORIZON, SHOWING THE USE OF THE ALIITUDE VARIATIONS IN WORKING OUT SEVERAL OBSERVATIONS SEPARATELY.

1913.-On April 16 th, at about 7 h. rom. a.m. M.T. at place. Suppose the following observations to have been taken at Observation Spot, Suez Dock. Index Error of Sextant -0' $34^{\prime \prime}$, Lat. $29^{\circ} 56^{\prime \prime} 3^{\prime \prime} \mathrm{N}$. , Long. $32^{\circ} 33^{\prime} \mathrm{I} 2^{\prime \prime} \mathrm{E} .=2 \mathrm{~h}$. $10 \mathrm{~m} .12 \cdot 8 \mathrm{~s}$.

$+27.0$
$\begin{array}{llll}17 & 2 & 18.3\end{array}$ It is evident that the last observation was in error, probably
owing to the altitude having been either read off or put down
incorrectly. It is therefore rejected, and a mean taken of the other six.
Observations with artificial horizon are not so much needed as they were twenty or thirty years ago, as of late years time signals giving G.M.T. have been established at most places of importance, and G.M.T. is also frequently given to steamers at sea from wireless stations. Still, it is well to be independent of such aids. In the first place, they are not always reliable, and, secondly, in these days of steam and rush a vessel sometimes arrives at and leaves a port again, as at Port Said, before the time when the signal is given; and there are still many places where such aids are not to Mean 16.03 be found. The writer, when second officer, used sometimes to check the chronometer by observations of stars in the quicksilver, in his middle watch at night, when tied up in the Suez Canal or at anchor in the Bitter Lakes. Results were very satisfactory, as proved by observations east and west of the meridian, which did not generally differ more than is. from one another.

He never found it possible to get such observations of the sun on board ship, as in the daytime so many people are moving about ; but in a large ship at anchor in smooth water observations in the quicksilver can often be taken at night, when all on board except the observer and time-taker are in bed, and everything is quiet.

Note.-Sets of sights at sea may be worked out separately in the same way.

## POSITION OF SHIP BY COMBINED OBSERVATIONS OF SUN AND PLANET VENUS． LONGITUDE AND EX－MERIDIAN OBSERVATIONS

1917．－December 29th P．M．at ship in approximate latitude $30^{\circ} \mathrm{S}$ ．the true altitude of sun＇s centre was $52^{\circ} 3^{\prime}$ when a chronometer（corrected）indicated M．T．G．I h． 51 m .58 s ．， and about the same time the true altitude of planet Venus（centre）was $74^{\circ} 43^{\prime} \mathrm{N}$ ．when chronometer．（corrected）indicated M．T．G．I h． $53 \mathrm{~m} . I_{5} \mathrm{~s}$ ．Run in interval N． $4 \mathrm{I}^{\circ} \mathrm{W}$ ． 0.3 m ．＝d．long． $\mathrm{o}^{\prime} 15^{\prime \prime} \mathrm{W}$ ．Required position of ship at time of second observation．

| Latitude | $301015 \frac{1}{2} \mathrm{~S}$ ． |  |  |  |  |  |  |

Note．－As the sun was on the prime vertical when the observation for longitude was taken， $10^{\prime}$ of error in the latitude worked with makes no difference in the longitude；the hour－angle deduced from the longitude for calculation of ex－meridian would be correct， and consequently the latitude by ex－meridian will also be correct without any further plotting on the chart，or further calculation．The hour－angle worked by direct spherics by logarithms gives exactly the same result as by the table to the decimal of a second．

# EXAMPLES IN THE USE OF THE TABLES <br> POSITION FROM COMBINED ALTITUDES OF SUN AND MOON 

1914.-April 30th, at about O h. 24 m . p.m., in approximate latitude $2^{\circ} \mathrm{N}$. and longitude $46^{\circ} \mathrm{E}$. Obsd. ## POSITION OF SHIP FROM COMBINED EX-MERIDIAN OBSERVATIONS OF TWO STARS, USING STAR-REDUCTION AND AZIMUTH EX-MERIDIAN TABLES

1917.-On March 26th, soon after sunset, at about 6 h. 5 m . and 6 h .12 m . p.m., in approximate latitude $18^{\circ}$ S., and longitude D.R. $3^{\circ} 36^{\prime}$ W., the true altitude of $*$ Capella was $24^{\circ} 5^{\prime}$ N.W ${ }^{\text {d., }}$, when chronometer showed M.T.G. 6 h .24 m .18 s ., and after running N. $45^{\circ} \mathrm{W}$. $1 \frac{1}{2}$ miles the true altitude of $*$ Sirius was $87^{\circ} 10 \frac{1^{\prime}}{}{ }^{\prime}$ N.Ed. when chronometer showed $6 \mathrm{~h} .3 \mathrm{I} \mathrm{m} . \mathrm{r}_{7} \mathrm{~s}$. Required, the position of ship at and observation. Run N. $45^{\circ}$ W. $1 \cdot 5 \mathrm{~m} .=1 \cdot 0^{\prime}$ N. $\mathrm{I} \cdot \mathrm{I}^{\prime} \mathrm{W}$.

Nore.-The calculated reductions of stars are not given when altitude is over $65^{\circ}$. Table VIII. (Azimuth Ex-Meridian Table) is therefore used for Star Sirius.

The calculation from two longitudes, using latitude $17^{\circ} 4^{\prime} \mathrm{S}$. at time of second observation, gave longitudes $3^{\circ} 30^{\prime} 20^{\prime \prime} \mathrm{W}$. and $3^{\circ} 44^{\prime} 45^{\prime \prime} \mathrm{W}$., with resulting position $17^{\circ} 51^{\prime} \cdot 1$ S. and $3^{\circ} 43^{\prime} \cdot 3 \mathrm{~W}$.

The slight error (oly ${ }^{\prime}$ ) in latitude from the ex-meridian observation is due to neglect to interpolate in the reduction table for $*$ Capella for $10^{\prime}$ of error in the D.R. latitude, and the $0^{\prime} \cdot 3$ of error in the longitude is due to curvature in the position-line in $12 \frac{1_{2}^{\prime}}{}$ of arc, with a small Z.D.

## Latitude by ex-meridian and longitude by equal altitude of ${ }^{*}$ procyon. WORK ALSO PROVED BY DOUBLE ALTTTUDE METHOD OF CALCULATION

1917.-April 5 th, at 6 h .30 m . and 6 h .50 m. p.m. in lat. by D.R. $6^{\circ}$ 10 N. and long. $93^{\circ} 30^{\prime}$ E. Suppose observed alt. of $*$ Procyon to S.Ed. $87^{\circ} 28^{\prime}$ when a chronometer which was 5 m . Io s. fast on M.T. Green. showed o h. 22 m .34 S., and again after an interval of about 20 m . the same alt. of the $*$ Procyon was observed to S.Wa. when chronometer showed o h. $4^{2} \mathrm{~m}$. II s. Run in interval east 5 m . Height of eye 26 ft . Required position of ship at time of and observation.

## PROOF OF FOREGOING WORK BY DOUBLE ALTTTUDE METHOD

| Lat. worked with Cor. | $\begin{array}{r} \circ \\ 6 \\ \\ 5 \\ 5 \end{array}$ | Long. (x) Cor. | $93^{\circ} 43^{\prime} 33^{\prime \prime} \mathrm{E} .$ |
| :---: | :---: | :---: | :---: |
| Latitude in | 615 N . | Long. in | 934500 E . |

Note.-Longitude re-worked with lat. $6^{\circ} 14^{\prime} .8 \mathrm{~N}$. gives long. $93^{\circ} 45^{\prime} \mathrm{E}$. at 2nd observation.

## BELOW POLE EX-MERIDIAN AND POSITION-LINE

19ro.-On April rst, soon after sunset, at 6 h .42 m . p.m., observed altitude of $*$ a Cygni (Deneb) $8^{\circ} 4^{\prime} \mathrm{W}$. of meridian when a chronometer indicated mean time at Greenwich 7 h .34 m .13 s . Approximate latitude $52^{\circ} \mathrm{N}$. and longitude $12^{\circ} \mathrm{W}$. Required latitude of meridian and position-line from it.

The above example is given to draw special attention to the great value of the ex-meridian problem when near the meridian below the pole. The observation gives with a minimum amount of work (when within the limits of these tables) the latitude on a certain meridian, and the position-line from this meridian. The curvature of this position-line is seen at a glance from the Azimuth Table, which is given on the same page as the Reduction Table. In this example the change of azimuth only amounts to 0.7 of a degree in 4 m . of time, or $\mathrm{r}^{\circ}$ of longitude.

The position-line at Loop Head would be N. $78^{\circ} \mathrm{E}$.
This position-line crossed by a bearing of Tearaght Island light (if sighted) would give a good reliable position, provided the observation was good. A sounding in conjunction with this position-line would also give a fairly accurate position.

The latitude and position-line could also have been quickly found at the same time by $*$ Sirius, through the use of the Reduction and Azimuth Tables in this work, the position-line of which would have then been $\mathrm{S} .79^{\circ} \mathrm{E}$. The crossing of these two position-lines would give an excellent latitude, but the longitude would not be reliable, as the angle is small, and both observations are west of the meridian.
